A second variable is the *obviousness of a conclusion*. This variable might explain the absence of an effect on attitude valence in Kardes' study. The advertisement in Kardes' study frequently mentioned the brand name (nine times in the open-ended ad and six times in the closed-ended ad), contained a large picture of the product captioned with the brand name, and never mentioned any other brand. Thus, even a casual processing of either ad might have led to a realization of which brand was concluded by the ad to be the best. Although subjects in Kardes' two message conditions differed in whether they came to a conclusion about whether the advertised brand was superior on three attributes they may not have differed in whether they made a conclusion about brand preference. If both messages were equally likely to result in conclusion drawing about the brand, then no difference in persuasion should result. In Sawyer and Howard's experiments, an equal amount of information was given about each of four competing brands in a comparative ad format and the target brand was not highlighted in any way. Thus, a conclusion about which brand was best was not possible unless a subject processed at least some of the details of the ad information that would lead to that conclusion.

The present experiment manipulates the obviousness of the conclusion and crosses that variable with message type (open-ended vs. closed-ended) for involved subjects. The obviousness of the message conclusion is accomplished by adjusting the two messages in the Sawyer and Howard study to create brand name in the opening headline (e.g., "Edge wants you to discover the Difference" vs. "Discover the Difference"), label the pictured product with the brand name in the comparative ad information (vs. not highlighting) and include the brand name in the bottom copyright (vs. a non-linked parent name).

Paired comparisons and a test of the interaction between the obviousness of the sponsoring brand and whether a message is closed-ended or open-ended will be used to assess whether, as predicted, the non-obvious sponsor, open-ended ad is most persuasive and there is little or no persuasion difference among the other three ads - the obvious sponsor, open-ended ad and the two closed-ended ads. Other measures that attempt to assess subjects' perceptions of their effort in processing the ads' information and whether they made inferences will also be analyzed.

It is expected that this presentation will lead to a better understanding of the conditions conducive to effectiveness of an open-ended ad which depends on

the audience making inferences on their own instead of merely processing the advertiser's conclusion in the ad. Together with the other papers in this session, this presentation should help the audience better understand the role of inferences in persuasion and information processing.

Consumer Inference Making and Indirect Effects of Advertising

Youjae Yi, University of Michigan

Advertisements frequently emphasize salient attributes of products so that consumers' beliefs about these attributes will change. It is commonly accepted that changes in beliefs lead to changes in attitude. Much research has therefore focused upon changes in attacked beliefs and related these belief changes to attitude change. However, substantial evidence suggests that an ad can affect unattacked elements as well. Since a consumer may infer beliefs about aspects of a product that are not mentioned in the ad, ad messages about one attribute can indirectly influence beliefs about other product attributes. That is, an ad may have indirect effects on unmentioned beliefs as well as direct effects on target beliefs.

Furthermore, an ad often contains information that can be interpreted in several different ways. For example, when consumers hear that a car is large with luxury features, they might infer either that the car will provide good riding comfort or that the car will have low gas mileage. In such cases, the product evaluation will depend on which inference is drawn from the presented information. As a consequence, we should understand how and when these inferences are made in order to fully understand advertising effects.

This paper proposes that indirect effects of an ad on unmentioned beliefs are a function of attribute interrelationships and information accessibility. The proposed presentation will include the theoretical development extending research on information accessibility as well as the results of studies conducted to test the theoretical framework. This research should be of interest to researchers who study basic information processing, inference making, attitude change, and consumer responses to advertising. The research is also relevant to practitioners of advertising. By investigating the moderator variables of inference making, this research will provide insights into the situations when strong indirect effects of advertisements are expected.

Contingent Inference Making

Carolyn J. Simmons, University of Illinois

John G. Lynch, Jr., University of Florida

Recent evidence suggests that inferences about missing attributes are common only under certain conditions (Dick, Chakravarti, and Biehal 1990; Lim, Olshavsky, and Kim 1988; Simmons and Lynch 1991). Dick et al. have presented an integrative model that predicts that an inference about a missing attribute will be made under the following conditions: the missing attribute is noted, a relevant inference rule is accessible in memory, the inputs to that rule are also accessible, the inference is believed to be diagnostic, and alternative diagnostic inputs are not

accessible or available externally. We manipulated factors that determined whether a missing attribute would be noted (competitive products did or did not provide information about the target missing attribute), the accessibility of an inference rule in memory (subjects were or were not reminded of a previous class exercise in which they were given the inference rule), and the relative diagnosticity of an inference for the task at hand (low diagnosticity = evaluation task or choice task in which neither alternative was described in terms of the target missing attribute, high diagnosticity = choice task in which one alternative was described in terms of the target missing attribute -- the assumption is that the desire for dimensional comparisons will make an inference highly diagnostic in this case). The inputs to the inference rule were always externally available. The results were generally consistent with the Dick et al. model. Inferences were unlikely unless the context drew attention to the target missing attribute. Increasing the accessibility of an inference rule increased the incident of inferences only when the inference was highly diagnostic.

Consumer Expertise and the Perceived Diagnosticity of Inferences

Frank R. Kardes, University of Cincinnati

John Kim, Oakland University

Jeen-Su Lim, University of Toledo

Recent empirical evidence indicates that consumer expertise is an important determinant of the extent and the direction on inferential activity about products (Maheswari and Sternthal 1990). Consumers who are knowledgeable about a particular product category possess the cognitive resources required to elaborate extensively on product-related information, and consequently, consumers are more likely to generate elaborative inferences spontaneously when level of prior knowledge is high (versus low). Given that inferences had been formed, consumers are more likely to trust their inferences and consider their inferences valid when prior knowledge is high. In contrast, when consumers consider themselves unknowledgeable about a particular product domain, they may distrust their inferences so much that they may consider explicitly-provided conclusions to be more valid than their own self-generated conclusions.

Subjects were exposed to four sets of arguments implying four separate conclusions about the benefits of a target product (a compact disc player). In spontaneous inference conditions, subjects were exposed to the arguments only (the conclusions were omitted). In prompted inference conditions, subjects were exposed to the arguments only and were asked to answer questions about the implied conclusions. In explicit conclusion conditions, the implied conclusions were presented explicitly. Subjects were blocked into high and low prior knowledge groups on the basis of their scores on a ten-item multiple-choice test about disc players.

For each implied benefit (conclusion), subjects estimated the percentage of high- versus low-quality CD players possessing the target benefit on scales from 0 (0 percent) to 10 (100 percent). Bayesian

likelihood ratios were computed from these subjective probabilities following Herr, Kardes, and Kim (1991). The ratio provides a direct measure of perceived diagnosticity. The results revealed that low knowledge subjects perceived the target conclusions as nondiagnostic in spontaneous inference conditions, moderately diagnostic in prompted inference conditions, and highly diagnostic in explicit conclusion condition (although the latter effect was not statistically significant). For high knowledge conditions, the results were nonsignificant. However, the direction of the diagnosticity results were opposite of the low knowledge conditions. High knowledge subjects viewed the target conclusions as moderately diagnostic in explicit conclusion conditions, and highly diagnostic in spontaneous and prompted inference condition. This pattern suggests that low knowledge consumers are unlikely to generate inferences spontaneously, and if they are prompted to generate inferences, they regard their self-generated inference to be less diagnostic than explicit conclusions. High knowledge consumers, on the other hand, spontaneously generate inferences and tend to view these self-generated conclusions as more diagnostic than explicit conclusions.

Mundane Everyday Consumption and the Self: A Conceptual Orientation and Prospects for Consumer Research

Robert E. Kleine III, Arizona State University

Susan Schultz-Kleine, Arizona State University

Jerome B. Kernan, George Mason University

ABSTRACT

The self--a sense of who and what we are--is offered as the organizing construct through which people's everyday activities can be seen as significant. The mundane tasks of daily life (and the consumer behaviors necessary to enact them) deserve greater attention than has been accorded them because they are inextricably intertwined with people's sense of well-being. A conceptual orientation to this genre of research suggests the kinds of issues involved as well as the variety of investigative approaches to each that seems congenial. At a minimum, the realm of mundane activities affords researchers the opportunity to select between buyer (acquisition) behavior and consumer (use and disposition) behavior as a focal perspective.

INTRODUCTION

"First, the very idea of consumption itself has to be set back into the social process, not merely looked upon as a result or objective of work. Consumption has to be recognized as an integral part of the social need to relate to other people, and to have mediating materials for relating to them. Mediating materials are food, drink, and hospitality of home to offer, flowers and clothes to signal shared rejoicing, or mourning dress to share sorrow. Goods, work and consumption have been artificially abstracted out of the whole social scheme. The way the excision has been made damages the possibility of understanding these aspects of life" (Douglas and Isherwood 1979, p. 4).

Consumer research continues to emphasize pre-acquisition phases of consumption. Consequently, the goods-in-use and disposition phases remain underexplored. Similar to Douglas and Isherwood, we submit that to understand *consumer* (cf. buyer) behavior, it should be studied as it is embedded in daily life--i.e., as part-and-parcel of mundane everyday consumption.

"Mundane and everyday" refers to those activities which constitute the bulk of daily life -- preparing meals, relaxing, or getting to work, for example. *Mundane everyday consumption* occurs while and as an integral part of negotiating these daily life-tasks. Although the study of such ordinary embedded consumption is not new (e.g., Boyd and Levy 1963), it remains an underspecified aspect of consumer behavior.

We believe that the *self* (James 1890) affords a particularly powerful lens through which ordinary consumption behavior can be viewed inasmuch as many of our daily life-tasks constitute self-enterprises--e.g., personal- and social-identity

development. As Belk (1988) has argued, possessions afford a person (and others) a sense of both who and what s/he is. In the context of Sartre's (1943) distinctions, we see the product clusters that people use ("having") as facilitating their daily activity patterns ("doing") and that these two, in combination, reflect people's sense of self ("being"). Thus the ordinary things people do (and consume) every day have profound implications for their sense of well-being. It seems remarkable that such fundamental concerns do not reside at the core of contemporary consumer research.

This paper is intended to: (1) direct researcher attention to mundane everyday consumption as a not-so-mundane and, in fact, rich research topic; (2) provide conceptual direction for its exploration; (3) illustrate that significant research questions are raised by such study; and (4) encourage consumer researchers (of whatever metaphysical persuasion) to study mundane everyday consumption phenomena.

MUNDANE CONSUMPTION: A CONCEPTUAL ORIENTATION

As noted above, mundane consumption is self-relevant; what we consume--in order to perform even ordinary human activities--both contributes to and reflects our sense of identity. Belk (1988) has proposed that possessions not only define who and what we are; they also afford us a link with the past and provide a marker for the future. Given such a self-as-nexus construal, it is not surprising that a variety of *human* concerns (quite apart from the traditional consumer research agenda) has been mirrored through the self--developmental psychologists, clinical practitioners, sociologists and anthropologists, as well as a host of critics (particularly of a post-modern bent) all see it as a reflection of individual and social mental health. However, we construe self broadly and do not implicate a particular self theory. Any number of theoretical orientations on the self--e.g., independent vs. interdependent (Markus and Kitayama 1991), public vs. private (Baumeister 1986), or social identity (Stryker 1980)--might be useful for studying mundane consumption. But following Sarbin and Allen (1968) and Wicklund and Gollwitzer (1982), we believe that mundane consumption is linked more closely with *specific aspects* of the self (e.g., cyclist, parent) than with individuals' wholistic self, even though consumer researchers traditionally have studied the relevance of consumption to people's wholistic self-concept (Sirgy 1982). Further, since the self is fundamentally dynamic, a developmental (Kegan 1982) or cultivation (Csikszentmihalyi and Rochberg-Halton 1981) approach to studying the self/consumption link may prove most beneficial.

Casting mundane consumption as self-relevant raises three characteristics of the phenomenon to which we believe consumer researchers have paid insufficient attention: (1) mundane consumption involves the patterned use of product clusters; (2) it occurs within an activity stream; and (3) it frequently involves social interaction. Each of these characteristics presents opportunities for consumer researchers.

Product Sets

Mundane consumption involves patterned use of sets of products. Although generally studied in isolation, rarely are products consumed that way (Boyd and Levy 1963; McCracken 1988; Michael Solomon 1988). Mundane consumption entails using sets of interdependent and complementary products in a particular way. A cyclist's bicycle, cycling shorts, shirt, shoes, helmet, and gloves exemplify the utilitarian and symbolic coherence of such sets. Product clusters cohere around and enable an aspect of the self (Kernan and Sommers 1967). This product-cluster-in-use orientation contrasts with traditional symbolic consumer behavior research which adopts a communication or person-perception perspective. Visible consumption patterns influence our impressions of an unknown person (Belk, Bahn, and Mayer 1982), for example, and the personality traits we attribute to them (Holman 1980). In addition, people can describe product clusters characteristic of certain cultural categories of "person types" (e.g., businessman; Solomon and Assael 1987). Yet such studies leave underspecified the role that personal inventories of product clusters have in individuals' daily lives. Consider the following issues raised by contemplating product clusters in daily life.

- How do individuals select from and combine elements of their existing product clusters? This process is not so simple when we recognize that one's inventory of products relevant to a particular aspect of self often contains more elements than one can use all at once. Consider, for example, the daily challenge of combining a set of things to wear to work. And what might precipitate surprising, unusual, and/or innovative patterning of items within a cluster or items from different clusters?
- Thinking in terms of self-relevant product clusters places a different spin on product acquisition and disposition. Such decisions become cast in a larger framework. Acquisition and disposition are influenced by the self-appropriateness of the product (cf. Kernan and Sommers 1967) and the impact that an item's addition or deletion has on the resulting cluster (cf. McCracken's [1988] Diderot principle). We know little about how individuals assess a product's self-relevance or how that changes over time. We understand even less about how consumers evaluate a product cluster's marginal utility

when a new item is added or an existing one is deleted.

Many research opportunities surround such product cluster dynamics. How, for example, does a product cluster change over time through acquisition, use, and disposition? What gave rise to the particular combination of products owned? What constrains its composition? Finally, what is the link between product clusters and self-cultivation? How do self-relevant product clusters help us become certain types of people? Do certain cluster elements serve as entry (exit) barriers for cultivating (or disposing of) a particular aspect of the self? Is it possible to create an aspect of oneself simply by owning a particular product cluster? In short, mundane consumption involves clusters of self-relevant products. This view spurs us to explore product clusters, each one of which coheres around some aspect of the self, how they arise, and their purposes in carrying on everyday activities. This leads us to the second characteristic of mundane consumption.

Activity Streams

Mundane consumption occurs within an activity stream. Ewen (1988, p. 108) observes that "life is caught between the polarities of having and doing." Yet, to suggest that everyday consumption is embedded within an activity stream recognizes that having and doing are complementary, not polar opposites. Activity streams generate, organize, and regulate consumption (Boyd and Levy 1963). Consumption, in turn, enables the activity. Cycling shoes, for example, enable one to ride a bicycle in a particular way. The combination of activity stream and product cluster forms a consumption system (Boyd and Levy 1963). Simply, we consume while doing something; but the *activity*, not the products consumed, is our primary focus.

- Casting product clusters as tools for supporting activity streams emphasizes questions like: How are goods used to perform an activity? How is product use embedded in an activity stream? Are there core vs. peripheral enabling products for an activity? If so, what happens to an activity if consumption of certain core or peripheral products is inhibited? How is self-cultivation influenced when this occurs?

Consumption-generating activity streams direct attention to consumers' procedural knowledge and expertise. Yet much consumer research is directed toward pre-having. These investigations emphasize attributes of specific brands, consequently consumer expertise is generally construed to reflect only consumers' factual knowledge of brand-attributes (e.g., Alba and Hutchinson 1987). It seems implicitly assumed that consumers know how, when, and in what combination products are used and where they can be acquired. An emphasis on consumers' procedural (i.e., how-to) knowledge, however, raises questions like: How do people acquire knowledge vis-a-vis a particular

aspect of the self (e.g., cyclist, gourmet cook, organic gardener) and the products--utilitarian as well as symbolic--that will enable this enactment? How does this learning affect who they *can* become (i.e., self-development)? What are the sources of this learning? What relative influence might friends, media, the marketplace, etc., have in cultivating one's sense of self? Additional issues arise when consumers encounter an unfamiliar (e.g., cross-cultural) realm. What are the implications of *not* knowing the relevant consumption systems--e.g., when one doesn't understand an activity stream and/or what products should/can be used to facilitate it? How does lack of such procedural knowledge inhibit one's ability to function in the context? Similarly, how are unusual or deviant consumption systems acquired and how do they affect self-cultivation? Such processes often involve other people, the third characteristic of mundane consumption.

Social Interaction

Mundane consumption frequently involves social interaction. The autonomous consumer has been consumer research's primary focus. (There is even a budding concern with solitary consumption--Goodwin 1990). Yet many self-tasks are carried out in social settings. Indeed, one purpose of self-relevant consumption is to help us get along with others. Mundane consumption thus facilitates and mediates social interaction (Douglas and Isherwood 1979). This raises questions concerning how consumers *use* consumption patterns in social interaction and, in turn, how social interaction *shapes* those consumption patterns. For example, how do certain products or product sets act as the nonverbal elements that facilitate social communication in family settings like the contemporary dinner table or consumers' exchanges with store clerks?

- The genesis (or culmination) of certain consumption patterns (including those that may be dysfunctional) often depends upon one's entry into (exit from) appropriate interpersonal networks. Parents, for example, worry that their children will become involved with the "wrong groups," which will introduce them to substance abuse. Similarly, one's active participation in a particular social-network--e.g., a sports-car club--can stabilize consumption patterns and this can make stopping or modifying consumption difficult. Participation in the sports-car club might discourage one from exploring more athletic activities. Apart from some nascent efforts (e.g., Reingen and Kernan 1986), we understand little of how acquaintance networks influence self-cultivation and accompanying self-relevant consumption patterns.
- Social-interaction can alter the course of a person's ongoing consumption system. The consumption repertoire one displays during (or in anticipation of) social interaction

emerges from the particulars of the intercourse; social exchange is a principle source of mundane consumption's dynamism. Thus, even though the topical context remains fixed, we bring a different set of behaviors to each new episode in the topical drama. ("What should I wear to work today?" "This is our third date; what does s/he expect?") How people modify their self-relevant consumption in response to interaction-embedded imperatives is scarcely addressed in the agenda of traditional consumer research, however.

- And we sometimes desire to *avoid* social interaction. Consumption patterns also are used to discourage or inhibit interaction, for purposes of privacy or self-boundary regulation (Vinsel et al. 1981). Listening to one's personal stereo, reading a book, and Nautilus workouts are common examples. Yet consumer researchers largely have ignored people's use of consumption patterns to inhibit social-interaction (Goodwin 1990 is an exception).
- Finally, this social-interaction emphasis highlights the under-explored domain of consumption that occurs *only* in groups. Board games, sporting events, college educations, and academic conferences are consumption activities for which social interaction is fundamental. Such group-consumption phenomena perhaps best exemplify our most basic premise: mundane consumption supports, but is not the conscious focus of, individuals' self-cultivation. They also challenge us, as consumer researchers, to enrich our understanding of such complex consumption. (Ward and Reingen 1990 represents an enterprising effort toward this end.)

SOME DARK-SIDE REFLECTIONS

To recognize that both buyer behavior *and* consumer behavior comprise self-relevant activities is to move beyond the ambitions of marketing managers to the sober concerns of society. If our consumption patterns fashion our identities, the consequences of mundane activities are far more profound than traditionally has been considered; both people's sense of well-being (a.k.a. mental health) and our society's values (a.k.a. the commonweal) are in play. And neither--at least according to the skeptics--is immune from jeopardy.

Self-identity has always been a problem, some uneasy confederation of the person, significant others, authority, religion and superstition. Historically, one managed this (while not preoccupied with daily sustenance) by negotiating a path between the tenants of Romanticism (love, emotion, moral values) and the Enlightenment (reason, empiricism). The postmodern era, however, complicated all this

with ever-expanding communication; one now is forced to relate to a multitude of people and institutions in a variety of ways. The result is that each of us is no longer one self, but many; this is the age of the "saturated self" (Gergen 1991). In the postmodern world the emphasis is on relationships--this *aspect* of "me" (never the generalized SELF), presented in whatever persona seems most appropriate. Gergen calls this the "pastiche personality" (perhaps the equivalent of high self-monitoring), a chameleon-like identity that is, in sum, *no* identity. Life and truth are so fragmented, relative, and ephemeral that no one has a residual sense of ME. As Ewen (1988) puts it, "... the primacy of style over substance has become the normative consciousness" (p. 2). Jack Solomon (1988) is even less sanguine, contending that we have lost our understanding of an "essential me," that there is no centering self-identity or inherent character that remains. He cites the careers of Madonna and Michael Jackson as semiotic paradigms of our society, challenging skeptics to define who or what these celebrities are.

If we *are* a society of fledgling neurotics, commercial depictions (advertising, cinema) of mundane activities and the product clusters that enable them surely bear scrutiny, although whether these shape, reinforce, or merely chronicle socially-responsible behavior may be a moot question. Apart from that sticky issue, however, it seems clear that a multidimensional self is the only tenable construal. We may long wistfully for a consummate "character," but a stable (tensile?) assemblage of self-definitions probably is requisite to contemporary life. Such a compartmentalized construal has been central to our conceptualization and is a tenet of Wicklund and Gollwitzer's (1982) provocative theory of symbolic-self completion.

Self Examination

Preference Spaces, Interpretive Inferences, and Consumption Systems

Jerome B. Kernan, George Mason University

On the face of it, the Hirschman, Holbrook, and Levy presentations don't have much in common; they address different topics and they engage various methodologies. Yet there is an underlying theme to them. (Discussants are expected to say something to that effect.) Each one shows us a way to "examine" the self--by asking people their preferences (Holbrook), by observing the systems in which they consume (Levy), and by interpreting depictions of people's consumption behaviors (Hirschman). In each case, though the nominal focus and investigative procedure is unique, we see self reflected in and driving consumer behavior. *Ordinary* consumer behavior. Indeed, as the Kleine, Schultz-Kleine and Kernan paper notes, mundane tasks (and the consumer behaviors necessary to enact them) are self-relevant.

We have suggested that such self-relevant mundane consumption is characterized by three themes: (1) the patterned use of product sets; (2) that are embedded in and enable activity streams; (3) which typically involve social interaction. And these papers reflect those themes in abundance. For example, the notion of a set of products--although inherent in the work of Alderson, Douglas and Isherwood, Holbrook, Kernan and Sommers, McCracken, and Solomon--is given a new emphasis by these papers. We are reminded that studying products out of their constellation context can be dangerous; that elements of a set can change over time; and that (similar to Belk's [1991] recent reflection) product sets can cohere for reasons quite beyond those posited by Cartesian rationality. Similarly, that products enable activities is so intuitively plausible as to be taken for granted; yet these papers illustrate how the enabling occurs as well as the great variety of use-motivations that typically are at play. Finally, the many forms of social interaction which affect and are affected by products are given a novel twist as we see their relationship to a variety of self-reflections, -presentations, and -perceptions. These papers establish for us (again, to cite Belk) that "...while the mysteries of possessions are ineluctable, they are not ineffable" (p. 42).

While it is likely that, except for certifiable materialists (for whom having *is* being), consumer behavior is not an overarching determinant of a person's wholistic Self or "character." Inasmuch as the things we have are inseparable from what we do, however, it is not injudicious to suppose that our day-to-day behaviors *do* affect who and what we are. The influence may be indirect and variegated, but it is real.

So long as we are willing to construe the self as an amalgam of specific facets--essentially the perspective of both Gergen (1991) and Wicklund and Gollwitzer (1982)--the ordinary things that people do can be seen as perspectives--as partial portrayals--of themselves. This relationship is evident in Levy's paper (where the laundering system chosen affects the kind of homemaker presented/perceived), in

Holbrook's (where product-set preference vectors reveal aspects of the personality), and in Hirschman's (where the feckless behaviors attendant to addiction depict the struggle to enshroud deviance with normalcy). In each case, a revealing facet of the self is adduced--by the preferences people state, the products they use, or the (duplicitous) behaviors they engage. Each of those facets is a partial clue to how these actors (and others) regard themselves. That the papers "differ" widely suggests that self-relevant consumption affords us both a variety of issues to address and a veritable cafeteria of methods to examine them. Consumer researchers are not often presented with such a delectable smorgasbord.

Patterns, Personalities, and Complex Relationships in the Effects of Self on Mundane Everyday Consumption: These are 495 of My Most and Least Favorite Things

Morris B. Holbrook, Columbia University¹

ABSTRACT

This paper explores the elusive relationship between Self and Mundane Everyday Consumption (M.E.C.). It suggests that early attempts to show that "Self → M.E.C." failed because concepts of "Self," "M.E.C.," and "→" were too simplistic. Accordingly, the paper extends our concept of M.E.C. to embrace enduring *patterns* of consumption preferences toward products (versus brands), objects (such as performing artists), or activities (manifested by allocations of time). It expands our view of Self to include such aspects of *personality* as visualizing-verbalizing tendency, romanticism-classicism, and intrinsic-extrinsic motivation. And it elaborates our view of the *relationships* involved (→) to represent complex mediating and moderating effects wherein personality influences the links in a causal chain from product features to purchase intentions in general and shapes the intervening role played by social impressions in particular.

INTRODUCTION

A Deep Conviction

Deep in the bones of every introspectively alert consumer researcher lies the buried conviction - implicit, inarticulate, or even inaccessible to consciousness - that one's *Self* somehow causes, influences, or shapes one's *Mundane Everyday Consumption*. Colloquially, most of us believe that "you are what you eat." In other words, at some level, we tend to feel that the "self" *is* or at least *determines* what a person "consumes."

An Elusive Butterfly

Yet, for decades, this seemingly apodictic intuition has proven amazingly resistant to empirical verification. Like an elusive butterfly, it has evaded efforts to catch it on the wing. In the earliest attempt that I can recall, Evans (1959) tried to show that Personality (measured by the Edwards Personal Preference Schedule or EPPS) explained Car Ownership (Ford versus Chevy) but found instead that the prediction was very weak and that simple-minded demographic, socioeconomic, or other "objective" variables worked just as well or better. This outcome set off a train of controversy that eventually culminated in the conventional wisdom - voiced by Kassarian (1971) - that personality variables work poorly in explaining buyer behavior.

We might view the early unsuccessful formulations in light of the following simplified representation:

Common Sense

[relationship]
SELF -----> MUNDANE
EVERYDAY
CONSUMPTION

Hypothesis

[correlation]
Personality -----> Buying

Operationalization

EPPS -----> Brand Ownership

Apparently, if the commonsense view that most of us hold somewhere deep down inside (SELF → M.E.C.) is translated into a plausible hypothesis (Personality → Buying) and tested via a simplistic operationalization (EPPS → Brand Ownership), it tends to fail. In short, if SELF is defined as a prepackaged personality measure (EPPS, GPP, MMPI, SVIB, CPI, etc.), if M.E.C. is measured as brand ownership (Ford vs. Chevy), and if the relationship investigated is a simple correlation (r or R), the "model" explains only the tiniest variance in the dependent variable. [Here, to avoid confusion, I should emphasize that my formulation views "self" as represented by "personality," whereas others have sometimes regarded "self" as represented by "consumption" (Greeno, Sommers, and Kernan 1973).]

Explanations

Subsequent thinking has suggested at least three reasons why the models just described did not work very well:

- (1) the personality variables were not specific to the buyer behavior of interest [hence, the development of psychographic measures like those advocated by Wells (1975)];
- (2) brand ownership was less relevant than more enduring commitments such as long-run brand loyalty or habitual product usage [hence, the move toward investigating clusters of consumption via "patterns of complementarity" by Bass, Pessemier, and Tigert (1969) or "behavioral life-styles" by Alpert and Gatty (1969); hence, also, the focus on product usage as opposed to brand choice recommended by Holbrook and Howard (1977) and emphasized by Holbrook and Hirschman (1982)];
- (3) the correlational relationships tested were too simplistic [hence, the development of more complex models of buyer behavior, beginning with Howard (1963) and blossoming from there toward the present state of the art].

¹The author gratefully acknowledges the support of the Columbia Business School's Faculty Research Fund.

Extensions, Expansions, and Elaborations

I want to continue these latter streams of thought concerning "Self → M.E.C." by proposing some further extensions, expansions, and elaborations. Specifically, I want to suggest that - in seeking *relationships* between the *Self* and *Mundane Everyday Consumption* (Self → M.E.C.) -

- (1) *M.E.C.* may best be regarded as *patterns* of consumption preferences at the level of *products* (e.g., toothpaste, soap), *objects* (e.g., Miles Davis, Paul Simon), or *activities* (e.g., tennis, swimming) rather than at the level of buying specific brands (e.g., Crest vs. Colgate; CBS vs. Warner; Prince vs. Head) [here, I adopt a focus on potentially self-revealing product clusters comparable to that proposed as early as the emphasis on role-related activity patterns suggested by Kernan and Sommers (1967) and the measurement application via self-related Q-sorts of products conducted by Greeno, Sommers, and Kernan (1973)];
- (2) the *Self* may fruitfully be viewed in terms of certain important consumption-related aspects of *personality* for which measurement indices can be developed, as in the cases of visualizing-verbalizing tendency (the VV Index), romanticism-classicism (the RC Index), and intrinsic-extrinsic motivation (the IE Index) [here, I draw primarily on my own work with an important reminder that others have done extensive research on other aspects of personality such as masculinity-femininity, self-monitoring, self-esteem, innovation proneness, sensation seeking, etc.];
- (3) the *relationships* of interest may need complications to include various sorts of *mediating* and *moderating* effects [where personality influences the roles of intervening variables along a chain of links from product design to purchase intentions (Anand and Holbrook 1990; Heath 1990) and where this chain involves various aspects of social interaction of special interest to this particular ACR session (Kernan and Sommers 1967; Schultz-Kleine and Kleine 1991)].

In what follows, I shall suggest some specific examples drawn from my own work to illustrate each of these three points. However, again, I remind the reader that many others have explored similar themes on related topics. Some of this apposite research is discussed by the other participants in the present ACR session. Other examples appear in the references mentioned earlier.

(1) MUNDANE EVERYDAY CONSUMPTION AS PATTERNS OF PREFERENCES

Using Versus Choosing

Holbrook, Lehmann, and O'Shaughnessy (1986) pursued the focus on product usage (as opposed to brand choice) earlier suggested by Holbrook and Hirschman (1982). Toward this end, they examined "patterns of relationships among product categories themselves" (p. 50) in connection with questions concerning the "psychological connections among product categories" (p. 50).

Specifically, the authors studied 53 products in categories ranging from consumer nondurables (coffee, cereal) to durable goods (bicycle, camera) to services (plumber, car repair). For each category, 41 British housewives considered *why* they made their most recent purchase and indicated the salience of eight different types of reasons (habitual, picking, intrinsic, economic, technical, social, legalistic, and adaptive) on a five-point numerical scale from "not considered at all" (1) to "sole basis for selecting" (5). Mean ratings were correlated among products across reasons; the correlations were converted to distance measures; and these distances were submitted to metric multidimensional scaling to obtain a product space in two dimensions with a correlation between input and output interpoint distances of 0.91.

The vertical dimension of this spatial representation appeared to discriminate between products used for their utilitarian properties (headache remedies, car repairs) versus those used for aesthetic or social reasons (hats, dress shirts). The horizontal axis posed more difficulties of interpretation but seemed to reflect the difference between repetitive commitments (pet food, gas, coffee) and more unique purchasing situations (calculator, bicycle, car). [Unfortunately, space does not permit the inclusion of this or the other visual representations discussed in the present review. For further details, please see the original sources cited.]

This representation goes part way toward the focus on patterns of product consumption mentioned earlier in that it positions products nearer together or farther apart according to the sorts of reasons that determine their acquisition and usage. However, in line with the purposes of the present inquiry, a more interesting question concerns the ways that products cluster together in a preference space to reveal patterns of product complementarity.

Patterns of Complementarity in a Preference Space

In connection with the phenomenon of product complementarity, several authors have suggested that the meaning or value of a consumption item may depend on the nature of the other goods and services jointly consumed with it (Bass, Pessemier, and Tigert 1969). Such "item collections" (Green and Devita 1974), "combinations" (McCracken 1988), "constellations" (Solomon 1988), "configuralities" (Holbrook and Moore 1981), "complementarities" (Holbrook and Dixon 1985), or "ensembles" (Bell,

Holbrook, and Solomon 1991) consist of products that group together into patterns because they tend to be liked (disliked) and consumed (avoided) jointly by the same people. Hence, by measuring relative preferences across a range of objects, correlating these preferences among products and across respondents, and submitting these inter-object correlations to some sort of MDS procedure, one can form preference spaces based on what Holbrook and Dixon (1985) call "complementarity in aggregate patterns of revealed preference" (p. 111).

Three examples at hand concern the patterning of preferences among various objects from the world of entertainment in general and jazz performance in particular. Thus, Holbrook (1982) asked 180 respondents to rate their perceived likelihood of buying new recordings by each of 180 jazz artists on a 9-point numerical scale from "not at all likely to buy" (1) to "extremely likely to buy" (9). Using a reduced set of 73 musicians (those with above-average purchase intentions), an MDS analysis of the correlations among artists across respondents produced a two-dimensional solution with a correlational fit between input and output distances of 0.75. Here, the horizontal axis appeared to represent commercialism, differentiating between those musicians with the closest ties to the purist jazz tradition (Gil Evans, Roland Hanna, Max Roach, Thelonious Monk) and those who have made the largest concessions to popular taste (George Benson, Grover Washington, Ramsey Lewis, Herbie Mann). Meanwhile, the vertical axis seemed to represent contemporaneity, with the more modern players at the bottom (Wayne Shorter, Joe Zawinul, Keith Jarrett, Weather Report) and those with more mainstream styles at the top (Count Basie, The Jones-Lewis Big Band, Zoot Sims, Oscar Peterson). One reasonable inference from such a preference space is that the neighboring musicians tend to cluster together in listeners' patterns of consumption. Some would own record collections featuring Shorter and Zawinul (both members of Weather Report); others would prefer listening to Sims and Peterson (both under contract with Pablo at the time of the study).

Closely comparable results appeared in research reported by Holbrook and Holloway (1984) wherein 327 respondents gave preference ratings for 59 jazz musicians on a 9-point numerical scale from "not at all enjoyable" (1) to "extremely enjoyable" (9). Multidimensionally scaled correlations produced a two-dimensional preference space with a correlational fit between input and output distances of 0.79. Again, the horizontal axis appeared to represent commerciality (e.g., Clifford Brown and Lester Young among the purists versus Grover Washington and Bob James among the sell-outs). And, again, the vertical axis could be interpreted as a continuum of contemporaneity from the more modern (Marion Brown, Sun Ra) to the more mainstream (Ray Charles, Louis Armstrong). Further, this representation of preference patterns suggests that certain artists tend to group together in the consumption styles of different consumers. Someone who listens to Hampton Hawes, Jim Hall, Bill Evans, Lee Konitz, and Art Pepper

probably does not devote much time or attention to Donald Byrd, Freddie Hubbard, Herbie Hancock, or Al Jarreau (and vice versa).

In a third study of jazz preferences, Holbrook and Dixon (1985) used essentially the same technique one more time with preference ratings of 50 jazz musicians collected from a sample of 220 respondents on a 7-point numerical scale from "do not enjoy at all" (1) to "enjoy very much" (7). Multidimensionally scaled correlations produced a two-dimensional preference space with a fit of 0.66. Again, one dimension appeared to represent commerciality - namely, the vertical axis with purists at the top (Jaco Pastorius, Wayne Shorter, Keith Jarrett) and sell-outs at the bottom (George Benson, Grover Washington, Ramsey Lewis). However, because all artists came from the set of currently active modern performers, the horizontal axis appeared to capture a distinction somewhat different from that observed earlier - namely, a continuum of familiarity based on a contrast between the better known jazz stars (Billy Cobham, George Duke, Herbie Hancock, Hubert Laws, Ramsey Lewis) as opposed to the more obscure artists (Cedar Walton, The Heath Brothers, Helen Humes, Benny Golson, Woody Shaw).

Patterns of Time Allocation

A phenomenon closely related to patterns of preferences among objects concerns patterns of time allocation among various sorts of activities. In this connection, Holbrook (1980) used multidimensionally scaled correlations to reanalyze some data on leisure activities originally reported by Duncan (1978). Specifically, Holbrook used summed cross-products from Duncan's factor-pattern coefficients to approximate the original correlations among the 25 leisure activities loaded highest on Duncan's five factors. MDS produced a two-dimensional space with a correlational fit between input and output distances of 0.77. Here, the horizontal axis appeared to represent a contrast between solitary activities (gardening, walking, reading) and those of a social nature (movies, volleyball, dancing). Meanwhile, the vertical dimension seemed to indicate a distinction between indoor activities (shopping, sitting, stereo) and those performed outdoors (hunting, fishing, camping). Moreover, the activities appeared to form meaningful patterns or clusters in the MDS space. For example, certain "woodsmen" tended to engage in fishing, hunting, and camping, whereas other "socializers" tended to pursue dating, dancing, and movies.

Holbrook and Lehmann (1981) undertook a comparable approach to assessing patterns of leisure activities. Following Bass, Pessemier, and Tigert (1969), they investigated complementarity among activities in the allocation of discretionary time by analyzing data from a Market Facts panel of 3,288 respondents who had indicated their participation rates in 88 time-consuming activities. An MDS analysis of distances based on partial correlations among the activities produced a two-dimensional solution with a fit of 0.54. Again, one dimension seemed to represent the distinction between indoor activities (crossword,

book, dinner) and those performed outdoors (swim, camp, hike). By contrast with the earlier findings, however, the solitary-social dimension was replaced by an axis that appeared to differentiate between essentially low-brow activities (cards, drinking, TV sports, bowling) and more high-brow pursuits (library, museum, classical concert, lecture). Further, activities high in *a priori* complementarity tended to occupy neighboring positions in the spatial representation. For example, camping, boating, hunting, swimming, and skiing clustered in one corner of the space, as did club, church, project, and volunteer in the opposite corner.

Limitations

The preceding analyses shed light on the *patterns* wherein products, objects, or activities group together into complementary clusters based on their tendencies to be thought about, preferred, or performed together or in similar ways by the same people. Hence, the various MDS spaces described in this section address the first of the concerns raised earlier - namely, that pertaining to the *patterns* that occur in *mundane everyday consumption*. However, questions remain concerning how these patterns are related, if at all, to underlying *personality* variables or to other aspects of the *self*.

(2) THE SELF AS PERSONALITY

Premonitions

Premonitions concerning the sort of approach that I would advocate appeared in the aforementioned paper by Holbrook and Holloway (1984) in which vectors were positioned in the MDS space for jazz musicians to indicate the differences in relative preferences between members of various demographic segments (e.g., Blacks vs. whites) and socioeconomic categories (e.g., less- vs. better-educated). The method used here regresses segment-specific relative preferences against the spatial coordinates of objects on the axes that underlie the preference space and plots a vector that passes through a point given by the coefficients of the axes in the regression equation (Carroll 1972). Thus, those objects whose perpendicular projections lie farther toward the positive end of this vector tend to be preferred relatively more strongly by members of the relevant consumer group. For example, the cluster of relative preferences for such jazz musicians as Hawes, Hall, Evans, Konitz, and Pepper (described earlier) is closely associated with being white ($R = 0.65$) and better-educated ($R = 0.73$). From here, it is only a short step to inquiring whether similar patterns of relative preferences appear for respondents differing in various psychographic aspects of their personality.

Psychographics and Preferences for Jazz Artists

The aforementioned study by Holbrook (1982) placed vectors in the product space for jazz artists to represent the preferences of groups defined by various psychographic items (each of which was used to split the overall sample of respondents into two

subsamples of those scoring above and below the mean, respectively). These psychographically anchored preference vectors provide hints on what sorts of personality types tended to prefer which clusters of jazz performers. For example, the purist musicians mentioned earlier (Evans, Hanna, Roach, Monk) tended to appeal to those who agreed with such statements as "I regard myself as a serious student of jazz" ($r = 0.43$), "I read music magazines to keep abreast of what's happening" ($r = 0.41$), and "Compared to most people, I am a little bit crazy in my love for jazz" ($r = 0.36$). By contrast, the more commercial musicians (Benson, Washington, Lewis, Mann) found their niche among those who agreed with "I like music you can dance to" ($r = 0.32$), "I frequently spend the evening dancing at a disco" ($r = 0.36$), and "To have music everywhere I go, I often carry a portable radio around with me" ($r = 0.46$). In sum, though they cannot be regarded as general measures of personality, these psychographic descriptors suggest some key differences between the self-descriptions of those who like the more versus less commercial jazz artists.

Gender, Visualizing-Verbalizing Tendency, and Preferences for Fashion Designs

In a study intended to explore the effects of cue configuralities among items of clothing worn together in one fashion ensemble, Holbrook (1986) collected measures from 64 respondents (42 males and 22 females) on a four-item index of affect toward 32 factorially designed outfits (composed of different shirts, ties, jackets, and pants). He used canonical correlation analysis to form a preference space for the fashion outfits and put preference vectors into this space to represent the affective responses of males versus females who scored high versus low on a 20-item index of visualizing-verbalizing tendency (the VV Index) originally developed by Holbrook, Chestnut, Oliva, and Greenleaf (1984). The results indicated that - by contrast with men (for whom visualizing-verbalizing tendencies exerted little influence on preference patterns) - the high-VV women tended to like "simple combinations with plain jackets and (at most) one isolated or two nonadjacent set(s) of stripes," whereas the low-VV women tended to prefer "plaid jackets, but only as long as these are combined with no more than one striped feature" (p. 345). Hence, this study indicates the potential for preference spaces with personality-based vectors to illuminate relationships between patterns of mundane everyday consumption and the self.

(3) RELATIONSHIPS OF INCREASED COMPLEXITY: FROM SIMPLE CORRELATIONS TO MODERATING AND MEDIATING EFFECTS

Thus far, the relationships between patterns of preference and aspects of personality have appeared in the form of straightforward simple measures of correlational association. Further issues concern the complications that arise when we examine the possible moderating and mediating effects wherein personality can intervene in the chain of effects

between stimulus properties and preferences or purchase intentions. In describing such models, I shall briefly mention four studies with escalating levels of complexity.

Romanticism-Classicism and Travel Preferences

At the simplest level of model building, one might inquire whether a personality variable exerts a moderating effect on the importance weights attached to different product features. In this connection, Holbrook and Olney (1991) used a method analogous to componential segmentation (Green and DeSarbo 1979) to test whether an index of romanticism-classicism (the RC Index) would account for shifts in the utilities attached to various features of vacation trips (pleasure, risk, viewing, warmth, and luxury). A sample of 115 student subjects evaluated 32 factorially designed stimuli based on all possible combinations of the five two-level travel features. Consistent with the authors' expectations, the results indicated gender-related differences in part worths - with women (versus men) displaying significantly more positive evaluative weights for pleasure ($p = 0.02$), warmth ($p = 0.01$), and luxury ($p < 0.0001$) and a significantly more negative evaluative weight for riskiness ($p = 0.001$). Further, the results showed a significant moderating role of romanticism-classicism in increasing the favorability of responses to riskiness ($p < 0.0001$) and warmth ($p = 0.0015$). Thus, it appears that romanticism-classicism does moderate the effects of certain travel features (risk and warmth) on preferences toward various vacation opportunities.

Romanticism-Classicism and Music Preferences

Pursuing a somewhat more complex modeling approach, Holbrook and Corfman (1985) manipulated various aspects of a music-listening task (including the design of the music itself) on a number of dimensions and studied the effects of these task differences on preferences (as measured by a four-item index of affect) as well as on various intervening value judgments (concerning beauty, quality, convenience, and fun). As tested on a sample of 21 student subjects across 32 listening experiences ($N = 32 \times 21 = 672$), the intervening value judgments (beauty, quality, and fun) and their various interactions with gender and romanticism-classicism provided a fairly strong explanation of preference ($R = 0.88$, $p < 0.0001$). Here, as expected, those higher in romanticism (versus classicism) showed a significantly more positive contribution of beauty to preference ($p = 0.002$).

Visualizing-Verbalizing Tendencies and Emotional Responses to Video Games

Using a path-analytic approach comparable to that employed in the study just described, Holbrook, Chestnut, Oliva, and Greenleaf (1984) extended the previous focus to the domain of leisure activities (Unger and Kernan 1983) by investigating the emotional responses of 60 student subjects to the experience of playing a video game (in either a verbal or visual format). Measures of emotional responses

included a global assessment of negative-positive feeling borrowed from Byrne (1971) and the six-item indices of pleasure, arousal, and dominance developed by Mehrabian and Russell (1974). The key personality variable of interest concerned an index of visualizing-verbalizing tendency (the VV Index). The results showed significant VV X game interactions in explaining three of the emotional measures (but not arousal). Specifically, for visual (versus verbal) games, visualizing tendency contributed significantly more positively to feeling ($p < 0.10$), pleasure ($p < 0.05$), and dominance ($p < 0.05$). This suggests that personality (visualizing-verbalizing tendency) plays a complex role in moderating the enjoyment of playful consumption experiences (video games).

Intrinsic-Extrinsic Motivation, Self-Monitoring, Social Impression, and General Liking

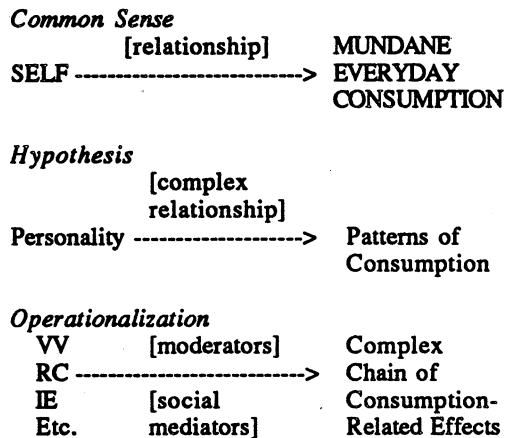

Finally, Bell, Holbrook, and Solomon (1991) have recently reported results for a still more complex model designed to link personality, esthetic, social, and attitudinal variables via various moderating and mediating effects. With particular relevance to the present discussion, this model proposes that personality variables determine one's ideal impression which, in turn, moderates the effect of product-related person perceptions on the favorability of social impressions that contribute to general liking. Specifically, evaluations of 32 factorially designed furniture combinations by 227 student subjects suggested that intrinsic motivation (Deci 1975) and self-monitoring (Snyder and Gangestad 1986) contributed positively to desired flexibility as part of one's ideal impression ($p < 0.0001$ and $p = 0.04$, respectively), that this ideal impression exerted a positive moderating effect on the contribution by the perceived flexibility of the furniture's person perception to explaining the favorability of its social impression ($p = 0.002$), and that social impression ($p < 0.0001$) and esthetic response ($p < 0.0001$) combined to determine general liking ($R = 0.88$). Thus, these results support a complex model wherein personality determines the ideal impression that one wishes to project which, in turn, moderates the effect that perceptions concerning the sort of person who would own the product exert on the favorability of its social impression and wherein this social impression works together with esthetic response to mediate the flow of effects from product features to general liking.

CONCLUSIONS

It should appear clear from the verbal description just offered that models designed to reveal the effects of personality on patterns of product preferences have become fairly complex and, indeed, that such complications must be included to address the issues of theoretical interest - namely, the role of Self (personality) in shaping Mundane Everyday Consumption (patterns of product usage, object preferences, and related activities) via the intervening role of Social Impressions.

If we return, for purposes of comparison, to the earlier oversimplified formulation that did *not* work, I

believe we are now in a position to construct an extended, expanded, and elaborated schema that might work - or, at least, that might work *better* than the discredited simplistic view. Specifically, the improved schema would be structured as follows:

This extended, expanded, elaborated representation only begins to suggest the host of questions that remain unanswered and deserve exploration in future studies. Perhaps the present brief overview has offered some grounds for hoping that such further investigations may prove worthwhile.

Mundane Addiction: The Cinematic Depiction of Cocaine Consumption

Elizabeth C. Hirschman, Rutgers University

ABSTRACT

Using three motion pictures depicting cocaine addiction during the 1980's (i.e., *Bright Lights, Big City*; *Less Than Zero*; *Clean and Sober*) five themes are identified that appear to be common, or mundane, aspects of the narratives. These themes are (1) self-deception, (2) deception of others, (3) drug use in response to anxiety, stress, and failure, (4) multi-drug use and desperation to use, and (5) continuity of use and physical deterioration. Mundane Addiction:

INTRODUCTION

Over the past decade consumer researchers have become increasingly aware of compulsive and impulsive purchasing (Rook and Hoch 1985; Rook 1987; Faber, O'Guinn and Krych 1987; O'Guinn and Faber 1989; Hoch and Loewenstein 1991). Closely related to these activities are drug addiction and alcoholism (Peele 1985), which have recently also come to the interest of consumer researchers (Hirschman 1991; Hirschman 1992 a,b). The majority of these studies are based upon phenomenological accounts of addicted and compulsive consumers and have provided several insights into the lived-world of compulsive-addictive consumption.

However, there is another vantage point from which it may be quite constructive to examine addictive behavior -- that is fictional depictions presented in motion pictures. Denzin (1991), for example has developed a compelling analysis of alcoholism as a cinematic genre in which he describes how cultural conceptions of this form of addictive behavior have been shaped by its portrayal in films over an eighty year period. "In the alcoholism film Hollywood would focus on the problem drinker and turn his or her problems with alcohol into occasions for moralistic, didactic discussions of alcoholism and its destructive effects on the person and society. Films such as those analyzed (here) serve as distorted mirrors or fractured reflections of the American concern for its 'alcoholism' problem (Denzin 1991, p. xiii)." Denzin's findings are based on an interpretive analysis of thirty-seven motion pictures spanning an eighty year time period.

The present paper is not nearly as comprehensive and detailed as Denzin's work. Instead, I will focus upon three films from the late 1980's which depict the effects of cocaine addiction; these films are 'Bright Lights, Big City' (1988), 'Less Than Zero' (1987) and 'Clean and Sober' (1988). As in Denzin's sample, these films were chosen because they were major motion pictures (i.e., were released by major studios), experienced wide-spread distribution and achieved at least moderate commercial success. They thus serve as impactful semiotic vehicles for encoding and communicating our cultural values regarding drug addiction.

As will be shown, these films are also instructive to consider as a set because they depict three different outcomes for their protagonists. In

'Bright Lights, Big City', the protagonist, Jamie Conway, overcomes his cocaine addiction through the exercise of personal choice and will power. In 'Less Than Zero', the protagonist, Julian Wells, takes an opposite path. After struggling to overcome and control his addiction to cocaine, he dies. In the third film, 'Clean and Sober', the protagonist, Daryl Poynter, enters a drug rehabilitation program denying he is a cocaine addict. Through the program, he ultimately comes to acknowledge his addiction and -- with group support -- is able to control it.

These three films, then, tell dialectically different stories about addiction and suggest that greatly disparate outcomes are possible for the cocaine addict. However, as I shall show, they also put forward remarkably similar portrayals of what it is like to be an addict. Brief synopses of each film are now presented¹:

Bright Lights, Big City

Jamie Conway (Michael J. Fox) is a clean-cut, aspiring, young writer working for an elite magazine in New York City. Originally from the Midwest, Jamie has taken up with a fast crowd. He frequently stays out all night dancing at discotheques; he drinks liquor heavily and uses cocaine. While the actual origins of Jamie's addiction are unclear, the narrative suggests that they are linked to the death of his mother from cancer, which occurred a year earlier, and his attractive wife, Amanda's (Phoebe Cates), desertion of their marriage for a modeling career.

The narrative covers a three or four day time period in Jamie's life, during which he is fired from his job due to sloppy performance, is pursued by his brother, Michael, to attend their late mother's memorial service, re-encounters Amanda at a fashion show where he is thrown out for drunkenness, and meets the virtuous, sensitive Vickie, who becomes his new love. The narrative suggests that after "hitting bottom" in his professional and personal life due to his addictions Jamie resolves his emotional conflicts over his mother and wife, abandons drugs (symbolized in the film by his trading his dark sunglasses for a fresh bread roll), and vows to begin life anew. The film ends with Jamie sitting on a pier overlooking the ocean early on a Sunday morning. He tells himself, "You're gonna have to go slowly. Have to learn everything all over again".

Less Than Zero

The narrative opens by showing three affluent friends at their high school graduation in Los Angeles. Clay (Andrew McCarthy) goes east to college, while his best friend, Julian (Robert Downey, Jr.), and Clay's girlfriend, Blair (Jamie Gertz), remain behind in California. At Thanksgiving, Clay returns home to

¹Extensive synopses are available from the author. All three films are available on videocassette.

discover that Julian and Blair have become lovers. He is angry and hurt. Prior to Christmas break, Blair calls Clay and asks him to come home to help her with Julian, who has developed an addiction to cocaine. Upon Clay's return to Los Angeles, the narrative provides a glimpse of the lifestyle in which the three were raised: incredible wealth and social privilege, coupled with broken homes and selfish, disinterested parents. (For example, Clay has no one to meet him at the airport, so he takes a cab home; Blair's father does not even come out of his bedroom to accept her Christmas present.)

Blair confides to Clay that Julian's attempt to become a record producer failed. Julian, despondent, then turned increasingly to cocaine and now owes his dealer \$50,000. Julian spends his nights dancing high at discos and his days 'coming down' from drugs at the beach, public parks, or Blair's apartment. Julian's father has forbidden him to return home because of his repeated, failed attempts at rehabilitation and his continued theft of money from the family for drugs.

Toward the end of the narrative several significant events occur: Julian is forced by his drug dealer to become a male prostitute and finally admits to Clay that he is an addict and owes a great deal of money. While Clay is attempting to help him, Julian steals jewelry from Clay's house. Clay and Blair later find Julian at Blair's house and help him through withdrawal. Julian promises them to stay off of drugs. Julian goes to his father and asks to be taken back. His father agrees. Julian then goes to see his drug dealer in Palm Springs to square away his debts. However, the dealer lures Julian back into homosexual prostitution and addiction. Blair and Clay arrive at the dealer's house and rescue Julian. While they are driving back to Los Angeles, Julian dies. After Julian's funeral, Blair -- who has given up her own cocaine habit -- agrees to return to college with Clay.

Clean and Sober

An affluent, young, commercial real estate broker, Daryl Poynter (Michael Keaton), awakens after a night of drinking and snorting cocaine to find his date has suffered a heart attack (due to cocaine use) in his bed. Daryl disposes of the drugs and calls the police. After they accuse him of cocaine use, he first tries to fly to Canada, but cannot because his credit card has been revoked. He then goes to a colleague's house where he drinks beer and asks to hide out. The colleague refuses. In desperation to elude the police, Daryl checks himself into a rehabilitation clinic, where his presence will be kept confidential.

Despite going through withdrawal, Daryl refuses to admit he is an addict and continues to try to obtain cocaine from outside sources. While at the clinic, Daryl falls in love with another recovering addict, a young, blue-collar woman named Charlie. Upon their release from the program, Daryl attempts to get Charlie to leave her addicted, petty thief husband, Lenny, and come live with him.

While in the clinic, Daryl reluctantly joins AA/NA and gets a sponsor named Richard. Richard

helps Daryl reconstruct his life away from the use of drugs and alcohol.

Daryl is fired from his job for having embezzled money to buy drugs when he was an addict. Daryl discovers Charlie is still using cocaine and has her flush it down the toilet. Charlie finds she cannot leave Lenny because he "needs" her more than Daryl does. Daryl finally lands a job and calls Charlie to tell her. She agrees to come see him. Driving over, Charlie snorts cocaine, has a car wreck and is killed. Richard comforts Daryl, telling him he could not have prevented Charlie's death.

The narrative closes with Daryl speaking at an AA/NA meeting. He tells the members that he entered the program merely to escape the police, but now has come to realize that he is an addict and must continue to recover.

THEMATIC COMPARISON: THE MUNDANE ASPECTS OF ADDICTION

These three films differ in structure, outcome, tone and texture and yet there are some striking commonalities across all three narratives that reveal our cultural conceptions of cocaine addiction. These commonalities constitute the everyday -- or mundane -- aspects of addiction, and it is to a consideration of them that we now turn.

Lifestyle. Cocaine consumption during the time period depicted in these films (e.g., late 1970's-early 1980's) was associated with a glamorous, sensual lifestyle (Hirschman 1992a); cocaine was culturally viewed as something the affluent did at "swinging" parties, at discotheques, and prior to sex (Hirschman 1992a). The narratives depict cocaine use in ways highly consistent with this cultural ideology. All three protagonists are well-educated, affluent professionals. All are young and single, and in all three films the use of cocaine is linked to sociability and sexuality.

In addition to these lifestyle commonalities, however, the three narratives tell us much more about the phenomenology of drug addiction, *per se*, including the texture of the daily life of an addict.

Self-Deception. One of the most commonly shared traits among addicts is self-deception (see Johnson 1980). Addicts typically construct elaborate systems of *denial*, which act to blind them the negative effects that their drug/alcohol consumption has on their personal and professional lives. For example, Jamie Conway, the central character in *Bright Lights, Big City*, is engulfed in denial. Through his cocaine and alcohol use he has avoided dealing with the two central losses in his life -- the death of his mother and the divorce from his wife. Instead of confronting and resolving his emotions, he runs away from them through frenetic activity at all-night discotheques and mind-numbing doses of stimulants and depressants.

Jamie's denial extends to his professional life as well. His editorial work has become sloppy and haphazard; he has all but abandoned attempts to complete a novel. Yet Jamie does not seem to notice these deficiencies. His life has become reduced to an existence of locating drugs and getting through the

days and nights of his life with as little introspection as possible.

The storyline of *Less Than Zero* revolves around life-after-high school for three friends. Clay has gone to college and no longer consumes drugs; while Julian and Blair have remained in Los Angeles, where both have become dependent on cocaine. Julian's addiction is by far the more serious. He has amassed a \$50,000 debt to his dealer, Rip, which signals not only the depth of his denial, but also of his addiction. According to the film, Julian "conned his way through" rehabilitation, meaning that he refused to take his addiction, or treatment for it, seriously. Despite a series of career failures and alienation from his family, Julian denies that he has a drug "problem". He continues to make elaborate plans to resurrect his life by opening up a night club. When Clay finds him sleeping on park benches and on beaches, Julian contends that it is because he has "trouble at home", rather than a cocaine dependency. Ultimately, Julian's self-deception leads to his death. He returns to see Rip, ostensibly to tell him that he is getting straight, but instead becomes (easily) lured back into cocaine use. His last consumption binge proves to be fatal.

Daryl Poynter in *Clean and Sober* has embezzled \$90,000 from his firm to buy cocaine, found a date near death from a drug overdose in his bed, drinks beer for breakfast, and *still* does not recognize that he is an addict. Craig, his rehabilitation clinic counselor, tells Daryl, "You've been straight for twelve whole days. That's how we do it... a minute at a time, a day at a time. *But you gotta know you got a problem*". Daryl does not.

Daryl's denial of his drug addiction continues despite his undergoing withdrawal, the admonitions of his counselors, and the questioning of his AA sponsor: "Daryl, are you an addict?" "Fuck you!" replies Daryl. Only slowly, gradually does Daryl come to recognize -- and accept -- his status as an addict. Thirty days out of rehab, after the deaths of his date and Charlie, and the loss of his job, Daryl stands in front of an NA/AA group and says: "I've been to a funeral, 9,000 job interviews and I'm \$52,000 in debt. And now I've got this... startling belief that I'm an addict".

Denial dies a slow and painful death in the addict's consciousness. But with the death of denial comes the birth of recovery. Daryl and Jamie both broke through their own patterns of denial, recognized themselves as addicts and, the narratives imply, lived. Julian never fully overcame his denial and died. Thus, these three films inform us that one must be able to discern the destructiveness of addiction to one's life before being capable of fully abandoning one's dependence upon it.

Deception of Others. Addicts typically engage in elaborate schemes to deceive others concerning their drug use (see Johnson 1980). Most commonly those whom the addict feels s/he must deceive are friends, family and coworkers. In *Bright Lights, Big City*, Jamie Conway engages in these mundane acts of deception most markedly with his coworkers and brother. Although he is chronically tardy for work and

often he has the red eyes, swollen nose and headaches associated with cocaine use, Jamie denies to his colleagues that he is using drugs. Ultimately he is fired for the poor quality of his work, but still refuses to associate it with his drug and alcohol consumption. Jamie also tries to avoid contacting his brother, fearing his addiction will be discovered.

Julian, in *Less Than Zero*, also acts in a manipulative and deceptive fashion on several occasions. In one instance, he asks his uncle for \$15,000 to open a nightclub, intending instead to use the money to repay his drug debts. In another instance, he breaks into his family's home and attempts to steal some audio equipment. Later, in desperation, he pleads with his friend, Clay, to help him get \$50,000. While Clay is attempting to obtain the money for him, Julian enters Clay's house and steals his mother's jewelry. As Julian's father tells him in one scene: "Trust was the first thing you ruined".

Daryl Poynter of *Clean and Sober*, like Jamie and Julian, has attempted to deceive many people in order to disguise his addiction. At the outset of the narrative he lies to a friend and coworker, Martin, about the escrow money he has stolen. He next lies to the police, telling them he does not use drugs. He lies to the personnel at the rehabilitation clinic, telling them he is not hiding from the police. Daryl attempts to manipulate Martin into bringing him cocaine in the rehabilitation clinic. When that fails, he calls his parents, tells them he is in a "financial bind" and asks them to mortgage their house and send him the money. When explaining the missing escrow account to his superiors at work, Daryl initially tries to blame a secretary for depositing the money in his checking account by error. Finally, he admits to them his drug dependency and recent treatment -- a signal that he is finally beginning to 'get honest' with himself and others.

As these three films suggest, active drug addicts are not truthful people. They will lie, cheat, steal and deceive to maintain their addictions. Family, friends and colleagues -- rather than being off-limits for this treatment -- are often the most likely to experience it.

Drug Use in Response to Anxiety, Stress, Failure. Addiction is often stimulated by the use of drugs / alcohol as a form of self-medication in response to anxiety, stress and failure (Brister and Brister 1987). The narrative of *Bright Lights, Big City* strongly suggests that Jamie's current dependence upon cocaine and liquor is his attempt to escape very painful emotions tied to his mother's death and the breakup of his marriage. Further, the film suggests that when facing a stressful encounter, Jamie also 'fortifies' himself with drugs and alcohol. For example, before encountering his ex-wife at a fashion show, Jamie gulps down two double vodkas. Upon encountering her again at a party, Jamie snorts cocaine. And when Jamie's brother tells him he must return home to attend his mother's memorial service, he responds by snorting cocaine and leaving for a party.

In *Less Than Zero*, Blair tells Clay that Julian's cocaine addiction is directly attributable to his failure

as a record producer: "He never ever failed before. He started getting high. He had a fight with his father. Mr. Wells threw him out". Julian's life is now one of constant stress and anxiety. He is estranged from his family, unable to function professionally, and deeply in debt. To cope, Julian consumes as much cocaine as he is able to obtain, getting quite sick when his supply is depleted. The 'medicine' that once enabled him to escape his problems, now has become the central source of his misery.

Unlike *Bright Lights, Big City* and *Less Than Zero*, the narrative of *Clean and Sober* provides us with few clues as to the origins of Daryl's drug and alcohol dependency. Once his addictions are established, however, he frequently attempts to turn to them in times of stress and anxiety. For example, the morning the stricken date is found in his bed, Daryl flushes the cocaine down the toilet to evade the police. However, as soon as he arrives at a friend's house, he gulps down a beer. Unable to flee the country, Daryl drinks liquor and smokes cigarettes. Thus we learn that these are his typical ways of responding to stressful events.

Like most addicts, Jamie, Julian and Daryl began their drug and alcohol use as a way of medicating themselves past painful emotions. However, as Brister and Brister (1987) observe, they are now trapped in a vicious circle in which the pain of withdrawal from drug use stimulates sufficient impetus for them to reinitiate their consumption.

Multi-drug Use / Desperation to Use. Another mundane aspect of addiction is that it often extends to include several substances or activities (Hirschman 1992b). In *Bright Lights, Big City*, Jamie Conway is presented as *cross-addicted* to cocaine and alcohol. This is a common "upper" (i.e., stimulant) / "downer" (i.e., depressant) pattern. In order to give himself energy for work or partying, Jamie snorts cocaine. In order to ease his "crash" from cocaine or to relax when he experiences anxiety, Jamie drinks vodka. As is typical of addicts, when these drugs of-choice are unavailable, Jamie will readily consume others. For example, when having dinner with his coworker, Meghan, Jamie gulps down wine and steals some Valium he finds in her bathroom. When his drug / alcohol supply is depleted, Jamie becomes desperate to obtain more. At one point he leaves work in midday to buy cocaine in a public park.

Like Jamie, Julian in *Less Than Zero*, exhibits multiple chemical dependencies. His drug-of-choice is free-base cocaine, but the narrative depicts him also smoking cigarettes and drinking liquor. In several scenes, Julian's drug dependence is depicted in desperate terms. He begs cocaine from Rip, even though he is deeply in debt and ultimately is forced into homosexual prostitution. In the final scenes of the film, Julian -- although vowing to have given up his drug habit -- is easily brought back into both his addiction and acts of prostitution simply by being offered a free-base pipe.

As with Jamie and Julian, Daryl exhibits multi-drug addiction. He is dependent upon cocaine, alcohol and cigarettes. By the end of the film, it is suggested that he has abandoned use of cocaine and alcohol, but

his status regarding cigarettes is left ambiguous². Daryl's desperation to use these substances is suggested vividly by two activities in the film. First, in the rehabilitation program and cut off from his drug supply, Daryl places repeated calls to his dealer attempting to obtain cocaine. In another segment of the film, he ransacks his office, searching desperately for drugs. When he can find none, he calls his parents, manipulating them for money to buy cocaine.

The addicts portrayed in these three films depict the extremes to which people will go in order to obtain more of the substances upon which they have become dependent. As these narratives illustrate, addicts lead lives of frantic -- not quiet -- desperation.

Continuity of Use and Physical Deterioration. Perhaps the most mundane aspect of addiction is the regularity with which it governs the addict's everyday life. All other personal and professional activities become subordinated to the consumption of the drug. At the extreme, the addicted consumer's life becomes consumed by the addiction. In *Bright Lights, Big City*, Jamie is depicted as under the influence of cocaine and / or alcohol in virtually every scene. He snorts cocaine in the morning to cope with his job, drinks at lunch and at dinner to cope with stress, drinks and snorts to have a good time on a date and so on. His personal functioning is depicted as a function of drug and liquor consumption. The unbroken continuity of Jamie's chemical dependencies take a dramatic toll on his physical appearance. He struggles to maintain his Preppie appearance, but his clothes become increasingly disheveled, his hair unkempt, his complexion unhealthy, his nose bloody.

Julian, in *Less Than Zero*, has reached an ever more disintegrated physical state due to his continuous cocaine use. Julian is shown becoming increasingly disheveled and emotionally distraught; his clothing deteriorates over the course of the film from L.A. chic to dirty and unkempt. His behavior declines from nightclubbing to acts of sexual perversion. Even more than Jamie, Julian's face displays the physical ravages of heavy addiction: his eyes are swollen and bloodshot; there are open sores around his mouth from frequent free-basing, his hair is dirty and his face remains unshaven for days.

As with Jamie and Julian, Daryl is depicted as continuously concerned with maintaining his addiction. He snorts cocaine and drinks alcohol at the outset of the day. When his cocaine supply is disrupted, he continues to drink and smoke cigarettes. Drug use is shown to be the constant in Daryl's life. He also exhibits a physical deterioration due to his chemical dependencies. The morning he checks into the rehabilitation clinic he is disheveled and unshaven. His Yuppie-style clothes are rumpled and dirty; his speech is too rapid and nervous. As yet unrecognized by Daryl, his life has become unmanageable.

²AA/NA permit both cigarette smoking and caffeine consumption.

DISCUSSION

As with impulsive and compulsive purchasing, drug addiction and alcoholism can disrupt and even destroy consumers' lives. The present paper has examined addiction through a novel venue -- motion pictures. Motion pictures which focus upon addiction can serve as instructive, semiotically-rich texts for communicating cultural knowledge about addiction.

By examining the behaviors of addicted consumers as depicted in cinematic narratives, we can learn about commonalities culturally perceived to characterize drug/alcohol addiction. The three films used in the present study, i.e., *Bright Lights, Big City*, *Less Than Zero*, and *Clean and Sober* are from the same time period (1987-1988) and document cultural beliefs surrounding cocaine consumption in the early-to-mid 1980's. Beyond distinctive lifestyle patterns, e.g., young, affluent, professional users; social/leisure usage occasions, these films suggest five common, or *mundane*, themes which inform our societal conception of cocaine addiction. These include: (1) self-deception, (2) the deception of others, (3) the use of drugs in response to anxiety, stress, and failure, (4) multi-drug dependency and desperation to use and (5) the continuity of drug use and accompanying physical deterioration.

The present study has made initial efforts to link these themes to the social science and clinical literatures on drug/alcohol addiction. However, a more concerted and systematic inquiry would be useful to discern the degree of overlap between our popular culture conceptions of addiction (as depicted in motion pictures) and social science theories of addiction. Both are culturally-constituted texts, yet they are constructed by different social groups and serve the needs/objectives of different constituencies. Understanding how they differ and overlap in the meanings they apply to addiction would be not only a useful exercise in social deconstruction, but would perhaps also provide insights into how popular and scientific texts influence each other in giving meaning to phenomena such as addiction.

A further constructive extension of the present study would be to inquire how much of a phenomenological affinity active and recovering addicts experience with the characters depicted as addicts in motion pictures. Do 'genuine' addicts view these cinematic portrayals of addiction as echoing their own feelings and behaviors or do they see them as false images?

The answers to these and other questions engendered by an examination of the various vantage points from which the meaning of addiction is constructed would likely prove useful to addicts and social scientists, alike.

Ethnicity and Consumer Product Evaluation: A Cross-Cultural Comparison of Korean Immigrants and Americans

Wei-Na Lee, University of Texas at Austin
Koog-Hyang Ro Um, Florida State University

ABSTRACT

The United States is currently becoming ethnically more and more diverse. To date, the majority of the acculturation studies have focused on African and Hispanic Americans. Very little has been done to understand the "Asian American" population. In recent years, Asian Americans have emerged as a major minority group in the U.S. They have been described by the media as the "superminority," "the fastest growing minority," and "the next hot market." This study compared Korean immigrants and Americans in their consumer product evaluation. A survey using personal interviews was conducted among Korean immigrants and Americans (N = 400). Results indicate that there are indeed ethnic differences in consumers' evaluation of product attributes across four product categories (automobile, stereo system, laundry detergent, and coffee). An important discriminating variable consistently appeared was that of individualism versus collectivism. Both traditional as well as alternative acculturation patterns were observed.

INTRODUCTION

Culture is a way of life shared by a group of people (Swidler 1986). As such, it is manifested in actions, behavioral styles and ways of expressions (Berry 1980; Padilla 1980). Culture may therefore also affect consumers' evaluation of product attributes. Past studies have indicated that oftentimes the perceived importance of product attributes is related more to cultural expectations than to their functional utilities (e.g., Bauer, Cunningham, and Wotzel 1965; Faber, O'Guinn and McCarty 1987). Cultural influences have also been observed in areas such as family decision making (Davis and Rigaux 1974; Douglas 1976) and the adoption of new products or ideas (Dayrymple, Robertson and Yoshino 1971). This notion of cultural influence on the evaluation of product attributes is important for the understanding of not only consumers in different countries but also ethnic minority consumers in the U.S.

Acculturation describes the changes in attitudes, values, and/or behaviors of members of one cultural group toward the standard of the other cultural group (O'Guinn, Lee and Faber 1986; Padilla 1980; etc.). It is essentially a process of cultural exchange. As the U.S. is experiencing more and more ethnic diversity, the study of acculturation and its relationship to consumer behavior has begun to receive more attention. Researchers have studied the extent to which and the manner in which process of acculturation is articulated in consumer behavior (Alba and Chamlin 1983; Deshpande, Hoyer and Donthu 1986; Garcia 1982; Hirschman 1981; Lee 1989; Massey and Mullan 1984; O'Guinn and Faber 1985; etc.). To date, the majority of acculturation research have studied African and Hispanic Americans. There is

little doubt that these two groups are the fastest growing minority groups in the U.S. However, since each ethnic group is inherently different, it is doubtful that the theory developed based on one or two ethnic groups will hold true for all minorities. Furthermore, since the process and the pace of acculturation depend largely on the cultural distance between the dominant host culture and the ethnic culture, it is very important that we start to look into different ethnic groups. By doing so, we will no longer limit ourselves to the often fragmented view of ethnic minority acculturation.

As individuals become acculturated into the American culture, their attitudes and values will change. Traditional acculturation theory has postulated that as individuals acculturate they are likely to become more and more like the Americans (e.g., Gordon 1964; Kim 1979). Here, acculturation is considered as a uni-directional process. However, some recent studies have raised serious doubts about this traditional assumption (Stayman and Deshpande 1989; Triandis, Kashima, Shimada and Villareal 1986; Wallendorf and Reilly 1983; etc.). The validity of such a "one-way" process, in view of the current trend toward cultural diversity, becomes questionable. In order to draw out a complete picture of ethnic minority acculturation, more ethnic groups need to be studied and different perspectives and research methodologies need to be incorporated.

The present study aims to understand the impact of acculturation on consumer behavior of immigrants in the U.S. by focusing on Korean immigrants. Specifically, the study examines the evaluation of product attributes as a function of acculturation. Two key research questions are addressed in the study: (1) Are there any ethnic differences between Korean immigrants and Americans in their evaluation of consumer products? and (2) Will those ethnic differences become blurry as immigrants become acculturated?

CONSUMER PRODUCT EVALUATION

The process of choosing a particular consumer product can be a fairly complicated event, especially for immigrants. Various theories have been proposed to explain why and how consumers choose a particular product or brand (Mitchell and Olson 1981; etc.). Among the many attempts, consumer behavior researchers have studied extensively on how a consumer develops attitude toward a brand (Sheppard, Hartwick and Warshaw 1988). Fishbein and Ajzen (1975) suggest that there are two major components influencing an individual's attitude toward an object -- belief structure and evaluative criteria. An individual's belief that a brand possesses given characteristics may be formed through direct personal experience with the brand and indirect means such as interpersonal and mass media sources. The impact of cultural norms and

values on the belief structure may come from any one of the above sources depending on the acculturating individuals' chosen route to acculturation.

The second component, evaluative criteria, is where culture exerts the greatest impact. A consumer judges a product by certain attributes he or she feels are pertinent to the purchase decision of that product. They constitute the primary evaluative criteria for consumers' attitude toward a brand. These criteria can be either objective (e.g., price or warranty) or subjective (emotional benefits). Culture affects consumers on two fronts. First, culture provides a consensual validation on what attributes are considered pertinent and important to the decision of purchasing a product. Secondly, culture tends to highlight the subjective criteria through an implicit symbolic meaning system for consumer products in a society.

Previous cross-cultural studies have found that while attributes used for evaluating products are basically standard, certain attributes are considered more important to one group of consumers than to the other groups (e.g., Faber, O'Guinn and MacAdams 1984; Lester 1983). In fact, Faber, O'Guinn and MacAdams (1984) argue that "one of the most significant cultural manifestation in consumer behavior is the way in which a product is evaluated as a function of various attributes." An example may help illustrate the point that cultural norms and expectations influence the relative importance of certain product attributes. For instance, Koreans consider stickiness the most important attribute in rice. Also, they favor short grain rice. The stickier and the shorter the rice, the better it is for the Koreans. The opposite is true for Americans who prefer fluffy and long grain rice. Stickiness, in particular, is the least desired attribute for the Americans. Therefore, both groups may use the same attributes for different reasons. Faber, O'Guinn and MacAdams (1984) also state that stressing irrelevant attributes or ignoring a product attribute central to a given cultural group can lead to an increase in counterarguing against the message, lower recall and less attitude change within the ethnic segment.

Few scattered studies have focused on cultural variations manifested in the perceived importance of product attributes between ethnic minorities and Anglo Americans. African Americans have been found to prefer brand name and the status and image associated with a product (e.g., Aker 1968; King and Demanche 1970), and they are more concerned about price (Bauer et al 1965; Feldman and Star 1968). Hispanic American consumers, however, tend to be brand loyal and price conscious (e.g., Bellenger and Valencia 1982; Gillet and Scott 1975; Hoyer and Deshpande 1982; Sagert, Hoover and Hilger 1985), and they prefer prestigious brands (Guernica and Kasperuk 1982; Segal and Sosa 1983; Watanabe 1981; Yankelovick, Skelly and White 1984). Some evidence even suggests that Korean Americans are brand-conscious, family oriented, and rely on word-of-mouth (Venture 1987; D & B Report September/October 1986). Japanese Americans are likely to be rational consumers (Dalrymple et. al 1971). Although it is

generally believed that there is a difference between immigrants and Americans in their evaluation of consumer product attributes, exactly how they are different may depend on many other factors.

The cultural influence on the perceived importance of product attributes becomes a complicated issue if acculturation is taken into account. Immigrants' attitude toward a brand may be influenced by either their culture of origin or the new host culture. The traditional progressive learning model suggests that the acculturating individuals tend to be in a position somewhere between "total acculturation" and "total ethnicity" (Kim 1979; Padilla 1980). If they have achieved a very high level of acculturation, their evaluation of product attributes are more likely to be influenced by the norms and expectation of the host culture. In some cases, however, immigrants remain isolated from the host culture voluntarily or involuntarily, thus their evaluation of product attributes are likely to be affected by their culture of origin. Recently, this traditional view has been challenged. Wallendorf and Reilly (1983) suggest that acculturation may not be uni-dimensional. Triandis et. al (1986) argue that there could be the so-called "ping-pong" effects of acculturation depending on whether subjective or objective culture is being examined. Stayman and Deshpande (1989) empirically illustrate that ethnicity may even be situation dependent. Consequently, a general null hypothesis can be stated as:

Hypothesis 1: The highly acculturated individuals will fall between the Anglo Americans and the immigrants whose acculturation level is low.

THE STUDY

The present study is designed to compare immigrants in the U.S. and Americans in order to answer two key questions: (1) Are there differences between immigrants and Americans in their evaluation of consumer products? (2) Do these differences (if any) become blurry as immigrants become acculturated?

A survey was conducted among Korean immigrants and Americans during the summer of 1989. Self-administered questionnaires were distributed to Korean immigrants through friends' referral as opposed to some random selection procedure. This is due to Koreans' general negative attitude toward survey. Several previous studies on Korean immigrants (Hurh 1979; Hurh and Kim 1984) have pointed out that Koreans are unwilling to give out personal opinions to a stranger. In order to overcome the difficulty of obtaining responses, this study relied on friends' referral in selecting Korean immigrant respondents. Korean immigrants were selected from four metropolitan areas -- Los Angeles, Houston, Dallas, and New York -- since over 60% of the total Korean immigrants live in these areas (1980 U.S. Census). American respondents were approached in places such as shopping malls and supermarkets from

similar cities. A total of 400 questionnaires were returned (Korean immigrants = 180; Americans = 220).

Research Instrument

Two sets of questionnaires were used in this study (one for Americans and one for Korean immigrants). Both contained sections on various purchase considerations for the four product categories (automobile, stereo system, coffee, laundry detergent) and demographic information. An additional section with acculturation measures was included in the questionnaire for Korean immigrants. The English version of the questionnaire was translated into Korean so that Korean immigrants may feel more comfortable with and favorable toward participating in the study. Translation and backtranslation techniques were used in order to ensure the equivalence of the two instruments (Brislin, Lonner and Thorndike 1973).

Measurement of Major Theoretical Variables

There are two sets of major theoretical variables in the study, namely, acculturation and the evaluation of product attributes.

Past studies have employed a variety of measures for identifying levels of acculturation (e.g., Lee 1989). The variables included in this study are derived from the several sets of commonly used acculturation measures (Table 1). Acculturation may occur from both direct and indirect contact with the American culture. Direct acculturation is therefore defined as the direct physical contact with American social environment and operationalized as an acculturating individual's: length of stay in the U.S.; use of language at home, school/workplace, and among friends; favorite food; neighborhood ethnic composition; best friends' ethnicity; plan for future settlement; and number of visit back to Korea. Indirect acculturation generally occurs through media exposure to the American environment. It is operationalized as an acculturating individual's amount of exposure to American mass media (broadcast and print).

The evaluation of product attributes is operationalized in the present study as the importance an individual assigns to the product attributes for four different categories (automobile, stereo system, laundry detergent, coffee) when it comes to purchase decision-making. The four product categories were selected to represent a diverse spectrum in terms of product involvement levels. Product involvement is usually defined by three major factors: price, purchase interval, and perceived risk. At one end of the spectrum, automobile is considered as high involvement product since the purchase interval is long and price and perceived risk are usually high. Laundry detergent and coffee are usually at the low end of the involvement level given that they are low risk items and do not command high price tag. Comparatively, a stereo system should be somewhere between automobile and laundry detergent and coffee in its involvement level. All four products have seven common evaluation attributes: brand name/make of the model, price, product performance (comfort for

automobile, sound quality for stereo system, cleaning ability for laundry detergent, taste for coffee), advertising, friend's recommendation, brand that friends use/have, and family's preference. Each product then has either one, two, or three additional attributes (warranty for automobile; whether it's on sale for stereo system; whether it's on sale and coupon for laundry detergent; sale, coupon, type for coffee). For each attribute, respondents were asked to respond to "When you buy a (product), how important is (attribute)?" on a 7-point scale with 1 being "not important at all" and 7 being "very important."

RESULTS

An acculturation index was constructed based on the 15 variables that were used to measure the levels of acculturation of Korean immigrants. These 15 variables include: the amount of time respondents spend on American network television, radio, newspapers and magazines; language used at home, at work and among friends; length of stay in the U.S.; number of visit to Korea; place of future settlement; restaurant of choice; ethnic composition of their neighborhoods; and the ethnicity of their two closest friends. This acculturation scale was first tested for internal validity. The results of a reliability test indicated that the scale had a reasonable internal consistency with Cronbach's alpha of .77. Since those variables had different units of measurement, the score for each variable was standardized. Those standardized scores were then given equal weighting and summed together to get an acculturation score for each individual. The acculturation scores for Korean respondents ranged from -12.29 to 13.94. The mean was 0.147 with a median of -0.973. The median acculturation score was used as a cut-off point to divide Korean immigrants into two groups. Those falling below the median were classified as "low" in terms of acculturation level, while those with scores the same or above the median were classified as "high." Therefore, three groups were used for subsequent analyses: Korean immigrants low in acculturation, Korean immigrants high in acculturation and Americans.

Multiple discriminant analysis was first used to investigate the relationship between ethnicity and product evaluation. Each of the four products was analyzed separately, with their respective attributes serving as independent measures. Wilk's lambda was the selection criterion since it allows us to maximize heterogeneity as well as group homogeneity (Klecka 1975). The respective attributes for each product were entered into the analysis simultaneously. Once the functions were derived, they were interpreted according to the relative size and direction of the standardized canonical discriminant function coefficients. In selecting product attributes which discriminate the three groups, only those coefficients that were at least half as large as the greatest were considered to produce nontrivial variance and were used as the discriminant function (Tatsuoka 1970). An analysis of the direction and magnitude of the group centroids followed. The group centroids allow us to assess which group considered the product attributes more

2. When did you come to the United States? _____

3. During your stay here, how many times have you visited Korea? _____

4. Would you say you would...

1. definitely go back to Korea
2. very likely to go back to Korea
3. somewhat likely to go back to Korea
4. somewhat likely to stay in the U.S. permanently
5. very likely to stay in the U.S. permanently
6. definitely stay in the U.S. permanently

5. Would you say your current neighbors are...

1. all Koreans
2. mostly Koreans
3. equally Americans and Koreans
4. most Americans
5. all Americans

6. If you have a choice to go to a restaurant tonight, what type of restaurant would you like to go to?

1. Korean
2. Chinese
3. Japanese
4. Mexican
5. Italian
6. American Continental
7. Others, please specify _____

7. Whenever you have free time, what type of books or magazines would you prefer for your leisure reading?

1. only readings in Korean
2. mostly readings in Korean
3. both Korean and English equally
4. mostly readings in English
5. only readings in English

8. What is the ethnic background of your very best friend?

1. Korean
2. Chinese
3. Japanese
4. Whites
5. Hispanics
6. Blacks
7. Others, please specify _____

9. What is the ethnic background of your second best friend?

10. How much time in a typical weekday do you spend with

1. American television programs
2. American radio programs
3. English newspapers
4. English magazines

important. The results of the discriminant analysis was then cross-checked through ANCOVA to make sure that the group differences in the evaluation of the product attributes were not caused by the influence of other variables.

Automobile

Multiple discriminant analysis with automobile attributes yielded two significant discriminant functions (Table 2). The first function, which accounted for 30.7% of the total variance, was characterized by family's want. Analysis of group

centroid indicated that low acculturating Koreans rated the highest on this discriminant function, followed by high acculturating Koreans and the Americans. It indicates that the less acculturated Koreans were most concerned with their "family's want" whereas highly acculturated Koreans were not as concerned but much more so than the Americans. The rank ordering of these group centroids was consistent with the traditional progressive learning model of acculturation. ANCOVA showed that after controlling the effects of income there was a significant difference in rating the importance of family's want across the

* Significant at $p < 0.05$

three groups. The less acculturated Koreans rated the attributed the most important (mean = 5.45) followed by the highly acculturated Koreans (mean = 5.11) and the Americans (mean = 3.58). It appears that the highly acculturated Koreans fall between the Korean culture which emphasizes family-centered decisions (collectivism) and the American culture which focuses on the self-centered decision (individualism).

The second function accounted for a meager 5.7% of the total variation. This function was mainly characterized by price (0.47), what their friends have (0.62), and advertising (0.30). Analysis of group

centroids showed that high acculturation group ranked highest (0.43), followed by the Americans (-0.05) and the low acculturation group (-0.29). This indicates that highly acculturated Koreans considered a combination of what their friends have, advertising and price to be more important attributes in their purchase decisions than Americans and the less acculturated Koreans. The rank ordering of the group centroid, therefore, did not support the linear progressive pattern of acculturation. ANCOVA results revealed that the three groups are statistically different on the evaluation of the three automobile attributes.

However, the rank order of group means show different patterns. First, Americans (mean = 6.38) were most concerned with price followed by highly acculturated Koreans (mean = 6.29) and the less acculturated Koreans (mean = 5.73), supporting the progressive learning model. Second, the highly acculturated Koreans gave the highest rating on their friends' brand (3.13) and advertising (4.10). The highly acculturated Koreans in fact overshot in terms of their position. An alternative pattern of acculturation is observed here.

Stereo System

Discriminant analysis on stereo system produced two significant discriminant functions (Table 2). The first function, which accounted for 44.6% of the total variation, was mainly characterized by family's want. As was in the case of automobile, the less acculturated Koreans ranked the highest (group centroid = 1.13) on this function, followed by the highly acculturated Koreans (0.40) and the Americans (-0.51). This implies that the highly acculturated Koreans tend to depart from the traditional Korean value of family priority. ANCOVA reports the rank order of the group means to be consistent with that of the group centroids. The mean difference among the three groups is significant at the confidence level of 95%.

The second discriminant function accounted for 5.9% of the total variance. It was a combination of "the make and model," "sound quality," "advertising," "friends' recommendation" and "sale." Analysis of group centroids showed that the highly acculturated Koreans ranked highest on this function (0.46), followed by Americans (-0.07) and the less acculturated Koreans (-0.26). This pattern failed to support the linear progression pattern of acculturation. ANCOVA results for the four attributes (make and model, sound quality, advertising and sale) yielded significant differences across the three groups. The highly acculturated Koreans considered sound quality (6.54), make and model (6.13), advertising (4.51) and sale (5.46) to be important attributes more so than the other two groups.

Laundry Detergent

One significant discriminant function emerged for laundry detergent (Table 3). The function accounted for 39.7% of the total variance, and was mainly characterized by a combination of price, sale and family's want. The rank order of group centroids revealed the less acculturated Koreans falling highest on this function (0.77), followed by highly acculturated Koreans (0.74) and Americans (-0.52). The order of group centroids confirmed the progressive learning pattern of acculturation. ANCOVA showed that the three groups are significantly different in rating the importance of friends' recommendation and family's want. The less acculturated Koreans valued family's want the most (4.90), followed by highly acculturated Koreans (4.60) and Americans (2.70). The less acculturated Koreans' reliance on friends' recommendation (4.03) was almost as high as the highly acculturated Koreans (4.07) whereas Americans

had the lowest reliance on friends' recommendation (2.69) in making laundry detergent purchase decision.

Coffee

One significant discriminant function was produced for coffee attributes (Table 3). The function was mainly characterized by a combination of type (-0.64) and family's want (0.63) and it accounted for 41.1% of the total variation. Analysis of group centroids showed a traditional linear learning pattern with highly acculturated Koreans (0.52) falling between Americans (-0.59) and the less acculturated Koreans (0.82). In other words, the highly acculturated Koreans departed from the traditional value of family priority and learned the importance of coffee type for purchase decision-making. ANCOVA reported that both the type of coffee and family's want have significantly different means across the three groups after controlling for the effect of income. Americans have the highest scores on coffee type (5.88), followed by highly acculturated Koreans (5.36) and less acculturated Koreans (5.24). On the other hand, less acculturated Koreans scored the highest on family's want (5.44) followed by highly acculturated Koreans (4.54) and Americans (3.03).

DISCUSSION AND CONCLUSION

Results from this study indicate mixed patterns of acculturation. The linear/uni-directional pattern was found in terms of family priority which accounted almost 30% to 45% of the total variance. The nonlinear/alternative pattern was found in a combination of advertising, friends' recommendation and friends' brand which accounted for less than 5% of the total variation. It appears that family's want is the most important variable that discriminates the three groups across all four product types. Less acculturated Koreans tend to keep the traditional Korean value of family priority even in their evaluation of product attributes. This family priority is still manifested in product attribute evaluation among highly acculturated Koreans. However, compared with less acculturated Koreans, they seem to have made the move toward an individualistic orientation -- a distinctive American value.

Other discriminating variables differ from product to product. For the two high involvement products (automobile and stereo system), the second discriminant function revealed a nonlinear pattern of acculturation. In other words, highly acculturated Koreans tend to "overacculturate" into the American culture. This nonlinear pattern again raises doubts about the traditional progressive learning model. There has been some empirical evidence suggesting that the acculturating minorities may stray from the linear progression pattern of acculturation. Wallendorf and Reilly (1983) assert that the acculturating Mexican-Americans' cultural pattern is not a nice median between American culture and Mexican culture. Rather, they seem to have a unique cultural style of their own. This may come from the over-adoption of the stereotypical American culture without a deep understanding of the reasons and inner

logic behind the cultural style. The same reason may also apply here. The highly acculturated Koreans tend to want to become more like the Americans and thus actively adopt the American cultural styles. They observe what their friends buy, listen to what advertising says and adopt their friends' recommendations. Of course, their peer group at this stage could include more American friends. This might be the main reason why highly acculturated Koreans outscored Americans and the less acculturated Koreans on advertising, friends' recommendation and what their friends own.

A series of multidiscriminant analyses show that there are indeed ethnic differences in the evaluation of product attributes between Americans and Korean immigrants. The major difference is the different weights that each culture puts on the importance of family. Koreans tend to be more family-oriented in their product evaluation than

Americans. The highly acculturated Koreans still has this value even though they have made a substantial progress toward the individualistic American value. Other than this significant attribute, others tend to vary widely from product to product. Therefore, it is difficult to have a definitive conclusion. Since the traditional theory can no longer accommodate the dynamic process of acculturation observed in this study, as well as several other, new and alternative conceptualization needs to be explored. Results from this study, if anything, confirms such urgent need.

The Cultural and Political Economy of the Indian Two-Wheeler

Bruce de Pyssler, University of Texas-Austin

INTRODUCTION

This paper is part of a project that combines political economy, communication theory, and cultural anthropology to examine India's economic liberalization, its accompanying consumer boom, and the communicative resources unleashed by the recent flood of consumer goods in India. More specifically, the project addresses the conceptual relationship and interaction of what John Fiske, in his volumes, *Reading the Popular* and *Understanding Popular Culture* (1989), calls "two parallel, semi-autonomous economies." In these two studies, while demarcating between production and consumption, and while stressing that the conditions of production of a cultural system are not the same as, and do not predetermine, the conditions of use and consumption, Fiske makes a crucial distinction between what he terms the *financial* and *cultural economies* of television texts. In his work, the financial economy refers to the role television texts play generating wealth (advertising revenue, syndication fees, etc.), while the cultural economy refers to the ability of texts, combined with creatively active readers, to generate "meanings, pleasures and identities" (*Understanding*, pp. 26-27).

My project, based on a study of the product category of Indian two-wheelers, assumes that Fiske's distinction can be productively applied to consumer goods. I, however, will expand his conceptualization of the financial economy to reflect my wider concern with the flow, distribution, allocation, and accumulation of economic surplus and its accompanying socio-political arrangements (production relations, legal strictures). I will rename it a political economy of texts/goods.

The cultural economy of goods, on the other hand, is concerned with the "manufacture and trajectory" (the terms are McCracken's) of cultural meaning. While a political economy impels us to track the movement, distribution, and institutional arrangements accompanying the flow of surplus, a cultural economy directs us to track the flow and movement of significance and cultural meanings and their cultural implications - Fiske's "meanings, pleasures, and identities". The argument here is that a full cultural analysis of the significance and meaning of a given consumer good must explore a textual meaning, how that meaning was arrived at (meaning movement, a cultural economy), and how the larger political economic context frames meaning-making.

Many questions arise when we consider the relationship between the productive and symbolic orders. One concern here will be how the productive order, certainly a major player shaping social conditions and social positions, resonates via a steady flow of consumer goods with the symbolic order. How that is the design, marketing, and advertising - literally, the production of meaning - that accompanies the world of goods must, in order to resonate with the social world, give due regard to

reigning social conditions and subject positions. One purpose here is to make a contribution to a cultural economy of the meaning of consumer goods in light of these questions. Another is to provide some instances where the symbolic order - here consumer goods cum material culture - has been used to reflect on the institutional arrangements of the productive order.

After a short social history of the scooter, I will examine these questions by combining my work on the Indian two-wheeler - a product category including scooters, motorcycles, and mopeds - with two very illuminating papers, one by Grant McCracken (1986) and the other by Dick Hebdige (1988). Some examples of actors reflecting on the less directly meaningful domain of political economy via the medium of consumer goods will be provided.

RANDOM NOTES ON THE HISTORY OF THE SCOOTER

Italy. The scooter, as we know it today, emerged from post World War II Italy. Both Innocenti's Lambretta and Piaggio's Vespa (Vespa means Wasp in Italian) emerged simultaneously to capture the mood and market of the post-war generation. Scooters were cheap, stylish, and importantly, they could negotiate war torn roads. Scooters were sharply distinguished - nitched as they say in the trade - and marketed as friendly, sociable vehicles. Advertising campaigns targeted women and an emerging genre of consumer - teenagers. As Hebdige points out: scooters were gendered "feminine" both by design and mediation. Adverts emphasized ease of use, simplicity, social touring, tourism, picnics, and the like. Machismo motorcyclists condescendingly referred to the scooter as "the hairdresser on wheels."

D'Ascanio, Vespa's designer, drew on emerging production processes to incorporate motifs from airplane design (such as the scooter's stressed skin, or sheathing, and stub axle wheel mounting). The political economic frame of scooter production required a bricolage of surviving Italian talent, production processes (whatever remained standing after the war) and the import of financial and productive capital (Marshall Funds).

The scooter also can be seen as a commodity that typified, like the products coming out of Harley Earl's GM Styling Division, the emergence of a new post-war theory of selling (or profit realization) - the packaged, stylized post-war product had arrived. This "theory" must be understood as representing important shifts in production processes, in the scale and rate of capital accumulation, and in the relation between the commodity and the market. Likewise, the new theory of selling must be understood as linked to the Fordist production line and in corporate/monopoly efforts to protect massive capital investment by managing patterns of consumption.

Britain. While this productive frame evolved in Italy, in Britain the cultural significance of the

object took on new and diverse cultural meanings. Hebdige identifies a major fault line in what he calls the national "official reception" of the scooter. On the one hand there was the reception, or reading, of the scooter by those social actors identified with declining heavy industry. These actors, having technical and financial capital tied up in the existing motorcycle product and market, tended to promote and identify with a negative reading of the scooter-text as an object clashing with prevailing definitions of masculinity. On the other side of the fault line, were those, positioned in the ready-to-boom design/fashion sector, who gave a much more positive reading of the scooter-text. Their alternate reading of the consumer good was guided, Hebdige suggests, by their interest in transforming the market and in aestheticizing its products. Perceived as "foreign competition" by one sector, to the other, the scooter-text was "the look of the future."

A complex reflection of this response to and reading of the scooter, was the Mods subcultural incorporation of the scooter as a "product complement" (in McCracken's terminology) to a consumption style that included consumer goods such as Hush Puppies and French Berets. The Mod's scooter served to mark them apart from the Rockers, who were oriented to motorcycles and a variety of more masculine consumer goods, such as boots and leather jackets. In Britain also, the scooter suffered through two different phases of customization: a baroque phase, marked by the use of streamers, extra mirrors, chrome, and the like, and a minimalist phase, where the scooter was returned to the "masculine" by the stripping of its sheathing. These activities - the ritualized reconstitution of the consumer good - fit nicely into McCracken category of possession rituals.

India. The Lambretta was introduced to Indian consumers in the early 1960's via a production agreement between Bombay-based Automobile Products of India and Innocenti. Indeed, in northern India "Lambretta" or "Lamby" rapidly became the Indianized generic name for scooters. Several years later Bajaj Auto formed a production agreement with Piaggio to produce a line of Bajaj "Vespa" scooters. Today, having divorced itself from Piaggio, Bajaj produces its own "Vespas," and Piaggio collaborates with LML, an Indian firm. During the 1960's and 1970's, because of restrictive government policy (licenses, production controls), a family could remain on a list for up to seven years waiting for the opportunity to purchase a scooter. Now, largely because of an emerging competitive environment, there is no longer a wait, and the scooter is the top selling two-wheeler in the country: 1) scooter sales per month = 65,000 units; 2) mopeds = 34,000 units; 3) motorcycles = 36,000 units.

Thinking in terms of a two-wheeler "code of commodities" and what scooter ownership signifies, as opposed to other two-wheelers, statistically the situation is as follows - 1) mopeds: these are associated either with lower income families, as their primary means of transport, or with pre-university students from the upper classes; 2) motorcycles: this is a mixed genre whose ownerships is split between

the upper peasants who prefer heavy 1950's Polish and UK designed motorcycles, and the new Indo-Jap collaboration 100cc's which are the rage amongst upper class college students and young, yuppie-type professionals, and 3) scooters, which, excepting the Kinetic, are associated with salary earners and shopkeepers, who have started families.

Owning a scooter today in India appears to be similar to owning a station wagon in 1950's and 1960's America. Indeed, it is the scooter's use value - its durability, its repairability, and, especially its floor board, a feature providing the scooter owner with the ability to carry his family, which determines to a great extent the scooter's symbolic and commercial value. In a movement reversing both Marxian and classical utility theory, the scooter's monocoque/sheathing design - signifier in Italy of gender, and then of subculture in Britain - only took center stage as a use-value when transplanted into India.

Oddly, this functional use of the scooter's floorboard cannot be shown in scooter advertising - government regulations prohibit showing a third rider on the scooter. Consequently, this utility function is removed from mass mediation. Bajaj Auto markets its scooter's in a sentimental nationalistic tone, while LML stresses its vehicles' safety features. Both advertising campaigns pitch to the consumer's sense of identity either, in the one case with India, or in the other, with the family.

In the southern state where I conducted my research, Karnataka (pop. est. 45 million), there are, as of 1990, 887,000 two-wheelers, 120,000 cars, 44,000 auto rickshaws, and 15,000 buses. Fully 70% of all vehicles in the state are two-wheelers, and only 10% are private cars. Over 50% of the state's 400,000 two-wheelers are in Bangalore city, where I conducted my field work. Nation-wide penetration of the two-wheelers (per 1,000 households) is as follows: 1) mopeds: urban 6.14; rural 2.13; total 3.23; 2) motorcycles: urban 3.83; rural 1.17; total 1.90; 3) scooters: urban 11.21; rural 1.59; total 4.22.

The growth of two-wheeler ownership in Bangalore, with its 4 million inhabitants, has been: 18,000 in 1970; 97,000 in 1980; 399,000 in 1988. This growth reflects several things, but primarily, a growing population, a rapidly expanding middle class, a government incomes policy that directs purchasing power to the middle class, and the 1980's economic liberalization.

THE SCOOTER IN INDIA

I would now like to try to give some sense of the consumer meanings, pleasures and identities attached to the Bajaj scooter. These comments are culled from my research and are intended only to capture some of the object's cultural significance, and not the trajectories by which that significance has been arrived at, the latter being a question of what I have earlier called the cultural economy of the commodity.

1) Focus group with school children. On the look of the scooter:

"a normal useful vehicle," "a family friend," "for shopping," "looks friendlier than an Enfield," "its meant for shopping," "king of the road," "absolutely smashing," "it looks like it is smiling," "I can see images of small people standing in the front," "good for Indian roads and middle-aged people," "looks delicate but is sturdy and tough"

- 2) Lintas ad agency account rep. On the differences between a Bajaj Scooter vs. a Yamaha 100cc user:

unlike the motorcycle user, the scooter user has a slightly more conservative profile; he's much more of a family man; he's slightly older than the typical motorcycle rider; he's more into functional usage of the product and not really for the fun of riding it; unlike a motorcycle rider there may not be much of this man-machine relationship; a Yamaha guy is brash, on the move, quick to take decisions, the kind of guy who on a weekend likes a girl on the back, the wind in his hair; the scooter user has a sedate, mundane life style; he is through with the good things in life.

- 3) Review, "The Lion Whelps," *Car & Bike*, Nov. 1987:

The first scooter I saw on Indian Roads was the Innocenti- Lambretta. Time was when colloquially Lambretta meant Scooter - any scooter ... The scooter's visual appeal took the urban middle class by storm. As opposed to classic motorcycles wherein almost all parts are visible and exposed, in the scooter *everything* (not almost but exactly) that did not need touching by the rider was covered. ... the Lambretta did not get 'branded' as a ladies vehicle which proved to be a great boon to API, and its popularity among urban males shot up ... sales soared and API rode the crest of the profit wave three decades ago. Enter the dragon - in the form of a buxom looking scooter more than two and a half decades go. Its eye appeal was even great, But people did express reservations at that time. Some said, 'how can a scooter be stable when the engine is on one side?'; but the dragon steamrolled over all of them to become the greatest success story on two wheels in India.

- 4) Editorial to " Scooter Buyers Guide," *Car & Bike*, May 1989:

There is something about a scooter. As a genre scooters arrived half a century after motorcycles. Why did no one think about them before? As a race, we Indians are genetically fond of scooters. More so than motorcycles ... the sales figures are proof. The genetic theory holds true even more because of what one sees overseas. In Malaysia and Singapore ... 90% of scooter riders are ... genetically Indian. The

scooters they ride are not imported from India but genuine Vespas ... So their preference for scooters cannot be because of any affinity to India. ... Why is the Indian gene so scooter oriented? That's one for psychologists, psychiatrists and sociologists to answer. The reason therefore has to be social and/or need based [mentions carrying space, can carry kids or suitcase on floor, lockable dickey space]; Is that the reason why scooters are such a hit in India? Imagewise, a scooter projects the rider as a solid family man, rather opposite that of a man on an Indo-Jap out to sow wild oats. Even the cops are more considerate to a man on a scooter ...

- 5) Interview with sociologist (Bangalore):

there is perhaps a stagnant craze for the Bajaj scooter ... everyone seems to feel that the ultimate answer to your two-wheeler requirement - its the Bajaj; every person with whom I have discussed my vehicle - it's a Vijay Supra - in every context I've talked to some one - either you've had a toss or had a puncture or a breakdown or whatever - the moment you stop talking they say 'see you shouldn't have gone for this here, you should have gone for a Bajaj'; this is the one constant thing...why this fixation on the Bajaj?

Interviewer: But the young university student, he doesn't want a Bajaj, he wants a 100cc Yamaha, right?

Karanth: Right - but wait till he gets married and has a child ... the moment there's a child. *[And much later in interview]:* I am still unable to resolve this fixation for Bajaj. Let me tell you a story of a good friend: He bought a vehicle - a Bajaj Chetak - he bought it out of the sheer fixation that he had that this is the only vehicle you should buy at all if you are buying a vehicle; and now he's telling me that he's looking for another vehicle which has a lower seat because he was so shocked he couldn't even reach the pedal; he never knew; he never thought of that; this is another extreme, you see that fixation is so much ... and then there is this fixation of all my colleagues who have bought a Bajaj; so many of them have bought it because of 'resale value'; you just go to any mechanic today - just go - you ask them one standard question: 'how many of your customers who come for repairs will ask you - every time they go back taking the vehicle - as to what the cost would be if he were to sell this vehicle? he wouldn't sell it, he wouldn't; but he'll ask nevertheless; he'll ask the mechanic: 'how much would I get for this?' and the mechanic says, 'well 6,000/7,000 rupees - like that'; he gets emotional satisfaction; he'll freak out on that; yet he'll never contemplate on selling it.

In short, what we see from the combined random notes on the social history of the scooter, and from the material culled from my research, is that the scooter in Italy, Britain, and India, while materially the same physical object, has taken on very different cultural meanings. Operating within different political economic structures, seen by different people, at different times, from differing perspectives, the scooter has generated diverse meanings, pleasures, and identities. For actors spread across social space and through time, it has been a different object. Appreciating this diversity, is one question, theorizing its movement, however, another.

MCCRACKEN & HEBDIGE

In order to begin to build a conceptual framework to account for the meanings, pleasures and identities identified above, we will now turn to two important papers. The first is Grant McCracken's, "A Theoretical Account of the Structure and Movement of the Cultural Meaning of Consumer Goods" (1986). McCracken's insightful, clear-headed accounting, amounting to a prescriptive outline for following the manufacture and trajectory of meaning in consumer goods, falls into what I have above called a cultural economy of meaning. As I've stated earlier, McCracken stresses the mobile quality of meaning, suggesting that we track the intentional agency-driven transfer of meaning from the already-existing cultural world *into* the product (design), *onto* the product (advertising), and *out of* the product (use). Importantly, he stresses how the manufactured meaningfulness of consumer goods ultimately loops back to assist social actors in the construction of the social world.

Following McCracken's model, and recapping the short history given above, we've seen how, first, as originally designed, the Italian scooter gives form to the gender category "feminine," and, as a kind of motivated sign, it actually displays the ideological principle guiding this gendering - the smoothness, the separation of mechanical parts from the consumer, etc. Secondly we've seen that, in mass mediation, first the quality of "sociability" (in 1950's Italy) and then the quality of "nationhood" (in 1980's India) were intentionally attached to the original Vespa cum Bajaj scooter. Thirdly, we've seen some examples of the ritualized extraction and reconstitution of commodity meaning. These are those instances where, as McCracken puts it, goods are used to "affirm, evoke, assign, or revise the conventional symbols and meanings of the cultural order" (1986, p. 78).

Here are some examples of these ritualized actions in Europe and India: the Mods use of the scooter in the subcultural revision of their social lives; the baroque and minimalist phases of scooter customizing; a proud 100cc owning Indians who, in addition to meticulously cleaning his cycle, goes to the extreme, on a weekly basis, of switching out stale for fresh air in his motorcycle tires; the ritualized marking of social passage or transition marking via parental gift-giving (eg., of mopeds to young upper class Indian girls to mark their passage of the pre-university exams, or of 100cc's to young Indian men

upon entering university); and lastly, as an incorporation ritual, the Hindu puja performed at the purchase of a new vehicle.

Also, and lastly, along McCracken's model, we see a fashion system which, as he maintains, often outruns the mass mediated meaning-producing reach of the capitalist class's agents of surplus realization. A major element of the two-wheeler fashion system is something I would call street media, the everyday spectacle of persons of certain caste, class, ethnic, generation, and gender identities, wearing other identifying signs - such as clothing - driving specific models of two-wheelers. In this fashion system a Levi-jeans and Adidas-clad university student or a safari-suited, middle-aged, middle-class Bajaj-scooter driver might closely fit the set of meanings a company considers to fit best their sales strategy, but the street media of Indian women driving Kinetic Hondas - and thereby making it a "sissy scooter", as one informant said it, may be quite out of tune with the image a company has in mind for its product.

Other instances of the fashion system at work occur in magazines such as *Car & Bike* and *Indian Auto*. These magazines provide abundant materials reflecting both McCracken's concern with the manufacture of meaning, as well as Fiske's textual concern with meanings, pleasures and identities.

- 1) Self/consumer good, practices (letter to the editor, *Car & Bike*, Aug. 15-Sept., 1989):

I am the proud owner of a RX 100. With respect to your May '89 edition ... Mr Satish has praised his KB. I think he has never ridden a RX 100. It is the best bike in the 100cc class. You just can't feel the power in the KB. Whereas in RX, one can really feel the thrust under him urging him on. The more power you want, the more you get. I'm just 19 years and of course would like to show off to the girls. In this matter RX has never let me down. Doing a wheelie is so simple and the sound is just great when you rip across the street. - Shekar Reddy

- 2) Product reviews also can contain interesting examples of the self/consumer good relation (*Car & Bike*, December 1989):

After our road test supremo Dilip Bam had finished his test and the bike was handed over to me for the performance tests and photography, it became a problem for me to leave the bike alone. The RX had captivated me - it was like I had fallen in love for the first time like a 16 year old adolescent, who wanted to be with his girlfriend all the time. ... Just as Gene Wilder went crazy over Kelly McGillis in *Woman in Red!* The RX100 had some sort of similar effect on myself as I went completely bonkers over it ... and I can say that the RX 100 HAS NEVER LET ME DOWN.

- 3) Here a product review captures nicely both the sensibility of the typical 100cc owner, and the excited response of an entire generation of young upper- and middle-class Indians to the 1980's consumer boom (*Car & Bike*, January 1988):

My own conclusion is that the RX is the bike of youth. Of impatience. Youth just *has* to get ahead. Overtake everything in sight. The RX responds beautifully to young desires. The greatest feature of the RX is its ability to overtake everything on Indian roads - including the Maruti.

The strength of McCracken's model is, of course, its anthropological and communicative orientation to material culture. Examining the trajectory and manufacture of meaning certainly gets the researcher on the right track. But one wonders if the model is possibly a little too tidy. Is it only a question that, as McCracken so nicely puts the cultural issue, "goods have a significance that goes beyond their utilitarian character and their commercial value" and that "this significance rests largely on their ability to carry and communicate cultural meanings" (p.71)?

Do we want to organize our theoretical imagery of the cultural significance of consumer goods as a kind of layer cake of values where there's utility (or use value), then there's commerce (or exchange value), then there's cultural meaning (or sign value)? Or are we possibly looking more at a kind of irregular marble cake where, at varying moments and across social space, the values of utility, commerce, and cultural meaning swirl to alternatively dominate one another.

Only by addressing the question in this manner can we begin to understand how the cultural connotations of something such as the Bajaj scooter are bound up with the productive order. And please note that I don't believe that offering an account of this linkage goes beyond what social actors sometimes actually do when they engage themselves with the cultural meanings of consumer goods. As evidence I offer this commentary from a product review of two scooter brands, a reflection comparing two productive units - one private, the other public sector - which addresses the possibilities of innovation and labor productivity under private versus state ownership (*Car & Bike*, May 1989):

But then how can a public sector company innovate? It had to fail and it did. The only plus point in favour of this scooter was the time it appeared: Exactly when Bajaj Scooters were selling at a massive premium. Today the factory is closed, it's employees on strike. Rahul Bajaj wanted to take over this company, the government too wants that to happen, but the employees don't want that - they are afraid that if Bajaj takes over, they might have to actually work! (a review of the Vijay Super, a public sector scooter made by Scooters India).

By this accounting the quality of the Vijay is defiled, justly or unjustly, by its association with state production. But, and importantly, this need not always be the case. Indeed, one of the messages of the little Maruti auto is just the reverse - the Indian government, at least in collaboration with the Japanese, can produce quality.

But the cardinal point is this: We must also begin to understand how social relations of production and other questions relating to production, such as, with the Bajaj, production shortages, and consequently, interminable waiting, can play a role in molding what the informant above called the "stagnant craze" for the Bajaj. We must begin to understand how, in an impoverished country, the scooters' utility function - its ability to carry three and four family members - shapes not just the commercial value, but also the cultural meaning of the scooter.

Thus, in reconstructing commodity meaning, while we must take into account, as McCracken maintains, the passage of consumer goods from the frames of design to mediation to use, we also must draw back on occasion to examine the structures within which these frames operate. So that, to give one of many possible examples, understanding the designed meanings of consumer goods requires not just an analysis of how goods do duty incorporating cultural principles, such as, for example, how something like a push-button auto transmission can encode the cultural idea of progress. But also how, beyond mediated events such as design, advertising, exhibitions, reviews, advertising, user groups, and owner consumption rituals, commodity-meaning is also tied up with things like: 1) the intracorporate division of labor (say, between, at the design stage: engineering, styling, and management); 2) constraints of available technical resources, ability and willingness to modify plant; 3) labor relations and labor processes; and 4) distribution and retail.

Dick Hebdige's paper, "Object as Image: The Italian Scooter Cycle" (1988) provides a strategy. While Hebdige's approach is similar to McCracken's in that he stresses that we track meaning, in addition, he strains to account for the political economic issues discussed above so that the the cultural analysis of consumer goods can be placed into the structures of the political economic context. Earlier I provided Hebdige's accounting of how different sectors within Britain's social structure reacted to the arrival of the Italian scooter. Along these same lines we certainly would want to consider Mahatma Gandhi's mobilization of India's peasants to nationalism and socialism around the indigenous cotton, khadi.

By this accounting the meaning of a particular consumer good, say of the Vijay scooter, must be subject to a sociology of knowledge; that is, to an accounting of the subject and social position of the reader. How many, for example, within the social structure are able to factor into his or her decoding of the consumer good things such as labor and productive arrangements? This also reinforces the idea that the cultural significance of a consumer good must at many moments, according to the social position of the

actor, be interpreted as occurring in a dynamic state of tension with the reigning political economic order.

Only if these issues are addressed will we be able to claim that we have provided an accounting of the cultural significance that provides for every possible point and moment where meaning is fixed. Only then can we claim to provide what Hebdige calls a "a unified account of all the multiple values and meanings which accumulate around a single object over time" (1988, p. 81).

CONCLUSION

In the Upanishads Maitreyi questions Yajnavalkya as to whether her wealth will bring her immortality. Receiving a negative answer she then asks: "What then should I do with that by which I do not become immortal?" By now I hope that the answer to Maitreyi's question is clear: We are to *communicate* with our wealth. I hope if nothing else that this paper has established that, while this is fully a matter for cultural analysis, it is a cultural analysis which must be carried out in the context of a larger, largely political economic context. I conclude with a final example of the merging of the political and cultural economies of meaning: Several days before finishing my field work and returning to the USA, a close friend and informant, Hari, made a special trip to visit me at the home where I lived. He had with him a photograph he had clipped from the *Deccan Herald*. Before showing me the photo however, he sang, with the utmost delight and with a glimmer in his eyes a line from the jingle of a popular TV advertisement for the TVS Champ moped. The line: "Oh What a Way to Get Carried Away! TVS Champ." The photo: A completely burned-out and destroyed shell of a bus. The bus in fact was TVS's executive bus. It had been attached and destroyed just outside Bangalore while fully loaded with its precious cargo. What was "getting carried away" in Hari's mind and rendition was, of course, not some proud TVS Champ owner, but an angry labor force. It struck me then and there that the little TVS Champ would forever have a slightly different connotation for Hari. The productive order had intruded successfully into the carefully managed meaning of the TVS Champ.

The Ethnicity and Consumption Relationship

Johanna Zmud, University of Southern California
Carlos Arce, NuStats, Inc.

ABSTRACT

This paper investigates the influence of situational factors on the relationship between ethnicity and consumer behavior. Findings based on analyses using data from a 1989 Survey of Hispanics in the Los Angeles metropolitan area conducted for *The Los Angeles Times*, suggest that behavior is a function of ethnicity, social surroundings, and product type. Results also indicate that ethnicity is a dynamic, complex construct that is comprised of both inherited and acquired characteristics. While the available data are limited, this analysis raises the possibility that the situational ethnicity model proposed by Stayman and Deshpande (1989) can be improved with the addition of the variable, cultural identity.

The dramatic rise in immigrants to the U.S., especially from countries in Latin America and Asia, has prompted researchers to investigate the hypothesis that one's ethnicity influences consumption patterns (Stayman and Deshpande, 1989; Deshpande, Hoyer, Donthu, 1986; Pitts, Sheth, and Valencia, 1986; Hirschman, 1981; Belk, 1974, and Lutz and Kakkar, 1975). Most recent work in this area has focused upon refining the concept of ethnicity. As Deshpande, Hoyer, Donthu (1986) assert, the lack of discipline that has been followed in defining ethnicity (i.e., surname, country of origin, paternal ancestry, self-identification, language spoken at home) has led to inconsistent and contradictory findings which hinder theory building. The discrepancy in definitions is problematic also in that it implies differing assumptions about the nature of ethnicity. Contributing much to both the conceptualization of ethnicity and to the literature on consumer subcultures is the work of Stayman and Deshpande (1989), who have specified a model of situational ethnicity. (See Figure 1.)

According to Stayman and Deshpande, situational factors (i.e., social surroundings and type of product) influence the relationship between ethnicity and consumer behavior. In other words, such behavior is a function of ethnicity, social surroundings, and type of product. Social surroundings and type of product are rather straightforward variables. However, ethnicity continues to be a troublesome concept. "Felt ethnicity" is a new concept identified by Stayman and Deshpande; it is defined as a transitory psychological state of individuals that is manifested in different ways in different situations. It is distinguished from the idea of ethnicity as a stable, sociological trait that is manifested in the same way at all times. The theoretical rationale underlying this idea of dynamic ethnicity is the contention by sociologists (Yancey et al., 1976) and psychologists (McGuire et al., 1978) who argue in different literatures that ethnicity is not just who one is, but how one feels in different

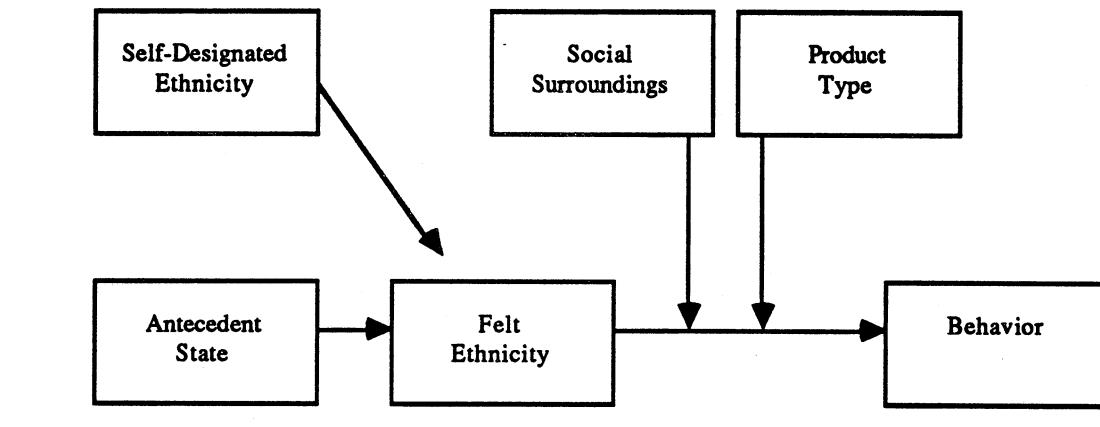

situations. In specifying ethnicity as a dynamic concept, Stayman and Deshpande have found consistent support for the effect of situational factors on consumer behavior. For example, in their most complex test of the model (a four-factor, mixed effects design), Stayman and Deshpande (1989) found that Hispanic, Asian, and Anglo subjects switched the type of food consumed (among Mexican food, Chinese food, and American food) based on their social context. Their use of situation-specific, felt ethnicity increased explained variance in likelihood of choice over that explained by either self-designated ethnicity alone or use of non-situation specific, felt ethnicity. The present study seeks to more rigorously test this finding through the use of structured-equation modeling with the LISREL program (Joreskog and Sorbom, 1988). Thus, the first hypothesis to be tested in this study is as follows:

H1: *Behavior is a function of felt ethnicity, social surroundings, and product type.*

With the understanding that an individual's ethnicity is a complex state of being, Stayman and Deshpande specify it with by use of two theoretical concepts: self-designated ethnicity and felt ethnicity. In terms of the relationship between these two variables, felt ethnicity is a function of self-designated ethnicity, and antecedent state. According to Stayman and Deshpande, antecedent state refers to how ethnic one feels in the face of bias towards the target group. Stayman and Deshpande supported the earlier work of Deshpande, Hoyer, and Donthu (1986) in finding that self-designated ethnicity and antecedent state influence felt ethnicity. However, a relationship not specified by Stayman and Deshpande was the notion that social surroundings may influence felt ethnicity as well. For example, research in language acquisition and sociolinguistics has uncovered the phenomenon of "code switching". This is a practice of bilinguals who switch languages according to the social context in which the language use takes place. While early in the field of linguistics code-switching was thought to connote the idea that the individual was in a transitional state — going from one language system to another one. More recent work has shown that code-switching is actually a function of changes in an individual's strength of ethnic identity which may vary according to social context (Gumperz, 1978, 1976; Valdes Fallis, 1980). Thus, it may be that the Stayman and Deshpande model could be improved with the conceptualization of social surroundings as an antecedent condition to felt ethnicity and not simply as a moderator of the felt ethnicity and behavior relationship.

Another potentially rich modification in the model involves the addition of a new variable, cultural identity. While Stayman and Deshpande found that situation-specific felt ethnicity is a better predictor of

FIGURE 1
Casual Model of Situational Ethnicity and Consumption

behavior than non-situation specific or self-designated ethnicity, the differences in R-square among the three conditions are not highly significant. This implies that the construct, felt ethnicity, can be improved. In going back to earlier work of Deshpande (Deshpande, Hoyer, and Donthu, 1986), it appears as though Weber's definition of "ethnicity" was used in early theorizing. According to Weber (1986), ethnicity is a common inherited and inheritable trait that actually derives from a common descent. Viewed in this way, ethnicity is seen as a stable trait. One way to view ethnicity as having both stable and varying properties is to suggest (as does anthropological theory) that ethnicity functions in two distinct ways: a cultural identity which is stable and a social identity which varies (Fitzgerald, 1974). Social identities, then, vary to suit the social surroundings. The individual shifts behavior with each adaptation to new situational demands. Social identification facilitates change; and opens the individual up to experiences that produce new identities or new social stances. In anthropological terms, social identity refers to the phenomenon of "acculturation." This is the integration of ethics at the primary level (i.e., kinship, neighbors, and close friends) (Alba, 1976, Gallo, 1974).

Cultural identity, on the other hand, refers to one's basic group identity. It refers to identity at the group level vis-a-vis some other group. A sense of cultural identity supplies a unifying "identity" thread as people strive toward consistency from one situation to another. McGuire et al. (1978) suggests that individuals in a multi-ethnic society such as the United States are likely to have a set of ethnic and other identities that may be differentially salient. Thus, there appears to be theoretical support for the addition of both social surroundings and cultural identity to the list of variables that predetermine felt ethnicity. The second hypothesis to be tested is:

H2: *Felt ethnicity is a function of self-designated ethnicity, antecedent state, social surroundings, and cultural identity.*

In essence, I am suggesting that the more elaborate situational ethnicity model (see Figure 2) is a more promising representation of reality than the Stayman and Deshpande model presented in Figure 1. In using structural-equation modeling to test this proposition, I submit the final hypothesis:

H3: *The modified situational ethnicity model is a good fit to the observed data.*

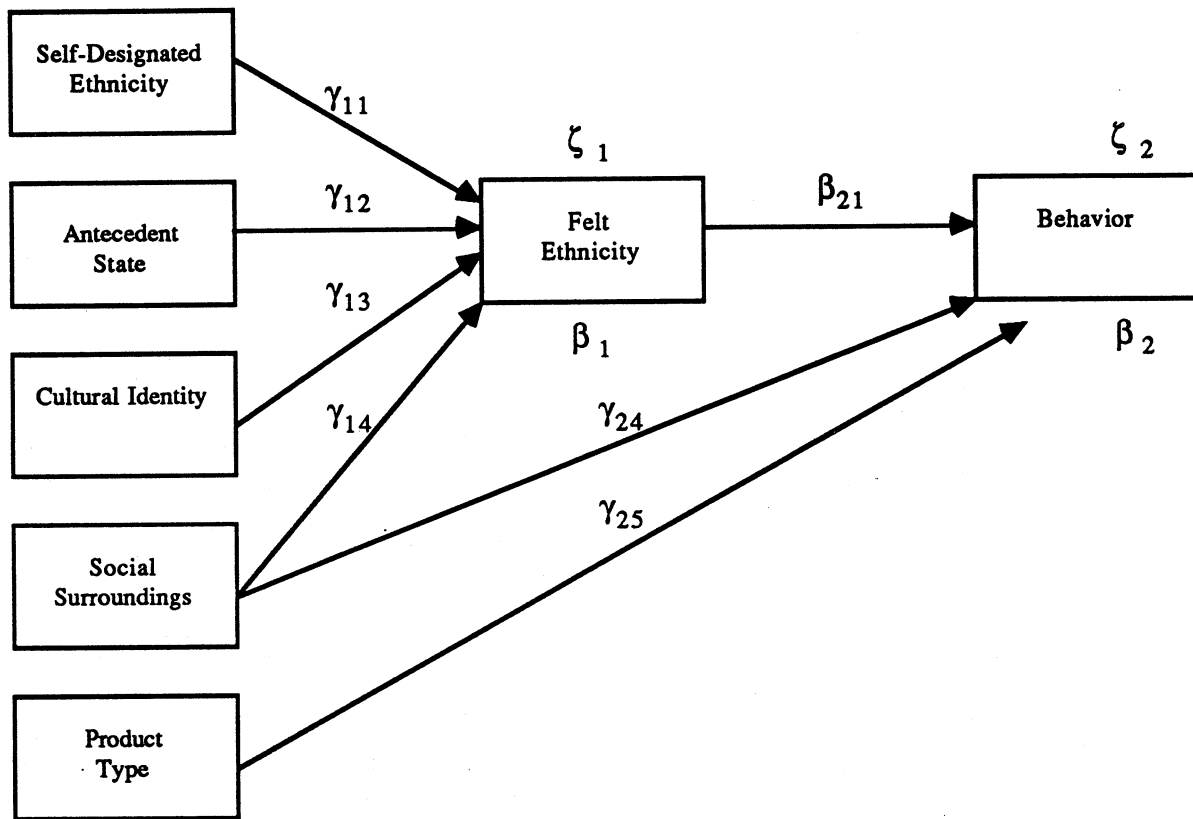

METHODS

Design

This study is a sub-study, using data collected in a 1989 Telephone Survey of Hispanics in the Los Angeles Metropolitan area, conducted for the *Los Angeles Times* newspaper. This researcher was a member of the team that conducted the study in July/August 1989. The researchers followed two criteria in drawing a stratified sample representative of the area: (1) random digit sample production of households in all zip codes which contained at least 20% Hispanic population; (2) Spanish surname random sampling in all zip codes with less than 20% Hispanic population; and (3) purposive sampling of Hispanics without telephones. A total of 1,733 Hispanic adults, including 165 in non-telephone households were interviewed in summer 1989. A total of 420 non-Hispanic interviews were conducted as comparative data, using a random digit sample. From this larger sample, the subsample for the present study was selected. A primary goal of the study was to develop a theory on the dynamics of ethnicity in a multi-cultural society and effects on consumer behavior. Thus, Hispanic subcultures were used as the subsample: Mexican-Americans, Mexicans, and Central Americans (N=1337).

Three survey instruments were developed: (1) English language; (2) Spanish language; and (3) non-Hispanic. The Spanish language questionnaire was concurrently developed with the English, and then back-translated to English to identify and resolve any problems with disequivalency of language.

FIGURE 2
Proposed Situational Ethnicity Model

Bilingual/bicultural interviewers conducted the interviews.

Measurement

The *Los Angeles Times* questionnaire contained a number of questions from which measures of the variables of the study were operationalized. The measures for the exogenous variables are as follows. Self-designated ethnicity was measured using the emic self-report method asking, "What is your ethnic background?" Antecedent state, as conceptualized by Stayman and Deshpande, is measure of "how ethnic one feels". Their assumption is that perception of discrimination would affect this state. For purposes of my analysis, the variable was measured on a 4-pt. scale of agree-disagree with the statement, "being too Hispanic gets you more problems than benefits." The new variable, cultural identity, was measured on a 4-pt. frequency scale in answer to the question: "Would you say you go to social gatherings with non-Hispanics?" (frequently, sometimes, seldom, never). The assumption underlying this measure is that Hispanics would frequent such gatherings as they assimilate. Thus, the stronger the assimilation score, the weaker the cultural identity. Social surroundings is a dichotomous variable measuring the presence of "change" in behavior from one type of social situation

to another. This operationalization is conceptually equivalent to the Stayman and Deshpande manipulation of social surroundings in their experimental design. The items from the *Los Angeles Times* survey used to measure this concept was: "What language do you use when you talk to your parents?" and "When you talk to your co-workers?"--only English, mostly English, both, mostly Spanish, only Spanish. A dummy variable was constructed of change, no change. Product type was also a measure of the presence of "change", using the dummy variable technique. The items chosen concerned the change in use of language in the context of two different product types--a media product (newspaper) and a banking product (loans).

Endogenous variables were measured in the following manner. Felt ethnicity was a measure of strength of ethnic identification. A 5-point scale of frequency of attendance at local Hispanic community festivals was used. The assumption was that strong ethnic identifiers would attend such festivals more frequently than weak ethnic identifiers. Behavior was a measure of a consumer choice between a Spanish-language newspaper and an English-language newspaper.

Correlation Matrix

	Felt	Behav	Eth	Anth	CultID	SocID	Ptype
Felt	1.0						
Behav	.10	1.0					
Eth	-.01	-.10	1.0				
Anth	-.05	-.06	-.03	1.0			
CultID	.07	-.36	.07	-.01	1.0		
SocID	-.01	-.14	.08	.06	.11	1.0	
Ptype	.10	.23	-.02	-.11	.07	.19	1.0

Analysis

The original data file was used in the re-analysis of *The Los Angeles Times* survey data. Descriptive statistics and a correlation matrix were estimated using SYSTAT. The structural-equation parameters were estimated using the LISREL VII program. The correlation matrix (see Table 1) was input to the LISREL VII program. Each correlation coefficient is based on 1336 cases.

RESULTS

Macro Results

Hypothesis 3 tested the overall fit of the model. The data did not provide well-founded support for this hypothesis. The initial iteration produced a model with $X^2=245.37$, $df = 4$, $p = .000$. The large value of X^2 , relative to the degrees of freedom, indicates that the proposed model did not fit the data well. The difference between the observed correlation matrix and that resulting from the hypothesized model was statistically significant. The Goodness of Fit Index (GFI) was .953; however, the Adjusted Goodness of Fit (AGFI) was .674. The AGFI takes into account degrees of freedom; therefore, it is a more accurate indication of the fit of the model. This lower AGFI indicates a problem model. A better fit might have been found if LISREL had been used to test the interaction between social surroundings and felt ethnicity or behavior. As the model was specified, the test becomes one of situational change in behavior but not change "specific" to a particular situation.

Micro Level

Hypothesis 1 tested the proposition that behavior is a function of felt ethnicity, social surroundings and product type. The R^2 for this equation was .088. Much of the variance was left unexplained. In terms of the individual links, the maximum likelihood estimates were: .138 for the link between felt identity and behavior; -.191 for the link between social surroundings and behavior; and .266 for the link between product type and behavior. All of these were significant at the .01 level.

Hypothesis 2 tested the proposition that felt ethnicity is a function of self-designated ethnicity, antecedent state, social surroundings, and cultural identity. The R^2 for this equation was .036,

indicating that much variance is left unexplained. The maximum likelihood estimates were: -.034 for the link with ethnicity; -.040 for the link with antecedent state; .001 for the link with social surroundings; and .122 for the link with cultural identity. Of these only the link with cultural identity was significant at the .01 level. The total coefficient of determination for structural equations was .104, indicating the presence of much unexplained variance in the whole model.

Post-Hoc Analyses

The modification indices, presented in the LISREL VII printout, indicated that the model could be significantly improved with the addition of a link between cultural identity and behavior. This link makes theoretical sense because of anthropological studies which indicate that cultural identity transcends situational adjustments and in doing so gives common meaning, stability, and predictability to the individual's behavior (Fitzgerald, 1974). With this rationale, another iteration of the LISREL analysis was conducted. In this second iteration, all the previous links were left "as is."

Macro Results

The second iteration produced a model with $X^2=11.43$, $df = 3$, $p = .000$. The smaller value of X^2 indicated a much improved fit of the new model with the observed data. The GFI was .998, and the AGFI was .977. The close match between the GFI and the AGFI indicates a good fitting model. Another indication of an improved model is found in comparison of the root mean square residuals between the first and second LISREL iterations. An estimate under .05 is considered acceptable. The estimate for iteration #1 was .076; the estimate for iteration #2 was .016. This parameter supports the good fit of the post-hoc model.

It must be noted that the chi square statistic tends to be sensitive to sample size, implying that the low chi square estimate obtained may be an artifact of the large sample size ($N=1337$). To test the robustness of the chi square obtained, the post-hoc model was tested against a null model. The null model hypothesized no links among variables, and this model was run in LISREL. Using a chi square difference test, it was found that a X^2 of 297.80 with 8 degrees of freedom is significant. It appears more likely that the post-hoc model is a good fit of the data.

Micro Level

The R^2 for hypothesis 1 was .218; it was much improved. In terms of the individual links, the maximum likelihood estimates were: -.363 for cultural identity; -.14 for felt identity; -.154 for social surroundings; and .285 for product type. All of these were significant at the .01 level.

The R^2 for this equation was .024, which is slightly lower than the first iteration. The maximum likelihood estimates were: -.006 for the link with ethnicity; -.040 for the link with antecedent state; -.001 for the link with social surroundings; and .121 for the link with cultural identity. Again, only the link with cultural identity was significant at the .01 level. The total coefficient of determination for structural equations was improved to .229.

DISCUSSION

This study lends support to the growing body of research on the link between ethnicity and consumer behavior. Most importantly, this study supports the notion of ethnicity as a dynamic, complex concept. The new variable, cultural identity, proved to be a significant addition to the Stayman and Deshpande model. Figure 3 illustrates the post-hoc model and reports the LISREL VII estimates of the parameters in this model. The model, as estimated, supports the proposition that behavior is a function of felt ethnicity, cultural identity, social surroundings, and product type.

However, the proposition that felt ethnicity is a function of self-designated ethnicity, antecedent state, product type, social surroundings, and cultural identity is only weakly supported. There is good reason to believe that problems may lie in the operationalization of the variable, felt ethnicity. The diagnostic information contained in the LISREL VII printout indicates that the standardized residuals for this variable are problematic (i.e., larger than 2.48 for the links with behavior, cultural identity, and product type.) The present study relied on data collected for a different purpose; and thus, the researchers were constrained by limitations in the pre-existing items. For this reason, several leaps in logic were made in operationalizing the variables. For example, the measure of felt ethnicity was behavioral rather than perceptual. Social situation was measured as situational change in general, rather than as a specific change in the situation under which a particular behavior was performed. While the study suggests an improved model of the ethnicity and consumption relationship, the results are limited.

In examining the relationship between ethnicity and consumption, this study suggests that cultural identity may have a greater influence on behavior than felt ethnicity. In order to fully explore the implications of this finding, it is necessary to examine more closely the conceptual differences between a social identity and a cultural identity. As was mentioned previously, social identities are assumed to vary situationally, while cultural identities have been conceived as stable. Evidence has been mounting since the 1970s that the phenomenon of situational variance in ethnic identity exists.

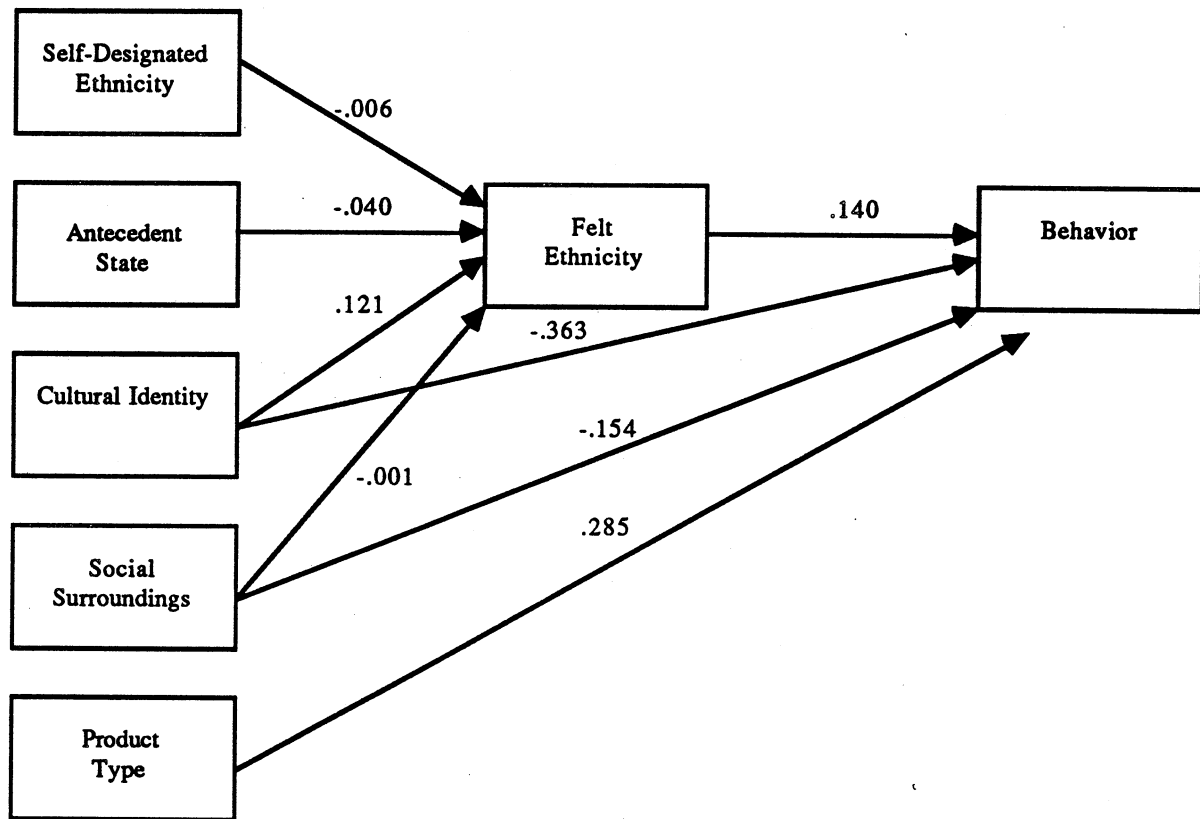

Theorists, such as Stein and Hill (1977), Gans (1979), and Padilla (1985), discuss the situational aspects of ethnicity as strategic or symbolic manipulations. According to Webster's Ninth New Collegiate Dictionary, situation can be defined as "relative position at a certain moment." When people shed, resurrect, or adopt ethnicity at certain moments only, it can be assumed that they do so out of "choice." If so, then race would act as a constraint on the range of choices. Therefore, Whites would enjoy a great deal of freedom in terms of situationally choosing ethnic identities; those defined in racial terms as "non-White" would enjoy much less freedom. Then in terms of situational ethnicities, the important research questions should be: how and why people choose a particular ethnic identity from a range of possible choices. The recognition of such questions has led to a recent increase of work investigating the conditions for choosing identities among White ethnics (Waters, 1990; Alba, 1990). It is suggested that further research investigate the differences in situational effect between Whites and non-Whites, with the hypothesis that situational effects will be stronger among Whites. As Coleman and Rainwater (1978) argue, Whites do not perceive ethnic discrimination to be a threat to their individual life chances, and their ethnic identity can be used at will and discarded when its psychological or social purpose is fulfilled.

This view that Whites are more likely to be "situational ethnics" should not be taken to mean that non-Whites do not exhibit situational variance in behavior. In fact, the present study documented the situational variance in language use among Hispanics. Bilingual Hispanics are likely to speak Spanish with their parents and English with their children. However, the range of possible choices for situational variance is much less among Hispanics than among Whites.

The more fundamental way in which ethnic identity influences consumption could be through cultural identity. Cultural identity is comprised of what people have inherited (e.g., race, origin, history, religion, language) and of what they have acquired (e.g., language, nationality) (Isaacs, 1975). As was mentioned previously, cultural identity could be the "stable" dimension of an individual's ethnic identity as it refers to one's basic group identity. Of importance, differences in consumption patterns have been evidenced by culture. In the U.S., for example, evidence exists that Hispanics are brand-loyal (Saegert, Hoover, Hilger, 1985; Segal and Sosa, 1983). While cultural identity does influence behavior, its strength of influence is dependent upon the importance attached to a particular identity. It is likely that the level of importance one attaches to a particular cultural identity will vary. Presumably, some individuals will attach a great deal of importance to that identity. For others, a cultural identity will be intermittently important, and still others will assume the label and little else.

Theory supports the notion that one's cultural identity is not stable but dynamic. Because what people acquire can be constantly new and changing, their cultural identity under certain conditions (e.g.,

FIGURE 3
Post-Hoc Situational Ethnicity Model

immigrant status) is dynamic — almost in a continuing state of becoming. Thus, the strength of influence of cultural identity on consumption behavior is dependent upon the level of importance placed on that cultural identity. For any given member of an ethnic group, the level could vary. For this reason, it is suggested that further research explore the varying strength of ethnic identification among individuals of a particular ethnic or minority group. In a follow-up study currently in progress, the researchers are testing the differential effects of a cultural identity on behavior on a large sample of Hispanics in three cities: New York, Miami, and Houston. The study was specifically designed to test the associations between cultural identity and behavior as well as the dynamic nature of culture identity given the process of assimilation. It uses a full LISREL model that combines both a measurement model and a theoretical model. Such information is useful to the prediction of consumer behavior which relies both on knowledge about individuals within a particular cultural context and on knowledge about individuals in their social relations.

"All the World's a Stage": Drama and Consumer Research Introduction¹

Barbara B. Stern, Rutgers University

SESSION OBJECTIVE

The purpose of this session is to integrate various streams of research on *drama* in order to encourage synergy among a multiplicity of approaches. The session aims at facilitating better communication among diverse drama researchers in marketing, sales management, advertising, and promotion. By presenting diverse perspectives on drama in the context of consumer research, the session is designed to generate rich answers to the question, "How does drama affect consumer behavior?" Multiple approaches to a single question may help researchers ascertain *what* engenders consumer effects and *why* these effects occur. To this end, the goal of this session is to bring together researchers whose views may complement each other, conflict with each other, or simply go off in different directions, in order to stimulate lively interchange and a spurt of creative borrowing among all of those interested in the protean concept of drama.

MULTIPLE PERSPECTIVES

Drama is a broadly defined category, for recent practitioner and academic research affixes the label to products, sales encounters, advertisements, and people. The session presents researchers representing humanistic, sociological, and psychological perspectives who locate the phenomenon of drama in different places. The humanistic tradition (Stern) is represented by qualitatively-oriented research that adapts Aristotelian language and concepts to study drama in advertising text. The sociological approach (Grove and Fisk) examines drama in service experiences in order to understand marketplace exchanges. The psychological approach is twofold, including a theoretical consideration of consumer "performance" in the marketing theatre (Deighton) and an information-processing model of consumer empathy (Boller and Olson). To date, these varied descriptive, analytical, and empirical perspectives have operated independently of each other, thus forfeiting the opportunity for seeds sown in one area to blossom in another.

CONCEPTUAL AND METHODOLOGICAL ORIENTATION

On a *conceptual* level, the session includes a range of perspectives spanning both traditional and innovative schools of drama criticism. The participants present dramaturgical concepts ranging chronologically from Aristotle's works on Greek tragedy (Stern) to modern cinematic theory (Boller and Olson), and conceptually from Bruner's psychological concept of meaning (Deighton) to Goffman's dramaturgical view of social behavior (Grove and Fisk).

Stern's presentation, "*What's in a Name?*" *Aristotelian Criticism and Drama Research*, begins by introducing terminology and concepts drawn from the Aristotelian tradition, the well-spring of dramaturgy and the foundation for later theories. Her presentation introduces basic Aristotelian elements such as "plot," "character," and "theme" as terms whose meanings provide a groundwork for coherent discussion. Her purpose is to provide a generally accepted vocabulary for discussing drama to ensure that multiple participants in the dialogue mean the same thing when they use these terms.

Next, Grove and Fisk's paper, *The Service Experience as Theatre*, presents a modern theory of drama as a metaphor of human behavior in the service experience. They draw from Goffman's dramaturgical theory to examine the traditional aspects of drama -- actors, setting, and performance. Their purpose is to study the service experience as a performance by analyzing the relationship of service characteristics to their theatrical counterparts.

Deighton's presentation, *Sincerity, Sham, and Satisfaction in Marketplace Performance*, proposes consideration of two aspects of marketplace performance - the concepts of "quality" and of consumer satisfaction. He employs Bruner's theory of dramaturgics to address the paradox of consumer enjoyment of theatrical performance as authentic versus distrust of marketing performance as insincere. His purpose is to revise the model of consumer satisfaction by adding the element of satisfaction with performance.

Last, Boller and Olson's paper, *Empathy and Vicarious Performances of Meaning During Exposure to Commercial Dramas*, focuses on empathy as a consumer response to a dramatic advertisement. The paper defines empathy as a response to dramatic advertisements -- those that present a story about one or more characters' experience -- and examines empathy in terms of consumer identification with the characters. The purpose is to present a model of processing that focuses on empathy as the key to understanding the power of persuasion in drama advertising.

Wells's discussion adds practitioner/academic insights, for his research and practical experience permit a multi-faceted overview of the concepts presented by the panelists. He provides a summary of the session's eclectic view of drama research and an evaluation of drama concepts from the practitioner's point of view.

On a *methodological* level, the session represents a cross-section of multidisciplinary research by utilizing methods drawn from the humanities as well as from the social sciences. Stern uses humanities methodology adapted from literary criticism, and Boller and Olson borrow from cinematography to develop a model of consumer processing. Deighton turns to psychology and

¹This paper is the introduction to Special Session 6.4.

marketing science, and Grove and Fisk rely on social interaction theory to analyze drama as a performance/response phenomenon. In this way, the session encourages the free flow of communication among researchers unfettered by disciplinary boundaries so that knowledge generated in one field can become the property of all.

In sum, the session proposes that multiple perspectives on drama in products, personal sales, and promotion can shed light on its behavioral and attitudinal effects on consumers. Both managerial/advertising practitioners and academic researchers can benefit from greater understanding of the nature of drama and its unique ability to evoke consumer responses. To this end, the session's comprehensive outlook affords the ACR audience an opportunity to sample a variety of drama research products with one-stop shopping convenience.

"What's in a Name?": Aristotelian Criticism and Drama Research

Abstract¹

Barbara B. Stern, Rutgers University

One genre may generate another....Or one genre might supplant and replace another as the historically or situationally dominant form of "social metacommentary" (to use Geertz's illuminating term). New communicative techniques and media may make possible wholly unprecedented genres of cultural performance and thus new modes of self-understanding (Turner 1981, p. 155).

Advertising as a form of cultural performance (Levitt 1970; Schudson 1984; Spitzer 1962) has generic affiliations with the textual family known as *drama*, one of the three major genres of literature (the others are poetry and the novel). The term "drama" has come into widespread use to describe a variety of marketing, advertising, and consumer behavior phenomena, perhaps as a sign of the importance of "the drama of consumer satisfaction" in marketing strategy (Leiss, Kline, and Jhally 1986, p. 232). Since recent research on products, consumers, sales encounters, and advertisements uses "drama" to refer to things, people, and text, a problem arises in terms of what the concept means in varied research streams. Better communication among researchers might be facilitated by adoption of an accepted vocabulary for discussing drama, for at present no common set of definitions prevails. The purpose of this paper is to alleviate that situation by introducing a vocabulary based on terminology and concepts from Aristotle's *Poetics* (Fergusson 1961). Our aim is to disseminate a clear technical language so that researchers coming from different perspectives can be sure that they are discussing the same phenomena.

Because drama is an umbrella term for a large genre of works, it is first necessary to clarify the species to which researchers refer. Ordinarily, when advertisements are labeled "dramas," the reference is to the theatre of realism, rather than to the "theatre of the absurd" (but see Stern 1990). In this regard, advertising dramas have been termed "capitalist realist art" (Schudson 1984), "tractor realism" (Berman 1981), "slice of life" (Ogilvy 1985), and *cinema verité* (Rossiter 1987). Perhaps because the categorization of advertising as realistic drama rests on the assumption that everyone knows what drama is, some important pre-questions have gone unasked. These are, "What is an advertising drama?" "What are its component parts?" And, "How can we analyze or explicate (Stern 1989) the elements in individual advertisements?" These questions can be addressed by turning to Aristotelian criticism as the most accessible source of the technical vocabulary of drama. The concepts and definitions are familiar to anyone who has taken a

college English course, read a theatre review, or glanced through a playbill.

This paper begins to answer the definitional questions first by identifying the basic elements of drama and next by analyzing a sample advertisement as text. Since our purpose is limited to setting forth a language for conducting multidisciplinary research, we do not venture beyond the definitional issues that emerge in close examination of the stimulus. The link between dramatic stimuli and consumer responses is the province of the other presentations in the session, notably those of Boller and Olson and Deighton.

SIX ELEMENTS OF ADVERTISING: ARISTOTLE'S FRAMEWORK

Drama is the literary form designed for theatrical performance, in which actors take the roles of characters, characters perform the actions, and characters utter the written dialogue (Abrams 1988). It is composed of separate but connected elements, much as a product is composed of distinct but related attributes. Aristotle's framework defines drama in terms of six basic elements: plot, character, theme, diction (choice of words), "spectacle" (visual aspects such as settings, costume, make-up and hair-styles), and "music" (the sounds of words as well as songs/musical compositions). The terminology has been refined over the centuries to fit ever-changing notions of what constitutes theatrical performance, and adaptation of this vocabulary to advertisements represents but one more instance where one genre generates another (Turner 1981).

Plot

Most of what the critical tradition has handed down about plot comes from Aristotle's *Poetics* (Martin 1986), where its essence is identified as "imitation of action." "Imitation" refers to the art of "showing" characters in action that distinguishes dramatic performance from narrative "storytelling" (see Martin 1986; Wells 1989). "Action" refers to a series of related events (Brooks and Warren 1959) with a unified meaning, in that the arrangement of events (Fergusson 1961) answers the question, "what happened?" (Holman 1980).

A plot imposes order on the raw material of events (Frye 1973) by following a set of conventions (or rules) for their arrangement. In dramas, the purpose of the actions is to enable characters to display their personality traits, behavioral modes, and moral nature. Realistic plots imitate the action of life by following temporal chronological order -- they have a beginning, a middle, and an end. However, even realistic drama lends structure to life's shapelessness by arranging the incidents into a unified and meaningful whole. Plot progression involves both chronology and causation, for plots

¹This paper is an abstract of the presentation for Special Session 6.4.

provide not only a record of what happens, but also the reason why things happen.

Some key terms used to describe various aspects of the plot are conflict, complication, crisis, suspense, surprise, and solution. Many plots contain *conflict*, defined as an oppositional relationship between two characters or forces. A *complication* occurs when the conflict works itself out in one or more *crises*, often arousing *suspense* when there is uncertainty about what is going to happen (Abrams 1988). A *solution* is reached when the crisis is resolved, frequently by means of a *surprise* ending. In its negative sense, a surprise ending is one in which the author resolves the plot without adequate earlier grounds in characterization or action. The solution is manipulated by the introduction of a forced or improbable coincidence -- a *deus ex machina* or god descending on stage. In its positive sense, a surprise ending is realistic when it turns out, in retrospect, to have been grounded in what has gone before (Abrams 1988).

Character

Aristotle's second principle of drama is character, defined as the imaginary person(s) created by the author (Holman 1980) and presented in a dramatic work. Characters are endowed with moral, dispositional, and emotional qualities that are expressed in what they say (dialogue) and what they do (action). A character's personality is revealed by his/her words, deeds, and gestures; the words and deeds of others in relation to him/her; and the settings (Barnet 1985). The basis for speech and action that are rooted in a character's temperament, desires, and moral values constitute his/her *motivation*. The chief character in a work is called the *protagonist* (alternatively, the hero or heroine), and if s/he is pitted against an important opponent, that character is called the *antagonist* (Abrams 1988).

Theme

Theme describes the underlying idea of a text, its view of life, and its *gestalt* meaning (Barnet 1985). It refers to a general claim, or doctrine, whether implicit or asserted, which an imaginative work is designed to incorporate and to make persuasive to the reader (Barnet 1985). It is, in brief, what a drama is about.

Diction

Dramatic language or diction includes everything that the words mean, encompassing not only denotation (literal dictionary definitions) and connotation (associations and imagery), but also grammatical structure, length, and complexity of syntax. The language of drama is no longer considered limited to dialogue (Esslin 1969), for it also refers to deeds, facial expressions, and body movement associated with a stage performance (Barnet 1985).

Setting

This is the composite bundle of indicators that signify place and circumstances: the physical background described or shown, consisting of

geographical location, occupation and lifestyle of characters, time of action, and general socio-economic environment (Barnet 1985; Holman 1980). The setting of a dramatic work includes everything about the locale -- the historical time, physical surroundings, and social circumstances -- of the action. It denotes the visible or picturable items on stage in a theatrical production, also called *décor* or *mise en scène*, terms denoting the scenery and the properties or movable objects ("props"). Nearly everything on stage falls under the rubric of setting, for the purpose of *visibilia* is to reveal character. Setting also includes the positions of actors in a scene (Abrams 1988), because their entrances, exits, and on-stage movements occur in relation to scenery, props, and costumes.

Music

Music refers to the sound of words -- the rhythm and rhyme patterns as well as to the songs and/or musical compositions incorporated in a performance. Its importance in advertising lies in its connection to the *chorus*, a group of characters in classical drama who sang or chanted verse and engaged in dancelike movements. As drama evolved, it abandoned music and dance, and the choral group developed into a single choral character who served as the author's spokesperson. The "choral character" now refers to any character within the play itself who stands apart from the action and by his/her comments provides the spectators with a perspective for viewing the characters in action (Abrams 1988). This character may also represent the author, a communal point of view, or the perspective of group norms, since his/her function is to provide the point of reference by which the audience can judge the play.

While music in its own right (Scott 1990) serves rhetorical purposes in advertising, the modern manifestation of a choral character represents an important link between advertising drama and its classical antecedents. In classical drama, direct authorial commentary was considered intrusive and amateurish -- Aristotle evaluated an author's skill in terms of his ability to present action without resorting to explanatory comments. However, in advertising drama, some narration is considered necessary (see Deighton, Romer, and McQueen 1989; Stern 1991) to direct attention to the sponsor's message. In this regard, the choral character may be viewed as an ancestor of the advertising announcer, for just as the chorus emphasized the author's point of view, so too does the announcer emphasize the sponsor's point of view. The need to ensure audience comprehension by guiding attention to the intended meaning suggests that interpolation of commentary into modern commercial messages resembles earlier instances of the hybridization of narrative and dramatic techniques.

The tradition of a choral character seems to underlie advertising's blend of show and tell, for few examples of dramas that "show" all but "tell" nothing can be found (Stern 1991). Rather, advertisements more often begin with "a word from the sponsor" and end with a sponsorial reminder to purchase the product (the action close). In sum, while we can define the

basic elements in drama by turning to Aristotelian concepts, we can expect advertising to tailor genre conventions to suit its own needs. The genre has historically been flexible enough to move in multiple directions, and the value of learning its lineage and its language lies in increased awareness of the longevity and power of dramatic art. Jameson's comment (1975, p. 157) reinforces our view of commercial drama as a new tributary of an ancient stream:

So generic affiliations and the systematic deviation from them, provide clues which lead us back to the concrete historical situation of the individual text itself, and allows us to read its structure as ideology, as a socially symbolic act, as a prototypical response to a historical dilemma.

The Service Experience as Theater

Stephen J. Grove, Clemson University
Raymond P. Fisk, University of Central Florida

INTRODUCTION

The increased interest in services marketing during the past decade reflects a growing appreciation of the role services play in the economies of the United States and the world. Nearly 70 percent of the Gross National Product of the United States and other industrial nations can be traced to services (Lovelock 1991), while up to three-quarters of those employed in some countries labor in service sector occupations (Bateson 1989).

Scholars and researchers have given significant attention to how the marketing of services differs from the marketing of goods (Berry 1980; Sasser 1976; Zeithaml, Berry and Parasuraman 1985; etc.). One key characteristic that distinguishes services marketing is the simultaneity of production and consumption of the service product (Bateson 1989; Berry 1980; Zeithaml, Berry and Parasuraman 1985). Services exist only in the time in which they are rendered and are living processes that cannot be disassembled (Shostack and Kingman-Brundage 1991, p. 243). Essentially, services are fashioned from the interaction between service providers and customers and, as such, service quality is comprised of both process and outcome dimensions (Grönroos 1982; Parasuraman, Zeithaml and Berry 1985; Sasser, Olsen and Wyckoff 1978). These various aspects of service delivery underscore the notion that services are complex, behavioral phenomena that can be quite difficult to understand or describe. A review of the services marketing literature compiled by Fisk, Tansuhaj and Crosby (1988) reveals that less than fifteen percent of the total service literature to attempt to conceptualize the service experience. In short, conceptual frameworks are needed (Bowen 1990; Upah, Berry and Shostack 1983; Lovelock 1991) that demonstrate common characteristics of services, capture the processual nature of services, and address the "descriptive language problems" (Shostack 1984) plaguing the services literature.

In an effort to satisfy this need for conceptual frameworks, the discussion that follows posits a general framework for services marketing based upon the metaphor of behavior as drama. The underpinnings of the drama metaphor are presented, along with several key concepts that it offers for the description of services marketing. The service experience as theater is further developed and implications ensuing from the framework are given. Finally, some research issues are examined and concluding comments are given.

BEHAVIOR AS DRAMA

The metaphorical depiction of behavior as drama is the basis for a distinct model of human interaction that offers insights most forcefully when examining face-to-face interactions among individuals (Brissett and Edgley 1990). As such, it is particularly relevant as a means to describe service encounters. As

a sociological school of thought born from the symbolic interactionist paradigm, the behavior as drama metaphor has generated wide attention. Writers such as Kenneth Burke (1945, 1950, 1968), Erving Goffman (1959, 1967, 1974) and R.S. Perinbanayagam (1974, 1982, 1985), have contributed much to the development of the dramaturgical perspective. Underlying their observations is the tacit understanding that people are symbol users who interact with each other based upon the meanings they assign to the sundry elements present at any behavioral setting. Dramaturgy, then, is greatly concerned with the broad issue of communication, both discursive (speech and language) and nondiscursive (gestures, clothing, and other objects), and the connection between the two (Brissett and Edgley 1990). Definitions of reality emerge as action occurs and those present strive to make sense of behavior situations. Social reality, then, is not simply like drama, it is drama in so far as it is a discourse involving articulation, definition and interaction (Perinbanayagam 1974, p. 533).

The application of the drama metaphor to behavior is probably best represented in the scholarly efforts of Goffman (1959, 1967, 1974), and most readily in his work, *The Presentation of Self in Everyday Life*. Goffman describes social behavior as theatrical "performances" in which "actors" present themselves and their actions in such a manner as to fashion desired "impressions" before an "audience." During interaction actors continually adjust the expressions which they "give" and "give off" in the context of a "front region." To a large extent, the success of the actors' front region performance (i.e., how believable, sincere and/or authentic it appears) is enhanced by rehearsal in "back regions," away from audience's view. Here critical aspects of actors' presentations are planned and practiced to arrive at a general coherence among the dramaturgical elements necessary to staging a believable performance. Through it all, however, is the realization that performances are fragile processes that are easily undermined by the most minor of mishaps.

The role of the audience in developing and maintaining a definition of an interactive situation cannot be ignored. The audience's evolving expectations and continuous communication (verbal and nonverbal) of its responses to a performance as it unfolds provide the actors with needed information to guide their behavior toward a desired outcome. While the meanings and interpretations that an audience assigns to a behavioral encounter may be partially a function of previous learning, their validation occurs during or following the interaction. In other words, meanings are not absolute or static characteristics of the world, but are the result of a continuous social process (Burke 1945). Further, it is important to note that this negotiation of a definition of the situation occurs, whether or not it is by design, since all

behavior is ostensibly expressive in nature (Zicklin 1968). Actors may vary with respect to their awareness of the dramaturgical character of behavior; being aware simply enables one to transform the impression formation character of his/her behavior to impression management (Miller 1984).

The metaphor that behavior is drama and the various principles that it engenders provide a framework for describing, understanding, and communicating about services experiences. Based upon the metaphor and, to a significant degree, some of Goffman's (1959) observations, we develop a view of services experiences that unifies and extends beyond much of the extant services principles. In essence, our contention is that services themselves are drama and may be understood as theatrical performances.

SERVICES AS THEATER

The nature of services marketing and the proposition that behavior is drama share several parallel characteristics. Both are concerned with the tactics and strategies employed by people to create and sustain desirable impressions before an audience. Both, also, suggest that one way to achieve this is by careful and prudent management of the actors' expressive behavior and the physical setting in which it occurs. Reflecting observations of services scholars, Goffman (1959) notes that in their performance "... service personnel ... enliven their manner with movements which express proficiency and integrity .. to establish a favorable definition of their services or product" (p. 77). Clearly, Goffman recognized that services issues are resplendent with dramatic character.

Many of the drama concepts and principles may be used to capture the service experience. Among those most central to services understanding are actors/audience, setting and performance.

Actors/Audience

Similar to a theatrical production whose success relies upon the acumen of those on stage, the quality of one's service experience is largely affected by the service's contact personnel. The service's actors, the performers of the service, are often perceived by their audience, the customers, as the service itself (Grönroos 1985). Their appearance and their actions are central to the audience's service experience. Consequently, just as theatrical performers must commit themselves to a plethora of considerations to stage a believable performance, the service "actors" must subscribe to a variety of concerns to foster a desired impression before their audience. Among these are the actors' manner and appearance, (their "personal front" in Goffman's (1959) terminology), their ability to enact their service role properly, and their overall dedication to the service performance.

One's dress, grooming and demeanor impart an attitude, mood and/or identity to others (Solomon 1985) and can add tangibility to a service (Berry 1980). The actors' skill may be reflected in their knowledge, courtesy, competence and communication

abilities, each of which represents an aspect of service quality (Parasuraman, Zeithaml, and Berry 1985). Diligence in learning and performing one's service roles contributes quality to the consuming audience's overall impression of service excellence (Shostack 1977; Zeithaml, Parasuraman, and Berry 1985). The actor's commitment to a service production is likely to be at least partially a function of a service organization's internal marketing effort (Grönroos 1985; Sasser and Arbeit 1978) that is designed to impart a consumer orientation. The various dimension of the actors' service performance are most critical in service encounters that rely on a high degree of personal contact with the customer, such as restaurants, hospitals, cruises, etc., or that are characterized by repeated contact, such as banks, the postal service, etc. Among these industries there exists the opportunity to create a competitive advantage through service actors, a notion discussed by Berry, Parasuraman, and Zeithaml (1988) as the "people factor."

Of course, it is impossible to discuss actors' performance without implicitly or explicitly considering the audience. The audience plays a critical role in the determination of a service production across many diverse services. In many services, the audience (customer) must be present for the service to occur (e.g. hairstyling, air travel, etc.). This is a circumstance recognized by services scholars as inseparability of production and consumption (Berry 1980; Lovelock 1981, 1983; Shostack 1977). In short, the person receiving a service or other audience members present at the service encounter may affect the quality of the service's delivery and/or outcome (Booms and Bitner 1981; Lovelock 1983; Parasuraman, Zeithaml and Berry 1988; Pranter and Martin 1991). A customer's unwillingness to cooperate in a service production or inappropriate, disruptive behavior on the part of other customers sharing a service experience can destroy a service performance.

Similar to the audience of a theatrical production (that has a measure of responsibility to ensure that a satisfying performance is staged by adhering to certain standards of behavior), the customers of a service are also obliged to embrace various behavioral rules. Among these are expectations that the customers will refrain from disrupting others' service experiences, learn how they can aid the actors in producing a satisfying show (e.g., provide service personnel with the necessary information to perform their responsibilities properly) and be tolerant of slight imperfections in the service production to preserve the sanctity of the overall performance. These considerations are particularly important in high contact services, in self-service operations whose outcome is so reliant on the audiences' participation (Lovelock and Young 1979), and in services that demand a high degree of customization (e.g., physician services).

Setting

Another key component in the depiction of services as theater is the physical setting in which the

service is delivered. As in the staging of a theatrical production (that uses scenery, lighting, props, and other physical cues to influence the audience's perceptions), a service's "setting can play an enormous role" in affecting consumers' impressions of a service (Shostack 1977, p. 78). The various features of a services setting combine to help define and facilitate the service exchange (Baker 1987; Booms and Bitner 1982; Zeithaml, Parasuraman and Berry 1985) and provide evidence and tangible cues of its reality. As in theater, by manipulating and/or mixing the elements of the physical setting in different ways, the audience's perceptions of the service can be changed or variously rearranged. Consider the perceptual differences created by different settings found at a Motel 6 versus a Hyatt Regency Hotel or at a Denny's restaurant versus a Bennigan's restaurant.

The setting plays an important role in positioning a service organization and attracting a specific clientele (Booms and Bitner 1982). Further, it can be used to inform new customers as to the nature of a service (e.g. upscale or mass appeal) or aspects of the service delivery (e.g. full service or self-service).

Performance

Performance is the set of activities that occur before an audience. Likening the process of service delivery to a theatrical performance seems a reasonable proposition given the role that the setting, actors and audience play in both. The service performance, like its theatrical counterpart, relies upon the of many elements: (1) those operating in the back region who support the front stage "show"; (2) the management of the front region's setting; (3) the actors' commitment to the importance of sustaining a believable performance; and (4) the coordination of the overall effort among the various cast members.

The importance of region behavior is based upon Goffman's (1959) observation that a perceptual barrier bounds a front area where a performance occurs and a back area where actors may act out of character, rehearse their routines and plan the front stage action. Behavior in the front region is devised to meet an audience's approval, while behavior in the back region is normally not open to the audience's inspection. In fact, in most service designs, it is imperative to keep the two regions separate so as to avoid compromising the credibility of the performance. The audience is not normally granted access to back regions of restaurants (kitchen area), auto repair (the garage itself), hospitals (doctors and staff lounges), etc. Nevertheless, much of what contributes to a satisfying front stage performance occurs in the back area.

One function that often takes place back stage is the management of the physical setting. The control of the front region's atmospherics, (e.g., lighting, temperature), the coordination of the physical evidence with the actors' service (e.g., ensuring the props, equipment, and other tangible cues are available, maintained and properly expressive) and the overall service design are part of the back region activity. A physical setting breakdown may profoundly damage the audience's perception of the service performance.

Another component of performance is the actors' overall commitment to the show, as evidenced by their adherence to various "defense practices" (Goffman 1959). Involved here are service workers' subscriptions to dramaturgical loyalty (acceptance of a moral-like responsibility to sustain a believable performance), discipline (commitment to learning one's part and avoiding gestures or mistakes that might compromise the performance) and circumspection (determination in advance of how best to stage the show). These considerations collectively comprise the foundation of service workers' ability to project a performance which the audience finds satisfying. Whether contact personnel in restaurants, hospitals, professional offices, airlines, hotels, or other such services, their performance is enhanced through internalization and adherence to these dramaturgical principles.

The success of a service performance, like that of a theatrical production, requires that all involved cooperate as team members to stage the performance. A single actor in the front region or support personnel in the back can undermine the overall effort simply by failing to sustain vigilance during the show. The audience's perception of service quality is a fragile phenomenon that is easily affected. Consequently, service workers must share a common respect for the importance of the performance.

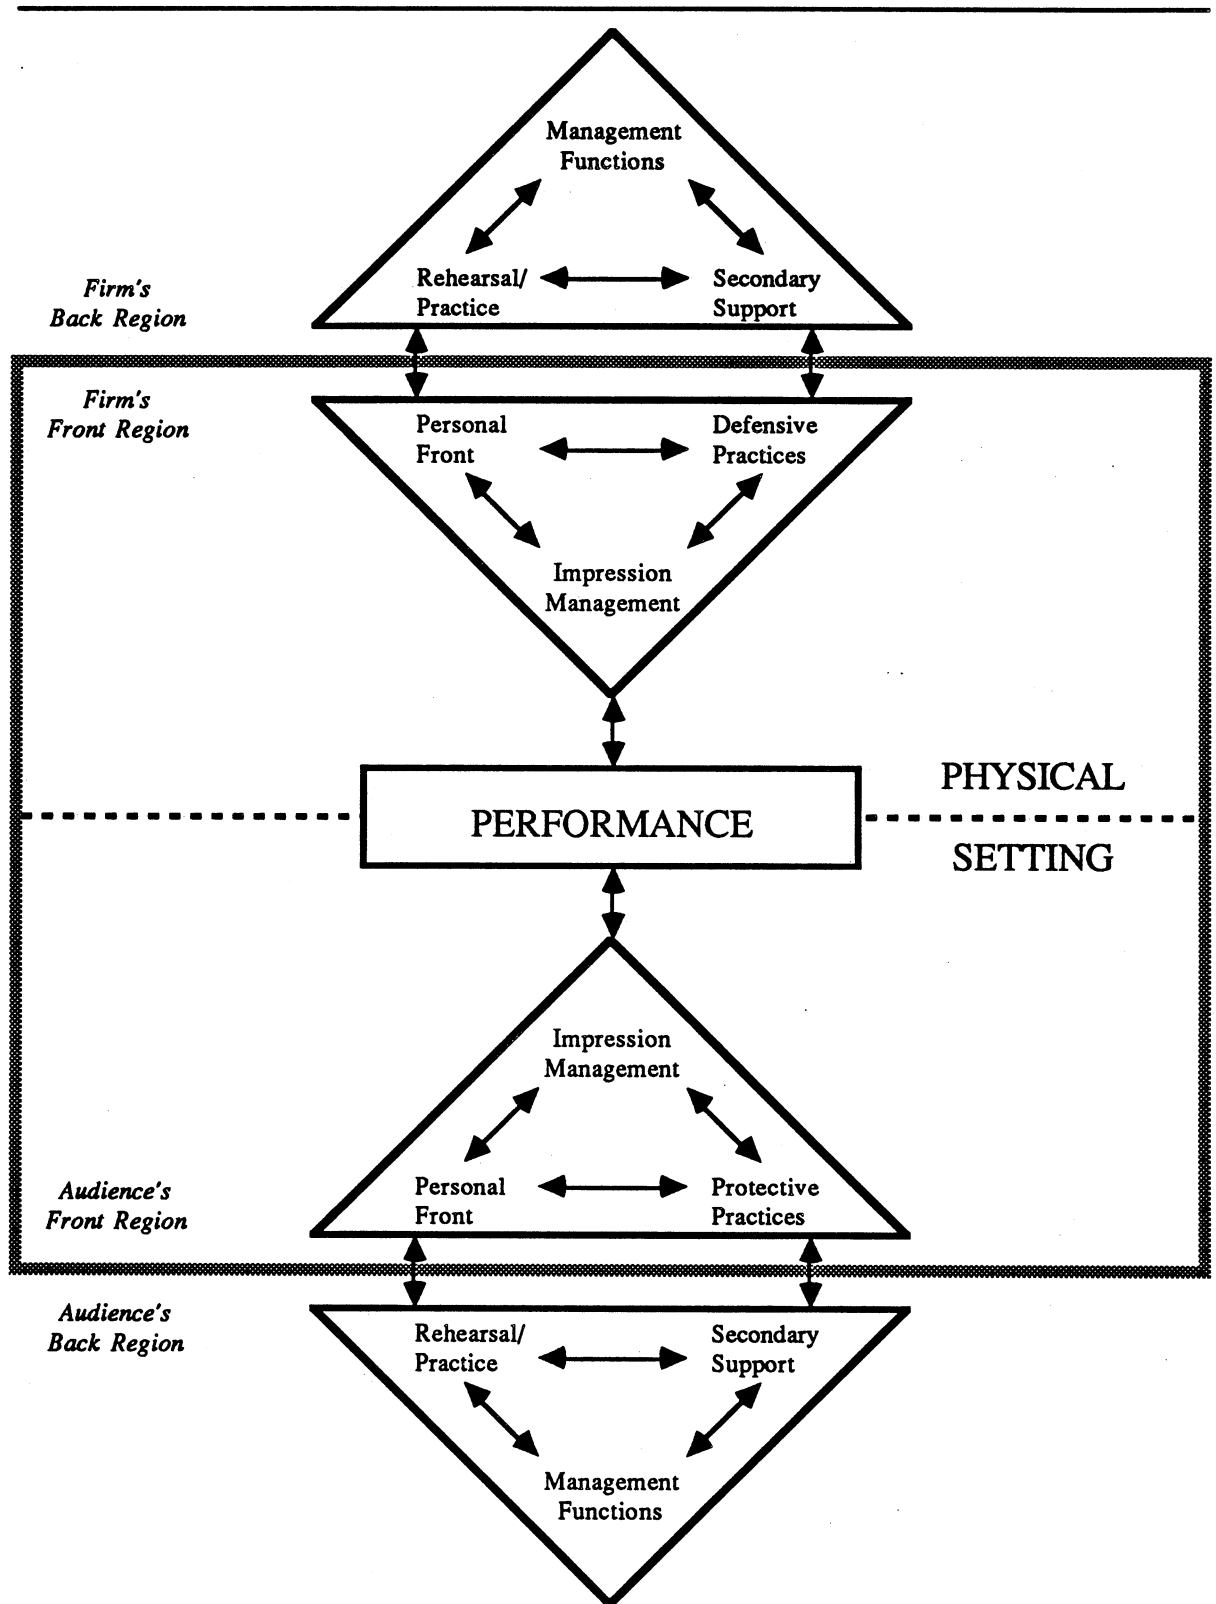

MODELING THE SERVICE EXPERIENCE AS THEATER

Figure 1 conceptually models the service experience as theater. At the heart of every service experience is the performance. Both the firm and the audience share in the creation and continuance of the performance. Surrounding the performance is the physical setting. Typically, the physical setting is owned or controlled by the firm. However, if a service is delivered to people's homes, then the physical setting is owned or controlled by the audience member.

The "physical setting" of the firm includes the furniture, decor, and atmospherics in the front region of the service theater. Most service organizations are sensitive to the influence the physical setting of their service theater may have on the audience. The architecture of a service firm's building conveys first impressions to customers. A well-chosen architectural design can make the service organization much more approachable (Donovan and Rossiter 1982). The internal furnishings and decor of the service theater are especially important influences on consumers. For example, the Olive Garden restaurant chain follows through on its name by decorating with large quantities of living plants to make its restaurants garden-like.

Surrounding both the performance and the physical setting is the front region. This includes both the firm's front region and audience's front region, which overlap. In the "front region," the performance is given in "public" and is open to the audience's inspection. Behaviors in the front region must meet the approval of the audience. Of course, the firm and the audience each have a back region.

FIGURE 1
The Service Experience as Theater

Normally, the back region and front regions are kept quite separate. In the model, arrows are shown connecting the front and back regions to highlight the fact that information, people and things must pass between the two regions. Audiences that are allowed access to the back region of the firm may witness behavior inappropriate for the front region (cursing, slovenly demeanor, complaining, and other "out of character" activity). To prevent mishaps, the corridor between the front and back regions is routinely closed to the audience. Further elaboration on the model in Figure 1 will be structured around the front and back regions.

The Firm's Front Region

The firm's front region is a complicated mixture of personal front, defensive practices and impression management. The "personal front" concerns the appearance and behavior of those representing the firm. All customer contact personnel present a personal front to the audience. A major part of the training given service employees concerns teaching them to successfully convey the proper personal front. In some service organizations, this is little more than smile training. In others, extensive training is provided. Walt Disney Co. puts new employees through Disney University to indoctrinate them in guest relation procedures. New Disney employees are also taught the "Disney Look," which includes specified make-up colors for women and the absence of facial hair for men.

"Impression management" relies upon the actors' adherence to the "defensive practices" of loyalty, discipline, and circumspection (Goffman 1959, pp. 212-218). In terms of loyalty, the service actor learns to avoid any behaviors that might destroy the impression for the audience. Discipline concerns actors' learning their parts thoroughly and avoiding unwittingly committing gestures or mistakes, which are potentially disruptive to the desired impression. Discipline includes keeping one's personal problems away from the front regions and exercising self-control in difficult situations.

The Firm's Back Region

The firm's back region exists to facilitate the firm's front region. Many back region activities are indispensable to a successful service production but are not, by their nature, appropriate for front region observation (e.g., rehearsal of routines, attention to defensive practices, etc.). In the back region, actors often drop their "personal front" and step out of character. Also, service performers may use the backstage to memorize their scripts or rehearse their parts.

A well-staged performance depends upon the ability of secondary support staff to provide the correct inputs. Secondary support can include a technological dimension. For example, restaurants must depend on the proper operation in the back region of ovens, stoves, food preparation appliances, and dish washing machines. Also, much like a theater, most service management functions occur behind the

scenes. The traditional management functions of planning, organizing, staffing, directing and control occur in the back region.

The Audience's Front Region

Like the firm, the audience's front region is a complicated mixture of personal front, protective practices and impression management. The "personal front" concerns the appearance and behavior of the audience members. The issue of how to behave in public (i. e., on stage) is quite significant to consumers. Every consumer has personal anxieties concerning the potential embarrassment of inappropriate public behavior. A major part of the consumer training given to children by their parents concerns teaching them to successfully convey the proper personal front in public settings.

Consumers learn through experience that some service organizations expect their audience to arrive bathed, shaved, coiffed and dressed in formal style. Such expectations are common for gourmet restaurants, the opera, a courtroom appearance, or a college graduation. Other service organizations are less rigid in their expectations. A consumer entering a convenience store is often greeted with a sign at the door saying "No Shirt, No Shoes, No Service."

"Impression management" as practiced by the audience relies upon "protective practices." Protective practices are the audience's efforts to overlook occasional miscues or problems with the performance in the interest of preserving the impression fostered by the actors. While there are limits to the customers' willingness to protect a performance, quite often one may overlook a dirty utensil or a slight billing error in order to allow the "show to go on." Challenging such minor errors may create a major disturbance and affect the delicate balance of the interaction. Therefore, there is a implied understanding or expectation that the audience should endeavor to allow the actors and their performance some measure of latitude.

Also, to a limited degree, it may be said that the audience engages in "defensive practices" on its own behalf. Loyalty means that they avoid behaviors that convey negative impressions about themselves or their companions. For example, a married couple seeking a home improvement loan from a bank would seek to convince the loan officer that they were both good money managers. Discipline refers to the actors' obligation to learn their parts thoroughly and avoid committing mistakes, which are potentially disruptive to the desired impression. The couple that has a fight in a restaurant or the child who throws a temper tantrum in the grocery store disrupts the performance for other audience members.

The Audiences's Back Region

The home is the audience's back region. It is a place of refuge from public performances. At home, consumers may dress and act according to their own rules. Consumers are known to go to great lengths to protect the privacy of their back regions. This may include unlisted telephone numbers, the use of

answering machines, and the creation of "rules" as to when the person can be contacted at home.

At home, consumers mentally rehearse their parts in planned service experience. This might include reviewing what to tell a physician about the symptoms of one's illness or what to tell a travel agent about one's vacation travel needs. The home is also a source of secondary support, though usually done by the consumers. These activities would include wardrobe maintenance and personal grooming. Secondary support would also include maintenance of a car for transportation to the service theater. Further, the consumer must manage the back region, which includes planning future service needs and budgeting for service expenditures.

RESEARCH IMPLICATIONS OF THE SERVICE EXPERIENCE AS THEATER

The experiential nature of services suggests that the service experience as theater may be effectively researched with observational research techniques that capture the processual and subjective nature of the service product (Grove and Fisk 1991). One promising observational method is participant observation (Grove 1986; Hirschman 1986). In participant observation, information about the effectiveness of various drama devices (actors' personal fronts, the physical setting, defensive practices, etc.) for creating and maintaining a desired impression may be gathered by observers who participate in the service encounter. Participant observation is a technique well-suited to dramaturgical analysis (Meltzer, Petras and Reynolds 1978). In addition, participant observation has been employed via "secret shopper" programs to investigate the service delivery of several organizations. For example, Walt Disney Co. routinely hires professionals to shop its parks and rate its stores, amusements, personnel, etc., all under a condition of concealment to protect against "unnatural" respondent behavior (Meister 1990).

The Critical Incident Technique (Flanagan 1954) is a promising observational technique for studying the service experience as theater. The Critical Incident Technique uses in-depth interviews with customers to assess specific instances of services experiences that were especially satisfying or especially dissatisfying. A recent study of airline, hotel and restaurant services resulted in an extensive classification of critical incidents that affect customer satisfaction/dissatisfaction (Bitner, Booms and Nyquist 1990). Similar critical incident studies could focus on the actors, audience, setting and performance as sources of satisfaction or dissatisfaction.

Other qualitative and/or unobtrusive data gathering methods might prove valuable for investigating the services experience as theater. Focus group research, case studies and non-directive interviews represent additional means for studying drama aspects of the service experience.

CONCLUSION

In depicting the service experience as theater, we have assumed that the sociological concepts of

dramaturgy can be fully applied to services. This assumption is a mild one. Dramaturgists claim that all human interactions can be assessed from a dramaturgical framework.

The service experience as theater framework captures many of the experiential dimensions of a service. From the marketer's perspective, attention to the dramaturgical details of a service exchange may enable the marketer to deliver consistently higher levels of consumer satisfaction. From the consumer researcher's perspective, the service experience as theater offers a novel perspective for describing and analyzing consumer service experiences.

Sincerity, Sham and Satisfaction in Marketplace Performance

John Deighton, University of Chicago

"... the giant swarm of poor moths and gnats, rushing silently and madly into the enticing flame! What unanimity in agreeing to let oneself be deceived! Here quite clearly there is in operation a general human need, implanted by God Himself in human nature ... an indispensable device in life's economy."
Confessions of Felix Krull: Confidence Man
Thomas Mann

This talk explored the implications of the idea that fraud is marketing at its most artful and consumer judgment at its most inept. It contended that the mechanics of a successful fraud should show us the points at which consumers make errors in processing evidence and the methods by which these errors can be magnified. A confidence trick, or con, was identified as the most revealing form of fraud for this purpose.

THE DRAMATIC STRUCTURE OF A CON

The structure of a con maps well into the language of dramaturgy: roles, setting, plot, script and so on (Brissett and Edgley 1990, Leff 1976, Nettler 1982).

Four roles are common to most scams. The *mark* is the victim, selected on the basis of some psychic susceptibility to the appeal, much as a marketing prospect is psychographically profiled. The *roper* is the prospector who seeks out, or 'bird dogs' the victim. The scam depends on the mark's confidence in the roper, so the characters and interests of mark and roper are similar. In some scams the roper works alone, but in many there is a confederate, or *inside man*. Finally there is the character, usually offstage for the entire drama, who is the source of the *bundle* or fictitious payoff.

A prop common to many con stories is the *poke*. This is a reward received by the mark as bait to increase the probability of the *score* or ultimate act of defrauding. Poke and bundle are usually in the same currency, often money but in some cases affection, respect or affiliation.

The objective of the perpetrator of a con (and indeed of the initiator of any transaction) is to convince the mark that playing his or her part in the transaction will bring returns greater than the value of what is given up. To make this belief credible, a *spiel* or plot is needed that asserts mutual gains from trade between the mark and the roper.

SOME PARTICULAR PLOTS IN THE GENRE

The bald structure of a con as just outlined is not the source of its interest, any more than the fascination of generations with Romeo and Juliet could be attributed to its 'boy meets girl' structure. The phenomenon of interest is the tensions and resolutions in a particular plot.

One particular plot is the *pigeon drop* plot (McCormack 1976). In the preamble to this solution the roper selects a mark and arranges for the mark to find a 'lost' wallet or notebook or diary. This item discloses that a third person, the inside man, is engaged in a very profitable illegal enterprise, for example the fixing of gambles in a syndicate. Roper and mark return the article, and in gratitude the inside man invites them to participate in a round of his enterprise. In this way the mark is compromised, and receives the poke in the form of a small win.

The score then follows. The inside man announces that he wants to exit the syndicate. He would like to make a last, very large, win, but to place the bet would tip off the syndicate to his intentions. So the mark is invited to conduct the last transaction, pooling his money with that of the inside man and sharing the winnings. The drama ends and the mark emerges into reality when the inside man defects with the stake.

The *Ponzi* is a variation of the structure. The roper tells the mark that he will give extraordinary returns on any investment. The mark tries a small investment, and receives back a large fraction of the stake (the poke). The mark tries larger stakes, and lets on to others that they can do the same. When the roper is satisfied with the size of the potential score, he defects. This plot, once started, becomes self-sustaining. The challenge is to start it.

Charles Ponzi started it in Boston in 1920 by saying that, in the aftermath of the First World War, several European currencies were trading at rates far below the rate at which the US Postal Service would exchange their International Postal Reply Coupons into dollars. His scheme, he said, was to use dollars to buy the foreign currencies, then buy the Coupons, remit them to Boston and sell them for dollars. He advertised in Boston newspapers that he would give fifty percent interest on ninety day unsecured deposits to raise the capital to run the scheme. While his statement about exchange rates was correct at the time of the first announcements, he in fact never purchased any coupons. Investors sent him \$15 million within months from which he returned them their interest. The scale of the response took Ponzi by surprise and he was arrested before he could score.

The consumer's qualm in a Ponzi scheme is not why he or she is being offered the deal. The deal is advertised to anyone smart enough to see its merit. So the issue is whether the deal is as good as it seems. Ponzi constructed a story good enough to pass this test. As the story came under public scrutiny, however, experts hastened to explain its defects. The story's fictional quality became clear, in every respect except the payment of interest, which was quite real. Consumers then faced the question of whether to continue to act in a fictional drama paying them real money. The choice amounted to calculating whether the fiction could go another round, and the consumer's

analysis of this question was clouded by the desirability of the answer being yes.

The *Trinity Church* con, which took place in lower Manhattan in the 1920's, cast the mark as entitled to the bundle by birth. Willis Gridley identified thousands of descendants of one Anneke Bogardus, whose children had sold the church in 1705. He approached them with a spiel that asserted that there had been an error in the conveyancing, so that each was heir to a share in the property. His drama involved no poke, yet three thousand of the descendants paid him \$50 each to press the claim.

Nettler, Gwynn (1982) *Lying, Cheating, Stealing*. Cincinnati: Anderson Publishing Company.

MARKETER-CONSUMER INTERACTION

When an interaction between marketer and consumer is compared to the interaction between roper and mark in a confidence trick, three crucial similarities appear.

1. *Enticement*. The marketer allows the consumer to glimpse a vision of the desired end state of product use. Just as the con depends on the pull of the bundle, so consumer action is driven by the enticing sense of a future with the product.

2. *Scripted Action*. The marketer contrives a role for the consumer to play which is well-defined and leads plausibly to the bundle. Levi's 401 Jeans work hard to coach consumers on how to walk, how to talk, how to be and where to be in their jeans. American Airlines tell business executives how they will have to act if they want to earn the right to be 'something special in the air.' Ed Debevec's restaurant employs gum-snapping, brassy waitresses to paint patrons into the roles that will ensure that they will feel they are having a good time.

3. *Confirming Experiences*. Corresponding to a poke in a con, a satisfying consumption experience contains a steady stream of small rewards that convince the consumer that he or she is on track toward the glimpsed vision of ultimate satisfaction. As we have argued elsewhere (Deighton 1984), marketers are more tempters than adversarial debaters. Their claims easily find partial confirmation in a consumer's experiences.

Feminist Theory and Marketing Thought: Toward A New Approach for Consumer Research

Mary Ellen Zuckerman, SUNY Geneseo
Mary Carsky, Barney School of Business¹

ABSTRACT

This paper looks at the effect of feminist theory on the conceptualization of marketing thought. Specifically, it examines the effect of feminist theory on the formulation of research in marketing generally and consumer behavior in particular. Finally, it discusses implications of feminist theory for the marketing paradigm.

INTRODUCTION

Over the past fifteen years, feminist scholarship has had a significant impact on a number of disciplines, including anthropology, literature, psychology, sociology and history (see Langland and Gove 1981; DuBois et al. 1987). This scholarship argues that hidden assumptions about men and women have influenced standard academic subjects. Such assumptions are embedded in the theoretical frameworks, the formulation of research questions, the methodology and data collection, the interpretation of results, and the conclusions drawn.

Feminist theory may influence the fields of marketing and consumer behavior differently from the way it has affected disciplines such as history and literature or even social sciences such as psychology and anthropology. In these latter fields, feminist theory provided a totally new perspective. Because marketing theoreticians and practitioners have always focused on "women as consumers," the feminist perspective may not *initially* appear to offer something new and unique. We argue, however, that by incorporating the tenets of the feminist perspective, consumer behavior theory can be significantly enriched.

This paper first describes the foundations of the feminist perspective as they are applied to research. It then poses questions such an approach raises concerning the conceptualization of consumer behavior theory and research. Finally, it develops implications for reshaping the consumer behavior, and, more generally, the marketing, paradigm.

Questions to be considered include:

- 1) How does feminist theory affect research?
- 2) How does gender affect the formulation of consumer behavior research?
- 3) How do researchers in consumer behavior and marketing view their subjects? How does the researcher/subject relationship affect research and its outcomes?

- 4) What is the effect of gender on our research methodologies?
- 5) What is the interdisciplinary dimension of research in consumer behavior and marketing?

These questions stem from a feminist approach to research. Such an approach extends beyond consideration of women's issues into a fundamental investigation of gender differences and their impact on a discipline's body of knowledge. Several of these issues have received attention in the marketing literature, without being seen in a specifically feminist context. Exploration of all these areas should lead to new insights which can ultimately operate to influence the paradigm.

A FEMINIST RESEARCH PERSPECTIVE

A feminist perspective is one that challenges and questions underlying assumptions in the discipline that have to do with gender (see Gergen 1988; Childers and Grunig 1989). This process allows scholars to see how these assumptions have affected research approaches and the development of thought in a field. Langland and Gove have articulated this usefully, writing that "A feminist perspective...seeks to correct the bias present in our academic disciplines by uncovering and questioning the hidden assumptions about men and women that have shaped and informed standard academic subjects" (1981:3).

A feminist approach however, does not *only* focus on women and gender, although that is its fundamental perspective. However, it also takes a holistic view of research, recognizing the interrelationships that exist between constructs within a domain. The perspective advocates a nonhierarchical methodology, wherein subjects are treated as equal partners with an investigator. It maintains that research cannot be value-free, because both the values of the researcher and the traditions of the discipline guide inquiry. A feminist approach fundamentally questions the status quo, forcing researchers to explore the assumptions they hold. As applied to consumer research this perspective would allow us to re-examine consumer behavior theory, consumer research agendas, and more generally, the academic marketing discipline overall.

The marketing discipline as a whole is ripe for such re-examination; as Shelby Hunt has pointed out, according to the definitions set by Thomas Kuhn (1970), marketing is actually "pre-paradigmatic," still in that first stage of debate over what constitutes the scope and content of the discipline, what the important questions are. It is not yet firmly shaped and solidified (see Hunt 1991: 332; see also Firat, et al 1987: xii-xiii). In this sense the feminist point of

¹ Authorship of this paper is equal. A longer, more general version of this paper was presented at the 1991 Conference on Gender and Consumer Behavior.

view can simply join all the other points of view competing for inclusion, as marketing sets an agenda in terms of its content, methodology and epistemology. It is crucial that the feminist perspective be considered now, and, where relevant, incorporated, since the discipline's paradigm sets the rules for research formulation and administration. As one scholar has noted:

A paradigm (1) serves as guide to the professionals in a discipline for it indicates what are the important problems and issues confronting the discipline; (2) goes about developing an explanatory scheme (i.e. models and theories) which can place these issues and problems in a framework which will allow practitioners to try to solve them; (3) establishes the criteria for the appropriate 'tools' (i.e., methodologies, instruments, and types and forms of data collection) to use in solving these disciplinary puzzles; and (4) provides an epistemology in which the preceding tasks can be viewed as organizing principles for carrying out the 'normal work' of the discipline. Paradigms not only allow a discipline to 'make sense' of different kinds of phenomena but provide a framework in which these phenomena can be identified as existing in the first place (William J. Filstead, quoted in Deshpande 1986: 113).

However, despite its early stage of development, the marketing discipline already operates from some basic assumptions, values and methodologies which often go unchallenged and which affect research in consumer behavior. Marketers do not necessarily recognize that they are influenced by these beliefs in choosing what they consider to be salient research problems, appropriate research design and methodology, and proper analysis. Using a feminist approach forces us to uncover and reexamine those beliefs, particularly as they relate to gender.

APPLICATIONS OF FEMINIST THEORY

Feminist Theory and Research

The feminist approach to research builds in part on the work of those who have examined gender differences in personality, cognitive development and socialization, work which holds strong implications for scholars in consumer behavior (see, for example, Carlson 1971; Miller 1976; Gilligan 1982). This body of research has found differences between males and females in processing skills and cognitive structuring. These lead to different world views, which in turn result in the preference for alternative approaches to seeking knowledge and to conducting research. Such gendered cognitive and social differences between males and females affect both female scholars in the marketing profession generally, and perceptions and research about female consumers. (Such gender differences are *learned*

behavior, thus are culture bound. This paper reviews studies pertaining predominantly to men and women in the United States).

Women, feminist scholars conclude, frequently interpret experiences in relatively interpersonal, subjective, and contextual ways. Men, on the other hand, frequently interpret experiences of self, others, space, and time in individualistic, objective and distant ways. For example Carlson (1971), in studying personality and gender, used conceptions of *agency* and *communion* to differentiate the aggregate of males from the aggregate of females. As she defines it,

Agency is seen in differentiating of self from the field, in intellectual functions involving separating and ordering and in interpersonal styles involving objectivity, competition exclusion and distance. Communion is seen in merging of self with the field, in intellectual functions involving communication, in interpersonal styles involving subjectivity, cooperation, acceptance and closeness (Carlson 1971:271).

Carlson found that men were more selective in the information cues they use in interpreting and acting upon the world; women were found to be more comprehensive in cue perception and more likely to consider problems within a context or frame of reference.

Gilligan (1982) and Belenky, et al. (1986) reached similar conclusions about gender differences. Like Carlson, they reported that women exhibit greater complexity of constitutional-psychological processes, and that they are more concerned with interpersonal relationships than men. Gilligan (1982) attributed differences in personality and cognitive structures to fundamental developmental differences that had not previously been recognized. She and Belenky et al. (1986) studied the developmental and socialization processes of females and found them to differ significantly from those of males. Through examining developmental differences these authors have identified men's knowledge as "separatist." Men (and women adopting this pattern) use impersonal procedures for arriving at the truth. This can be contrasted with women's "interconnectedness," in which truth emerges through empathy and understanding (Belenky et al. 1986: 102). Where men, as separate knowers, prefer to separate out or extrapolate a singular factual error or logical contribution as a basis for analysis, women have a tendency toward a more holistic view. Belenky et al. (1986) defines this interconnectedness as "constructed knowing." Women, according to these researchers, integrate knowledge of self (that which is personally important) with knowledge gained from others. Such "constructivist" thinkers understand that the answers to all questions vary depending on the context and the frame of reference.

Meyers-Levy (1989) has reviewed much of the research on gender differences and proposes a theory called the "selectivity hypothesis." She argues that

men and women select different cues from the environment, and interpret them in dissimilar ways. This affects their modes of inquiry. For example, Meyers-Levy notes, females engage in comprehensive information processing and attempt to assimilate all available cues; males used heuristic devices to select singular cues and tend to be driven by reliance on those that are highly available and particularly salient in the focal context. Males' processing is characterized by efficiency-striving heuristics whereas females' is characterized by pronounced attempts toward maximizing the comprehensiveness of processing of available cues.

Belenky et al. (1986) concluded that "women tend not to rely as readily on hypothetico-deductive inquiry, which posits an answer (the hypothesis) prior to data collection as they do on examining basic assumptions and the conditions in which a problem is cast" (p.139). Hence, the positivist approach, the scientific method, seems more appropriate to male information processing and research than to that of females. In addition, recent studies have pointed to the differential nature of the graduate school learning experience for women and men (see e.g., Aisenberg and Harrington 1985; and Belenky, et al. 1986). This could result in female scholars perceiving and choosing research issues in new areas, and framing research questions differently than males.

Women now represent approximately 20% of the AMA educators, and since 1986, nearly 50% of the doctoral degrees in marketing have been granted to women (National Center for Educational Statistics 1988). The marketing profession generally is recognizing the growing number of females coming into the field, with special sessions at the last three AMA education conference, as well as at ACR and AMS meetings within the past year. These sessions addressed issues such as problems encountered by females being trained predominantly by men, and the difficulty of developing research agendas on topics of interest to women and/or those using a feminist perspective. Historically, however, students of the marketing profession have been trained in a male-dominated environment.

While few studies in marketing have attempted to determine how gender affects the conceptualization and administration of research, a study has been conducted recently on female marketing academics (Carsky, Kennedy and Zuckerman 1989; Carsky, Kennedy and Zuckerman 1990b). The results show that research interests of female educators center on consumer behavior and promotion, while those of male educators are divided evenly among subfields including management, strategy, channels, sales, pricing, promotion and consumer behavior (Kennedy, Carsky and Zuckerman 1990).

Gender and the Framing of Research Questions

In framing research questions, we are of necessity guided by the paradigm of the discipline. We frequently frame our questions in light of prior research. We critically review the literature, looking for important issues left unsolved by previous

research. We formulate the problem and design the study based on this. But to what extent do we look beyond the scholarly body of literature to inquire about the validity of prior research? How often, for example, do we question the accuracy of prior research in reflecting the issues, concerns, attitudes, and behaviors of consumers interacting in the marketplace? Feminist theory would suggest that when conducting an inquiry on marketplace behaviors, the research begin by asking potential subjects about their conception of reality. It is essential to consider a broad frame of reference, to view situations and issues within a context as opposed to using a "separatist" perspective (see Gilligan 1982; and Belenky et al. 1986). Often this calls for unstructured information gathering on a large scale preceding the use of structured questions, to increase the likelihood that the information to be quantified reflects the circumstances of the respondents' lives.

More specifically, we need to consider whether or not we are asking the right question, focusing on relevant gender differences in behavior. Have we, for example, acknowledged male and female differences in processing and conceptualization which can impact our research findings? To what extent have we, in consumer behavior, relied primarily on men to provide us with information about women? To what extent has the literature previously developed accurately recorded women's experiences, providing a reliable foundation and context for studying issues salient to female consumers?

For example, the supermarket has provided researchers with a rich environment in which to study consumer purchase decisions, particularly with respect to information processing and the selection of informational cues. Although studies report that up to 40% of food shoppers are men, *women* are still primarily responsible for food shopping and food purchasing decisions within the household (*Food Marketing Institute* 1989): 63). In recent years a number of studies have examined the use of nutritional information in the store. For the most part, these investigations relied on sales data as the dependent measure. In five separate studies, no change in the sales of the "most nutritious brand" was found (Carsky 1988). In none of these studies were food shoppers asked about 1) their perception of nutritional differences between brands, 2) the importance of nutrition for selected products, 3) whether nutrition decisions were made at the brand level, and/or 4) whether the format of the information display was comprehensible or important enough to warrant notice. No consideration was given to these issues, or to the context in which food shoppers made decisions. The design of each of these studies relied upon the previous literature. McGrath et al. (1982) has suggested that the worst method to choose for taking a step forward on a research problem is any method that has been heavily used in the past. Yet, because of traditions in the discipline, that is often precisely what is done.

We might also ask whether the experiences of men are represented as the norm, those of females as different, as other. An historical example illustrates

how such a construction can occur over time. When the Curtis Publishing Company put out a promotional brochure about consumer behavior called *Selling Forces*, it contained a section called "Selling to Men," and another called "Selling to Women" (Curtis Publishing Company 1913). In 1952, Curtis issued a new book by the same title. This updated and revised version again contained a section called "Selling to Women," but none on selling to men; it was assumed that men, the norm, formed the target of all other advice in the book (Hobart and Wood 1952). Similarly, some marketing and consumer behavior texts have discussed women, a numerical majority in this country, as a sub group (see, for example Shiffman and Kanuk 1987: 520-535).

The association of women with the private and men with the public sphere, documented by feminist scholars (Rothman 1978; Evans 1989), may also affect research formulation. Research in the social sciences (from which much consumer research theory and methodology has derived) has often operated under assumptions and techniques developed to examine the public sphere. These techniques frequently fail to provide sufficient information about the private sphere. For example, Graham offers a critique of survey methodology, a technique frequently used in consumer research. She notes four assumptions made about units of analysis: 1) units are single and complete; 2) units are equivalent; 3) units and their products have an object-form external to the individual; and 4) units and their outputs are measurable (Graham, cited in Driscoll and McFarland 1989). These assumptions remove the individual from his/her social context. This masks the structure of social relationships and treats patterns of action and attitude as personal characteristics rather than dimensions of social structure. Graham points out that the assumptions behind survey measurement presumes a precise definition of social phenomena, which in and of itself is inherently ambiguous. Finally, she argues that measurement is "closely tied to the marketplace, where activities are quantified and regulated through the medium of money," thus tied to the public sphere (Graham, cited in Driscoll and McFarland 1989: 189). This analysis is particularly salient to the marketing discipline generally which initially developed to solve the problems of the distribution of goods, and hence, was concerned primarily with the public sphere. Marketing only came to recognize the importance of measuring consumer behavior (played out at least in part in the private sphere) in the 1960s. Marketing's long tradition of focusing on the public sphere has undoubtedly spilled over into the way it assesses the private. The effect of this spillover needs to be examined.

Researcher-Subject Relationship

A feminist approach calls for a non-hierarchical methodology. Feminist scholars believe that researchers, subjects and the knowledge that emerges from the research process are interconnected, rather than independent (Gergen 1988: 94). This means recognizing what the scholars Childers and Grunig describe as "the interconnectedness between

scientists' gender and their relationship to subjects and facts" (Childers and Grunig 1989).

Interconnectedness between researcher and subject is not the norm in research about consumers, even when the research seems on the surface to deal with feminist or woman-oriented issues. For example, when the women's liberation movement reached a peak in the late 1970s, a number of marketers focused their research on women and gender effects, most notably in the field of advertising. A flurry of studies were conducted (Sexton and Haberman 1974; Poe 1975; Venkatesan and Losco 1975; Venkatesh and Tankersley 1979; Venkatesh 1980; and Skelley and Lundstrom 1981), which looked at stereotyping of women in advertisements, effectiveness of various portrayals of women, comparison of portrayal of men and women, and media readership and viewing by sex. Yet none of these studies fundamentally questioned the nature of the researcher-subject relationship in doing this work; none of the researchers (male and female) questioned their own formulations or views (and stereotypes) about their subjects.

No studies in consumer research have been uncovered which examine the effect of gender on research. In psychology, however, a meta-analysis performed on a series of research topics revealed significant effects for sex of researcher on the outcome (Eagly and Carli 1981; and Eagly and Crowley 1986). The investigators found that authors are more likely to report behaviors that are socially desirable for members of their own sex. Other studies have found interactions between sex and the task characteristics in experimental designs. Results have indicated that some tasks are not gender-neutral, and that either males or females are more likely to excel (see Deaux 1971; Deaux and Taylor 1973; Major and Deaux 1982; Deaux 1984).

The feminist analysis of the researcher-subject relationship is clearly in line with the interpretivist stance which Hudson and Ozanne describe, writing that:

Interpretivists hold that researcher and people under investigation interact with each other creating cooperative inquiry. If the social reality is based on individuals' or groups' perceptions, then in order to be able to understand those perceptions, these individuals must be involved in creating research process. Thus, the individual who is studied becomes a participant in the experiment, guiding the research as well as supplying information. Interpretivists believe that in the social sciences the scientist is a member of social reality; no privileged Archimedean vantage point exists. This view results in emerging research designs that require ongoing adaptability on the part of the researcher. From the interpretivist's point of view, the merging designs are better able to take into account the subject's knowledge (Hudson and Ozanne 1988:512).

Similar statements on the importance of mutual interaction between the researcher and the subject (informant) can be found in Hirschman 1986; Levy 1981; Thompson et al. 1989, and others who have contributed to a growing body of "crisis literature" (Hunt 1990).

Whether or not one cares to conduct inquiry using the interpretivist or phenomenological path to knowledge, one should at least attempt to understand the "reality" of the individuals under study. Where we have sound evidence, through the accumulation of studies on gender, that males and females conceptualize differently, we should, at a minimum, keep this in mind when investigating phenomena where such distinctions are important.

Research Methodology

Empirical knowledge is always contingent on the methods, populations, situations, and underlying assumptions involved in the process by which that knowledge was captured. As Driscoll and McFarland note, "Feminist research methodology is oriented toward contextualizing the research process, the researcher, and the subject of the research based on a nondualistic world view" (1989). While calling for a holistic approach, a feminist perspective does not negate the validity or usefulness of the scientific method, with its attendant experimental design and statistical analyses. It does, however, posit that knowledge requires a convergence of substantive findings derived from a diversity of methods of inquiry. It advocates the multi-method approach advanced by Campbell and Fiske (1959), which suggests knowledge acquisition through a convergence of findings, involving observations, humanistic inquiry, and experimental studies. For statistical analyses, the feminist approach would imply greater use of causal modeling techniques and multivariate statistics, as it maintains that multiple influences exist for any behavior.

In consumer research, the experimental design is perceived to be the "purest" form of research. The true experiment allows us to isolate a construct, to measure it with precision and accuracy, thus forwarding the advancement of knowledge and building of theory. For example, we often examine the "behavior" of college students when given an artificial task, in a contrived setting, and then generalize this into consumer behavior in the marketplace. The experiment is seen to be value-free, as it seeks to eliminate the threats to internal and external validity. The feminist perspective would question how well an isolated task performed in a contrived setting actually represents consumer interaction in the marketplace. It also would argue that this is not value-free research. The conceptualization and framing of the experimental questions, along with their method, are steeped in the traditions of the discipline, with current research often mirroring past research.

Interdisciplinary Dimensions of Research

Just as they believe in interconnectedness of knowledge, so feminist scholars stress the importance

of an interdisciplinary approach to research (see e.g. Keller 1987). In order to understand and comprehend the complexities of any phenomenon it must be examined from several perspectives. The salience of an interdisciplinary approach to understanding human behavior is self-evident.

In this area the consumer behavior discipline appears very strong. By incorporating psychologists, anthropologists, home economists and economists, it draws on a variety of disciplines; the Association for Consumer Research specifically notes that it is an interdisciplinary body. Consumer research has often been at the vanguard of interdisciplinary and innovative perspectives (e.g. Firat, et al. 1987). It has been within this domain of marketing that logical empiricism or logical positivism as the only legitimate mode of seeking knowledge has received the most attention. The work of scholars from divergent backgrounds with different philosophical methodologies and ontological frameworks are provided with a forum for presenting alternative world views of the consumer environment. While Anderson (1983) suggests that paradigmatic conflicts cannot be resolved as they require too great a "conceptual leap," the emergence of new paradigms arising from the interdisciplinary nature of ACR and its journal may occur as a result of exposure through this association that acknowledges the legitimacy of different philosophies and methodologies.

IMPLICATIONS FOR RESHAPING THE PARADIGM

Marketing has moved from a study of products and services, to a study of social interactions (human behavior). When considering the design of a product, for example, we are interested not in the product itself, but rather in the benefits that will accrue to the user of the product. Marketers' inquiry then must turn to understanding the attitudes, motivations and desires of the actors involved in the exchange transaction. Yet as suggested more than twenty-five years ago (Halbert 1964), there is no simple route to understanding human behavior: "...our scientific research must be turned inward as well as outward. We must study marketing operators and marketing scientists... and we must study ourselves. Only after we know what we do and how we do it can we begin to do it better" (1964: 32).

The feminist approach offers a conceptualization and suggests methodologies for studying such social phenomena, and behavior by consumers. It emphasizes the context or milieu in which individuals operate in the exchange relationship, with each acting in his or her own self interest to maximize the perceived benefits and minimize the costs of the transaction. If a general theory of marketing is to be developed, we must study actors in the transactions within the natural environment, something a feminist perspective facilitates. Through the tenets of interconnectedness, a holistic view, anti-elitism, and a non-hierarchical research methodology, a better understanding of marketing phenomena will be realized.

In defining marketing as the behavioral science that seeks to explain relationships, Hunt (1983) delineated four sets of marketing explananda, which apply to consumer behavior as well, including: 1) the behavior of buyers directed at consummating exchanges; 2) the behavior of sellers directed at consummating exchanges; 3) the institutional framework directed at facilitating exchanges; and 4) the consequences on society of the behaviors of these parties. The feminist approach can broaden marketers' perspective in each of these areas.

Women have long been the primary target for the marketing efforts of producers and distributors of many consumer goods. Feminist theory offers an understanding of women's ways of knowing--of the female mode of conceptualization and processing of information that will lead to better comprehension of the manner in which women engage in the selection, consumption and disposition of goods, and how it may differ from that of men. The theory specifies that most women view things in a context. To separate out one minute aspect of the purchase process for study is inappropriate for understanding their buyer behavior.

Knowledge about the behavior of sellers can also be furthered by using a feminist perspective. To understand why sellers produce, price, promote and distribute as they do requires anti-elitism and a non-hierarchical research approach. We must, as feminist theory suggests, seek to empathize with the position of the seller, to utilize interactive modes of inquiry in which both the research and researched learn from the process. We must use inductive and qualitative methodology. As women now fill the ranks of the industrial salesforce, we should also examine the differences in the ways men and women operate within the occupation. In light of the feminist scholarship on cognitive differences between the sexes, we might find that male and female salespeople respond to customer service needs differently. Successful salespeople of the two genders may differ both in their routes to success and in their reasons for success.

In examining marketing's institutional framework, we must employ an historical methodology, one which looks at the societal environment in which institutions have evolved over time. In viewing this history we need to consider the societal conditions involving not only the public sphere of marketplace transactions populated principally by men, but also the private sphere, typically the domain of women. We need to examine the interactions between these two arenas, and how this interaction might have influenced the development of institutions important to marketing. For example, changes in the nature of women's work in the home influenced the development of department stores in the nineteenth century. In more recent years, the changing role of women, the dual earner family, and smaller household size have forced changes in the retailing community.

To look at changing institutions without considering the last of the four explananda, the effects on society, would be to examine one aspect of the environment out of its context. From the end of the last century women have been instrumental in

spearheading movements to improve working conditions, the safety of products, and the inequities of the marketplace. They have been leaders in the environmental movement and the consumer protection movement. We must study what particular factors motivate women to take up and/or support a cause, and investigate how and why they are frequently earlier than men in spotting inequities and spillover effects of production. By understanding the world view of women, we can better learn to identify potential problems with our marketing efforts and correct them as they are about to occur.

In summary, the feminist approach calls for a rethinking of consumer behavior. In so doing, it will enrich the field. As Belenky et al. note, to see "knowledge as a construction and truth a matter of the context in which it is embedded greatly expand(s)... the possibilities of how to think about anything, even those things we consider to be the most elementary and obvious" (1986: 138). Conversely, consumer research tools and analysis can be used to explore more deeply and understand more completely gender construction in our society. The areas outlined here point to new areas of inquiry for consumer researchers, feminists, and feminists within the consumer behavior discipline.

Are the Models Compatible for Empirical Comparison? An Illustration with an Intentions Model, an Expectations Model, and Traditional Conjoint Analysis

Rajan Nataraajan, Auburn University
Paul R. Warshaw, California Polytechnic State University

ABSTRACT

Before models are compared empirically, it must be ascertained that they are indeed comparable at a theoretical level. Unfortunately, the literature does not contain a standard procedure for making theoretical comparisons of models. The authors attempt to fill this lacuna by suggesting a scheme for checking the compatibility among models prior to empirical comparison.

Currently there is a plethora of models and techniques in marketing. These have emerged from several perspectives. Some are based on economic utility theory, some are purely attitudinal in nature, and others appear to be based on both economic and psychological perspectives. There are also those that are based on the interface of economics and probability theory, and some are purely stochastic in nature. Unfortunately however, our understanding of marketing phenomena in general and the prediction of consumer behavior in particular does not appear to have reached a reasonable level of perfection (Hoyer 1984; Jacoby 1978). One way to enhance this understanding is to significantly increase the extent of empirical comparisons of existing models and techniques in a variety of situations within the consumer-marketplace domain. The revelations from such comparisons would aid not only in model selection for various situations but also in the building of new models and techniques.

However, before models are compared empirically, it must be ascertained that they are indeed comparable. A theoretical comparison of the chosen models would reveal whether or not the models are actually comparable and if not, it would reveal the specific points of incompatibility among them. In some cases, it may be possible to get around the points of incompatibility and then make a "correct" empirical comparison. Currently, there does not seem to be any standard procedure for carrying out theoretical comparisons of models and techniques. In this paper, we suggest such a scheme, and then illustrate it with three selected models.

A SCHEME FOR CHECKING COMPARABILITY OF MODELS

The suggested scheme for a theoretical comparison of models is depicted in Figure 1, and consists of six main steps. Step 1 deals with the *contextual terms* (e.g., reliability, involvement, perceived control etc.) pertaining to the impending empirical testing. In this step, a clear explanation of the test context, and a semantic as well as a methodological clarification of the contextual terms figuring therein are furnished. In step 2, the selected

models are compared in terms of *purpose*. This essentially involves answering the following questions: (a) What is the main reason for the existence of each model? (b) What can be accomplished through the use of each model? (c) Is there compatibility among the chosen models with respect to (a) and (b)? In step 3, the models are compared on *focus*, and this involves answering two questions, and they are: (a) In a theoretical sense, what does the model basically stress? (b) What is the required level of analysis, individual or group? In step 4, the models are compared on *theoretical base and structure*. In step 5, their *boundaries and constraints* are compared.

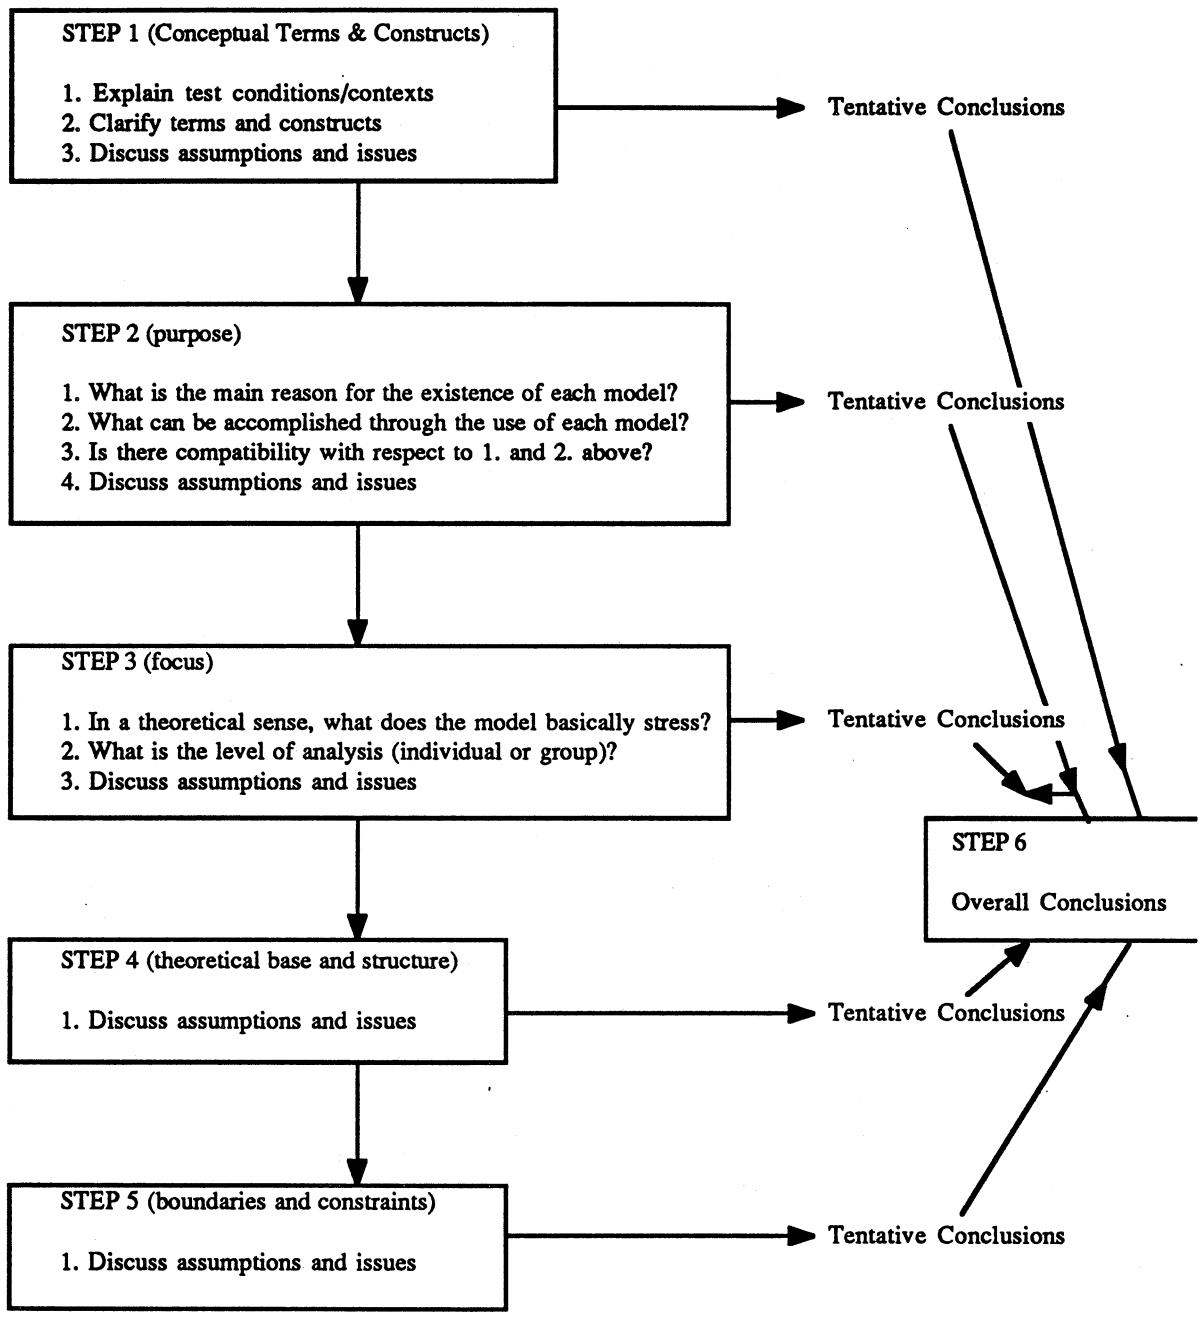

In each of the above steps, the assumptions of the models are taken into account at appropriate junctures. Relevant issues (if any) are raised and discussed in light of the above assumptions, and tentative conclusions are drawn. Based on all the tentative conclusions, overall conclusions are drawn (step 6), which pave the way for speculations on performance of the models.

An Illustration

Let us assume that a researcher wants to empirically compare the external predictive validity of a behavioral intentions model, a behavioral expectations model, and traditional conjoint analysis in a reasoned choice situation within the consumer-market place domain; note that any other set of models would be just as effective in illustrating our scheme. Since the theory of reasoned action (Ajzen and Fishbein 1980) has been the most widely adopted attitude framework within social psychology (Warshaw and Droge 1985), we choose it as our behavioral intentions model. For our behavioral expectations model, we use a modified version of Warshaw (1980)'s behavioral intentions model. We have picked conjoint analysis (Luce and Tukey 1964; Green and Rao 1971) mainly because, in recent times, it is probably the most widely used marketing research tool in the industry for measuring consumers' multiattribute utility functions (Green 1984). The surveys conducted by Cattin and Wittink (1982; 1989) provide evidence for the increasing use of conjoint analysis in the industry.

Note that in the interest of making the illustration clear and effective, a hybrid conjoint model was not chosen. The self-explicated part of hybrid conjoint models bears a close resemblance to attitudinal models in the sense that both rely on direct consumer input. Consequently, if a hybrid conjoint model is chosen, the distinction between "compositional" and "decompositional" would become blurred, thereby reducing the "contrast" effect between the attitudinal models and conjoint analysis.

FIGURE 1
A Scheme for Theoretically Comparing Models and Techniques

Since it was felt that having such a clear "contrast" would enhance clarity and comprehension of our scheme, traditional conjoint analysis was chosen for this illustration.

To ascertain theoretical compatibility among the above models, we apply our scheme as follows:

Step 1

Here, there are two contextual terms, *external predictive validity* and *reasoned choice*. The term

external predictive validity refers to the extent of agreement between what is predicted by a model and what actually occurs in reality. The qualification "external" warrants that the test setting be real and not contrived or hypothetical. The term *reasoned choice* is an off-shoot of the term "reasoned action" (Ajzen and Fishbein 1980) and simply refers to "reasoned actions" in a choice situation; the qualification "reasoned" refers to rationality.

Step 2

Here, the three models are compared in terms of their purpose. To facilitate presentation, the acronyms TRA, BEM, and CAS are used to refer to the theory of reasoned action, the behavioral expectation model, and traditional conjoint analysis respectively.

TRA: Ajzen and Fishbein (1980) have renamed the Extended Fishbein model and promoted it as a viable theory to predict and explain virtually any type of human behavior. Since they view consumer behavior as just any other behavior of interest, and that no novel or unique processes need to be invoked to explain or predict it, TRA may be used to explain and predict consumer behavior. Further, Ajzen and Fishbein (1980) recognize that consumer behavior is human action involving a choice among various alternatives. In view of this, by restricting its generality to consumption choice, TRA may be used for predicting consumer choice. The hypothesis underlying the application of TRA to consumer choice situations would be that a consumer has a certain level of "intention toward choosing an alternative" (the predictor of choice behavior) for each of the alternatives in the choice set, and would end up selecting that alternative for which the consumer has the highest level of the above predictor.

BEM: This model has been designed specifically for the purchase situations which is, by and large, characterized by the choice process. Therefore, the use of BEM as a predictive model of consumer choice is justified. The hypothesis underlying the application of BEM to consumer choice situations would be that a consumer has a certain level of "expectation toward choosing an alternative" (the predictor of choice behavior) for each of the alternatives in the choice set, and would end up selecting that alternative for which the consumer has the highest level of the above predictor.

CAS : In an essentially pragmatic discipline like marketing, CAS is used to estimate consumers' preferences among multiattribute stimuli. However, the ultimate purpose of doing this is to aid the marketer in the task of prediction of behavior in the market place with greater exactitude (Leigh, Mackay, and Summers 1984). This seems to be an accurate assessment of the role of CAS because for whatever intermediate purpose it is used in marketing, there is always the implicit assumption that it will help in the revelation of the behavioral tendencies of the consumer based on which better marketing strategies could be developed. Thus, the ultimate purpose is to help in the prediction of choice behavior in the market place. The hypothesis underlying the application of CAS to consumer choice situations would be that a consumer has a certain level of "total utility toward choosing an alternative" (the predictor of choice behavior) for each of the alternatives in the choice set, and would end up selecting that alternative for which the consumer has the highest level of the above predictor.

Issues: The proponents of TRA and BEM imply that the algebraic formulations in their approaches correspond to the consumers' cognitive processes, and thus, the models are primarily concerned with

explanation of behavioral phenomena. Prediction is relegated to secondary status. In contrast, CAS does not assume that consumers actually process cognitively according to the maximization principle (subject to constraints) but only that consumers choose as if they did. Thus, in a sense, CAS is more concerned with the end result rather than any cognitive process that may occur in the mind of the consumer prior to the end result. Perhaps because of this, Green and Srinivasan (1978) have opined that users of CAS have been concerned more with prediction than explanation.

Tentative Conclusions: In light of the foregoing, it may be concluded that if the purpose is prediction of consumer choice behavior in the purchase phase, then the three models are definitely comparable.

Step 3

In this step, the models are compared in terms of their main focus. TRA and BEM stress the subjective perceptions (salient subjective consequences) and evaluations rather than objective measures. It is to be noted that the saliency concept inherent in these models implies individualization in that the salient beliefs about the consequences of behavior may be different from individual to individual. In the ideal application of any of these two models, the analysis (including the elicitation of salient beliefs) should be done totally at the individual level, and conclusions drawn at the individual level only. In other words, the ideal application in the consumer choice context would be to explain and predict *individual* choice behavior.

CAS focuses on the characteristics of the choice objects. In other words, it is really an object based approach. Objects are analyzed in terms of certain basic features (attributes), whose juxtaposition in a particular product is viewed as the basis of choice. Thus, the preference is initially defined on individual attributes (e.g., prefer low price; prefer black color), and choice is effected on the objects (e.g., prefer a low priced, black colored car among the many cars). However, there is the implicit behavioral assumption that preferences are a manifestation of the subjective perceptions and evaluations of the individual. Further, the saliency aspect figures in CAS also, but in the form of salient attributes of the object. As regards the level of analysis, it is the same as in TRA or BEM. The ideal application of CAS would be to elicit salient attributes for every individual, conduct analysis at the individual level, and draw conclusions on preferences (or choice behavior) only at the individual level.

Issues : In the operationalization of any of these three models, the ideal application referred to above, does get diluted in rigor. From a marketing decision point of view, behavioral prediction at the individual level is of very little use because that would be like the extreme of treating every individual as a separate segment. This, of course, would be realistic and proper in many industrial marketing situations. For most consumer good situations however, unless these individual predictions can be meaningfully aggregated and some concrete conclusions drawn at the

target market level, realistic and economical marketing strategies cannot be formulated. But aggregation dilutes theoretical rigor. For instance, in the operationalization of TRA or BEM, aggregation actually takes place in two stages. First, the saliency aspect gets diluted because individual salient beliefs are aggregated and a few modal salient beliefs are obtained. These are then used in a questionnaire designed for the entire sample. The purity of measurement and analysis at the individual level gets tarnished at this stage itself because some of the modal salient beliefs may not be salient to every respondent. The second dilution takes place when the results of the individuals are aggregated to draw conclusions at the sample level.

In CAS, the salient attributes (and levels) of the product for each individual are aggregated, and only a few modal salient attributes (and levels) are used to construct profiles or attribute-level combinations. In other words, the perceived attributes (and levels) are assumed to be constant across individuals in the sample. This assumption of homogeneity of perceptions has been questioned by Ritchie (1974). Despite the implicit assumption in CAS that differences in perception are captured totally by the individual preferences, this homogeneity of perceptions assumption can only be deemed as the first dilution of the saliency or the individual level analysis aspect. The second dilution in CAS takes place when the results are aggregated to draw conclusions at the target market level. However, it must be pointed out that in applications of CAS, the individual differences are retained to a relatively greater degree because the second aggregation takes place usually through a choice simulator, which is a relatively more rigorous method.

Tentative Conclusion: In light of the foregoing, it may be concluded that despite the difference in focus, there is compatibility among the three models because they are all essentially individual level models, and the ideal application of any of these models would be at the individual level. But in the operationalization of these models, this ideal state gets tarnished in every model owing to aggregation. However, it is realized that without aggregation, there would be very little use for these models in a pragmatic discipline like marketing. So it seems that it does not serve any useful purpose to debate the comparative theoretical rigor of these models because they all lose rigor when they are operationalized, at least in marketing scenarios.

Step 4

Here, these models are compared in terms of their theoretical base and structure. TRA is based entirely on concepts of social psychology. BEM is based on a mixture of social psychology (attitudinal formulation), economics (utility maximization/satisficing principle), and mathematical psychology (probability theory). However, both models belong to the compensatory type, and rely on direct consumer input. Further, each one uses a compositional

approach in that responses obtained on simpler components are combined in some fashion to yield a numerical representation of the main component (behavioral intention or behavioral expectation depending on the model). However, there are important structural differences between these two models.

Figure 2 furnishes a pictorial description of TRA. As per this, behavioral intention is the immediate antecedent of behavior. Intention is determined by an attitudinal (personal) component and a normative (social) component. The model can be symbolically stated as,

$$B \sim BI = w_1 (A_B) + w_2 (SN) \text{ where,}$$

B is Overt behavior, BI is Behavioral intention (subjective probability of intending to perform behavior B), A_B is Attitude toward performing behavior B (e.g., attitude toward buying a brand; note that this is not attitude toward the brand itself.), SN is Subjective norm (normative influence; the collective perceived influence of "important others"), and w_1 and w_2 are empirically determined weights denoting the relative influence of the two components. A_B is determined as $\sum b_i e_i$ where, b_i is the subjective probability that performing the behavior will result in outcome i , e_i is the individual's evaluation of outcome i , and n is the number of salient outcomes. SN is determined as $\sum NB_j MC_j$ where, NB_j is the belief that referent j thinks the individual should/should not perform the behavior, MC_j is the individual's motivation to comply with referent j , and N is the number of salient referents.

BEM emerges when the behavioral intention model proposed by Warshaw (1980) is treated as a behavioral expectation model after necessary modifications in the constructs. Essentially, the logic in the model is based on "working backwards" from the antecedents of behavior and deriving a framework of cognitive constructs and their interrelationships with each other and behavior. Assuming that the subjective probability (expectation) of performing a specific behavior (e.g., purchasing the New York Times) is often conditional upon the formation of more global antecedent expectations (e.g., purchasing a newspaper), an operational equation for product purchase contexts is derived, which may be stated as,

$$BE_y = BE_Y \times BE_{y/Y} \text{ where,}$$

BE, behavioral expectation, is the individual's estimation of the likelihood that he/she will perform some specified future behavior, Y refers to the product type, and y refers to the specific brand of Y. $BE_y =$ Expectation to buy specific brand y, $BE_Y =$ Expectation to buy product type Y, and $BE_{y/Y} =$ Expectation to buy brand y assuming purchase of product type Y.

FIGURE 3a
The Behavioral Expectation Model

Determinants of Brand Specific Expectations (BE_y)

Expectation of purchasing product type Y

Expectation of buying brand y of product type Y

Expectation of buying brand y assuming purchase of product type Y

Source: This is a modified version of the diagram furnished by Warshaw (1980).

Figure 3a illustrates the above formulation. Figure 3b furnishes the antecedents of BE_Y and $BE_{y/Y}$. Product type expectation, BE_Y , is stated to be a function of purchasability (X_1) of product type Y and felt need or desire (X_2) to purchase product type Y. The antecedents of (X_1) and (X_2) are as shown in Figure 3b.

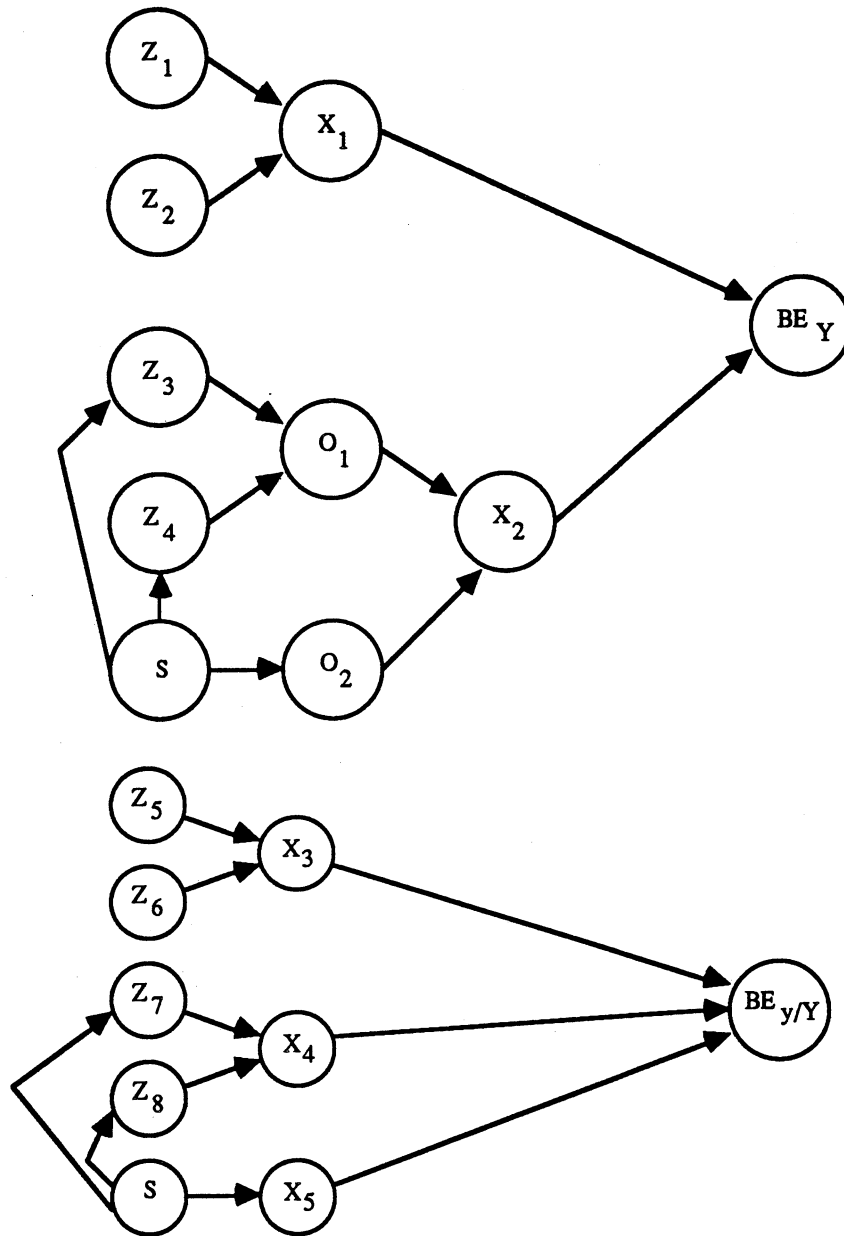

Brand choice expectation assuming purchase of product type, $BE_{y/Y}$, is stated to be a function of

relative purchasability of brand y (X_3) as compared with alternative brands of Y, relative ability of brand y (X_4) to satisfy own product use needs (for instance, in the case of a newspaper, international news, sports coverage etc.), and felt pressure (X_5) from others to buy brand y instead of some alternative brand of Y. The antecedents of (X_3), (X_4), and (X_5) are as shown in Figure 3b.

While the origin of conjoint measurement can be traced to the work of some economists of the last

FIGURE 3b

Determinants of BE_Y and $BE_{y/Y}$

Z_1 = Affordability of product type Y; Z_2 = Accessibility of product type Y; X_1 = Purchasability of product type Y; Z_3 = Own actual need to buy product type Y; Z_4 = Own longing to buy product type Y; O_1 = Own desire to purchase product type Y; S = Societal norms; O_2 = Felt pressure from others to buy product type Y; X_2 = Felt need or desire to purchase product type Y; BE_Y = Expectation (likelihood) of purchasing product type Y. Z_5 = Relative affordability of brand y; Z_6 = Relative accessibility of brand y; X_3 = Relative purchasability of brand y; Z_7 = Relative ability of brand y to satisfy own actual product use needs; Z_8 = Relative ability of brand y to satisfy own product use desires; X_4 = Relative ability of brand y to satisfy own product use needs; S = Societal norms; X_5 = Felt pressure from others to buy brand y instead of some alternative brand of Y; $BE_{y/Y}$ = Expectation (likelihood) of buying brand y assuming purchase of product type Y

century, the field of conjoint analysis formally came into existence only with the work done by Luce and Tukey (1964). Since that article, the field has developed rapidly in a theoretical as well as an applied sense, and consists of a variety of models and generalized techniques (see Green 1984; Green and Srinivasan 1978). CAS is based on the fundamental principles of maximization and decomposition in decision making by rational human beings, and makes use of the occurrence of polynomial structures in the various fields of study. It uses a decompositional approach in the sense that overall judgments of the main component (attribute-level combinations) are broken into numerical measures for simpler components (attribute levels).

Compensation also comes into play here in the sense that the respondent may rate a particular combination that is weak (for the respondent) on one important attribute level highly if other attribute levels in the combination are strong. For a simple mathematical exposition of CAS, we refer the reader to Rao (1977).

CAS essentially involves asking the respondent to give overall or global judgments/evaluations about a set of alternatives and then decomposing these overall judgments/evaluations into separate utilities or part worths that, given some type of composition rule, are most consistent with the respondent's overall judgments or evaluations. In other words, the technique yields utilities from which the original global judgments or evaluations can be closely reconstituted. Note that a part worth is simply the value or importance of an attribute level as perceived by the respondent. Note also that the utility measures (parameter estimates) are statistically derived.

Issues: The general model of conjoint measurement is, strictly speaking, context free and does not provide ground rules to develop some kind of usage typology (what model would be suitable for a particular situation) for conjoint models (Rao 1977). This forces researchers to either rely on past empirical research concerning the performances of various conjoint models or use a trial and error approach or simply assume that a particular model would be suitable for a particular situation and use it. This situation is unlikely to be altered unless - as Rao (1977) has pointed out - a theory for evaluation of multiattribute stimuli akin to multidimensional psychophysics is developed. In contrast to this, with TRA or BEM, a change in context does not alter the basic structure of the model itself. In other words, the same model is applicable in all contexts. However, the basic model accommodates a change in the belief structure of the individual whenever the context is changed.

Tentative Conclusions: Despite differences in the theoretical bases and structure there seems to be compatibility among the models on a broad theoretical level. All these models assume human rationality to prevail in decision making. Also, each model has some form of compensation coming into play in its application. However, there are two key

differences between TRA and BEM as one group, and CAS. First, while the attitudinal models adopt a compositional approach, CAS adopts a decompositional approach. Second, whereas the attitudinal models rely on direct input from the respondent for parameter estimation, CAS relies on statistical techniques to derive parameter estimates.

Step 5

Researchers (Bagozzi and Warshaw 1990; Warshaw and Droge 1985; Warshaw et al. forthcoming) have stated that TRA actually applies to a relatively circumscribed domain, and have pointed out its boundary conditions as follows: (i) Behavior is restricted to mean single, observable, reasoned acts performed by an individual. (ii) Outcomes experienced by an individual are explicitly excluded, unless the individual fully has the means to achieve those outcomes, intends to do so, and there is no intervention (and possible prevention) in the form of external situational forces to the achievement of the outcomes. (iii) i and ii are tantamount to saying that behavior is completely determined by one's volitions, and performance is typically under one's self control; in other words, total volitional control must be there for both behaviors and outcomes. It follows therefore that TRA does not make a distinction between a behavior and an outcome; in reality, one typically has much less control over outcomes. Consequently, TRA does not regard succeeding in a race, gaining stamina, lowering cholesterol level, etc. as behaviors because "complete control" will typically not be there in any of them. Thus, TRA does not apply in cases of behaviors occurring because of non-volitional psychological processes (habit, impulse) or situational contingencies (fear, coercion). (iv) Further, phenomena such as goals (desired end-states), plans (mental procedures for achieving these ends), and behavioral expectations (self-predictions of the likelihood of goal attainment and/or behavioral performance -Warshaw and Davis 1985), which act as antecedents to the initiation and/or actual performance of acts, are outside the scope of TRA. It must also be realized that under some circumstances, to state an intention is to express a goal, plan, and expectation. These mental events are often distinct, and combinations of these states can occur. These are brought out in the following examples. One may have a firm intention to stop eating desserts yet possess no plans to do so; one may even believe that such stopping is unlikely. One may have a strong expectation that he or she is going to drink some wine yet at the moment neither intend nor plan to do so. But such combinations of states of intentions, goals, plans, and behavioral expectations do not fall within the boundaries of TRA except when intentions equal expectations. In view of the above, it would be more correct to view TRA as a model designed to explain and predict a wide range of *voluntary* and *reasoned* behaviors of interest, and not as a model that can explain and predict virtually any type of behavior as contended by Ajzen and Fishbein (1980).

Strictly speaking, TRA is an unconstrained choice model in the sense that constraints are not endogenous to the model. However, this does not mean that the proponents of TRA have not talked about constraints; constraints are assumed to be in the form of exogenous factors (situational forces that may impede the enactment of behavior). In a sense, TRA implicitly assumes that the individual takes constraints into consideration in decision making. However, there is nothing explicit in this regard in the model.

The boundaries of BEM, by virtue of its design, are restricted to purchase situations. Constraints pertaining to the purchase situation are also introduced (e.g., affordability). It is, therefore, a constrained choice model in the domain of purchase behavior.

A common feature of the two attitudinal models, TRA and BEM, is that they incorporate a normative (influence of important others) aspect through the subjective norm construct (TRA) or the social norm construct (BEM). Another common feature is that no interaction of any kind is considered by them, and other researchers (e.g., Miniard and Cohen 1979; 1981; 1983) have raised questions concerning TRA in this connection.

CAS essentially estimates only preferences even though conclusions about choice behavior are drawn through likelihood of purchase type of measurement, and /or through the use of a choice simulator. The latter method is, strictly speaking, an extension of basic CAS. This is in the same vein as the extension of mathematical programming to predict choice behavior (Bernardo and Blin 1977). Regarding constraints, there is nothing explicit in the model itself. However, users of CAS can create contexts for the respondent, and thereby expect the respondent to take contextual constraints into consideration while rating attribute-level combinations. But this is, no doubt, an assumption that actually stems from the greater assumption of human rationality. Further, the constraints (assumed) are treated as fixed across individuals. Also, there is nothing normative (what ought to be or ethical or both) about the conjoint model. However, CAS, in contrast to the attitudinal models, accommodates interactions among attributes.

Issues: The extent of realism in the choice scenario would particularly affect the effectiveness of BEM. For instance, if a "forced choice" scenario were to be adopted (which is often the case in comparative tests), the effectiveness of BEM would be considerably eroded because the first stage of the model becomes irrelevant ($BE_{\gamma} = 1$, and so X_1 and X_2 become meaningless).

Tentative Conclusions: In a theoretically rigorous sense, TRA and CAS are unconstrained choice models. On a less rigorous level however, they may be considered as constrained choice models because constraints are there, albeit implicitly. BEM accommodates constraints to choice behavior, and can therefore be considered, both theoretically and pragmatically, as a constrained choice model even though its domain of application is limited to purchase situations.

Step 6

Here, we arrive at overall conclusions. Figure 4 provides a gist of the results of the foregoing structured theoretical analysis. While it is very clear that each of them can be used individually to predict (if not explain) consumer choice behavior in suitable settings, a meaningful comparison of their predictive abilities can take place only when, 1. the choice behaviors are all reasoned behaviors, and 2. the test setting involves a real life choice scenario in the purchase phase with all its vagaries and uncertainties. Any limitation(s) imposed on the test setting that cuts into realism would in turn cut, particularly, into the richness of BEM. In view of the above, while the universal constraints of time and money always interfere with the desires of researchers (forcing them to adopt scenarios that lack realism), it is important to realize that a fair comparison of these three models *cannot* be done in artificial settings.

Conclusions

In this paper, we have suggested a general scheme for theoretically comparing models *before* empirical comparison, and determining, given the test setting and other criteria (external predictive validity or efficiency) whether in fact they are comparable under all conditions or only under some conditions or not at all. It should be noted that this is *not* a comprehensive scheme for discussing the results from an empirical comparison of models. In other words, we are not looking at the problem of determining which is truly a better orange given two oranges. Instead, we are looking at two fruits and determining whether they are both oranges. In the process, one may turn out to be an orange and the other a banana, or one may be a grapefruit and the other an orange, or both may turn out to be oranges of the same strain or different strains. The scheme would also enlighten as to the criteria under which two somewhat different models may be compared meaningfully. For example, a tangerine may be compared to a tangelo or a clementine on sweetness, juice content and vitamin C content.

It should also be noted that we have given only an illustration of the scheme; other illustrations may be given. Naturally, the specific items discussed under the dimensions of our scheme would depend upon the test setting and other criteria specific to the particular impending empirical comparison. However, it does not alter the logic of the scheme. It may also be noted that while alternative structures are possible, the proposed structure lends itself to a logical step by step flow, and thus has "programmable" or "flow chart" appeal.

The desire to sensitize researchers to the need for rigorous theoretical comparisons of models prior to actual empirical comparisons was the sole driving force behind this paper. By suggesting a scheme for doing this, we have endeavored to instill some degree of standardization in the task involved. It is our hope that the suggested scheme would contribute to creating order out of anarchy in model comparisons.

FIGURE 4
Findings of the Comparative Analysis

Purpose and Focus

TRA and BEM	CAS
EMPHASIS ON PREDICTION AND EXPLANATION	EMPHASIS ONLY ON PREDICTION
SUBJECTIVE PERCEPTIONS AND EVALUATIONS	OBJECT BASED APPROACH
SALIENCY ASPECT IN BELIEFS	ESSENTIALLY ESTIMATES PREFERENCES
IDEAL APPLICATION IS AT INDIVIDUAL LEVEL	SALIENCY ASPECT IN ATTRIBUTES
NORMATIVE ASPECTS	IDEAL APPLICATION IS AT INDIVIDUAL LEVEL
	NO NORMATIVE ASPECTS

Theoretical Base and Structure

TRA	social psychology based; assumes rationality to prevail; compensatory; compositional; direct consumer input; no interactions of any kind
BEM	social and mathematical psychology based; assumes rationality to prevail; compensatory; compositional; direct consumer input; no interactions of any kind
CAS	mathematical psychology based; assumes rationality to prevail; compensatory among attributes; decompositional; statistically derived measures; interactions among attributes allowed

Boundaries and Constraints

TRA	single, observable, reasoned acts; assumption of total volitional control; behaviors and outcomes indistinguishable; constraints are implicit
BEM	strictly for purchase situation; constraints are explicit
CAS	essentially estimates preferences but conclusions about choice behavior may be drawn by Luce's axiom or through choice simulator; essentially context free; constraints are implicit

Ho, Ho, Woe: Christmas Shopping for "Difficult" People

Cele Otnes, University of Illinois
Young Chan Kim, University of Illinois
Tina M. Lowrey, University of Illinois

ABSTRACT

This study is a qualitative examination of gift selection strategies used by Christmas shoppers. While conducting this study, we noticed that shoppers described certain recipients as difficult to buy for. Thus, we explore the following issues: 1) who consumers identify as difficult; 2) why these recipients are perceived as difficult; and 3) what strategies consumers use in selecting gifts for difficult recipients. As such, this paper complements recent research by Sherry, et al. (1991a, 1991b) on the "dark side" of gift exchange behavior. Implications of the findings are discussed.

For almost two decades, consumer behaviorists have been interested in the study of gift exchange. Such issues as the influence of motivations (Wolfenbarger, 1990; Goodwin, et al., 1990), perceived risk (Heeler, et al., 1979; Mattson, 1982), balance (Belk, 1976) and involvement (Clarke and Belk, 1979; Belk, 1982) on such behavior have been explored. And while Belk (1979) compares the appropriate dimensions of gifts across some common occasions, researchers generally have not focused upon the gift exchange activities pertaining to a particular event.

However, some attention has been paid to gift exchange surrounding the Christmas holiday. Belk (1979) notes that Christmas gifts selected by parents often served as socialization agents. Caplow's (1982, 1984) studies of Christmas gift-giving behavior in "Middletown" reveal that people unknowingly follow specific rules pertaining to the display and distribution of gifts. More recently, Sherry and McGrath (1989) reaffirm Caplow's earlier finding that Christmas shopping is the "work of women" (p. 162). Lastly, Fischer and Arnold (1990) examine the influence of gender role attitudes upon Christmas shopping, and find that male and female shoppers with more liberal attitudes searched longer for, and bought more gifts, than did those with more traditional attitudes.

These studies have certainly improved our understanding of gift exchange at Christmastime. Yet the economic importance of the holiday -- with expenditures of Christmas gifts in America placed at \$37 billion in 1990 (Conference Board, 1990) -- makes the study of Christmas gift-buying and gift-giving worthy of continued investigation.

PURPOSE OF THE STUDY

The data for this paper emerged from a larger study on Christmas gift exchange. While collecting and interpreting our data, we noticed that most gift-givers categorized some of their recipients as particularly difficult to shop for. With this finding in mind, we have narrowed the focus of this paper to address the following research questions:

1. Who are the difficult people on gift buyers' Christmas lists?
2. Why are some recipients considered difficult to shop for?
3. What gift selection strategies do consumers employ in selecting gifts for difficult people?

By examining these questions, this paper complements the recent research by Sherry, et al., (1991a, 1991b) and Rucker, et al. (1991) on the "dark side" of gift-buying. Furthermore, it examines gift selection strategies used for a distinct subset of recipients.

METHOD

To recruit informants, we placed ads in a university paper and a local paper of a Midwestern city (population 100,000) during the first week of November, 1990. To solicit consumers with more complex Christmas shopping tasks, students were requested not to answer the ad. The copy explained that we wished to conduct two in-depth interviews with each informant, accompany them on two Christmas shopping trips and hold a brief follow-up interview in January. An incentive of \$30 was offered for participation.

Out of the 18 volunteers for the study, we chose the 15 consumers who indicated they would be accessible for all stages of the research. Each researcher was then assigned five informants.

In terms of demographic characteristics, 14 out of the 15 informants were women. The literature indicates that women are more involved in Christmas shopping (Caplow, 1982; Cheal, 1988; Sherry and McGrath, 1989). Thus, while we were disappointed by the lack of response by men, we were not surprised by it. The socioeconomic status of the informants ranged from lower middle class to middle class, and ages ranged from the early twenties to the mid-forties.

With the exception of the follow-up interview, the study was conducted from mid-November to one week before Christmas, 1990. To establish a basis for comparison across informants, we asked each one the same questions during the preliminary interviews. The first shopping trip occurred at least one week after the preliminary interview, so that we could acquire information about gift selection activity that we had not actually observed. As each of us became familiar with our informants' shopping tasks, we created specific questions relating to their tasks, a procedure similar to what Lincoln and Guba (1985) call "memoing."

TABLE 1
 "Difficult" People Specifically Mentioned by Informants

<u>Difficult People</u>	<u>Number</u>
In-Laws	10*
Fathers	7
Grandparents/ Elderly Relatives	7*
Steprelatives	6*
Mothers	4
Husbands	3
Sisters	3
Friends	3
(Opposite Gender)	
Friends	2
(Same Gender)	
Teachers	2
Other Affinal 2* Relatives (Niece, Cousin)	
Totals	47

*Affinal Relatives

The length of each shopping trip ranged from 1-2 hours. Informants chose the sites for all shopping trips. These included discount stores, department stores, drugstores, hardware stores and a wide variety of specialty shops.

RESULTS

Who Are the Difficult People on Gift Buyers' Christmas Lists?

Informants named 207 people as potential Christmas gift recipients. Of these, they specifically described 47 people as "difficult" recipients. Table 1 lists the relationships of these recipients to our informants. The largest number of difficult recipients are what Caplow (1984) terms "affinal" relatives, or people who are peripherally related to givers. However, a considerable number of more closely related family members were also considered difficult. Finally, some difficult recipients -- including friends and teachers -- are not related to informants at all.

Why Are Some Recipients Considered Difficult?

Our shoppers offered nine reasons why they categorized gift recipients as difficult:

1. *Perceived Lack of Necessity/Desire.* Almost one-fourth of "difficult" recipients were characterized as such because givers stated these people either did not want or did not need any type of gift. For instance, Anne¹ commented that her 94-year old grandmother has "got[ten] everything she ever wanted." Likewise, Betsy noted that her grandparents and her father were

difficult because they "have everything. There isn't anything I could buy them that they would want and wouldn't have. Or sometimes that they would even like."

2. *Fear of Being Unappreciated.* This category -- mentioned by seven of the informants -- emerged through descriptions of past gift choices that, in givers' opinions, had "flopped." Karen described her experience as follows;

K: One year my ex-husband and I, we made something for my Mom in the studio...between the two of us, we thought it was great. And as soon as we saw the look on my Mom's face, we knew that she didn't get it. It was a sculpture, she just didn't get it. We should have thought ahead of time, where is she going to put this, in terms of how she had decorated her environment.

Informants were also concerned with whether "difficult" recipients might appreciate gifts presented at the upcoming Christmas holiday. Patty commented on getting her husband a train set:

P: I want to get him something nice, and he doesn't want me to spend any money on him...Itold him it was a lot of money and he said,"Don't get me anything, don't get me anything." I said, "I'll go and get it and if you want to hurt my feelings and break my heart, and return it, then go ahead." He just laughed.

3. *Different Tastes/Interests.* Many recipients appeared problematic because their tastes and interests contradicted those of our informants. Hannah and Liz

¹All names have been changed to ensure anonymity.

both reported that their fathers' tastes were dissimilar enough to hamper their gift-buying efforts. Furthermore, the tastes of some "significant others" were cited as stumbling blocks to gift selection. Shopping with Kate, one of us observed:

[After looking at wrenches for her boyfriend, Kate] said she couldn't believe that her boyfriend wanted this, and what's more, that he would want her to buy it for him. She didn't know anything about them, couldn't he just buy them himself and let her get something else?

4. *Unfamiliarity with the Recipient.* Still other recipients were regarded as difficult because they were, for all practical purposes, strangers to informants. Many recipients described in this manner were affinal relatives, such as in-laws, cousins, uncles or stepparents. Karen described the dilemma of shopping for her stepfather as follows:

I don't know him very well. He married my Mom after I moved out. I like the guy, but he's my Mom's husband and I...after a certain amount of flannel shirts and tools, it's like...I just don't know what the man wants. So I find it very difficult to shop for him.

5. *Perceived Recipient Limitations.* We also observed that often, our informants regarded some aspect of a recipient's physical condition or personality to be a limiting factor in gift selection. For example, Anne described her boyfriend's mother in the following manner:

A: She's kind of an odd person...She doesn't do a lot...she can't drive, so she's at home all day. And what she does, she'll like sit on her bed and play cards...I, you know, have found so many things that could get her to do something and they don't work. It's like, I've just given up on that.

Other givers also discussed recipients' lack of hobbies as a stumbling block in the gift-buying process. Patty noted that her father "doesn't do *anything*...He's not into sports or anything, he really doesn't have a hobby -- except for sleeping. Get him a [sleeping] bag, I don't know."

Informants also mentioned that ill or elderly recipients were difficult to shop for. Furthermore, recipients who were passing from one stage of the life cycle to another were often categorized as "difficult." For instance, Rhonda noted that she "usually got her [mother] clothes for work but she was retiring soon, so that wouldn't be a good idea."

6. *Imposed Giver Limitations.* In contrast to the limitations described above were those imposed *a priori* on the gift-selection process by givers. Often, these took the form of pre-set spending limits. Lana, who had always spent just a few dollars on a gift for her niece, commented that "It was easy [staying in that price range] when she was little, now it's hard to find

[a] \$2-3 [gift] for a big girl." In addition, Hannah noted that she always had to choose "something small" for her father, because she mailed him his Christmas gift.

7. *Imbalance.* Desire for balanced gift exchange has been explored in the literature (c.f., Belk, 1976). For two of our informants, perceived imbalance appeared to explain why certain recipients were difficult. Betsy noted that because her in-laws always spent more on her and her husband for Christmas, she often found herself "going 'Oh God, what am I going to get them'?" Likewise, Patty described her husband's Christmas shopping as "very lavish, which is ironic...He just thinks it's OK to spend lots of money on you, but he doesn't want you to spend a lot of money on him."

8. *Personality Conflicts.* Many researchers (c.f., Barnett; 1954, Sherry and McGrath, 1989) have observed that the obligatory nature of much Christmas gift exchange may mean some gift-buyers find themselves buying gifts for people with whom they are experiencing conflict.

Our informants mentioned this situation five times. The most extreme example occurred with Anne. She had recently borrowed money from her grandmother. Unlike other relatives who had borrowed from her, Anne had to pay "dear old Grandma" back. Her bitterness over their arrangement could explain why Anne was so apathetic while shopping for her grandmother's gift:

After a few minutes of wandering [around the store] Anne said she needed to find domestics because that's where [a lap blanket] would be...She looked at all the various designs they had. They had some large ones which were more than she wanted to pay...Then she found one smaller lap blanket which was the price she wanted...She mentioned that would be "good enough."

9. *Thwarting of a Gift Selection.* While informants identified most "difficult" recipients early in the Christmas shopping season, some recipients appeared to "become" difficult when a gift idea that was either considered or actually purchased by an informant proved to be inappropriate. For example, Patty bought a stroller for her cousin, then learned that it was not the one on her cousin's list. Her frustration with this experience was revealed on the second shopping trip, when the researcher commented it appeared Patty was almost done shopping:

Patty agreed but said she was tired of the whole thing...She said she had just run out of steam and wasn't in the spirit of it at all. She mentioned that she was particularly frustrated about the stroller. She had even already thrown away [her cousin's] list and had to call her mother to find out what was on it.

What Strategies Are Used When Shopping for "Difficult" People?

Informants employed ten gift strategies when selecting gifts for difficult people.

Latching On. Of all the gift strategies used for difficult recipients, one we call "Latching On" occurred most often. With this strategy, the giver conducts fairly extensive external and/or internal search early in the Christmas shopping season, and then arrives at a gift idea for a recipient. Consumers mentioned using newspaper ads, catalogs, stores and the information they had in memory about the recipient as information sources. However, they rarely consulted interpersonal sources when employing "Latching On" for difficult people.

"Latching On" is so termed because once givers conceive of a gift idea, they focus their buying efforts upon finding an acceptable -- or even ideal -- representation of this idea. Furthermore, once an idea is generated by "Latching On," it is rarely discarded by the gift-buyer.

"Latching On" can take two main forms. "Same As Last Year" involves buying the recipient an item similar to something that the giver has purchased them previously. The rationale behind doing so stems from the fact that a previous gift has been well-received. For example, Liz describes how last Christmas, she gave an aunt who collected frogs a frog umbrella that had been her "favorite." This year, Liz looked at a stuffed frog, a frog perfume cachet, a frog whistle, a frog Christmas ornament, frog stickers and assorted frog jewelry before buying the stickers and a frog pin. Thus, "Same As Last Year" does not necessarily mean the giver *actually* duplicates a previous present, but rather that he or she offers the recipient a variation of it.

The second variation of "Latching On" was labelled "New This Year." Patty used this strategy when she saw a newspaper ad for a train set early in the Christmas season and thought it would be a "neat idea" for her husband. Over the next few weeks, Patty consulted numerous stores and ads, and compared prices for the set. In addition, because her husband did not want her to buy him an expensive gift, she actually negotiated with him so that she could spend more than usual. Thus, all of her activities for his gift centered around acquiring an item that she had seen in an ad early that Christmas season.

Impulse Purchasing We also observed that when some consumers shopped for difficult people, they appeared to almost grab items off of the shelves. These spontaneous urges to buy -- as well as recipients' excitement over what they had selected in this manner -- resembles what Rook (1987) calls "impulse buying." Yet informants also expressed some concern that an item they selected in this manner matched what they knew about the recipient.

We also observed that immediately before consumers employed "Impulse Buying," they experienced an instant recognition that a gift item in the store was appropriate for a difficult recipient. We called this phenomenon "sudden enlightenment." The following episode illustrates this occurrence:

[Karen] started talking about what she was going to get her brother and sister-in-law. She said that the only thing she knew [he] liked was boxing... I told her how we had just watched "Rocky" the night before. She kind of perked up and asked me how much movies cost. [We went into the movie store]...she was over in the music video section and she kneeled down. She picked up a video of the new "The Wall" concert...She stood up and said "That's it...Pink Floyd is one common interest that I know they have." [Total time: about 20 seconds.]

Making Gifts Many informants noted that making gifts was time-consuming, yet some stated they used this strategy for difficult recipients "out of desperation." This point is supported by the fact that often, informants did not begin making gifts for difficult people until close to Christmas. For example, Betsy could not decide what to give her son's teachers, and at the last minute made them food. Likewise, Rhonda decided two weeks before Christmas to make her father a lap blanket, but then did not have time to finish it. Thus, this strategy often seems to be a "last resort" for informants.

Pawning Off This strategy, used in four gift-buying instances, involved delegating the selection of gifts for a difficult person to someone else. For instance, Lana said that her husband "could figure out" what to get his brothers and uncles. Likewise, for the past few years, Jane let her children decide what to give their grandparents and teachers. And after two unsuccessful shopping trips, Andrew asked his girlfriend to pick out gifts for his female roommate because she "knew her tastes better."

Thus, "Pawning Off" can apparently take two forms. Namely, givers can either delegate the task of thinking of a gift idea, or they can delegate the entire search and purchase process as well.

Buy What I Like In using this strategy, informants simply bought recipients something they would like themselves. For instance, Hannah said she had no idea what to get her father for Christmas. During the shopping trips, she showed tremendous interest in tiny glass ornaments, often kneeling down at displays and telling the researcher exactly which ornaments she owned. On the last trip, Hannah told the researcher she was going to buy similar ornaments for her father.

Likewise, Kate said she had no interest in buying her boyfriend tools and other "practical things" he had requested. But she did buy him a magazine that she thought was cute and an ornament in a series that "they" were collecting (although she had purchased all of them).

Joint Recipients This strategy, in which one gift was selected that could be presented to more than one difficult recipient, was often used when the recipient was relatively unfamiliar to the giver. Karen used it when buying one gift for both her brother and sister-in-law. Likewise, Kate reported that she counted her boyfriend's parents as "one ...because I usually just try to get them one thing."

Recycling Two givers used the strategy of giving recipients items that they had bought for themselves, but for some reason had decided to discard. Apparently, this strategy was only used when the giver had little regard for the recipient. For example, Liz reported she did not get along well with her father. She later revealed that the shirt she had used for her Halloween costume was going to be her father's Christmas present. Likewise, Betsy was considering giving her husband's "old and mean" grandmother a scarf that she had bought for herself, but that her husband disliked.

Habitual Buying A few givers noted that they selected certain types of gifts for difficult people because they could not (or would not) think of anything else to get them. Rebecca stated that if she drew a man's name in the family gift exchange, she always bought him "a shirt...because there's nothing else to think of." Patty noted that she usually got her father tins of popcorn because it was one of the few things she knew he would like. This strategy differs from "Latching On," in that givers employ little or no new search when selecting these habitually purchased items.

Joint Giving One person used the strategy of actually "going in" with someone in her family to buy a gift for a difficult recipient. Specifically, because Rhonda's mother was retiring and no longer needed "clothes for work," Rhonda was at a loss as to what to buy her. During the second interview, Rhonda reported that her brother had "decided we should buy her a VCR for Christmas -- I was really relieved!"

Relationship-Affirming Gifts One giver chose gifts for difficult relatives that echoed or reaffirmed her relationship with them. For example, one shopping trip with Betsy revolved around trying to find a coffee mug that had the word "Grampa" on it. In addition, she gave her grandmother a suncatcher for her window. The poem on it began "Grandmothers are...."

INTERPRETATION

In examining the nature of the strategies we identified, it appears that they can be distinguished along two main dimensions. The first of these is whether a gift-selection strategy is more recipient- or giver-centered. Specifically, different strategies are apparently used, depending upon whether a gift idea is more influenced by the giver's or the recipient's desires. Thus, this is similar to Belk's (1979) distinction between self-directed and other-directed giving.

The second dimension that differentiates these strategies is whether the strategy helps the giver more to minimize social risk or psychological risk. Heeler, et al. (1978) note that the perceived social risk in a gift-buying relationship is in large part due to "the pressure to be perceived well in a close continuing relationship" (p.326). However, perceived psychological risk has yet to be defined for a gift-buying situation. Given the complexity of the Christmas shopping task for our informants, we define psychological risk as the perceived level of internal discomfort that a gift-giver experiences when he or she must grapple with an onerous buying task.

Figure 1 depicts how the gift selection strategies used for difficult people can be arranged with respect to these two dimensions. While it is likely that social and psychological risk are present in every gift exchange, it appears that consumers shopping for difficult people select a strategy that helps them minimize one type of risk over the other. For example, those strategies that help consumers select a gift acceptable to the recipient involve either extended search (e.g., Latching On), or some sort of personalization of a gift. Simply put, it would seem difficult to reject a gift such as a "grampa" mug, because to do so might be interpreted as rejecting the relationship as well.

Likewise, those giver-centered strategies that involve the lessening of the gift-buying task tend to result in either delegation of gift selection (Pawning Off or Joint Giving) or minimizing the effort of gift selection. Indeed, the most extreme form of minimizing, Recycling, involves skipping the purchase phase of gift selection entirely.

As would be expected, strategy use will vary greatly, depending upon the nature and salience of the giver/recipient relationship. It is therefore not surprising that the more demanding types of gift selection strategies -- in terms of search effort -- are usually used when the relationship with the recipient is more salient to the giver. Likewise, shoppers used those strategies that delegate or minimize gift selection for relatives who were less closely related or for people with whom they were experiencing conflict.

Several questions arise from our interpretation. First, it is unclear whether a recipient is categorized as difficult *before* a consumer attempts to use a gift-selection strategy, or after he or she attempts to use a strategy that then proves to be inappropriate. One clue stems from the fact that many of our informants appeared to have a favorite strategy for selecting Christmas gifts. Thus, a recipient might become "difficult" when a giver realizes that use of a preferred strategy would not result in an appropriate gift.

IMPLICATIONS

Many findings of this study should interest consumer behaviorists, marketers and consumers alike. Above all else, it appears that the Christmas buying task is a much more complex phenomenon than has been previously described. Furthermore, consumers may consciously or unconsciously weigh the social and psychological risk involved in buying a gift for each recipient on their list. They then employ a strategy that helps them to both select a gift and to alleviate what they perceive to be the most burdensome type of risk for that particular situation.

And it appears that there is a tendency for certain types of people -- e.g., in-laws, stepparents and other affinal relatives -- to be labelled as difficult. This categorization appears to stem from a lack of familiarity or communication with the recipients. As such, retailers and marketers might target their efforts toward helping customers buy gifts for these types of people. Indeed, one reason that consumers may curtail search when buying for "difficult" relatives is that

FIGURE 1
Gift Selection Strategies Used for Difficult People

	Alleviates Social Risk	Alleviates Psychological Risk
Source of Gift Idea	Latching On (New This Year)	Pawning Off
Giver's Taste	Relationship- Affirming Gifts Making Gifts	Buy What I Like Joint Recipients Recycling Joint Giving
Recipient's Taste	Latching On (Same as Last Year)	Impulse Purchasing Habitual Buying

advertising and marketing communications may not specifically help givers select gifts for them. Finally, it appears that consumers themselves might be able to ease the burden of Christmas shopping by taking matters into their own hands -- by actively seeking to enhance communication with those familiar with the needs and wants of gift recipients, or with the recipients themselves. Indeed, those gift-buyers who did so appeared to have fewer difficult people on their Christmas lists.

CONTRIBUTIONS AND LIMITATIONS

Our study: 1) explains the choice of gift selection strategy for difficult people both in terms of the origin of the gift idea and the type of risk the giver seeks to minimize; 2) reveals that Christmas gift selection strategies do not always involve the actual purchase of a gift; and 3) is the first examination of Christmas gift selection to enlist informants in a naturalistic setting, so that we can both observe gift selection processes and confirm our observations about such processes with informants. However, our study also had the following limitations: 1) we obviously could not observe every gift-selection incident that occurred; 2) our sample was comprised primarily of female middle-class shoppers; and 3) the informants that answered our ad obviously had an interest in our study, and in many cases appeared to resemble what Bellenger and Korgaonkar (1980) call "recreational shoppers." Thus, we may have examined gift selection behavior among people who invest more time and effort in Christmas shopping than is typical.

SUMMARY AND CONCLUSION

This study examines the gift-selection strategies used by Christmas shoppers for potential gift recipients who were labelled "difficult". The reasons why recipients were placed in this category were examined. We argue that the choice of gift

selection strategy depends upon the choice of the giver to minimize either perceived social or psychological risk and upon the nature of the giver/recipient relationship.

We believe that our examination of Christmas gift-selection strategies has provided new insight into the most complex gift-giving occasion in America today. Hopefully, other researchers will continue exploring the issues that arose from this study.

Thanks But No Thanks: Rejection, Possession and Disposition of the Failed Gift (Abstract)

Margaret Rucker, University of California, Davis
Tamara Balch, University of California, Davis
Fiona Higham, University of California, Davis
Kimberly Schenter, University of California, Davis

As illustrated in the model constructed by Sherry (1983), the gift giving process may be divided into three stages, namely, gestation, pre-station and reformulation. While a good deal of research has been directed at gaining an understanding of the first two stages, little attention has been paid to the third, including disposal of items. In fact, disposition of possessions from any source has been a generally overlooked area with a few notable exceptions (e.g., Belk, Sherry and Wallendorf 1988; Herrmann and Soiffer 1984; Jacoby, Berning and Dietvorst 1977; Soiffer and Herrmann 1987; Young and Wallendorf 1989).

The present study used interview data from 154 subjects to characterize the negative gift exchange experience and determine what actions are taken when the gift is not a wanted item. Gift disposition themes drawn from these interviews were then compared with general disposition themes reported in previous literature.

A classification of gift failures by product type indicated that clothing was mentioned most often as the worst gift received, followed by decorative household objects. The most frequent complaint was wrong style, followed by wrong color and fit. Although most of the complaints about gifts of clothing were directed toward specific attributes of the items, some respondents objected to the general concept of clothing as gift. Clothing was faulted as too utilitarian to be an appropriate gift.

Another classification was by relationship of the giver to the recipient. Three categories were formed, i.e., nuclear family, extended family and nonfamily. Overall, more failed gifts came from nonfamily than either nuclear or extended family members. However, most of this difference could be attributed to respondents in one ethnic category.

Ways in which respondents dealt with unwanted gifts included placing the item in storage, giving it to someone else, returning it to the retailer, and rejecting/returning it to the giver. At the time of the interviews, over 75 percent of the respondents still had the unwanted gifts in their possession. The data provided support for Young and Wallendorf's (1989) "Transition to Disposition" theme in that several respondents seemed to evaluate their connectedness to the giver and the gift before making a decision to transfer the items out of their inventory. There was also evidence for the "Disposition as Communication" theme. Some respondents noted that disposal could communicate disrespect for the giver whereas others worried about how passing along an undesirable gift would reflect on their own taste level.

Not being able to identify the store where the gift was purchased or not being located close to it were major impediments to exchanging an item for something else. In addition, respondents seemed to set a value below which going to a store was not worth the effort.

Respondents who did take their unwanted gifts back to the store mentioned several problems encountered in using this method of dealing with the items. As Corrigan (1989) found in his study of product distribution patterns, the site from which the gift was selected, as well as the gift itself, may be unacceptable to the recipient. Even if the store was considered to be an acceptable place to shop, inventories were generally low following a holiday, making it difficult to find a suitable replacement for the returned item. Several strategies are proposed to facilitate the gift return process for both the recipient and the retailer, including the establishment of some type of gift exchange clearing house.

SESSION OVERVIEW

On November 8, 1990, Congress updated the 1973 Food and Drug Administration nutritional labeling rule (Public Law 101-535). Previous to this law, the FDA only required a nutritional label on supermarket items when a company made a nutritional claim for a product. The label had to include information about the calories, sodium, fat, protein, and carbohydrates in a single serving. In addition it had to list the percentages of the USRDA for protein, five vitamins, iron and calcium. The new law requires label listing on more food items and more information about more ingredients.

This special session addressed two important and controversial questions about public nutrition programs. *First, what should be the consumer behavior objective of such programs?* This is an important but unresolved issue because the answer affects the criteria we use to evaluate such programs. One can ask whether these programs should simply attempt to increase the public's awareness about the value of nutritional information? Alternatively one can ask whether increasing consumer knowledge should be a goal? Finally, should we expect consumer eating behavior to change in a desirable way as a result of the public nutrition programs?

Second, what factors influence whether or not public nutrition programs work? The costs and benefits consumers perceive from using nutritional information are some important factors. Other influencing factors include individual difference variables (such as age, education, and social group). In addition, because food means more than just nutrition, these programs may not successfully change behavior even if they increase awareness and knowledge.

We brought together researchers who have attempted to answer these and related questions. The backgrounds of these researchers are rich and diverse, as are the methods which they have employed in the studies included in the session. These methods included literature reviews, surveys, experiments, econometric analysis, and household refuse analysis.

SESSION SUMMARY

The Russo and Leclerc research set a framework for the session by presenting results from a review of 28 field-tested product information programs. Their review revealed the characteristics that distinguish successful from unsuccessful programs. Programs which successfully change consumer purchase or consumption behavior are associated with increases in information benefits and decreases in processing efforts. They may also incorporate consumer input, especially through goal setting. In contrast, hortatory reminders to consumers that neither provide new benefits nor reduce costs are unsuccessful. Similarly a program's magnitude per se is unrelated to its success. The speakers concluded that a cost-benefit analysis of information use from the consumer's perspective should guide the design of product information programs.

Cole and Balasubramanian presented evidence from a preliminary field experiment. In this study, they observed shoppers who were selecting cereals in a supermarket. They told half the shoppers to select a cereal that met certain nutritional constraints; they gave no instructions to the other half. In the no instruction condition, most consumers were satisficers, selecting the first cereal that they inspected. These consumers virtually ignored the nutritional panel on the cereal. In a subsequent interview, most consumers could not recall much nutritional information about the cereals that they had just selected. When the researchers gave consumers the decision rule, they found that elderly consumers searched less extensively and made poorer choices than younger adults. However, accurate nutritional recall improved significantly for both age groups. Apparently to be successful, nutrition programs cannot simply make more nutritional information

available. Rather, in order to change buying behavior, programs need to instruct the consumer on how to use the information. In addition, these programs may need to provide additional instructions to groups such as elderly consumers. For example, dietitians might suggest that consumers write relevant information down.

Putler and Frazao noted that prior researchers have not assessed how public nutrition programs affect consumers' total diets. To remedy the deficiency, they studied changes in fat intake between 1977 and 1985, during public information campaigns on the fat/heart disease and cancer link. Consumers who are more aware of the relationship between fat intake and chronic disease have made relatively greater changes in their dietary sources of fat through time. However, the same consumers did not reduce their fat intake to a greater extent than consumers with lower awareness levels. This suggests that increases in diet/disease awareness have not translated into effective dietary changes. The authors speculated about reasons for this contradictory behavior. In addition, they made suggestions for improving the efficacy of public nutrition information programs.

The Levy and Stephenson study discussed findings from national telephone surveys conducted jointly by the Food and Drug Administration and the National Heart, Lung and Blood Institute in the 1980's. There has been a dramatic increase in consumer awareness of dietary fats and cholesterol as risk factors for chronic disease. However, there has not been a parallel increase in consumer knowledge levels about how to implement the dietary recommendation to eat less fat. For example, many people do not know what kinds of foods contain saturated and unsaturated fats, nor do consumers understand their co-occurrence in foods. In addition, consumers have substantial problems when they try to draw inferences from common label claims about dietary fats and cholesterol. The most knowledgeable consumers are more educated than less knowledgeable consumers. These results suggest that there is a gap between consumer awareness and effective dietary change. Consumer education initiatives that supply skills and knowledge could bridge the gap but these initiatives should also be easily accessible and understood. (Levy and Stephenson recommend broadcast media for the less-educated population groups.)

Wallendorf noted that a variety of research methods can be used to study food consumption including surveys, direct observation, participant observation and content analysis of household refuse. Each method contributes particular insights on consumers' beliefs about and practices regarding food and nutrition. Use of multiple methods can contribute to a deeper understanding of the confluence of consumer statements (e.g., "I am very concerned about nutrition") and seemingly contradictory consumer behaviors (e.g., observation of the person eating chocolate cake with a cup of coffee). This presentation relied on empirical reflections on these different methods to produce a set of guidelines regarding the contributions and problems of each research approach.

Future researchers should be especially careful to allow for differences across social groups (e.g., social classes, ethnic group).

CONCLUSION

This session has provided some answers to questions which arise now because of the 1990 update of the Food and Drug Administration nutritional labeling law. First, these programs should not simply try to increase the public's awareness of the value of nutritional information. Consumers need education regarding both nutritional facts and how to use that information when selecting foods, if buyer behavior is to be affected. Second, makers of public nutrition programs should be aware of factors which influence how these programs work. Specifically, target market characteristics such as age, education and social group should be considered. In addition attention needs to be paid to the market's perceptions of the costs and benefits of using nutritional information. Finally, programs are more likely to be successful if the programs explicitly recognize the expressive role that food plays in consumers lives. When future investigators assess program effectiveness, they should employ multiple research methods.

Influence of Problem Recognition on Search and Other Decision Process Variables: A Framework for Analysis

Girish Punj, University of Connecticut
Narasimhan Srinivasan, University of Connecticut

ABSTRACT

Though Problem Recognition (PR) is a critical phase of the consumer decision making process, it has been relatively under-researched. Since PR frames the problem-solving situation, the remaining stages in the purchase decision are dependent on it. An analytic framework of problem recognition, consisting of four segments -- "new need," "product depletion," "expected satisfaction" and "current dissatisfaction" -- is proposed. A sample of 1056 new car buyers is used for empirical validation. The "new need" and "product depletion" groups differ significantly from the others in terms of several pre-search, search, alternative evaluation and satisfaction variables.

INTRODUCTION

The problem recognition stage in the consumer decision making process has been generally regarded as the event or "trigger" that initiates a purchase decision. It is the precursor of all consumer-initiated activities, such as pre-purchase information search, evaluation and choice processes, preceding any transaction. The idea that initial consumer actions affect future ones is both simple and intuitively appealing. First, the problem recognition phase frames the problem-solving situation. Second, other stages of the decision making process sequentially linked to the problem recognition stage have a dependent relationship with it. Hence we can expect this stage to have a crucial influence on all subsequent decision process activities. Surprisingly, despite the potential significance of the problem recognition phase, it continues to be an area of limited research (Bruner 1985; Bruner and Pomazal 1988), though its importance is recognized in most models of consumer behavior (Howard 1989; Engel, Blackwell and Miniard 1986; Wilkie 1990).

Some of the difficulties associated with problem recognition (PR) research appear to be the consequence of an inadequate theory of problem recognition and hardly any empirical specification of the construct. In this paper, we present an exploratory study which attempts to address both these issues to some degree. Given the preliminary nature of this investigation, we propose and test a theoretical framework of PR. We validate the proposed framework rather than test specific hypotheses.

First, we specify a theoretical framework of the problem recognition process, drawing upon previous PR research (Dewey 1910; Bruner 1986, 1985; Bruner and Pomazal 1988; Sirgy 1983) and existing descriptive concepts in consumer decision making models (Howard 1989; Engel, Blackwell and Miniard 1986; Hawkins, Best and Coney 1989; Wilkie 1990). Second, we attempt to validate our framework of the PR process using data from a large sample of new automobile buyers. The results of the empirical test

are then used to modify our framework of problem recognition.

PREVIOUS RESEARCH

Previous research on PR tends to view the construct in a variety of ways. For instance, Engel, Kollat and Blackwell (1968) describe PR as being caused by a significant difference between a desired state and an actual state, with respect to a particular want or need. While such a conceptualization is useful in understanding PR as the event or "trigger" initiating the consumer decision process, the operational aspects of the precedents to problem recognition, such as the definitions of the 'actual' and 'desired' states and their relative strengths are left unspecified. Similar descriptions of the PR construct are offered by Wilkie (1990) and Hawkins, Best and Coney (1989).

An abstract conceptualization of PR is provided by Sirgy (1983) who regards the construct as representing a homeostatic process disrupted whenever there is a significant incongruity between a "perceptual stimulus" and an "evoked referent." Also, a distinction is offered between problem and opportunity recognition. Essentially, a consumer is perceived to be vigilant and aware of the 'actual,' 'desired' and 'available' states. Bruner (1985, 1986) makes a contribution to our understanding by regarding the fulfillment of the discrepancy between the "desired" and "actual" need states as a matter of consumer style, rather than the manifestation of particular situations i.e. problem recognition is a person-specific construct, rather than a situation-specific construct. Bruner and Pomazal (1988) attempt a comprehensive model offering a process view of the PR construct, using the earlier conceptualizations. However, in their attempt at providing a detailed cognitive understanding of the PR process, they offer a model that cannot be easily specified and tested.

TOWARD A FRAMEWORK OF PR

A primary consideration in developing a framework for the PR process is the recognition that the framework be empirically testable to encourage further theoretical developments. A starting point would be a parsimonious conceptualization that retains the essence of the elaborate cognitive descriptions of the construct.

A second criterion deals with the importance of incorporating both the internal states of the consumer and the overt actions in depicting the PR phenomenon. Taking both aspects assists in developing an actionable framework of PR useful in developing marketing strategy.

A final consideration relates to the importance of linking PR to other aspects of the decision process. Ideally we would expect our framework to be both descriptive and predictive of the subsequent constructs

FIGURE
A Framework of Problem Recognition

and processes. However, the degree to which this might occur could vary across different purchase contexts.

Based on these considerations, we assume that PR may be regarded as a cognitive event that is simultaneously manifest as an overt action representing the start of the consumer decision process. We acknowledge that several perceptual and motivational sub-processes are likely to lead up to the PR event but these are appropriately viewed separately as they are quite different in character. Such a conceptualization allows us to consider PR as a construct rather than a process, thus providing an useful anchor for formulating an analytic framework.

A FRAMEWORK OF PR

A framework of PR is shown in the Figure. The main theoretical proposition in our framework is that the nature of the occurrence of the PR event influences the cognitive and physical resources utilized for the subsequent stages of the consumer decision processes. The cognitive and physical resources are measurable in terms of typical decision process activities such as the nature of presearch decisions, the amount of information search, decision time, usage of a purchase pal, etc. Thus corresponding to "routine" PR events such as replenishment, we can expect "routine" decision activities with a low degree of search, and in new purchase contexts, the expenditure of cognitive/physical effort would be akin to "extended problem solving" i.e. a greater degree of effort and decision time.

The second theoretical proposition in our framework is that the perceptual and motivational sub-processes which precede the PR event are predictive of it, thus providing an understanding of how and why various PR events differ from one another.

A third proposition in our framework refers to the role of long term memory in determining the decision process activities triggered in response to various manifestations of the PR event. We suggest that the latter serve as important retrieval cues in

facilitating the remaining steps in the purchase decision.

Finally, we posit that the nature of the PR event influences the criteria consumers use in assessing satisfaction with the purchase decision. For some contexts these criteria are likely to be of a satisficing nature, but not so for others.

Consistent with the literature, the present framework of problem recognition proposed in this paper assumes that the PR event occurs in response to a discrepancy between a desired state and an actual state with respect to a consumer need (generic PR) or want (selective PR). We may not be able to empirically distinguish between needs and wants because this difference merely influences the scope of the decision, and not the nature of it. Further, we assume that the desired state is typically influenced by external factors (i.e. culture, social class, reference group, lifestyle, household and marketer influence) while the actual state is generally influenced by factors internal to the decision maker (i.e. motivation, learning, memory, personality, etc.) The above partitioning is obviously a simplification, but it is consistent with those frequently used in understanding the multitude of influences on consumer decision processes (e.g. Hawkins, Best and Coney 1989). Furthermore, it parallels the distinction often made between the controllable and uncontrollable determinants of PR, from the viewpoint of a marketer.

In understanding the influence of the actual state with respect to a need/want on the PR event, we can see that there are basically two sets of internal circumstances that are likely to trigger the decision process. The first has to do with the depletion of the current product corresponding to a existing need/want, whereas the second relates to dissatisfaction with the current state or product performance. Turning to the influence of the desired state corresponding to a need/want on the PR event, we similarly find two major external conditions initiating the consumer purchase decision. The first condition relates to acquisition of a product representing a completely new

need/want, while the second corresponds to the possession of products promising higher satisfaction than the current one.

It is important to recognize that the time element (Bloch, Sherrell and Ridgway 1986) corresponding to both the depletion of current product and the acquisition of a product corresponding to new need is not explicitly modeled in our framework. For instance, in the former case the depletion can be sudden (like in a product failure/ breakdown) or more routine (like in planned replacement). In the latter instance, the acquisition could also be sudden (like in an impulse purchase) or more contemplative in nature. The incorporation of this time effect in our framework awaits additional research (see Bayus 1991 for current work in this area). Additionally, it is possible that the time effect is also related to the magnitude of the discrepancy between the desired and actual states, thus leading to the classification of certain consumer purchase problems as "active" or "inactive" (Hawkins, Best and Coney 1989). However, this is again in the realm of future research.

Hence our framework of PR proposes that discrepancies between desired and actual states is driven by completely new or routine product purchases at the extremes and by existing dissatisfactions (with current products) or potential satisfactions (with new products) at intermediate levels. It is important to note that the above four part categorization of the PR event captures the essence of the broad range of causes of PR currently considered in the literature (Wilkie 1990; Hawkins, Best and Coney 1989; Bruner and Pomazal 1988). Yet, it provides a parsimonious and empirically verifiable formulation of the first stage of the consumer decision process, as shown in the Figure.

DATA

The data used in this research were collected as part of a study of new car buyers in three geographically separate metropolitan markets. The sample consisted of households that had recently purchased a new automobile for personal use. A stratified sample (by make of car) was drawn from all new car registrations in the markets during a particular time period, and was obtained through R.L.Polk & Co. Potential respondents were contacted by telephone to solicit their participation in the study --and also to ensure that they belonged in the sampling frame. Approximately 2400 questionnaires were mailed to households that could be contacted via phone and 1056 usable responses were received, representing a 44% cooperation rate.

Prior to their use in the analyses, the data were subjected to a series of extensive consistency tests to identify biases that would require correction during the analyses phase. In almost all instances the data held up well to the verification checks. (For more details of the data, please refer to Punj and Staelin 1983).

TESTING THE FRAMEWORK OF PR

The main variable in this study is PR. Four groups corresponding to the Figure were formed. Details of the formation of these groups and

operational specifications of the other variables used in this study are given below.

Problem Recognition (PR): We recoded nine specific categories (and the open ended responses) which best described the reason that led people to think about buying their new car, into the following four PR groups, corresponding to the framework of PR presented earlier. Presenting respondents with the major possible PR scenarios and asking them to identify with the most applicable in their case appears to be a reasonable method of assessment. The task is simple and recall did not appear to be a problem.

Group I: *HIGHER EXPECTED SATISFACTION*

- * Had a car but wanted one more.
- * Old car ran fairly well, but the *new models had better styling.*
- * Old car ran fairly well, but could get *better gas mileage* with a new car.

Group II: *CURRENT DISSATISFACTION*

- * *Old car needed repairs too often* and was not reliable.
- * Old car ran fairly well, but *if it broke down, it would not be worth fixing.*

Group III: *PRODUCT DEPLETION*

- * *Old car stopped running* and had to be replaced.
- * Old car ran fairly well, but *it is best to trade every two or three years.*

Group IV: *NEW NEED*

- * Old car ran fairly well, but *wanted a car for a different purpose* -- recreation, hauling things, carrying more people (or fewer people).
- * *Did not have a car* and wanted to get one.

The sizes of the segments were appreciable, as seen from the Table. The four PR groups (labeled as Expected Satisfaction, Current Dissatisfaction, Product Depletion and New Need groups hereafter) account for 24%, 43%, 19% and 14% respectively. A fifth of the market (PRODUCT DEPLETION segment) is seen to exhibit regularity in product purchase. Two out of three buyers (combining the EXPECTED SATISFACTION segment and the CURRENT DISSATISFACTION segment) are susceptible to product promotions/new product introductions at any time. Apparently, a lot more buyers express dissatisfaction with the state of the currently owned car, compared to the buyers who can be attracted into the market with promise of new potential benefits, such as improved styling, new product features, design, etc.

The remaining variables examined in our study were split into four categories corresponding to the well known stages in the consumer decision making process:

- (a) Presearch Stage: This included the number of makes which consumers were willing to

TABLE
Results of Oneway Analysis on PR Groups

Variables	Problem Recognition Groups				Findings
	Expected Satisfac I	Current Dissatis II	Product Depletion III	New Need IV	
Size of Segment	228	399	176	133	—
NMAKES	3.10 (2.1)	3.13 (2.1)	2.61 (1.8)	3.40 (2.0)	a
PREDEC	1.32 (1.0)	1.28 (1.0)	1.70 (1.1)	1.10 (1.0)	a
DEC.TIME	2.55 (1.1)	2.71 (1.2)	2.02 (1.0)	2.59 (1.1)	a
ACTVTS	6.62 (2.6)	6.45 (2.6)	5.22 (2.9)	6.92 (2.4)	a
NON.STOR	17.2 (18)	17.7 (19)	14.6 (19)	19.6 (27)	b
RTL.SEAR	8.60 (8.9)	8.61 (9.8)	6.66 (7.8)	11.7 (11.8)	a,c
PUPL.USG	1.35 (0.9)	1.44 (1.1)	1.39 (1.0)	1.52 (1.2)	d
NBRNDS	3.63 (2.5)	3.94 (3.1)	3.30 (2.4)	4.80 (4.0)	c,e
RTL.VSTS	4.54 (3.3)	4.64 (3.8)	3.90 (3.1)	6.02 (5.2)	c,e
FNL.CER	5.82 (0.9)	5.85 (0.9)	6.02 (0.8)	5.77 (1.1)	a
SATISFAC	5.52 (1.3)	5.47 (1.3)	5.68 (1.3)	5.41 (1.4)	d

Standard deviations are shown in parentheses below the means.

a: Group III is significantly different ($p < 0.05$) from the other three groups.

b: Group III is significantly different ($p < 0.05$) from Group IV.

c: Group IV is significantly different ($p < 0.05$) from the other three groups.

d: No two Groups are different ($p < 0.05$).

e: Group II is significantly different ($p < 0.05$) from Group III.

consider seriously and the degree of predecisions about manufacturer/dealer at the start of the information search process.
(b) Information Search Stage: This consisted of the length of time from serious consideration of purchase to the actual purchase; the count of several search activities; the pattern of search, such as dealer/non-dealer; and use of others to assist in the decision process.

(c) Alternatives Evaluation Stage: This dealt with the number of models examined and the number of retail visits made, and finally
(d) Postpurchase Stage: We examined the self rating of buying performance and the satisfaction with the new car purchased.

Details of the operational specifications of the above variables are described below:

Number of Makes willing to consider for purchase (NMAKES): Respondents were queried as to the makes they were willing to consider buying, before visiting any dealer. The multiple choice format considered divisional level makes, such as Buick, Cadillac, Chevrolet, Dodge, Ford, Lincoln, Mercury, Oldsmobile, Plymouth, Pontiac, Honda, Toyota, etc. It is assumed that the NEW NEED group would be willing to consider more makes compared to those who engage in replacement purchases. Also, the EXPECTED SATISFACTION group may be expected to have a smaller latitude of acceptance compared to the CURRENT DISSATISFACTION group, since the latter would probably eliminate only their current make and show greater acceptance of the other alternatives in the market.

Degree of Pre-Decisions made (PREDEC): Responses to queries about whether manufacturer/model/dealer were known at the beginning of the search process were categorized into the following four groups: (a) Nothing was predecided, (b) Manufacturer pre-decided (like GM, Ford, etc.), (c) Specific make or dealer pre-decided, and (d) both the specific make and dealer were predecided. It may be expected that the PRODUCT DEPLETION group would exhibit the highest degree of pre-decisions compared to the other groups, whereas the NEW NEED group would show the least amount of pre-decision making.

Purchase Decision Time (DEC.TIME): The elapsed time between first considering a car purchase seriously and the actual purchase was recoded into the following four categories: (a) Less than a month (b) Between 1 and 3 months (c) Between 3 and 6 months, and (d) More than 6 months. Once again, we expected that the NEW NEED group would take the longest time for the purchase decision since it is a new problem-solving situation. The PRODUCT DEPLETION group which may be expected to have engaged in a lot of prior planning would take the least time for making the purchase decision.

Search Activities (ACTVTS): Count of the participation in the following activities: (a) Talking to friends/relatives about new cars or dealers (b) Reading books and magazine articles (c) Reading advertisements in newspapers and magazines (d) Reading about car ratings in magazines (e) Reading automobile manufacturer brochures and pamphlets (f) Driving to and from dealerships (g) Looking around the showrooms (h) Talking to salespersons and (i) Test driving cars.

The NEW NEED group may be expected to engage in the greatest degree of search and the PRODUCT DEPLETION group the lowest, due to the greater degree of prior deliberation in the latter case. It is difficult to make a distinction between the EXPECTED SATISFACTION group and the CURRENT DISSATISFACTION group since the source and degree of the dissatisfaction is unknown.

Non-store search (NON.STOR) is the difference of the total hours spent in information search and the time spent at dealerships. For the major part, it may be taken to reflect the effort spent in gathering of general or preliminary information about models

considered suitable for purchase. Generally, the decision about the make/model has to be made by a consumer before entering a dealership. Of course, the gathering of non-store information does continue concurrently while going through the process of dealer visits. Non-store information sources includes all non-dealer sources, such as friends/relatives, advertisements, brochures and auto ratings in magazines. Time is assumed to be a common denominator for measuring the effort expended across a variety of sources which may require differential cognitive resources.

Once again, we expect the NEW NEED group to spend the greatest effort in non-store search, since past experience may not be available to play a compensatory role, while the PRODUCT DEPLETION group would spend the least time due to better preparedness. The EXPECTED SATISFACTION group may conduct less non-store search compared to the CURRENTLY DISSATISFIED group, but as explained earlier, this depends on the nature and scope of dissatisfaction.

Dealer Search (DLR.SEAR) is the aggregate time, in hours, spent in visiting dealers. This represents focused search since dealer visits occur during the later part of the car buying process, usually after one has narrowed down the choice to some specific model(s). While some dealer visits may be made for information gathering or assessing the suitability of any model considered, some other visits might be accounted for by price shopping behavior. Non-Store search and Dealer Search constitute the pattern of information search considered in this paper and represent a dimension different from the degree of information search.

The NEW NEED group is expected to have the highest number of dealer visits due to the extensiveness of the decision process necessary whereas the PRODUCT DEPLETION group would have the lowest. The EXPECTED SATISFACTION group may be expected to be lower than the CURRENT DISSATISFACTION group if particular and desired feature(s) are not readily available.

Use of a purchase pal in the decision process (PUPL.USG): This is a dimension not commonly studied due to the assumption that the decision making is done by individuals, for the most part. However, it may be a joint decision to some degree, involving significant others such as friends/relatives/mechanics outside the immediate family. Respondents were queried whether such a purchase pal helped in deciding the new car to buy. It is a binary measure and does not capture the degree to which there was reliance on the purchase pal. It is possible to conceive of the PRODUCT DEPLETION group to have the least necessity of depending on someone to assist in the purchase decision, whereas the NEW NEED group would probably seek outside assistance. As before, the other two groups may not be distinguishable.

The number of models shopped for (NBRNDS): The respondents were queried on the number of models seriously considered for purchase during each dealer visit. NBRNDS is the aggregate of all the models shopped for during all the dealer visits. The NEW

NEED group is expected to have the highest number of models shopped for, because of less prior knowledge. The PRODUCT DEPLETION group is expected to have the fewest NBRNDS since the search process was initiated much earlier, compared to the other groups.

Number of retail visits (RTL.VSTS): This captures the store dimension found in studies investigating search across stores and brands. Consumers might be shopping for the same model across dealers or shopping for different models at the same dealer. Since the former is more likely, this measure can be expected to reflect inter-store shopping. The PR groups are expected to show a similar pattern, as discussed for NBRNDS.

Certainty about the purchase (FNL.CER): Buyers were asked to assess how good a buy they thought they had gotten when they first rode in the new car after the purchase. The response was gathered on a 7 point scale (1 = Worst buy, 7 = Best buy). We did not have any expectations on how this variable would differ across the PR groups.

The overall satisfaction with the decision made (SATISFAC) was measured on a 7 point scale (1 = Totally dissatisfied, 7 = Totally satisfied). We expected the NEW NEED group to have the lowest satisfaction due to cognitive dissonance, while the PRODUCT DEPLETION is expected to show the highest satisfaction, given prior purchasing experience. Relative to the CURRENT DISSATISFACTION group, we expected the EXPECTED SATISFACTION to have a greater score since this is the motivation driving the purchase for this PR group.

ANALYSIS AND DISCUSSION

Essentially, we were interested in determining whether there were any differences among the four PR categories, in terms of the patterns of relationships identified in the previous section. Hence, several one way analysis of variance were conducted to identify significant differences across the PR groups. Also, the mean and standard deviation for each variable across groups are shown in the Table.

The empirical results provide encouraging support for the PR framework postulated in this paper. At the extremes, the NEW NEED group and the PRODUCT DEPLETION group stand out distinctively. However, the EXPECTED SATISFACTION and the CURRENT DISSATISFACTION groups do not show any statistical significance ($p < 0.05$) between them. The nature and scope of dissatisfaction could be a reason for this finding.

To illustrate the results, consider the pre-search stage variables (NMAKES and PREDEC). As expected, the PRODUCT DEPLETION group shows the smallest value for NMAKES ($m = 2.61$, $s.d. = 1.8$). The other three groups differ significantly ($p < 0.05$) from this group, but not among themselves. The degree of pre-search decision making (PREDEC) follows an identical pattern, demonstrating consistency.

In terms of the alternatives evaluation stage, the results are stronger. The PRODUCT DEPLETION group differs significantly from the other three groups (for NBRNDS, $m = 3.30$, $s.d. = 2.4$). So does the NEW

NEED group (for NBRNDS, $m = 4.8$, $s.d. = 4.0$). The directional expectation of the means is most evident in this stage.

The most surprising finding in our study is that all the four PR groups do not differ significantly in terms of the satisfaction (SATISFAC) with the new car they bought. All's well that ends well? As long as customers engaged in whatever they deemed necessary and sufficient under the circumstances, which they appear to be controlling for, then they are satisfied with the new purchase made.

The findings indicate that the EXPECTED SATISFACTION and the CURRENT DISSATISFACTION group do not differ on any of the variables examined in this study. Yet, it is useful to conceptually distinguish between the two groups, since availability of an improved product causing PR is different from the case when it is caused by dissatisfaction with the currently owned product. However, the availability of better products may increase dissatisfaction with the currently owned brand and this might be the reason for the lack of statistical difference between the two groups.

We repeated the one way analysis of variance after collapsing the EXPECTED SATISFACTION and CURRENT DISSATISFACTION groups. As could be expected, the results showed the three groups being statistically different from one other for the following variables: PREDEC, DLR.SEAR, NBRNDS and RTL.VSTS. The PRODUCT DEPLETION group had significantly lower NMAKES, DEC.TIME, ACTVTS and higher FNL.CER, compared to the remaining two groups. However, in terms of satisfaction with the new car purchased, the three groups remained indistinguishable.

SUMMARY AND CONCLUSIONS

Problem Recognition, though recognized as being a critical part of the consumer decision process, remains relatively under researched. In this paper, we present a conceptual framework of Problem Recognition. The framework is tested using a sample of 1056 new car buyers. Results indicate that two segments -- a new need segment and a product depletion segment -- are clearly distinguishable in terms of the subsequent decision process variables. Two other groups, though conceptually distinct, do not reveal any statistical uniqueness. Additional research is needed to gain a richer and more precise understanding of how this important construct might actually frame and guide consumer decision making.

Effect of Locus of Control on Information Search Behavior

Narasimhan Srinivasan, University of Connecticut

Surinder Tikoo, University of Connecticut

ABSTRACT

Locus of control (Rotter 1966) is a significant personality variable in psychology. Some people feel personally responsible for the things that happen to them -- the internals. Others feel that outcomes in life are determined by forces beyond their control (e.g. luck, fate, other people, etc.) -- the externals. In this study, we examine whether locus of control influences pre-purchase external search for information. A survey of 1401 new car buyers is used for empirical testing. Internals are found to engage in a greater degree of information search than externals. Process variables, such as perceived benefits and search effort, account for the difference. Controlling for decision importance, financial risk and product interest, locus of control is found to influence search behavior significantly.

INTRODUCTION

The influence of personality has been studied on a wide spectrum of consumer behavior: response to advertising and design features (Holbrook 1986, Wright 1975); interaction style (Richins 1983), perceived risk (Schaninger 1976), information acquisition (Schaninger and Sciglimpaglia 1981), and social consciousness (Brooker 1976, Webster 1975).

Since Rotter's (1966) influential work, locus of control has been an important area of study in personality research (Lefcourt 1982; Strickland 1989). In the consumer behavior literature, Howard and Sheth (1969) suggested that personality variables (including locus of control) influence the consumer decision making process, in which pre-purchase external search for information is an important component. Beside influencing many other behaviors, locus of control has been known to influence cognitive activity (Blass 1977; Lefcourt 1982). However, research investigating the relationship between locus of control and information search is presently non-existent in the marketing literature, as far as we are aware.

In this paper, locus of control as a determinant of consumer information search is proposed. Several process variables, such as beliefs about the marketplace, benefit expectations and search effort are examined to further understand the relationship.

BACKGROUND AND LITERATURE REVIEW

In most situations, individuals exert at least some potential control over the amount and nature of information they seek or receive about an object or event before a purchase. One factor that may influence information seeking is the internal vs. external control dimension. This variable was developed within the context of social learning theory (Rotter 1954; 1975) and denotes the degree to which

individuals believe that the occurrence of reinforcement is contingent upon their own behavior.

In general terms, locus of control refers to a person's beliefs about control over events. Some people feel personally responsible for the things that happen to them. These people may be labeled as internals. Others feel that outcomes in life are determined by forces beyond their control (e.g., fate, luck, and other people). These people may be labeled as externals (Blass 1977; Rotter 1966). Obviously, most people fall between the two extremes, forming a continuous distribution of locus of control beliefs.

In social learning theory, it has been hypothesized that when an organism perceives two situations as similar, then expectancies for a particular kind of reinforcement, or a class of reinforcements, will generalize from one situation to another. Expectancies in each situation are determined not only by specific experiences in that situation, but also to some varying extent, by experiences in other situations which the individual perceives as similar. Over a series of past behaviors in related situations (like information seeking before purchasing a durable), a person develops generalized expectancies (GE) about the occurrence of the reinforcement that will follow a particular kind of behavior.

Now, in the context of buying consumer durables, it is expected that information search precedes the purchase, since the amount of money expenditure is high and buyers would be rather involved in the purchase process (Srinivasan 1990). Also, search behaviors are known to be influenced by the consumer's learning experience of similar behaviors (Srinivasan and Ratchford 1991). Based on learning from past experience, consumers may develop GE of the reinforcement they would obtain by undertaking information search. In buying situations that are characterized by a certain degree of ambiguity, individuals will develop expectancies about the dependence of the outcome upon one's ability. Having a higher GE that reinforcements are contingent upon their own behavior, internals would make attempts to more effectively control their environment by seeking relevant information. On the other hand, externals would have less need to acquire information since outcomes tend to be perceived as less dependent on their own actions.

An individual's belief about locus of control has been studied as an antecedent to important social behaviors and psychological states, including information seeking in a variety of contexts. Trice and Price-Greathouse (1987) showed that locus of control predicted whether college women would seek information on AIDS. In an organizational setting which encouraged personal initiative in career development, internals were found to initiate more job moves and were more satisfied with career experiences than externals (Hammer and Vardi 1981).

Thorton (1978) also found more career planning activities and career information-seeking behavior by internals, compared to externals. Plumly and Oliver (1987) discuss the significant influence of locus of control on the job search process. Individuals with an internal locus of control are found to engage in more systematic exploration and have more information than externals (Noe and Steffy 1987). This suggests that an external orientation may reduce motivation to demonstrate certain types of exploratory behavior.

Davis and Phares (1967) observed that internals made more attempts than externals to actively seek information relevant to influencing the attitude of others. Internals were also more effective in using information in a delayed task (a week) than externals (Phares 1968). Seeman (1963) found that internals are superior in information recall only when the information is relevant to personal goals. Avner, Moore and Smith (1980) found that locus of control of information processing differentially affected performance in decision making, but not in routine tasks. It is also known that externals tend to exhibit less persistence at tasks (Ducette and Wolk 1972).

Based on the above literature, we propose the following hypotheses in a new car buying context:

- Hypothesis 1: Internals will engage in greater information search than externals.
- Hypothesis 2: Internals would perceive greater payoffs to search and less effort than externals (as a result of higher positive GE).
- Hypothesis 3: Internals will seek less social approval than externals.
- Hypothesis 4: Internals will rate themselves as more knowledgeable than externals.

DATA

A mail survey was conducted in a metropolitan area in the Northeast. Registration of new car owners with the Department of Motor Vehicles (as listed by R. L. Polk Company), formed the sampling frame. A sample of 3043 (every other name on the list compiled for the month of May 1986) was sent three mailings commencing in September 1986, at two-week intervals. A total of 1401 usable responses were received -- a response rate of 46%. The questionnaire was directed at the person mainly responsible for buying the new car.

While the study shares a common problem with other surveys of search behavior -- the need to rely on recall of past events, the average time interval between purchase and participation in the study, four and a half months, was shorter than in virtually all studies of search behavior known to the authors (a comparable time interval for Punj and Staelin (1983) was about 6 months). To test whether "forgetting" was significant, the responses were split into three

groups based on the return postmark. Since there were no significant differences (using t-tests and $p < 0.10$) between those who responded initially and those who responded later, we can discern no significant pattern of forgetting over the time span of data collection.

MEASURES

The primary measure used in this paper is locus of control (LOCUS). We used the short form of the James' Internal-External Locus of Control Scale (1957), consisting of eleven items (shown in the Appendix). The scale was borrowed from Robinson and Shaver's (1973) *Measures of Social Psychological Attitudes*. The James' scale was chosen for its simplicity and suitability for the study design employed. It has been reported to have split half-reliabilities ranging from 0.84 to 0.96, test-retest reliabilities of 0.71 to 0.86 and nonsignificant correlations with the Marlowe-Crowne Desirability Scale. The scale is unidimensional, i.e. all items were expected to load on a single factor and show no gender differences. A median split is taken: the bottom half is the INTERNALS and the top half belong to the EXTERNALS category. These categories should be understood to be relative to one another. We must keep in mind that the James' locus of control is a general personality measure and is not context-specific. Also, it is clearly seen that there is no obvious criterion contamination between locus of control and the various dependent measures used in this study.

We examined several other measures found in information search studies (particularly on automobiles) including time spent in search, number of search activities, number of dealers visited, number of models examined and number of cars test-driven (Brucks 1985; Olshavsky and Summers 1974; Punj and Staelin 1983). These are outlined next.

1. Time spent in information search (HOURS): Respondents were asked to estimate the approximate number of hours they spent in gathering information before buying their car.
2. Number of search activities (ACTS): A count is made of participation in the following activities: (a) talking to friends/ relatives about new cars or dealers, (b) reading books/magazines articles, (c) reading ads in mags/listening to ads on tv/radio, (d) reading about car ratings in magazines, (e) reading auto manufacturer brochures/pamphlets, (f) driving to and from dealerships, (g) looking around showrooms, (g) talking to sales people, and (h) test driving cars.
3. Number of models examined (NMODEL): The number of models considered during the purchase process was assessed as [1], [2], [3], [4], [5-7], [8-10] and [>10] cars.
4. Number of dealers visited (NDEAL): The number of dealers visited before buying their

TABLE 1
Locus of Control and Information Search

Measure	Internals Mean (SD)	Externals Mean (SD)	t-value (d.f)	p
HOURS	15.93 (20.7)	13.27 (19.7)	2.38 (1301)	0.018
ACTS	7.75 (1.5)	7.52 (1.7)	2.22 (970)	0.027
NMODEL	2.74 (1.4)	2.57 (1.3)	2.26 (1324)	0.024
NDEAL	3.35 (1.6)	3.17 (1.6)	2.10 (1347)	0.036
NTEST	2.59 (1.5)	2.31 (1.5)	3.28 (1332)	0.001

new car was determined using the same categories as for NMODEL.

5. Number of cars test-driven (NTEST): The number of cars test driven prior to buying their new car was obtained using the same categories as for NMODEL.

6. Importance of decision (IMPORT): The importance of choosing the car was assessed on a 7 point scale (1 = Very important decision, 7 = Very unimportant decision).

7. Interest in product category (INTRST): The new car buyers responded on a 7 point Likert scale (1=Strongly Agree, 7 = Strongly Disagree) to the statement: I have a great interest in cars.

8. Financial Risk in the purchase decision (FINRISK): The respondents were asked to estimate the probability (1 = Improbable, 7 = Probable) that the car purchase would lead to a financial loss due to poor warranty, high maintenance costs, and/or high monthly payments. They also reported the importance of the financial loss if it should occur (1 = Unimportant, 7 = Important). FINRISK is computed as the multiplicative function of the probability of the loss and it's importance (Peter and Ryan 1975).

The new car buyers also responded to several statements on a 7-point Likert scale (1= Strongly Agree, 7 = Strongly Disagree), including prior beliefs about the market, complexity of the informational environment, expectations from search, felt stress, social approval and subjective knowledge about cars. These statements are detailed in Table 2.

ANALYSIS AND DISCUSSION

The sum of the 11 items constituting the locus of control scale showed a mean value of 12.7 and a standard deviation of 5.1. There was no gender

difference, as expected. The eleven items loaded on a single factor (with 38% of the variance being extracted) demonstrating unidimensionality. The reliability of the scale (Cronbach's alpha) was found to be 0.83. A median split was done to obtain the INTERNAL group (LOCUS \leq 12) and the EXTERNAL group (LOCUS $>$ 12).

Table 1 shows the means and standard deviations of internals and externals across a variety of information search measures. Compared to externals, internals are found to spend more hours in information search, engage in more search activities, consider more models, visit a greater number of dealers and test drive more cars. Thus, across all the measures of search used in this study, internals are seen to exhibit a greater degree of information search than externals. Using t-tests, the differences are found to be statistically significant ($p < 0.05$) in all cases, thereby providing empirical support for Hypothesis 1.

Table 2 shows the analyses of the two groups across several statements, constituting a variety of process variables. Externals appear to believe in the stability of the marketplace more than internals. i.e. generalizability of information from the recent past. Externals also believe that sales are a signal of quality to a greater extent than internals. Not surprisingly, externals think that advertising is more credible than internals, though they are both skeptical. Externals also find the informational environment to be more complex. The implication of such beliefs about the marketplace is that externals need to search less than internals.

In a cost-benefit framework, it has been hypothesized that buyers would search for more information with increased benefits and that costs would act as constraints (Ratchford 1980). We find that expected benefits of search are, indeed, higher for internals.

Internals may be gathering more information to find out which cars are more suitable and get exactly what they want, thereby also convincing themselves that they are making the best buy. In addition, they appear to be gathering information so that they may advise family members and friends. Not only do

TABLE 2
Differences Between Internals and Externals

No.	ITEM	Internals	Externals	t (Sig)
<i>Prior Beliefs about the marketplace</i>				
1.	Before I shopped around for a new car, I believe the same models tend to be best year after year.	4.21 (1.7)	3.91 (1.7)	3.28 (0.001)
2.	The best models are usually the ones that sell the most.	4.71 (1.6)	4.29 (1.8)	4.55 (0.000)
3.	Heavily advertised models are almost always good products.	5.41 (1.3)	5.15 (1.5)	3.45 (0.001)
<i>Complexity of Information Environment</i>				
4.	Information sources about cars are so numerous that it is impossible to know everything at one time.	3.66 (1.8)	3.23 (1.6)	-4.66 (0.000)
<i>Expected Benefits of Search</i>				
5.	I learned which cars are suitable for me by shopping around.	3.14 (1.8)	3.43 (1.8)	2.84 (0.005)
6.	I got exactly what I wanted by searching enough before I bought my new car.	2.82 (1.8)	3.11 (1.9)	2.81 (0.005)
7.	By searching for more information, I am certain of making the best buy.	2.29 (1.3)	2.60 (1.4)	4.34 (0.000)
8.	Family members and friends seek my advice before buying a new car.	4.42 (1.9)	4.71 (1.9)	2.81 (0.005)
<i>Effortfulness</i>				
9.	Extensive shopping around makes it harder rather than easier for me to make a choice of what car I want to buy.	4.93 (1.8)	4.28 (1.9)	-6.27 (0.000)
10.	The process of purchasing a car is a stressful experience.	4.22 (2.0)	3.64 (2.0)	-5.38 (0.000)
11.	Searching for information before buying a new car takes too much time.	5.13 (1.6)	4.49 (1.8)	-6.74 (0.000)
12.	Searching for information before buying a new car takes too much effort	5.17 (1.6)	4.59 (1.7)	-6.21 (0.000)
<i>Social Approval</i>				
13.	Approval of my family and friends of my new car means a lot to me.	4.47 (2.0)	3.97 (2.1)	-4.53 (0.000)
<i>Subjective Knowledge</i>				
14.	Please rate <i>your</i> knowledge of cars compared to the average buyer (1= least knowledgeable, 7 = most knowledgeable)	4.61 (1.3)	4.26 (1.3)	4.85 (0.000)
15.	Describe <i>your</i> familiarity with cars (1 = not at all familiar, 7 = extremely familiar)	4.73 (1.3)	4.39 (1.4)	4.61 (0.000)

1 = Strongly Agree; 7 = Strongly Disagree. Standard deviations are shown in parentheses below the means in the first two columns. Differences of all means are statistically significant (p<0.05).

TABLE 3
Regression Results Using Search Measures

Search	LOCUS	IMPORT	INTRST	FINRISK	R ²
ACTS	- 0.10*	- 0.06	- 0.17*	0.01	.04
NMODEL	- 0.08*	- 0.03	- 0.02	0.13*	.02
NDEAL	- 0.05	- 0.13*	- 0.03	0.08*	.03
NTEST	- 0.09*	- 0.07*	- 0.08*	0.08*	.03

* indicates significant beta values (p<0.05).

externals have less of the above incentives, but they feel that information search takes too much time and takes too much effort. In fact, the car purchasing experience was felt to be stressful and extensive shopping was believed to make the purchase choice harder rather than easier. Overall, we find that the cost-benefit framework is substantiated, thereby providing support for Hypothesis 2.

Externals also seek approval of family and friends (item 13 in Table 2) to a greater degree than internals, supporting Hypothesis 3. If someone is less dependent on others' approval, it might be expected that they (i.e. internals) need to spend less time worrying about such things. They may also be more knowledgeable, or at least think that they are more knowledgeable.

Using Brucks' (1985) subjective knowledge scale (items 14 and 15 in Table 2), we found that internals do indeed rate themselves as being more knowledgeable and familiar with the product class than externals, thereby supporting Hypothesis 4.

Besides determining that internals search more than externals, we are able to find the underlying reasons: internals have restrictive beliefs about the marketplace, see greater benefits resulting from search, do not see it as requiring too much effort and consider themselves more knowledgeable.

In addition to distinguishing internals from externals and understanding some of the reasons possibly causing the difference, we were also interested in determining whether locus of control is a theoretically significant variable for explaining information search. In a study of consumer search, Potter and Coshall (1987) observed that perceived risk, interest in shopping, social status of the purchase, and the perceived time pressure influence the number of stores shopped at. Thus, if we controlled for interest in the product category, risk perception and importance of purchase, would locus of control have any influence on information search? We ran multiple regressions, using each count measure shown in Table 1 as the dependent variable. The independent variables were (1) locus of control, (2) importance of product choice, (3) interest in the product class, and (4) perceived financial risk. The beta values are shown in Table 3.

Overall, the four regressions were significant ($p < 0.05$). However, only for NTEST did each of the four independent variables reach statistical significance. For ACTS, NMODEL and NDEAL, only two independent variables were significant. LOCUS achieved statistical significance in three out of the four cases. Relative to the other independent variables, it can be seen that the influence of LOCUS is pretty stable and the beta values are comparable.

Though consumer researchers have frequently studied personality as a predictor of consumer brand and product choice, most studies that have used personality as a predictor of brand and product choice have failed to explain a meaningful degree of variance (Kassarjian 1971; Sheth, Newman and Gross 1991). This study is no exception. Locus of control is a general personality measure. By their very nature, general personality measures cannot be expected to have high predictive power in specific contexts. Such measures represent only one of many variables which enter the prediction of behavior. However it is worthwhile to first establish a relationship between a generalized construct and the behavior under study before attempting context specific modifications. By providing a theoretical grounding for our study and using a standardized personality test for an appropriate purpose, we seek to improve our understanding of search behavior.

The findings of this study may be generalized to hold for search behaviors for durables, where involvement is high, but may not hold for most nondurables. Whether involvement plays a moderating effect is left for future investigation. Besides, it would be useful to compare how the locus of control construct compares with involvement, product knowledge and other predictors of search behavior and the possible interactions. This is also left for future research. Another recommended area of investigation is the development of a specific personality measure -- locus of control for information seeking -- that would improve predictive power.

SUMMARY AND CONCLUSIONS

In this study, we investigated the influence of locus of control on external search for information. Internals are found to engage in a greater degree of

information search compared to externals, using a variety of measures -- hours spent, number of search activities, number of models considered, number of dealers visited and number of cars test driven. Internals perceive greater benefits to search and find the purchase process less stressful. Internals see the informational environment as less complex and their prior beliefs about the marketplace are also less constraining. Finally, locus of control is found to have a statistically significant influence on search. Further research for developing specific locus of control measures for information search would help to improve predictive power.

APPENDIX

11 ITEM JAMES' LOCUS OF CONTROL SCALE

A number of statements were collected from different groups of people representing a variety of opinions. For each statement, there are large numbers of people who agree and disagree. There are no right or wrong answers. Please indicate whether *you* agree or disagree with each statement. Indicate your response by circling the number which most closely corresponds to the way *you* personally feel.

Strongly Agree	Agree	Disagree	Strongly Disagree
4	3	2	1

1. Many times I feel that we might as well make our decisions by flipping a coin.
2. Getting a good job seems to be largely a matter of being lucky enough to be in the right place at the right time.
3. It is difficult for ordinary people to have much control over what politicians do in office.
4. It isn't wise to plan too far ahead because many things turn out to be a matter of good or bad fortune anyway
5. When things are going well for me I consider it due to a run of good luck.
6. I have usually found that what is going to happen will happen, regardless of my actions.
7. Success is mostly a matter of getting good breaks.
8. There's not much use in worrying about things; what will be, will be.
9. Success in dealing with people seems to be more a matter of the other person's moods and feelings at the time rather than one's own actions.
10. I think that life is mostly a gamble.
11. Many times I feel that I have little influence over the things that happen to me.

Mapping the Relationship Between Preattentive Processing and Attitudes

Stewart Shapiro, University of Arizona
Deborah J. MacInnis, University of Arizona¹

ABSTRACT

While prior research suggests that preattentively processed information can influence attitudes (Janiszewski 1988), it has not (1) provided independent evidence for the existence of preattentive processing or (2) demonstrated why preattentively processed material may influence attitudes. This study attempts to address both issues. First, implicit memory is used as a process measure to document the existence of preattentive processing and its relationship to ad affect. Second, three possible mechanisms underlying the effect of preattentive processing on affect (mere exposure, classical conditioning and mood) are investigated. The results suggest that mere exposure accounts for the preattentive processing effect. Further, results indicate that given equal levels of priming, affect change occurred only in the three exposure (not the one exposure) condition suggesting that the mere presence of an implicit memory trace is not sufficient to influence affective responses.

INTRODUCTION

Though it has been proposed that attitude formation is a cognitive process involving focused, conscious attention (Fishbein and Ajzen 1975; Hastak and Olson 1989, Lutz 1975; 1977, Olson et al 1982), recent literature in psychology and marketing proposes that attitudes can also be formed preattentively (Dixon 1981; Janiszewski 1988; Kihlstrom 1984; 1987; Moreland and Zajonc 1977; Wilson 1979). In an advertising context, for example, Janiszewski (1988) showed that ad attitudes can be influenced when information in the ad is processed at a preattentive level, and that some relationship exists between the nature of the material to be processed (visual vs. verbal) and the dominant hemisphere in which the information is processed (right vs. left).

While interesting, much needs to be learned about preattentive processing effects on attitudes. Specifically, greater effort is needed to clarify that preattentive (vs. conscious) processing has actually taken place. Furthermore, greater effort is needed to uncover the specific processes which may explain attitude formation under the preattentive processing route. The purpose of this paper is two-fold: (1) to explore a methodology for assessing the existence of preattentive processing, specifically through the use of implicit memory, and (2) to test three possible mechanisms-- mere exposure, classical conditioning, and mood-- as processes potentially underlying the preattentive processing effect.

The paper is divided into four sections. The first describes preattentive processing, defines key constructs, and identifies factors thought to affect preattentive processing. The second section identifies potential mechanisms underlying preattentive processing effects on ad attitudes, and their possible dependence on implicit memory. An experiment designed to test each mechanism and its link to implicit memory is described in the third section. The final section describes limitations and implications of the study, as well as directions for future research.

PREATTENTIVE PROCESSING

Discussion of preattentive processing first requires differentiating conscious from nonconscious experiences. Consciousness includes both monitoring and controlling ourselves and the environment so that memories and thoughts that influence behavior and cognition are both represented in phenomenal awareness and can be voluntarily initiated and terminated (Kihlstrom 1984). Nonconsciousness involves memories and thoughts which are not represented in phenomenal awareness and which cannot be voluntarily initiated or terminated (Kihlstrom 1984). Preattentive processing refers to information not in focal attention but which receives cognitive processing (Kihlstrom 1984), and hence can be analyzed for its emotional significance and semantic meaning (Dixon 1981).

Preattentive processing has been studied using a variety of methodologies (e.g., dichotic listening and masking paradigms). In consumer research the methodology used by Janiszewski (1988) involved two factors, hemispheric processing style and contralateral conduction.

The two hemispheres of the brain have been shown to use two different processing styles (Bouma 1978; Sergent 1983). The right hemisphere is said to have a holistic style, allowing the simultaneous integration of multiple pieces of information. This hemisphere uses a template matching process, invoking a template to give meaning to incoming information (Janiszewski 1988). Because of this holistic processing style, the right hemisphere is more compatible than the left with processing pictorial stimuli. The left hemisphere is described as unit-integrative, as it combines well-learned individual units into a meaningful whole (Janiszewski 1988). Because of this unit-integrative style, the left hemisphere is more compatible than the right with the processing of verbal stimuli.

Contralateral conduction refers to the fact that stimuli observed in the right visual field are processed in the left hemisphere of the brain, while stimuli observed in the left visual field are processed in the right hemisphere. Combined with the differences in hemispheric processing styles noted above, this phenomenon implies that visual stimuli presented in the left visual field should receive greater processing

¹The authors would like to thank Susan Heckler for her comments as well as Kent Nakamoto and Jonathan Frenzen for their help with an earlier draft of this paper. The helpful comments of two anonymous reviewers are also gratefully acknowledged.

than verbal stimuli presented in the left visual field. Conversely, verbal stimuli presented in the right visual field should receive greater processing than visual stimuli presented in the same field.

Janiszewski (1988) extends notions of preattentive processing, hemispheric processing style and contralateral conduction to make predictions about the effect of preattentively processed stimuli on affective responses. Subjects' attention was focused on a task (e.g., an article) with a critical visual ad placed in subjects' peripheral vision to the right or left of the attended task (right or left visual field). This peripherally placed ad was the stimulus assumed to be preattentively processed. Following exposure to the article, subjects' attitudes toward the preattentively processed stimulus were assessed. The results indicated when the attended task was verbal, the pictorial critical ad was most preferred when it was placed in the left vs. the right visual field, even when subjects were unaware of having seen the ad.

While interesting, additional research in this area is needed to clarify that (1) preattentive processing did indeed take place and (2) what processes account for the observed effects. We propose a methodology (implicit memory) for assessing the existence of preattentive processing, and propose three potential processes as underlying the existence of the preattentive processing-affect relationship.

THEORY AND HYPOTHESES

Implicit Memory - A Process Check for Preattentive Processing

One problem with past research on preattentive processing in an advertising context is that the existence of preattentive processing is determined by its effects. However, using affect change as both an indicator of preattentive processing and as an outcome of such processing is problematic. Hence independent evidence for the existence of such processing is necessary to demonstrate the preattentive processing-affect relationship. By decoupling the measure of preattentive processing from that of its effects, it becomes possible to directly demonstrate that preattentively processed stimuli do influence affect formation processes. One indicator of preattentive processing is assessing whether stimuli supposedly processed at a preattentive level leave an implicit memory trace. As the implicit memory literature is just now burgeoning in psychology, and is unlikely to be familiar to most readers, a brief overview is in order.

Implicit Memory

Implicit memory refers to the expression of previously encoded information without conscious or deliberate recollection of prior exposure to such information (Schacter 1987). If information has been processed preattentively (e.g., the word *Stripe*), for example, this information is likely to be primed in memory, and hence more accessible, even though the individual may not tie the primed information with the preattentive processing task. Often implicit memory

is measured through indirect memory tasks which, unlike direct memory tasks, do not ask subjects to refer back to recently presented information when completing the memory task. In a stem completion task, for example, the subject may be presented with the stem *STR___* and asked to complete the word. If the word *STRIPE* has been primed in memory (through preattentive or other processes), one would expect a greater number of primed subjects to complete the above stem with the word *STRIPE* than with some other word.

Placement Effects, Implicit Memory, and Affect

Because not all stimuli are preattentively processed, evidence for preattentive processing effects should be demonstrated only in the conditions that favor preattentive processing. It is thus proposed that subjects in exposure conditions thought to be conducive to preattentive processing will demonstrate significantly greater priming for the exposure content than subjects in exposure conditions less conducive to preattentive processing. As indicated earlier, contralateral organization effects propose that the nature of the stimulus (visual or verbal) and its placement (left or right visual field/right or left hemisphere) produce effects that are more or less compatible with preattentive processing. Thus, we would expect greater preattentive processing (and greater implicit memory) when pictorial information is placed in the left vs. right visual field, and when verbal information is placed in the right vs. left visual field. As this study uses only visual stimuli to scale down the study size, we expect that:

H1: Subjects exposed to pictorial information in the left visual field will demonstrate significantly greater implicit memory traces for the visual information than subjects exposed to visual information in the right visual field.

If preattentive processing does promote affect, one would expect to replicate Janiszewski's (1988) finding of the relationship between placement effects and ad affect. Hence:

H2: Subjects exposed to pictorial information in the left visual field will demonstrate significantly more positive affect for the visual information than subjects exposed to visual information in the right visual field.

While the above hypotheses are geared toward establishing a direct linkage between exposure conditions, preattentive processing and affect, they do not indicate the process by which preattentively processed material results in more positive affect. Three potential processes by which this effect may occur (mere exposure, classical conditioning, and mood) are explored below.

Mere Exposure

Mere exposure theory asserts that a positive relationship can be found between the level of stimulus exposure and preference for the stimulus (Moreland and Zajonc 1977; Wilson 1979). Formally, the theory states that the higher one's objective familiarity with a stimulus, the greater one's preference for it. Note that mere exposure theory is concerned with objective, not subjective familiarity.

Uncertainty reduction, a proposed explanation for the mere exposure effect, asserts that cognitive elaboration during encoding reduces uncertainty, resulting in greater familiarity with, and hence greater positive affect toward the stimulus (Obermiller 1985). Suggesting cognitive elaboration during encoding does not eliminate the possibility that this process is done preattentively, for higher levels of mental processes involved in judgment and problem solving can all occur outside of phenomenal awareness (Kihlstrom 1987). If ad attitudes of preattended stimuli are affected in a manner suggested by the mere exposure theory, research which systematically manipulates exposure levels should find increasingly positive ad attitudes for preattentively processed ads as exposure increases.

If mere exposure does operate as a theoretical explanation for attitude effects observed from preattentively processed stimuli, pictorial ads placed in the left visual field should be most affected by an increase in exposure levels relative to pictorial ads placed in the right visual field. Specifically, uncertainty reduction (and hence mere familiarity) should occur only for those ads that are preattentively processed. Hence mere exposure theory posits that:

H3: When the stimulus is pictorial, ad attitudes will increase with increasing exposure rates, but only when the ad is placed in the left (vs. the right) visual field.

Classical Conditioning

Classical conditioning involves exposing subjects to a positively or negatively valenced unconditioned stimulus such as music (Gorn 1982) or visual images (Stuart et al 1987) along with or just preceding a neutrally valenced stimulus such as the ad or brand. Classical conditioning asserts that the pairing of a positively (negatively) valenced unconditioned stimulus with a neutrally valenced target ad (conditioned stimulus) will lead to positive (negative) affective response toward the target ad.

If ad attitudes of preattended stimuli are affected in a manner suggested by classical conditioning, research which systematically manipulates the valence of the attended task should find an interaction between stimulus valence (positive vs. negative) and placement (left vs. right visual field). Specifically, if the relationship between preattentive processing and affect is driven by classical conditioning, one would expect that:

H4: When the stimulus is pictorial, ad attitudes are most favorable when the

attended task is positively valenced and the ad is placed in the left visual field, and least favorable when the attended task is negatively valenced and the ad is placed in the right visual field.

Though conditioning can occur with the first paired CS-US exposure (Stuart et al 1987), it is hypothesized that greater exposures should strengthen the link between the CS and US, resulting in more extreme affect with greater levels of exposure. Valence and exposure levels should also interact with hemispheric compatibility. Specifically:

H5: When the attended task is negatively (positively) valenced, ad attitudes will be more negative (positive) with increasing exposure rates, but only when the stimulus is processed in the compatible hemisphere.

The use of the negatively valenced attended task helps differentiate classical conditioning from mere exposure. While both classical conditioning and mere exposure predict increases in ad attitudes when positive stimuli are used for the attended task, classical conditioning posits negative attitudes with repeated exposures for the negatively valenced attended task, while mere exposure posits positive attitudes with repeated exposures for the negatively valenced attended task.

Distinguishing Classical Conditioning from Mood

It may be argued that the effects of classical conditioning could be attributed not to the involuntary response conditioned by the CS-US pairing, but rather to the mood created by the unconditioned stimulus. Mood effects literature suggests that a positively (negatively) valenced stimulus (e.g., a happy/sad article) may put the reader in a positive (negative) mood, which would in turn, increase the accessibility of related thoughts in memory (Goldberg and Gorn 1987). When asked to rate their preference for an otherwise neutral stimulus (ad), the activated mood would prime likened material in memory, and the person would likely rate the stimulus (ad) in a mood congruent direction.

Having subjects rate ads that were both present and not present in the experimental context should enable an assessment of which theory is at work. Mood effects theory would predict that all ads evaluated after a positive (negative) mood induction would be rated higher (lower) regardless of whether they had been previously seen. In contrast, classical conditioning would predict effects only for those ads previously paired with the positively (negatively) valenced stimulus. Thus classical conditioning theory also predicts that:

H6: Consumers exposed to the positively (negatively) valenced unconditioned stimulus will have more (less) favorable

FIGURE 1
The Critical Object

ad attitudes only for those ads previously present in the exposure set.

METHOD

Stimuli

Two types of stimuli were developed for use in the study: preattentively processed stimuli and attended stimuli. For use in this study, preattentively processed stimuli had to be pictorial in nature, adaptive to an indirect memory test, and neutral in valence. The attended stimuli needed to differ in valence (positive vs. negative). Pretests designed to develop these stimuli are described below.

Preattended stimuli. Six dot patterns were created and assigned to 40 subjects (N=40 per dot pattern), who were instructed to draw lines to connect the dots in each pattern in any way they desired. This pretest was required to obtain baseline figures for the indirect memory test. The baseline figure represents the percentage of subjects who connected the dots to form the critical object used as the preattended stimuli.

Twenty four objects were formed by connecting the dots in each of the 6 dot patterns in four different ways. Thirty subjects were randomly assigned eight of the 24 objects (N=10 per object) and asked to evaluate each on four, nine-point bipolar items: unattractive/attractive, unappealing/appealing, unlikable/likable, unpleasant/pleasant ($\alpha=.95$). T-test comparisons indicated that 8 of the 24 objects were rated as having affective responses no different from the neutral rating of 5 ($p>.05$). Of those 8, two had acceptable baseline levels of dot completions to form the object [18.42% (7/38) and 15.00% (6/40)].

The object with the higher baseline level was randomly chosen as the critical preattentive stimulus. This stimulus is shown in Figure 1.

Attended stimuli. Seven newspaper articles, each 330 words in length, were taken from the Sunday edition of the Chicago Tribune. Seventy undergraduate subjects participating in a study ostensibly on processing style, were randomly assigned to one of the seven articles (N=10 per article). Subjects were told to read the article as quickly as possible while at the same time reading for detail. Following completion of the article, each subject evaluated the article on a set of nine-point bipolar items: unpleasant/pleasant, unlikable/likable, unenjoyable/enjoyable ($\alpha=.94$). Based on these pretest results, several modifications in the articles, and further pretesting, articles evoking strong positive and strong negative affective responses were identified. Subjects also indicated on a ten point scale the extent to which the article was very difficult to understand/very easy to understand and very difficult to follow/very easy to follow ($\alpha=.94$). None of the articles differed in difficulty level, and each was found to be relatively easy to read ($X=8.71$).

Subjects

Subjects were sixty three undergraduate students who participated in the experiment for course credit (N=44) or as part of a chance to win a \$50.00 cash prize lottery (N=19). Two subjects were suspicious of the true purpose of the experiment and were discarded. Due to time constraints, the remaining subjects were randomly assigned to only the 6-cells critical to the predictions made in this study, allowing at least 10

Baseline = 18.42%

subjects per each of the 6 conditions. Subjects were run in groups ranging in size from 3 to 18. Experimental sessions lasted approximately 40 minutes. When possible, all 6 conditions were represented during each experimental session.

Design and Procedure

A 2 x 2 x 2 between subjects experimental design was used, with valence of the attended task (positive vs. negative), exposure level (1 vs 3), and placement of the critical object (right vs. left visual field) as the independent variables. Data for two of the experimental conditions (see Table 1) are still in the process of being collected.

Subjects were informed that the purpose of the study was to examine how individuals' processing style affected their memory for the details of previously read newspaper articles. Subjects were told they would be exposed to a total of four short newspaper articles. Subjects were informed that they would be given an unspecified time limit to read the four articles, and that undivided attention to the articles would allow them to finish all articles before the time limit expired. Subjects were instructed to start with the article on the first page of the newspaper, and proceed to the next article until all four articles marked with an orange dot were read. An ostensible time limit was imposed to focus attention on the article and away from the critical object. In reality, subjects were not under any time constraint, and all were allowed to finish reading all four articles.

The stimulus material subjects received contained four double-sided mock newspaper pages. The first page of the newspaper was a no-treatment page. The following three pages contained the

positively or negatively valenced articles. In the one exposure condition, the critical object was placed alongside (right or left) of only one of the articles. Assignment of the critical object to the specific article was random. In the three exposure condition, the critical object was placed alongside (right or left) of each of the three articles following the first no treatment page. For a more detailed description of the newspaper layout see Janiszewski (1988).

After reading the last article, subjects completed a questionnaire which ostensibly measured processing style. They then completed the implicit memory task. As with the pretest, subjects were given the 6 dot patterns-- one per page-- and were asked to connect the dots in any way they felt fit. One of the dot patterns represented the critical stimulus. The order of dot patterns was randomized across subjects. To ensure that performance on the dot completion task was attributable to implicit vs. explicit memory, subjects were asked several questions that assessed their hypotheses about the purpose of the dot completion task, and their awareness of the relationship between the newspaper and the dot completion task (Bowers and Schacter 1990). Subjects who made no mention of the newspaper or objects within the newspaper were classified as test unaware. Only their responses were retained to test the implicit memory hypotheses.

The third part of the questionnaire measured subjects' affect toward the critical object, two other objects present in the newspaper, and three objects not present in the newspaper but rated as neutral in the pretests. After rating all six objects, subjects were instructed to re-examine each object and indicate whether they recalled having seen it in the newspaper.

Order of objects was randomized across subjects. The final part of the questionnaire assessed affect toward and perceived difficulty of the three newspaper articles.

Dependent Measures

Implicit memory was assessed by comparing the percentage of subjects who were test unaware and who formed the critical object in the dot completion task with the baseline percentage who formed the critical object in the pretest. A similar dot completion measure was successfully used to show priming of novel nonverbal patterns in a study by Musen and Treisman (1990).

Evaluation of the critical object, the noncritical objects in the newspaper, and the noncritical objects not in the newspaper was assessed by an averaged composite measure ($\alpha=.95$) of subjects' ratings of the object as unappealing/appealing, unattractive/attractive, unlikable/likable, unpleasant/pleasant. Each item was assessed on a nine-point scale.

The valence of the attended task was assessed by three nine-point bipolar items: unpleasant/pleasant, unlikable/likable, unenjoyable/enjoyable. Items were averaged to form a composite index ($\alpha=.95$). Perceived difficulty of the articles was assessed by taking the average of two ten-point bipolar items: very difficult to understand/very easy to understand, and very difficult to follow/very easy to follow ($\alpha=.86$).

RESULTS

Manipulation Checks Results

To check on the success of the valence of the attended task manipulation, the average ratings for the positively valenced attended task ($X=7.98$) and the negatively valenced attended task ($X=2.82$) were compared to the neutral score of 5. One-tailed *t*-tests indicated the valence of each task was significantly different from the neutral score (both $p<.001$). These results confirm the success of the experimental manipulation. Additionally, perceived difficulty of the articles was not found to be any different between the positively and negatively valenced conditions ($p>.1$).

Data on handedness and gender were also collected and used as covariates for all ANOVA analyses reported in the results section. As neither variable was found to be significant in any of the results, only the simple ANOVAs are reported here.

Recognition Test Results

Differences in recognition of the critical object across the two placement or the two exposure conditions would be problematic as such differences might suggest that conscious processing had taken place in one condition but not the other. To examine whether such differences existed, two nonparametric tests for comparison of two proportions were conducted using the recognition measure as the dependent variable. The recognition levels were not different when the stimulus was placed in the left

(20%) vs. the right (19.35%) visual field. Nor were recognition levels different in the one (15%) vs. three exposure (28.6%) conditions (both $p's >.10$). Thus any observed differences in the results should not be attributable to differences in recognition levels (conscious processing) across the various treatments. Additionally, a test for a positive influence of recognition on attitude toward the object was not significant ($p >.1$).

Test of the Hypotheses

H1 predicted that subjects exposed to the critical object in the left visual field would demonstrate significantly greater implicit memory for the critical object than subjects exposed to the same object in the right visual field. To test this hypothesis, a nonparametric test for comparison of two proportions was conducted for each of the six experimental cells. The results showed greater implicit memory for the positive/one exposure/right visual field and negative/three exposure/right visual field conditions (see Table 1). These two conditions did not differ from one another in their level of implicit memory. The results indicate that contrary to H1, implicit memory for visual stimuli is greater when they are placed in the right, not the left visual field. These results do not support H1.

H2 predicted more positive affect for the critical object when it was placed in the left vs. the right visual field. Mean affect ratings for the critical object are shown in Table 2. An ANOVA on affect toward the critical object revealed neither a main effect for placement ($F=1.53, p>.10$), nor a main effect for valence ($F<1, p>.10$). However, a placement by exposure interaction was observed ($F=4.06, p<.05$) with highest preferences in the negative/three exposure/right visual field condition. The observed interaction runs counter to H2 which predicted the object would be most preferred when placed in the left visual field. Thus, though a placement effect did exist it (1) was opposite the placement condition predicted and (2) was contingent on numbers of exposures.

H3 predicted that if the observed results are attributable to mere exposure, attitude toward the critical object should increase with increasing exposure, but only when the critical stimulus is placed in the left visual field. While the placement effect is reversed, as noted above, the proposed interaction did emerge. Preferences did increase with exposure, and the impact of exposure on preferences seemed to depend on where the object was placed. To gain greater evidence for the existence of the mere exposure mechanism, further analysis was conducted by cell. Specifically, a one-tailed test indicated that the evaluation of the critical object in the negative/three exposure/right visual field condition was significantly greater than the neutral rating of 5. Thus, under certain conditions, preattentive processing of pictorial stimuli can lead to increased affective responses in a way generally consistent with mere exposure theory.

H4 and H5 predicted that if the observed results are attributable to classical conditioning, evaluations of the critical object should be most positive (negative) when the attended task is positively

Attitude Toward the Object

Main Effects	ms	df	F	p
Visual Field (placement)	2.607	1	1.525	.22
Exposure	2.728	1	1.596	.21
Valence of the attended task	.291	1	.170	.68
Interactions				
Placement X Exposure	6.488	1	4.062	.05
Placement X Valance	2.832	1	1.658	.20

Due to the incomplete design, main effects were calculated with a 3 way ANOVA and interactions with two 2 way ANOVAs on attitude toward the critical object.

(negatively) valenced, particularly when the critical stimulus was processed in the appropriate visual field, and presented multiple times. However, the results revealed no main effects for valence of the attended task, nor interactions of attended task valence with either placement, exposure, or both. In fact, the critical object showed highest affect ratings in the three exposure/negatively valenced attended task condition. These findings cast doubt on classical conditioning as the mechanism responsible for preattentive processing effects.

The results also cast doubt on mood as an explanation for preattentive processing effects on affect. As noted earlier, if the valence of the attended task influenced subjects' moods, mood should transfer to evaluations of both seen and previously unseen objects. However, no effects involving valence of the attended task emerged. Furthermore, the mean score affect ratings of the three unseen objects (5.46) was not found to differ significantly from the neutral rating of 5 (p >.10). Additionally, the affect rating of the

critical object in the positively valenced conditions (X=5.19) was not found to be significantly different from the affect ratings of the unseen objects in these same conditions (X=5.35,p>.10). However, the affect ratings of the critical object in the negatively valenced conditions (X=5.67) was found to be significantly different from the ratings of the unseen objects in these same conditions (X=5.06,p<.05).

To ascertain whether an implicit memory trace represents a sufficient condition for a change in affective response, we examined the impact of priming (e.g., implicit memory vs. no implicit memory) on evaluations of the critical object across the two exposure conditions. This interaction (see Figure 2) was significant, and indicates that an implicit memory trace for a stimulus is not sufficient to influence affective response. Specifically, the implicit memory trace translates into more positive affective responses only after several exposures.

FIGURE 2
Attitude Toward the Object
Priming vs No Priming

DISCUSSION

This study observed several interesting effects regarding preattentive processing and affect. First, using implicit memory measures, the results indicated that some sort of preattentive processing did occur, and that those stimuli processed preattentively did influence affective responses in a manner predicted by mere exposure theory, but not classical conditioning or mood. However, the study did not find evidence for the hemispheric processing placement effects found in past literature. In fact, the placement effect was opposite that hypothesized. Two possible explanations could account for this reversed placement effect.

The first explanation is measurement based. Blaxton (1989) suggests that performance on an implicit memory test is facilitated by the degree to which the processing style used during study matches that used during test. The implicit memory test used in this study (dot completion) is very similar to a fragment completion task which is thought to utilize more of a data driven processing style than a conceptually driven processing style (Blaxton 1989). Therefore, performance on the dot completion task would be greater under those conditions favoring data driven versus conceptually driven processing during encoding. Because the left hemisphere is associated with a more analytic (data driven) processing mode and the right hemisphere is associated with a more holistic (conceptually driven) processing mode, the dot completion task was partial to the condition in which the stimulus was processed in the left hemisphere (i.e., when placed in the right visual field).

This explanation is weakened, however, when one considers the fact that there was an increase in evaluation of the stimulus only when it was placed in the right visual field and therefore processed in the left hemisphere. Unlike the dot completion task, an

evaluation task is conceptually based and therefore one's performance on it would be facilitated if encoding utilized a more conceptually based processing style as well. Using the same logic as before, performance on the evaluation task should have been facilitated if the stimulus was placed in the left visual field and therefore processed in the right hemisphere. As noted above, however, just the opposite was found.

The second explanation for the reversed placement effect is stimulus based. It is very common to divide stimuli into verbal and nonverbal categories when studying hemispheric asymmetries (Sergent 1983). Unfortunately, this categorization may be too simplistic, as there are many other stimulus based characteristics that could lead to a left or right hemispheric advantage. For example Pitblado (1979) examined hemispheric asymmetries, studying object identification using random dot stereograms. Under certain conditions he was able to show that the left hemisphere was more efficient when large dots were used whereas the right hemisphere was more efficient when small dots were used. Similarly, Sergent (1982e) found a left hemisphere advantage in visual search for large letters and a right hemisphere advantage for visual search for small letters. Other hemispheric reversals from the typical verbal/visual paradigm have been found under conditions of differing exposure durations, luminance, eccentricity and degradation (Sergent 1983). In the same vein, it is quite possible that while the stimulus used in this study appeared to be visual in nature, due to other characteristics it was in fact partial to the left versus right hemisphere.

The study also indicated that the mere presence of an implicit memory trace is not sufficient for a change in affective response. Specifically, even though priming was no different between the positive/one exposure/right visual field condition and

the negative/three exposure/right visual field condition, affect change occurred only for the latter condition. It may be that the strength, rather than the mere presence of the implicit memory trace determines whether there is a change in affective response. Repeated exposures (and perhaps other stimulus factors) may enrich or strengthen the implicit memory trace. Assessing the veridicality of this hypothesis, and identifying factors which may foster stronger implicit memory traces thus constitutes an important direction for future research.

The above findings and interpretations must, however, be considered in light of the study's limitations. A major limitation of the present study is the use of a simple geometric shape for use as the preattended stimulus. It is quite possible that a "real" pictorial ad (or a verbal ad) would lead to different results. It should be recalled, however, that the geometric figure was used in this study so that the implicit memory-affect relationship could be assessed. Additional study using stimuli more representative of those used in advertising should follow the present research. Furthermore, the study's conclusions should be held as tentative, pending further data collection to complete the experimental design.

Till Death Do We Part: Family Dissolution, Transition, and Consumer Behavior

Ritha Fellerman, University of Massachusetts
Kathleen Debevec, University of Massachusetts

ABSTRACT

The effect of marital dissolution on family consumption behavior is examined through a consideration of the Andreasen model, which links life status changes to changes in consumer behavior. A series of propositions are offered which enhance the Andreasen model by exploring the dimensions along which individuals evaluate life status changes, their effects upon stress, and the relationship between stress and consumption. Modifications of the Andreasen model are suggested which more fully integrate stress with life status changes and consumption behavior.

INTRODUCTION

Divorce is a fact of life. Few current trends affect our culture as profoundly or as pervasively as family dissolution. With approximately 49 percent of marriages ending in divorce (Glick 1984), the growing awareness that permanence is not an intrinsic part of the family relationship can be expected to have significant and long-term effects upon personal and family decision-making behavior. Researchers in a variety of fields have been studying the effects of divorce for decades; however, the impact of family dissolution upon consumer behavior has been virtually ignored in consumer research.

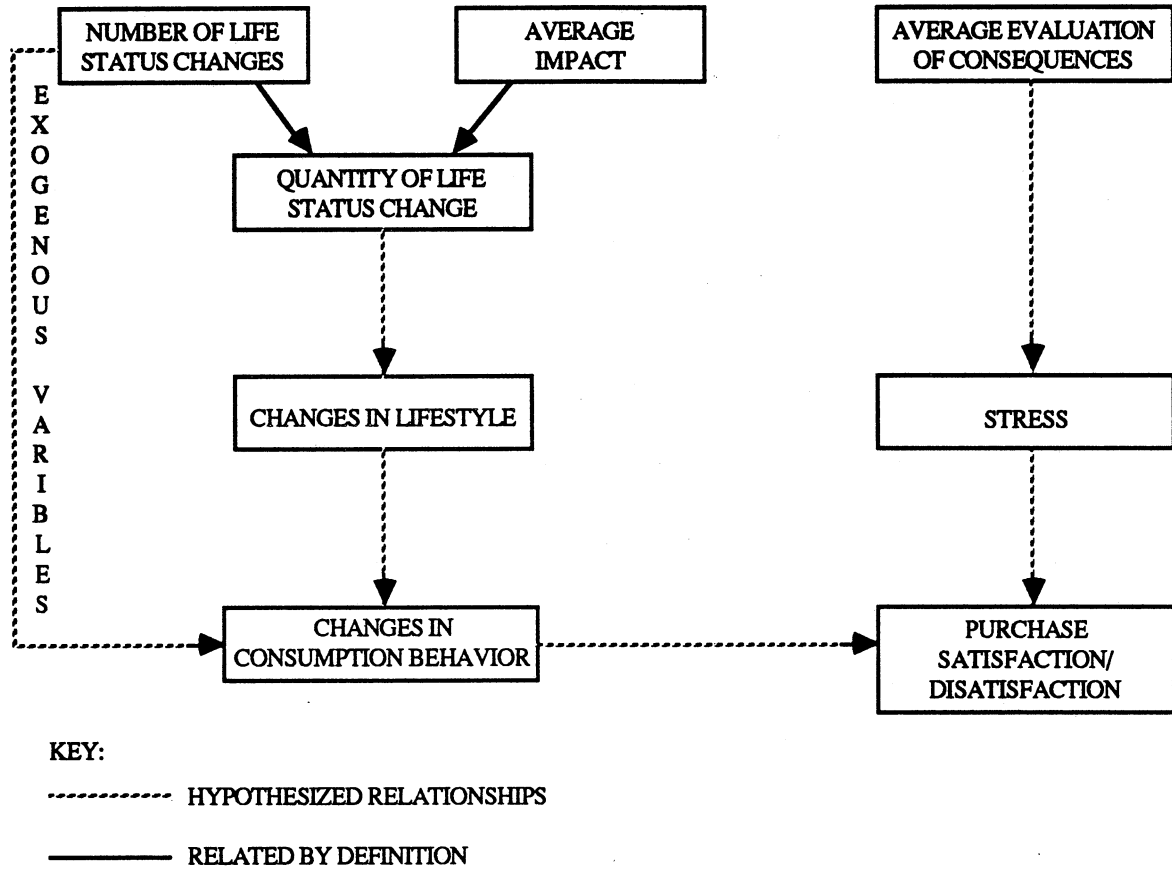

The ultimate result of divorce is family dissolution and the evolution of a new family structure. The increasing rate of family restructuring has led many consumer researchers to turn their attention away from the traditional family life cycle model to more transition-based models of family consumption (Bristor and Qualls 1982). In an attempt to conceptualize the effects of life transitions upon consumption behavior, Andreasen (1984) has proposed a model in which life status changes function as antecedents of stress and shifts in consumption. Andreasen's recognition and incorporation of stress in a transition-based consumption model provides a particularly useful tool for examining the effects of divorce on family consumption behavior. Focusing in greater depth on a specific type of status change such as divorce, which affects a significant portion of the population, allows the robustness of the Andreasen model to be tested and conceptually enhanced.

After careful consideration, our paper has been limited to the examination of the effect of divorce upon consumption behavior in families with children. There are two reasons for limiting the scope of this paper. First, approximately two-thirds of divorces involve children (McLanahan and Garfinkle 1989). Second, in the case of the childless couple, the effect of divorce is to dissolve the family unit and to create two new households; the original family as a social unit no longer exists. In this case, the consumption behavior of each individual is likely to resemble that of other single adults.

However, when children are involved, the bonds between parents and their children significantly affect the consumption behavior of both new households. At one extreme, which occurs when a spouse abandons the children, family dissolution results in that spouse experiencing consumption behavior resembling that of other single adults, and a family unit whose consumption behavior reflects the chronic stress caused by the greatly reduced financial resources and role overload experienced by the remaining parent. At the other extreme, which occurs when children split their time living with each parent under joint custody agreements, the family unit may not dissolve as much as it evolves into two separate family units sharing the same children. In this situation, the consumption behavior of each household may share characteristics of both married and single population segments. Family dissolution is not just complex, it is also multidimensional. Obligations resulting from kinship ties to children from former relationships can carry over and affect the consumption behavior of subsequent family units formed by the original partners.

In consumer research, the traditional tool for examining the consumption behavior of the family has been the family life cycle model. The model purports that the family unit passes through a series of stages, each of which has its own set of purchasing patterns. However, the model is only effective when the rate of change in the family structure is relatively low, resulting in the same family existing over a significant period of time. In spite of attempts to modernize the family life cycle model by expanding the number of family type categories, studies using family life cycle categories may fail to capture as much as 34 percent of subjects interviewed (Bristor and Qualls 1982). Many of these non-traditional family units exhibit marked differences in consumption behavior from traditional family units (Derrick and Lehfeld 1980). The family life cycle model has become a casualty of increasing divorce rates and other social and demographic trends. Any model which hopes to be relevant to the study of the contemporary family must be transition-based, such as the model proposed by Andreasen (1984). The purpose of this paper is to examine the literature on family dissolution and transition from the perspective of the Andreasen model, discuss limitations of the model, and propose several refinements which are suggested by research in family dissolution. For a graphic representation of our suggested enhancements to the Andreasen model, see Figures 1 and 2.

FIGURE 1
Andreasen Life Status Change Model

AN OVERVIEW OF THE ANDREASEN MODEL: THE LINKS BETWEEN CHANGES IN LIFE STATUS, LIFESTYLE, STRESS, AND CONSUMPTION BEHAVIOR

Referring to the "teachable moment", Andreasen (1984) has suggested that the probability that a consumer will change their perceptions, attitudes, and behaviors is directly proportional to the amount and type of life status change the consumer has recently undergone or is currently undergoing. Furthermore, each type of status change leads to specific consequences which are: 1) unique to the type of change, 2) occur in virtually all households experiencing the change, and 3) are relatively predictable.

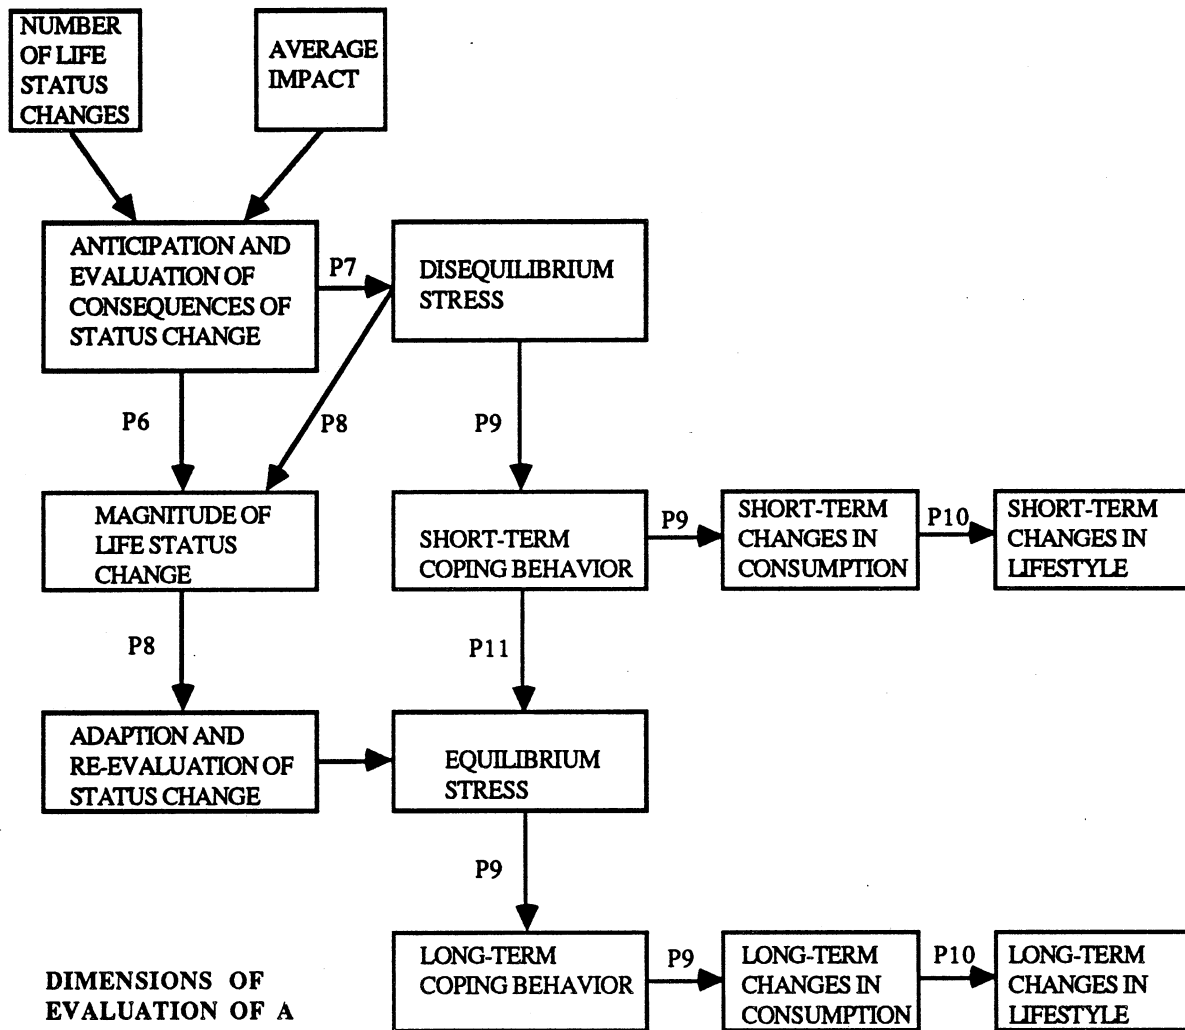

Andreasen proposes that the number of status changes and the impact of each change are positively related to the total magnitude of change experienced by the household. The magnitude of the change is positively related to shifts in lifestyle which in turn leads to shifts in consumption behavior. Andreasen also states that measures of status change should be seriously considered as predictor variables in

marketing, particularly when developing market segments.

Andreasen should be credited for introducing stress as a factor to be considered in consumer behavior. He asserts that the perception of stress occurs when an individual evaluates a status change and concludes that its consequences are negative. Stress leads to lower levels of satisfaction with life in general, and products, in particular. Andreasen hypothesizes that there is no direct relationship between stress and changes in consumption behavior, since some consumers may resist changing consumption as a means of coping with chaos elsewhere in their lives. Those who do elect to change consumption behavior, however, will experience more satisfaction with their product and service purchases.

One of the limitations of the Andreasen model is that it does not take into account the dimensions upon which individuals evaluate life status changes, which may result in positive or negative evaluations, and thus varying consumption behavior. Understanding these dimensions may enhance the explanatory power of the model and our understanding of the consumption outcomes. Nor does the model account for the temporal nature of the life status

FIGURE 2
Enhanced Life Status Change Model

DIMENSIONS OF EVALUATION OF A STATUS CHANGE (P1-P5):

1. Impact upon economic resources
2. Impact upon personal responsibilities
3. Impact upon social support structure

change, or the type of stress experienced by the individual or household over time. An individual or household may experience quite traumatic levels of stress in anticipation of and during the transition process. However, changes in life status can also lead to lifestyles which are simply more stressful. After the period of transition, the adaption to a new lifestyle means an adaption to the stressors which make up that lifestyle, and implies a shift in consumption as a means of coping with those stressors. Another limitation of the Andreasen model is that it underspecifies the relationship between stress and consumption; research on family dissolution and transition indicates that there are direct relationships

between stress and a much wider range of consumer constructs than outlined by the model.

Since each type of status change should lead to specific consequences which are unique to that change, the consequences of divorce should be specific to the divorce outcome (i.e., the division of property, custody agreements, and child support awards). Family dissolution can lead to significant changes along multiple psychological, social, and economic dimensions, and thus it is likely to have a profound impact upon the consumption of new family units. The pervasiveness of divorce throughout our culture, the size of the population which is affected, and the possibility that the consumption behavior and needs

of this segment are poorly understood make divorce and family dissolution a fertile area in consumer research for academics and researchers alike.

FAMILY DISSOLUTION AND THE EVALUATION OF A LIFE STATUS CHANGE

Research on family dissolution suggests possible refinements to the Andreasen model by providing insight into the way individuals evaluate the consequences of a status change. The research indicates that the primary dimensions along which individuals evaluate the consequences of a life status change are: 1) the impact on their economic well-being, 2) the impact upon personal responsibilities, and 3) the impact on social support structures, such as kinship ties.

It is suggested that the most negatively evaluated status changes may be those in which the individual or household is faced with increased responsibilities and decreased resources, such as in the case of families which are headed by divorced parents. Census data indicates that 36 percent of households headed by a single divorced parent live at or beneath the poverty level (U.S. Bureau of the Census 1991). The majority of mothers retain sole custody of their children. The survival of many divorced mothers depends upon child support; however, only 60 percent of divorced mothers heading a single-parent household receive a child support award (Teachman 1990). Of those who are awarded child support, only about 44 percent receive payment (U.S. Bureau of the Census 1991). The reduction in economic resources means that these households do not have the option of purchasing many of the goods and services that other households routinely use to deal with multiple responsibilities, such as hiring household help or dining out. The result is role overload, an increased perception of time urgency, and chronic levels of day-to-day stress. Propst et al. (1986) state that a large body of family dissolution research suggests that the higher levels of stress reported by divorced mothers is a result of financial difficulties. Single mothers may be more vulnerable than others to stress simply because they have fewer economic resources to cope with problems when they occur.

While the majority of divorced women experience substantial decreases in economic resources, men tend to experience stability or increases in economic resources (Kitson et al. 1989; Pett and Vaughan-Cole 1986). The combination of increased economic resources and decreased family responsibilities may lead some men to evaluate the consequences of divorce more favorably than women, and thus to experience less stress over time. Research on the gender effects of stress following marital dissolution has been sparse and inconsistent; however, Leupnitz (1986) found that when parenting is shared by joint custody arrangements, mothers experienced less stress.

A unique aspect of divorce with regard to the Andreasen model is that it is a transition which causes the household to dissolve and reform into two new households. Therefore, in the evaluation of the

consequences of divorce, a key component is the strength of kinship ties between children and their parents. While most life status changes do not result in the termination of the household, the importance of kinship ties following family dissolution underscores the influence not only of the emotional bonds within the family unit, but also of the family's social support structure in the community. Strong family ties and a network of friends who can be relied upon in times of crisis can mitigate many of the effects of life status transitions.

Many fathers continue to be actively involved with their children following family dissolution. The greater the father's role in his children's lives, the greater is his involvement with his children (Greif 1979). A key point obscured by the grim statistics on family dissolution is that non-custodial parents are not a homogeneous group. While Weiss (1975) found that reductions in visitation frequently occur over time, several studies indicate that, at least for certain demographic segments of divorced males, kinship ties remain intact and carry over into subsequent relationships. Although children from black and lower-income homes suffer the most economically, better educated men with greater socioeconomic resources tend to continue to provide for their children after marital dissolution (Teachman 1990). Weiss (1975) suggests that the three variables affecting the strength of kinship ties between divorced fathers and their children are social class, distance, and the ages of the children.

Research in family dissolution offers a unique opportunity to study the *process* by which households evaluate the consequences of a life status change. Changes in resources, responsibilities, and social support structures, such as kinship ties, are often dramatic, and may occur simultaneously, thus providing insight into how the interaction of these dimensions affects evaluations of status changes. Also, the effects are long-term and enduring, allowing researchers to study the links between status changes, stress, and consumption behavior suggested in the Andreasen model. This discussion leads to the following set of propositions:

- P1: Households evaluate the consequences of a life status change according to the impact upon economic resources, upon personal responsibilities, and upon social support structures, such as family ties.
- P2: Changes in resources, responsibilities, and social support structures interact to affect evaluations of the consequences of a status change.
- P3: Increases in the level of economic resources brought about by a status change positively affect the problem solving capacity of households who face increases in responsibilities; decreases in the levels of resources brought about by a status change

negatively affects the problem solving capacity of households in similar circumstances.

- P4: In the long-run, households who experience decreased economic resources and increased responsibilities following a life status change experience greater levels of daily stress, which results in a negative evaluation of the change; households who experience increased economic resources and decreased responsibilities following a life status change experience lower levels of daily stress, which results in a positive evaluation of the change.
- P5A: The strength of emotional bonds within the household and the quality of the household's structure network positively affects the ability of the household to cope with stress.
- P5B: Life status changes which positively impact an household's kinship and/or social support structure positively impact the family's ability to cope with the change; life status changes which negatively affect a household's kinship and/or social structure negatively impact the household's ability to cope with the change.

FAMILY DISSOLUTION AND STRESS

Family dissolution research indicates that the relationships between stress and life status changes, changes in lifestyle, and the evaluation of status changes may be more complex than originally perceived by Andreasen, and suggests several links which are not specified by the model. First, the *anticipation* of divorce is highly likely to be stressful. (Bloom and Caldwell 1981). Divorce or separation seldom comes as a complete surprise to partners; generally spouses carefully think over the pros and cons of marital dissolution, discuss family problems with friends and relatives, and/or consult with family counselors prior to dissolution. If stress can occur with a life status change, then stress can also occur prior to a complete evaluation of the consequences of that change because some of the consequences cannot be known prior to transition. In other words, part of the stress associated with a life status change may be caused by fear of the unknown.

Second, Andreasen views stress as a single dimension. Stress may actually be broken into two dimensions: disequilibrium and equilibrium stress. Disequilibrium stress can be interpreted in terms of crisis and recovery. As individuals move from familiar to unfamiliar life status positions they temporarily experience higher levels of stress, which decline with time and adaptation to the transition. The transition process brought about by marital dissolution can be especially traumatic. Following family dissolution, individuals may be simultaneously required to cope

with the loss of a key relationship, changes in social status, dividing up property, moving, purchasing new household goods, work, financial difficulties, domestic responsibilities, and childcare. It is not surprising that divorce is rated among the most traumatic events to which to adjust (Dohrewend et al. 1978). In extreme cases, when a traumatic transition such as death of a family member or divorce is unexpected, disequilibrium stress may be so severe that it produces a state of shock which *impedes* assimilation and evaluation of the status change (Kitson 1982; Parks and Weiss 1983).

Equilibrium stress is the day-to-day level of stress associated with one's particular lifestyle. Cohen, Kamarck, and Marmelstein (1983) contend that stress occurs when two conditions are met: 1) that the situation is evaluated as threatening or otherwise demanding, and 2) that insufficient resources are available to cope with the situation. These antecedents of stress are part and parcel of the lifestyle of the divorced custodial parent. A substantial body of research has found that single parents experience more anxiety, depression, and dissatisfaction with their lives than those in dual-parent families (Bachrach 1975; Fine, Schwebel, and Myers 1985; Weiss 1979). Wallerstein (1986) found that a significantly larger percentage of women than men continued to experience symptoms of stress for as long as 10 years after marital transition. The high level of stress commonly experienced by single divorced parents have led some researchers to question whether divorce should be treated as a life crisis or a chronic stressor (Kitson et al. 1989). This suggests that divorce may signal an increase in levels of equilibrium stress which can extend for years beyond the period of marital transition. This discussion leads to the following following propositions:

- P6: Stress can occur in anticipation of a life status change and thus prior to the life status change.
- P7: Stress can be broken down into two dimensions: 1) disequilibrium stress, which occurs during the period of transition and declines after adaption to the transition, and 2) equilibrium stress, which is the level of daily stress associated with one's lifestyle.
- P8: Stress can impede the evaluation and assimilation of a life status change.

FAMILY DISSOLUTION AND THE EFFECTS OF STRESS AND ROLE OVERLOAD ON CONSUMPTION BEHAVIOR

Although Andreasen hypothesizes that there is no direct relationship between stress and consumption behavior, other consumer researchers, such as Celuch and Showers (1990), make a convincing case to the contrary. Offering several examples of how stress can directly affect consumption, Celuch and Showers contend that the antecedent conditions of daily stress

are more predictive of consumption behavior than infrequently occurring life status changes which are the focus of the Andreasen model. The contribution of research on family dissolution is that it suggests that both conceptualizations can be reconciled and are, in fact, mutually enhancing. By broadening the focus of the Andreasen model beyond the period of transition to include the effect of status changes on daily levels of stress, insights can be gained into the process of how changes in life status bring about changes in consumption. Examining how *specific* status changes affect the antecedent conditions of daily stress allows predictions to be made about how certain demographic trends, such as divorce, may affect the consumption behavior of significant segments of the population.

Celuch and Showers also contend that stress can be directly linked to changes in consumption behavior as a result of two types of coping behaviors, mood regulation and problem solving. An obvious example of consumption behavior used to regulate mood is the use of products such as tobacco, alcohol, and drugs. In a study on marital dissolution and psychological well-being, Doherty, Su, and Needle (1989) found that women tend to increase their use of alcohol and other mood-altering substances following marital dissolution. A less obvious example of consumption behavior used to regulate mood is the use of mental health services. Divorced single mothers form the largest group of mental health consumers in the United States (Gutentag and Belle 1980).

Stress can also affect consumption behavior when a consumer uses products or services to solve the problems causing stress. Some individuals may change consumption behavior in order to solve *anticipated* problems. Several studies indicate that the contemplation of marital dissolution may lead a shift to autonomous decision-making and consumption behavior prior to the actual separation of the couple. Germer, Montalto, and Bryant (1990), found that women increased their participation in the workforce in the year or two prior to divorce. During a study on marital dissolution conducted by Kitson, Babri, and Roach (1985), several female respondents informally told them about opening personal bank accounts, saving money, putting the title for a new car in their names, establishing their own credit records, and/or returning to school.

Family dissolution can lead to role overload, which is an antecedent of chronic day-to-day stress. In interviews with over 200 single parents, Weiss (1979) found that, although parents reported that they were managing their responsibilities at home and at work, most described their situation as burdensome. In a study by Fine, Swebel, and Myers (1985), 60 percent of mothers reported that their children saw their fathers less than once a month, and that their former spouses offer little assistance with daily activities. Over half of the mothers reported that the worst part of being a mother was the 24-hour-a-day commitment. Pearlín and Johnson (1977) found that symptoms of stress experienced by single divorced mothers were positively correlated with the number of children in the household, and negatively correlated with the ages of the children.

When role-overloaded divorced parents attempt to reduce stress by cutting down on household tasks or reallocating them among family members, changes in consumption may occur. Comparative time-studies of married and single mothers indicate that marital status affects how time is allocated between housework, workforce participation, childcare, leisure and other activities (Mauldin and Meeks 1990; Sanik and Mauldin 1986). The reduction in time spent on housework which has been noted by many researchers may be due to reallocation of tasks to children within the family unit. Weiss (1979) reported that children in single parent families often assume more responsibilities in the household than do children in families with both parents intact.

For single-parent families in which children assume increased responsibilities for household tasks, it seems likely that those children also become more influential in making decisions regarding household purchases. Ahuja and Schuster (1991), in summarizing the conclusions of five marketing studies examining parental perceptions of children's influence in family decision making, found that single parents depended more on their children for help in the home, and that these children had more influence upon purchase decisions within the family unit.

When childcare is unaffordable, single parents may be forced to shop with children in tow. Shopping may become more stressful and result in less browsing behavior and fewer stores visited. Colletta (1983) found that working mothers reported shopping often with their children, that shopping was more stressful, and that it frequently resulted in impulse purchases of things which the children demanded. Single parents may rely on older children to go to the store to pick up items which are needed. When this occurs, although the actual consuming unit has not changed, the individual who makes the brand purchase decisions has. Several manufacturers are already experimenting with products for children which have traditionally been promoted to adults, such as microwave meals and bathroom cleansers. The preceding section leads to the following propositions:

- P9: Stress is directly linked to consumption through the coping behaviors of mood regulation and problem solving, and thus affects consumer behavior throughout the consumption experience, from purchase selection to post-purchase evaluation.
- P10: Changes in consumption as a result of coping behavior lead to changes in lifestyle.
- P11: The change in daily levels of equilibrium stress following a status change is a better predictor of consumption behavior than disequilibrium stress experienced during the transition process.

CONCLUSION AND SUGGESTIONS FOR FUTURE RESEARCH

This paper has focused in depth on a specific type of life status change which occurs frequently and whose impact causes a dramatic change in the family structure. A review of the family dissolution literature suggests several refinements to the Andreasen model. An important consequence of a life status change is its impact on equilibrium levels of daily stress associated with an individual's or household's lifestyle. Research on family dissolution suggests that levels of daily stress directly affect consumption through the mechanism of coping behaviors. Studies of households headed by single parents appear to be particularly promising in this regard.

The increasing trend toward joint custody agreements presents a challenge to researchers interested in studying the effects of family dissolution on consumption behavior. For example, how does a researcher define a family when spouses divorce, and their children split their time living with both parents, perhaps as part of blended households with their parent's new partners who also have similar childcare arrangements. The existence of ongoing relationships between divorced parents and their children is likely to be reflected in the consumption behavior of both households. When parenting is shared by joint custody arrangements, mothers have more time for personal and social activities, and thus experience different consumption patterns (Leupnitz 1986). Traditionally, family life cycle categories have lumped non-custodial parents in with other single adults, yet, when non-custodial parents are actively involved with their children, their consumption behavior is likely to be markedly different from other single adults. In one study on joint custody, all of the fathers had set up living space with special toys and clothing for their children; their children did not bring suitcases when they visited (Greif 1979).

A particularly useful tool for measuring the effect of family dissolution upon household consumption would be the development of a child burden index measuring the number, age, gender of the children in the household, as well as the level of involvement of the non-custodial parent. Variables measuring involvement might include the amount and regularity of financial assistance, length and duration of visitation, and the type of visitation (telephone calls, daily outings, extended visits, participation in school activities, care of sick children, etc.) Celuch and Showers (1990) suggest including measures of perceived time urgency as a predictor of stress induced changes in consumption behavior. These measurements could then be correlated with a wider variety of consumption activities in order to more fully capture the effects of family dissolution on the consumption behavior of households headed by *both* former spouses. Variables which seem likely to be affected by the present or absence of role overload include comparison shopping, browsing behavior, impulse purchases, frequency and duration of shopping trips, the relative influence of children upon the

consumption behavior of the household, and types of products and services purchased.

Another issue is the long-term effect of family dissolution on overall consumer trends. When a household unit is dissolved, it reforms into two households whose members carry information about the effects of the transition into their new relationships. If a transition, such as divorce, affects how an individual makes decisions, is there a cumulative effect of multiple status changes of the same type upon decision-making? Individuals may experience several divorces over the course of a lifetime, first as a child when parents divorce, then as an adult when they divorce. Do individuals who experience multiple family dissolutions exhibit consumption behavior that reflect their experience that permanence is not an intrinsic part of the family relationship? Some assets may be divided up only with difficulty should a divorce occur. If the accumulation of assets such as a house or business—or even the birth of a child—can result in loss or increased financial liability should a marriage dissolve, individuals who have experienced multiple family dissolution may be less inclined—or unable to afford—to engage in some types of consumption. Divorce financially batters people, and makes it difficult to build up assets over time. A long-term effect of the instability of the family unit may be a cultural shift to more autonomous and hedonic types of consumption.

Measuring Conflict in Household Decision Behavior: Read My Lips and Read My Mind

William J. Qualls, Massachusetts Institute of Technology
Francoise Jaffe, University of Michigan

ABSTRACT

In the present paper we empirically test the premise that husbands and wives, when involved in a joint decision task, experience both manifest (explicit) and cognitive (implicit) conflict. While manifest conflict affects the specific decision task at the time of the decision, cognitive conflict affects the current as well as future decision tasks. Results are presented from a field study of husband and wife households which indicates that significant conflict exists in household decision behavior and that husbands' and wives' similarity/dissimilarity affect the degree of household conflict and the method of conflict resolution.

INTRODUCTION

Research on household conflict is relatively sparse, and mostly conceptual. Little attention has been given to how conflict evolves in the event of a joint decision making task and to the ensuing conflict resolution process that takes place. However, it is our contention that household conflict plays a far more central role in the understanding of family decision making (FDM) than what its present treatment in the literature indicates. We agree with the conclusion of both Davis (1976) and Granbois (1971), that "understanding household conflict is critical to understanding the dynamics of household decision behavior and the decision strategies employed in family decision making".

A theoretical paradigm called interpersonal conflict proposed by Hammonds (1965, 1973) provides a useful framework for examining the process of conflict in household decision behavior. Specifically the interpersonal conflict paradigm suggests that when two people involved in a joint problem solving task experience conflict; they experience both explicit (manifest) and implicit (cognitive) conflict. Hammonds (1965, 1973) contends that the cognitive conflict experienced by an individual affects not only the current decision but future decisions as well. The process of conflict and conflict resolution is in effect a learning experience which the individual uses to update his/her understanding of the decision making preferences of other household members. If indeed one views FDM as a dynamic process in which every decision constitutes a learning experience for the participants, then the events which lead to conflict and the way conflict is resolved will constitute important pieces of information. The purpose of the present paper is twofold: 1) To examine the efficacy of the interpersonal conflict paradigm for explaining household decision behavior, 2) To develop and test an objective measure of conflict and conflict resolution.

THE COGNITIVE CONFLICT PARADIGM

The theoretical paradigm underlying the present study is based on social judgment theory (Hammonds 1973). The paradigm is conceptualized in a way that lends itself well to the formulation of a framework from which to examine interpersonal conflict in household decision behavior. The basic premise of the Hammonds paradigm is that in addition to the existence of *manifest conflict*, two people in a joint problem solving task also experience a degree of *cognitive conflict*. Manifest conflict is defined as the explicit conflict individuals experience when there are differences over desired outcomes or disagreements over the perception of influence. Cognitive conflict is defined as the difference between an individual's own desired outcome or perceived influence and what the individual thinks his/her partner desired outcome or influence perception will be.

Hammonds (1973), recommends certain conditions under which the cognitive conflict paradigm is best illustrated, and suggests that the cognitive conflict paradigm is best described as the interaction between two people who: 1) Attempt to solve mutual problems, 2) Have mutual utilities (ability to gain or lose), 3) Receive different training in a solution to a problem, 4) Find that their answers differ, 5) Provide a joint solution as the correct one, 6) Adapt to one another as well as to the decision task.

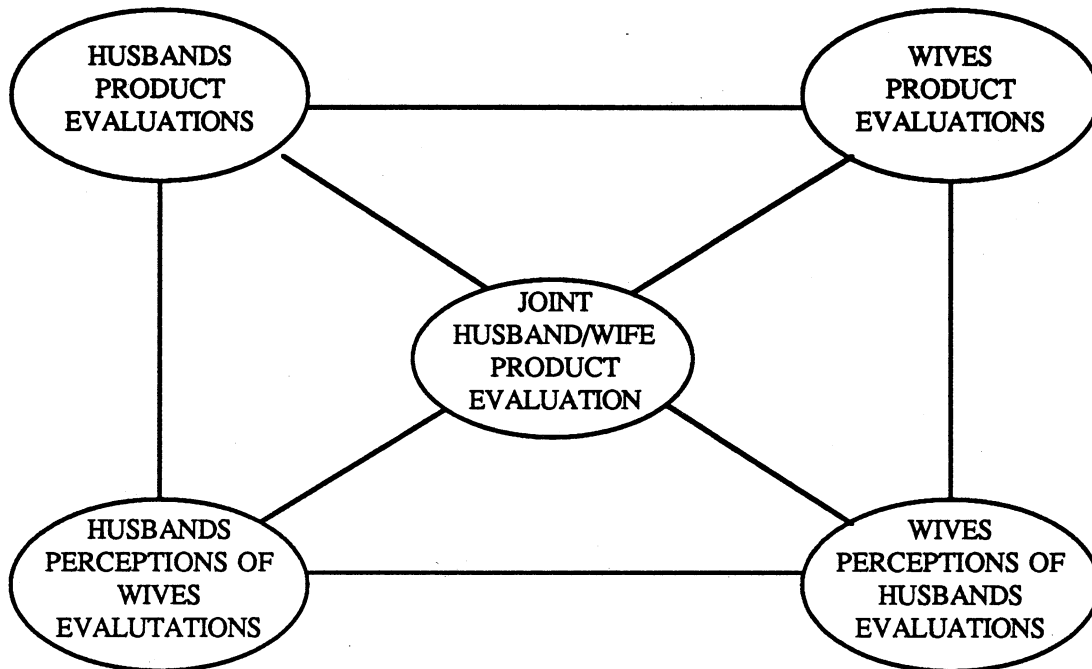

Households in which family members engage in joint decision making typically can involve family members with different preferences and attitudes who are motivated to reach a joint solution. To reach their joint solution, family members may have to modify their original preference positions or attitudes to ensure that a decision is made.

A CONCEPTUAL MODEL OF HOUSEHOLD DECISION BEHAVIOR

The assumptions implicit in our conceptual model are as follows: 1) conflict in a household occurs when both husbands and wives have different perceptions regarding the distribution of influence or different preferences about the object of the decision; 2) these preferences and/or role perceptions occur as a result of the different socialization experiences of these individuals; and 3) husbands and wives have learned over the course of their relationships about the other one's preferences and should be able to predict these preferences, even though they themselves may disagree with them.

The conceptual model presented in Figure 1 outlines the proposed relationships between a husband and wife involved in the evaluation of a product to be used by both the husband and wife. The model suggests that three types of judgments are of relevance when husbands and wives are involved in a joint

FIGURE 1
Conceptual Model of Household Conflict

decision task: 1) Individual judgments (i.e., product preferences, attribute importance), 2) Prediction of their spouses' individual judgments (for the same product preferences, or attributes), 3) Joint consensus judgments (of the same products, or attributes)

Individual judgments are needed to measure the existence of manifest conflict (i.e. difference between h/w individual judgements and joint product evaluations), while the prediction of a spouses' judgment is needed to measure the extent of cognitive conflict (differences between H/W individual judgements and perceptions of spousal judgements). Finally, joint evaluations represent the household utility associated with a specific decision outcome.

Unlike the original paradigm proposed by Hammonds (1965) the present model treats individual differences as a natural phenomenon resulting from the socialization of husbands and wives as a couple. Rappoport (1969) found that subjects who are different in the way they interpret information are more likely to experience conflict. Several variables have been found by FDM researchers that differentiate the decision behavior of husbands and wives, namely sex role orientation (Qualls 1987, Rosen and Granbois 1983), perception of influence (Davis and Rigaux 1974), and decision importance (Morgan 1961). A spouse's sex role orientation helps to determine the gender attitudes held by spouses which impacts the perception of influence (Qualls 1987). The perceptions of influence held by husbands and wives determine the extent of involvement in decisions. The perception of influence and its impact upon FDM practices is well documented in the research literature

(Davis 1970, 1971). Finally, the importance of the decision helps determine the exercise of influence (Morgan 1961).

Based on the importance of these constructs as an explanatory variable in previous research, it is hypothesized that an individual spouse's perception of their 1) sex role orientation, 2) influence, and 3) decision importance can be used as a measure of the similarity or dissimilarity between husbands and wives perceptions. As such we propose to test the following hypothesis:

- H1 Husbands and wives with similar perceptions regarding sex roles, decision influence, and decision importance will exhibit less conflict than husbands and wives with dissimilar perceptions.

Park (1982) found that it was fairly easy for husbands and wives to determine the other spouses' preference levels on salient objective dimensions as opposed to salient subjective dimensions. Such evidence suggest that the learning of each other's preferences by husbands and wives affects spouses' individual preference positions. The question of the degree of learning is yet unanswered but work by Davis, Hoch, and Ragsdale (1986) suggests that husbands and wives can better predict their spouse's ratings with their own ratings than they can by guessing the preference ratings of their spouse. Both studies appear to suggest that there is an exchange of information exchange that takes place between husbands and wives, which can contribute to learning.

This process of learning enables spouses to resolve potential conflict between husband and wife individual preferences cognitively before any interaction over the decision between spouses. Such behavior may lead to low levels of manifest conflict.

Burns and Granbois (1977) found (using the difference between first choices of husbands and wives) revealed very little discrepancy between husband and wife preferences, resulting in low levels of household conflict. We propose that the similarities in first choice preferences between husbands and wives may reflect the process of interpersonal learning and masks the presence of cognitive conflict. If cognitive conflict occurs, then there would be agreement between spouses on what the first choice is, however, underlying disagreement over subdecisions, or alternative individual preferences. The presence of individual preferences that do not match the joint preferences exhibited by a household, represents disagreements that are not manifested but concealed. In the above scenario, husbands and wives know what their spouse's choice might be, agree with their spouse to reduce conflict, but still hold on to their original preference positions. On the other hand, in the absence of interpersonal learning, spouses show their differences immediately on their first choices, as husbands and wives do not have any information on the preference position of their spouse. Conflict can be caused by either the exercise of influence by one family member or of the frustration of one spouse whose individual preferences are not met by the actual decision outcome. The difference in origin is important as the exercise of influence is an indicator of manifest conflict, while unfulfilled perceptions of influence or decision preferences would result in cognitive conflict. Based on this discussion, it is hypothesized that:

- H2 The greater (less) the degree of manifest conflict, the less (more) likely cognitive conflict will occur.

Household conflict is highly probable when one considers that the individual preferences of multiple family members must be combined and reconciled into a joint preference before any purchase decision is made. Thomas (1976) contends that conflict resolution behavior can be conceptualized as a function of 1) the extent to which a party tries to satisfy his/her concerns and 2) the extent to which a party tries to satisfy the concerns of others. Thomas' idea can be extended here to mean that the reason that one party tries to satisfy the concerns of the other reflects their ability to do so. In the present study it is suggested that in households that are similar, spouses will attempt to reach a compromise through bargaining and negotiation because of their understanding of each others preference positions or household roles. However, in cases of dissimilar households spouses will be unable to understand the other one's position and will not have the ability to understand the needs of the other party. In that case it is expected that the most likely mode of conflict

resolution will be concession by one of the spouses. Accordingly, it is hypothesized that:

- H3a Households which share similar husband/wife perceptions will compromise and bargain more frequently than households which are dissimilar
- H3b Households with dissimilar husband/wife perceptions structures will concede and avoid conflict more often than households with similar perceptions.

The hypotheses and the proposed relationships in the conceptual model are examined and tested in the next section.

METHODOLOGY

Subjects for the study consisted of 63 husband and wife households recruited from a cooperative housing complex which catered to married graduate students, located in a midwestern college town. Each couple was paid an honorarium of 20 dollars for their participation. Households were told they were participating in a survey by a major automobile firm who wanted to know their feelings on a new automobile to be marketed in the future. Only those couples who had indicated a probability of purchase of 70 percent or higher were recruited to participate in the study.

The automobile purchase decision was selected as the household decision task because it has proven to be a joint decision, important to husbands and wives and a product likely to be used by both spouses in previous research (Davis 1970, Green and Cunningham 1975). Based on the medium-sized car category, nine product concepts were created. Each concept was composed of several different product attributes known to be important criteria in the decision to purchase an automobile. The attributes included, color (red, blue, grey, tan), price (\$10,000, \$14,000, \$20,000), city mileage per gallon (12, 16, 20), manufacturer warranty (3 years/30,000 miles, 4 years/40,000 miles, 5 years/ 50,000 miles), and predicted repair record (above average, average, below average).

Data for the study was collected in two phases. In phase one, husbands and wives were asked to individually evaluate the automobile product concepts and to rank order these concepts according to their preferences. In addition, information was collected to capture the individual's sex role orientation, importance of the decision, and perception of influence across the product attributes. The second phase of the study, which immediately followed the first phase, was a joint decision task in which husbands and wives were asked to jointly rank order their preferences. The session took about 50 minutes to complete. If couples could not agree, they were allowed to stop the interview, but only after attempting to resolve any conflict.

The primary measurement variables are summarized in Tables 1 and 2. An index of husband/wife similarity was developed and used as

Summary of Principal Measurement Variables

Measurement Variables	Scale	Number of Items	Example
Sex Role Orientation (alpha = .86) decisions.	5-point Agree/Disagree	30	A wife should not have equal authority with her husband in making household
Decision Importance (alpha = .92) family car?	5-point Very Important Not Important	5	How important is it that you participate in making the decision about the
Perceived Influence (alpha = .77)	Constant Sum	5	In your family the fair proportion of husband/wife influence when making decisions about:
Husband/Wife Product Evaluations	Rank Order	9	Rank order the following automobile product concepts from first choice influence when making decisions about: to last choice.
Husband/wife Perceptions of Spouses Product Evaluations	Rank Order	9	Rank order the following automobile product concepts from first choice to last choice based on how you think your spouse will rank order them.
Household Conflict Resolution (alpha = .69)	5-point Agree-	20	I will give into my husband(wife) preferences to maintain peace in the family.

criteria on which the households were classified. Specifically, the index was calculated by defining household cognitive structure (HCSI) as:

$$HCSI = \frac{H_s \cdot W_s + H_{pi} \cdot W_{pi} + H_{di} \cdot W_{di}}{H_s + W_s + H_{pi} + W_{pi} + H_{di} + W_{di}}$$

where:

- $H_s W_s$ = Husband/wife sex role orientation
- $H_{pi} W_{pi}$ = Husband and Wife perception of influence
- $H_{di} W_{di}$ = Husband and wife decision importance

If the HCSI is greater than .55 the family was classified as cognitively different and if the HCSI is less than .45 the household was classified as cognitively similar. Those households that fell in between .45 and .55 were excluded from the final

sample. Only three households fell in the middle, reducing the original sample to 60 households.

Previous research has relied heavily on a single measure of conflict. In the present study, the construct of conflict is based on multiple measures which were calculated from the information obtained from key theoretical variables measured with paper and pencil tests.

- 1) *Overall relative influence* -- is calculated as the difference between the correlations between husbands' and wives' perceptions of influence.
- 2) *First Choice* -- is determined by the difference between the correlation of husbands' first choice preferences and wives' first choice preferences.
- 3) *Overt Conflict* -- is the difference between the correlation of the product evaluations

- produced individually by the husband and wife.
- 4) *Cognitive Conflict* -- is the difference between the correlations of the perceptions husbands/wives hold of how their spouses would rank order product concepts and the rankings produced individually by the husband and wife.
- 5) *Husbands' Conflict* -- is the difference between the correlation of husbands'

product concept evaluations and joint household preference rankings.

- 6) *Wives' Conflict* -- is the difference between the correlations of wives' product concept evaluations and joint household preference rankings.

The final set of measures employed in the present study was that of conflict resolution mode. A multiple measure of conflict resolution is employed to tap both the objective and subjective dimensions. A 20 item scale was developed and tested to confirm the

strategies used, specifically, four modes of conflict resolution were hypothesized a priori to exist:

- 1) *Competition* - represents attempts by a spouse to completely dominate a decision.
- 2) *Concession* - involves a spouse adhering to the preferences of the other spouse either unconditionally or conditionally in return for some future consideration.
- 3) *Bargaining* - efforts by husbands and wives to achieve a balance between their original individual preference positions.
- 4) *Avoidance-Withdrawal* - refers to inactivity or lack of action on a decision issue.
- 5) *Capitulation* - is defined when one spouse gives in to the preferences of the other, which was operationalized as the correlations between a spouse's individual preferences and spouses' with their joint preferences.
- 6) *Compromise* occurs when neither the first choice of the husband or wife is chosen jointly as the household choice.

Canonical correlation is used to evaluate the nature of the conflict relationship and examine the hypothesis that husbands and wives with similar cognitive structures will exhibit less conflict than those spouses with dissimilar cognitive structures. It is especially suited for examining phenomena which incorporate multiple dependent variables and multiple independent variables.

RESULTS AND DISCUSSION

Tables 2 and 3 provides an illustration of the results of the canonical correlation analysis used to test hypothesis 1. As indicated in Tables 2 and 3, the first canonical variate is made up largely of husbands' and wives' perception of influence for cognitively similar husbands and wives with a corresponding canonical correlation of .80.

Conversely, for dissimilar husband/wife households, the first canonical variate is determined by husbands' and wives' product preferences, with a canonical correlation of .53. As expected, husband/wife similar households exhibit less conflict than husband/wife dissimilar households. Stated another way, in husband/wife similar households, husbands and wives share similar perceptions of the levels of influence, first choices, product preferences, and spousal preferences.

For husband/wife similar households, the major discrepancy lies with the perception of influence and how it should be distributed between husbands and wives, while husband/wife different households disagree on the preference rankings between husbands and wives.

Table 4 presents the results of the canonical correlations used to test hypotheses 2. The predictive

canonical variate is based mainly on husbands' and wives' perception of influence (.708), wives' conflict (.626), and husbands' conflict (.606). The first canonical variate is largely determined by the perception of decision importance perceived by husbands and wives (-.824), and their joint preference rankings (-.676). The canonical correlation is .967, which when squared suggests that the level of explanatory power is .93 percent. It appears that as the level of decision importance increases and joint decision behavior takes place, households experience the greatest conflict between husbands' and wives' perceptions of household influence, and husband and wife conflict over individual preferences. The fact that discrepancies between husbands' and wives' perception of influence is larger than the correlation between wife and husband conflict provides support for hypothesis 2.

Examination of the second canonical variate suggests the overt conflict (-.695) and wives' conflict (.578) are correlated at the .805 level primarily with husbands' preference rankings (.615). As Table 2 illustrates the second dependent variate is mostly composed of overt conflict, wives' conflict, and conflict between husbands' and wives' perceptions of influence. The source of this conflict appears to be related to the husbands' preference rankings, with approximately 64 percent of the unexplained variance captured. The results suggest that there is a large discrepancy between wives' preference rankings and the final choice, which closely resemble husbands initial choices.

The one underlying theme observed in the results is the dominant role that wives' conflict, cognitive conflict and overt conflict play in determining the level of household conflict. Conversely, the effect of first choice differences between husbands and wives is minimal and almost nonexistent beyond the first canonical variate.

The second hypothesis examines the extent of cognitive conflict exhibited through first choice differences, as a measure of household conflict, when compared to alternative measures of conflict. Although the first choice measure (.615) contributed to the power of the overall measure of conflict, it did not act as the dominant or sole source of household conflict. Beyond first choices significant conflict occurs as a result of differences between individual spousal preference positions and the joint household decision. Such results also provide support for the hypothesis and the contention that multiple measures of conflict are better suited for measuring the true extent of household conflict. The use of multiple measures reveals a high level of conflict in household decision behavior. This contradicts the findings of earlier studies which relied on more objective measures such as the differences between first choices.

HOUSEHOLD CONFLICT RESOLUTION

Figure 2 illustrates the results of the canonical correlation analysis performed to test hypothesis 3. As Figure 2 illustrates there is a strong correlation between the mode of conflict resolution and the characteristics of husbands and wives from both

 Y6-Compromise

husband/wife similar and husband/wife different households. For husband/wife similar households, the conflict resolution mode of bargaining is largely determined by the level of decision importance perceived by husbands and wives. This is to say that the more important the decision is to the household, the more likely bargaining will be employed to resolve conflicts between husband and wife preferences.

Conversely, for husband/wife different households, the most common form of conflict

resolution appears to be capitulation and avoidance-withdrawal, largely determined by the importance of the decision to wives' and husbands' perception of influence. While avoidance-withdrawal and capitulation are the conflict resolution modes of choice for husband/wife different households, concession, bargaining and compromise are also used frequently to resolve household conflicts. Given these results, only partial support can be claimed for hypotheses 3a and 3b.

SUMMARY AND CONCLUSIONS

The results presented in the analysis of the study's hypotheses are strongly supportive of the premise that significant conflict exists in most household decisions involving the joint participation of two or more family members. The hypothesis that differences in husbands' and wives' similarity/dissimilarity affect the degree of household conflict, which constituted the premise of this study, is supported.

The present study developed and tested a framework to capture the nature of household conflict and conflict resolution. Husband and wife interaction as the result of household conflict causes family members to consider information and decision criteria that they may not have considered individually. The process of how husbands and wives make decisions is related to the strategies a household uses to resolve conflict. The research described here suggests that the role of cognitive processes of husbands and wives in household decision making remains to be understood.

Consumer Socialization Associated with Relocation to a New Community: A Framework and Pilot Study

Cathy Goodwin, University of Manitoba
Murphy Sewall, University of Connecticut

ABSTRACT

Studies of consumer socialization have emphasized socialization of children and adolescents. However, people experience socialization throughout adulthood. This paper develops a framework for studying consumer socialization associated with geographic relocation and reports a pilot study of consumers who moved to a remote arctic location.

Parallels between organizational and relocation forms of socialization are identified. The study suggests that people who are highly motivated to move will find ways to socialize themselves and cope with the new environment. Two forms of commitment are identified, suggesting alternate forms of identification with the new community. The study also suggests implications for other aspects of adult socialization.

"Since you're a cheechako, you'll need to winterize the car. Get some Sorels and bunny boots at the recycle sale and some Carmex at Foodland. You'll probably be going outside before runoff."

Understanding these sentences represents an outcome of consumer socialization to a particular region of the U.S. Consumer researchers have addressed the way consumers acquire skills and behaviors at various stages in the life cycle. Researchers have explored the way children learn to become effective consumers (e.g., Carlson and Grossbart 1988; Moschis 1985; Moschis and Moore 1979), media influences (e.g., Churchill and Moschis 1979; Ward and Wackman 1971) and the way adolescents are influenced with respect to shoplifting (Cox et al. 1990). However, throughout adulthood, people undergo life changes which alter effectiveness and desirability of previous consumption patterns. For example, people who relocate to a new geographic region also experience consumer socialization. The topic deserves study for at least two reasons. First, a large number of people undergo this experience: approximately 3 % of the US population moves to a new state each year (US Bureau of the Census 1990). Second, insights into adult consumer socialization associated with relocation may have implications for other instances of adult consumer socialization. This paper develops a framework for studying consumer socialization associated with geographic relocation and reports a pilot study of consumers who moved to a remote arctic location.

Fairbanks, Alaska, is a natural laboratory to study adult socialization associated with relocation. It is far enough from the contiguous Lower 48 to preclude quick trips to a previous residence: travel to Seattle takes at least four hours by air, while trips to other parts of the US take at least 10 hours. The culture is distinctly different from other parts of the U.S. with

respect to norms, values, even vocabulary, yet the language and money remain constant. The severe climate and daylight conditions require lifestyle changes even for people from the mountain states. Riesman and Roseborough (1955) note that people often relocate easily by maintaining a "standard package" of goods which can be purchased and used anywhere. However, the physical isolation of Fairbanks means that many products and services are either not available or are very expensive; therefore, people must learn new consumption patterns even when products and brands on the shelves are familiar.

PREVIOUS RESEARCH ON SOCIALIZATION

Socialization can be studied from several perspectives. Psychologists tend to focus on individual learning processes. Anthropologists focus on becoming part of a culture. Sociologists, on the other hand, often view socialization in terms of role acquisition. Thus, much sociological research has taken place within the context of organizations and professions. This form of socialization will be especially relevant to the study here.

Adult Socialization

When compared to research on childhood and adolescent socialization, adult socialization has been relatively neglected. Brim (1966, 1968) identifies a number of differences between childhood adult socialization.

First, Brim suggests that socialization consists of learning the role demands of society. For children, the reference group which prescribes role demands is composed of parents and peers; in contrast, adults refer to "earlier friends, great figures in history, spirits, men yet to be born" (p. 17), or even Mead's (1930) generalized other.

Second, adult socialization necessarily builds on the foundations of childhood socialization. Berger and Luckmann (1966) suggest that this "secondary" socialization occurs on a shallower level. People may experience an inability to take on values and behavior which contradict earlier learning (Brim 1966), also described as "resocialization" (Campbell 1975).

Finally, as people move through the life cycle, "the emphasis in socialization moves from motivation to ability and knowledge, and from a concern with values to a concern with behavior" (Brim 1966, p. 26). Childhood socialization develops primary motives, while adult socialization focuses on secondary motivations. The motivation adults bring to a new environment will influence their socialization because, unlike children, adults select their socialization experiences (Brim 1968).

A great deal of research on adult socialization has focused on career-related socialization. This focus

includes socialization to professional subcultures, such as those associated with medicine, nursing or the military as well as socialization to specific organizations following job changes. Each instance involves adjustment to a community which exists as part of a larger culture. People relate to work settings on a number of levels:

"...from the time individuals first enter a workplace to the time they leave their membership behind, they experience and often commit themselves to a distinct way of life complete with its own rhythms, rewards, relationships, demands and potentials" (Van Maanen and Schein 1979, p. 210).

This type of involvement resembles involvement with a residential community. Theory, models and variables associated with the occupational socialization literature may also have applications in other areas of adult socialization, such as socialization as a service consumer (Goodwin 1988) or socialization associated with relocation discussed here.

Consumer Socialization

Ward (1974) notes that consumer socialization may focus on developing knowledge, skills and attitudes either (a) directly relevant to behaviors associated with the consumer role, such as choice and purchase; or (b) "social motivation" arising from non-consumer roles which influence consumer behaviors. The latter focuses on the content of what is purchased, such as the need to buy a suit for an interview or a warm parka for a cold climate, while the former focuses on how to purchase, such as knowing of brands and consumer rights.

Moschis (1987), summarizing a large body of consumer research, identifies five types of variables as essential to any type of consumer socialization model:

1. age or life cycle position of the influencee;
2. social structural constraints, such as race, ethnic group or class;
3. socialization agent, including (but not limited to) mass media, family, peers;
4. learning processes, which may be behavioral, interactional, or cognitive; and
5. content or criterion behavior, i.e., "cognitions and behaviors...necessary for the performance of a given social role."

Consumer socialization research has focused on norms and orientations of children and adolescents (Moschis and Moore 1984). Therefore, relevance of variables studied in the context of childhood and adolescent socialization must be reexamined in applications of adult socialization. However, the literature on consumer adaptation has not examined adult adaptations to altered consumption environments brought about by geographic location. Variables from adult and consumer socialization literatures will be considered in addressing this topic.

Criterion Variables

While empirical studies of socialization often include a discussion of outcome variables, few writers have considered the question, "What does it mean to be successfully socialized?" Moschis (1987) suggests that, "an individual can be said to be socialized when he or she has learned to think and feel according to society's expectations" (p. 23) or "wise or unwise" decisions (Moschis and Moore 1984). Norms prescribed by contemporary Western society for purchase and use of products include energy conservation, budgeting and comparison shopping.

However, people who adjust successfully to a new community may use a diversity of tactics to achieve a desired consumption level. For example, in the remote community studied here, several people said they had difficulty finding the kind of bread they wanted. Adaptive strategies included learning to bake one's own bread, finding a nearby mail-order source, and searching until a small store was found which carried an acceptable substitute. Similarly, many people resolved their dissatisfaction with local medical and dental services by systematically "going outside" to receive care. Adjustment tactics are idiosyncratic and it may not be possible to identify the best or most correct behaviors.

This ambiguity can be described in terms of the role orientations identified by Van Maanen and Schein (1979). The custodial orientation involves learning customary strategies and prevailing norms associated with job requirements. In contrast, an innovative orientation involves "an effort to locate new knowledge on which to base the organizationally defined role or improved means to perform it" (p. 229).

Moving to a new region requires learning the "local resident" role--in this case, the role of Alaskan resident. A custodial orientation may be possible if one moved to a tightly-knit community where one's neighbors were demographically and psychographically similar. More commonly, individual households will be idiosyncratic in many consumption decisions. Van Maanen and Schein (1979) also note that an innovative role orientation is most likely to result when socialization is one-on-one rather than collective, informal rather than formal, and random rather than sequentially defined. As few if any communities offer group socialization as structured as a company training program, the type of socialization available is likely to result in an innovative role orientation.

Therefore, people can be expected to develop their own consumption heuristics and learning of specific knowledge will not be uniform. Other models of organizational socialization identify outcomes relating to job satisfaction and willingness to remain in the organization, operationalized as self-report measures (Jones 1986). Similarly, successful socialization will be measurable in terms of self-reported feelings of adjustment, satisfaction, and reluctance to move.

Anticipatory Socialization

Consumer researchers have studied the way children learn attitudes and values about adult roles and behavior, such as career and product ownership expectations, as well as how these expectations shape consumer behaviors (Moschis and Moore 1984). More generally, anticipatory socialization allows people to learn about roles they expect to enact in future (Heiss 1981; Thornton and Nardi 1975); for example, graduate schools often allow students to practice role behaviors relevant to their future professions.

When relocating to a new community, anticipatory socialization will often be voluntary: people will read about the new community and seek out information from people they know. A house-hunting trip or packet of information from the employer or Chamber of Commerce may supplement this activity.

Agents of Socialization

Parents, peers and school often serve as socialization agents for children and adolescents. The mass media also socialize consumers to a variety of roles. Within an organization, people have an opportunity to observe fellow workers and supervisors. When relocating to a community, agents of socialization will include neighbors, coworkers, new friends, members of groups--even strangers one encounters in the supermarket. Most communities, including the one studied here, have some equivalent of Welcome Wagon, a merchant-sponsored source of local shopping information.

To a large extent, people moving to a community will have some control over their interactions with others, and even more control over the decision to seek them out for advice and information. Participation in Welcome Wagon is voluntary, requiring newcomers to allocate time to meet with a representative.

Identity

While children learn consumer roles for the first time, adults bring a pre-existing identity to each life event. Because moving to a new community involves learning a new role, this pre-existing identity may be challenged or reinforced. Van Maanen and Schein (1979) contrast the investiture process, which reinforces the previous self, with divestiture, whereby people must give up a previous identity in order to acquire a new one. Divestiture has been discussed extensively in connection with total institutions (Goffman 1961) and training academies (Dornbush 1955). When people feel they have to give up part of their previous identities to join a new community, they can be expected to feel alienated. On the other hand, feelings of self-esteem and self-efficacy, associated with investiture, can facilitate socialization (Jones 1986).

Commitment

By joining a new organization or community, people realize they will be identified with a new label. Commitment has been expressed in terms of identification (cf. Ashforth and Mael 1989) with

organizational goals and values as well as pride in announcing that one belongs to the organization. A widely used commitment scale (Porter et al. 1974) incorporates both of these dimensions.

When moving, people can internalize the values of the community and also enjoy talking about their new citizenship. This identity will be especially salient when people live in places that seem unusually interesting, dangerous or mysterious, such as Hawaii, New York City, or Alaska. Cuba (1987) noted that people often didn't realize how much they identified with Alaska till they found themselves bragging to people they met outside the state.

Motivation

As noted above, socialization of children may involve shaping motivation, while adults tend to learn behaviors corresponding to this existing motivation. Schein (1968) suggests that successful organizational socialization will depend upon an individual's motivation to join; he cites the strong example of the fraternity pledge who is motivated to tolerate a variety of "uncomfortable socialization experiences."

The discussion of specific topics reinforces the importance of motivation, because the person experiencing socialization as part of a relocation controls many aspects of the process. The decision to seek out information, interact with potential agents, and develop innovative approaches to problem-solving will depend on the individual's motivation to adapt to the community.

Consumer Socialization Criteria

This paper suggests that consumer socialization to a new place of residence will be considered successful if the relocated individuals

1. demonstrate knowledge of local brands and products;
2. indicate agreement with prevailing norms and heuristics associated with consumption; and
3. have developed their own mechanisms/heuristics for coping with consumption issues unique to the location.

Propositions

1. Motivation, expressed as voluntariness of the move, will be positively associated with commitment to the place of residence.
2. Commitment to the place of residence will be positively associated with
 - a. anticipatory socialization
 - b. investiture, i.e., reinforcement of previous identity
 - c. seeking out agents of socialization in the new community
 - d. successful socialization, expressed as
 - i) objective knowledge of products and brands and
 - ii) self-reported feelings of satisfaction and adjustment.

EXHIBIT
Occupations of Respondents

Professional	15
Student	24
Technical	12
Managerial	8
Clerical	14
Blue collar	1
Military	12
Other/Missing	15

Results of Pilot Test

A questionnaire was administered to a convenience sample of members of the university community and other residents of Fairbanks, Alaska (n = 94). Respondents (47% male) ranged in age from 18 to 56, with an average of 32.7 years. An occupational distribution is shown in Exhibit 1. Only people who had moved directly to Fairbanks at the age of 18 or older were eligible to complete the form. People who lived here during high school years could not be expected to experience consumer socialization directly, as they would be living with parents. People who first moved to "the bush," remote areas of Alaska, would have developed coping strategies unique to those quasi-wilderness areas.

Cuba (1987) studied adjustment to Anchorage, Alaska, in the 1980's as an instance of adjustment to life on a frontier. She found that many people considered Anchorage to be different from the rest of Alaska, but that people all over the state tended to identify themselves with the state rather than a particular city or part of the state. Therefore this study focuses on Fairbanks but most questions have been phrased in terms of "Alaska" rather than "Fairbanks." As Cuba (1987) observed, it is hard to forget that one is in Alaska: street and business names have Alaskan connotations and Fairbanks still retains the appearance of a frontier town.

Commitment was operationalized as an 8-item scale. Items on this scale are based on those used in the Porter et al. (1978) scale of organizational commitment. Two dimensions emerged from a factor analysis (Table 1). The first, "belonging," represents an internal sense of belonging to the area, the second an impression management aspect of "showing." The "belong" group sought out opportunities for anticipatory socialization and feel at home in the new community. The "show" group displays souvenirs and signs of membership in the community.

The four items which loaded on each commitment factor were summed. Based on median splits of scores from each scale, four categories of respondents were identified: a "booster" group, those who scored high on both scales; a "belong" group, which scored high only on the first dimension; a "show" group which scored high only on the second dimension; and a "reluctant" group which fell below the median on both dimensions. These groups did not differ significantly with respect to age or gender.

Motivation was measured by summing scale items relating to voluntariness of decision to come, Alaska first choice location, looked forward to coming, anticipated an adventure, and expected to hate it (reverse scored). These items loaded on a single factor which accounted for 62% of the variance (Table 2). Booster, belong and show groups were not differentiated, based on a Scheffe test of multiple comparisons; the reluctant and show groups were also not differentiated. Thus, Proposition 1 appears to be supported, suggesting that motivation to come will be associated with commitment.

Anticipatory socialization was measured by two items: "Before moving to Alaska, I read about Alaska" and "avoided learning about Alaska" (reverse-scored). These items were significantly correlated (Pearson $r = .41$, $p < .0001$). While the univariate anova was significant ($F(3,90)=3.82$, $p < .01$), the four groups were not significantly different based on a Scheffe test of multiple comparisons (Table 3).

Investiture and divestiture were measured by seven items. Two scales emerging from a factor analysis (Table 4) represent investiture and divestiture, respectively. Investiture represents positive change which builds on previous strengths, such as "changed in positive ways" and "developed new interests and hobbies." Divestiture, which involves giving up essential aspects of the self, refers to personality changes and "resisted adapting my lifestyle to fit in." The booster group experienced lowest divestiture, significantly different from the others. The booster and belong group were not significantly different with respect to investiture, while the show group did not differ significantly from the reluctant group. Proposition 2b was supported with respect to "belonging" aspects of commitment.

Agents of socialization were identified by asking people to agree with statements about possible sources of information. Table 5 suggests that booster, belong and show categories learned from impersonal sources, such as newspaper ads, TV and Welcome Wagon. These sources require less interaction than other sources identified in pre-tests: learning from old-timers, observing other newcomers, offering advice, and asking friends for information. Interestingly, the "booster" and "show" groups reported learning more from personal sources than the "belong" and "reluctant" groups. Proposition 2c was supported.

TABLE 1
Commitment measures

	BELONG	SHOW
Would like to move away permanently (R).	.88	
Would miss Alaska if I had to leave.	.82	
Consider Alaska "home."	.76	
Would prefer to live elsewhere in winter (R).	.76	
Like to wear casual clothing that says "Alaska."		.82
Have Alaskan souvenirs and/or artifacts in my home.		.81
Find myself talking about Alaska often.		.68
Enjoy showing Alaska to visitors from the Lower 48.		.63

Varimax rotation. Two factors account for 68% of the variance.
Reliability (Cronbach's alpha) = .85 for belong, .74 for show.

Successful Socialization: Adjustment to Alaska

	HAVE ADJUSTED	RESIST MOVE
Found ways to obtain services I need.	.84	
Can find products I need to live comfortably.	.82	
Feel I have adjusted successfully to life in Fairbanks.	.80	
Learned ways to cope with cost of living.	.80	
Am satisfied with winter clothes.	.67	
Am satisfied with entertainment and culture available in Fairbanks.	.63	
Still feel like a newcomer to Fairbanks (R).		
Plan to move within five years (R).		.84
Plan to move within two years.(R)		.82
Plan to stay here a long time.		.64

Varimax rotation. Two factors account for 62% of the variance.

	Booster	Belong	Show	Reluct
Adjustment F(3,90) = 11.67, p < .0001 Cronbach's alpha = .88	33.4 ^a	29.9 ^{a,b}	28.6 ^{b,c}	25.2 ^c
Resist move F(3,90) = 15.04, p < .0001. Cronbach's alpha = .79.	10.9 ^a	12.0 ^a	7.7 ^b	6.0 ^b

Successful Socialization was measured by self-evaluation of adjustment and likelihood of moving. Table 6 indicates that boosters and belongers indicate greater adjustment than do show and reluctant groups, and they also plan to stay longer. Thus, the "belong" group feels more at home in Alaska and plans to stay. While a causal relationship cannot be inferred from this data, Table 2 suggests that these groups differ in motivation to come to Alaska. Therefore, people who liked Fairbanks and wanted to stay are highly motivated to seek out ways to satisfy their consumption needs. Proposition 2d was supported.

Local brand and product knowledge were assessed by a short vocabulary quiz, with a correct answer scored as 1 and incorrect answers scored as 0. Items were chosen to test respondents' knowledge based on one author's experience in moving to Alaska. During pretests, both newcomers and people who'd lived in Alaska since childhood were asked to suggest additional items. Table 7 indicates that booster and reluctant groups differ significantly with respect to product knowledge, with belong and show groups intermediate in knowledge. The reluctant group also obtained less general knowledge about Alaska than the others.

Agreement with norms and heuristics was evaluated based on a list of items generated by discussion with long-term Alaskans and by soliciting input from earlier pre-tests. Two norms that emerged related to acceptance of used ("recycled") clothing and furniture as well as beliefs relating to availability of

goods in Alaska. Surprisingly, there were no significant differences among the four groups. When only the most extreme groups--boosters and reluctant--were compared with respect to beliefs about availability of goods, the differences were significant (7.5 v. 6.1, p < .04, using a 3-item scale). Thus, while these norms do seem to reflect some correspondence with commitment, people seem to learn them to a similar degree. It is possible that these norms are so widely known that people learn them very quickly after moving to Alaska; a correlation between time in Alaska and the variable representing the sum of the scaled items was not significant.

Summary

In summary, the "show" group appears to be proud of their identity as Alaskans; however, they don't really enjoy living here and resist the cold weather. Their vocal praise of Alaska may reflect cognitive dissonance or a desire to wear the uniform without joining the service. They are more like long-term tourists than residents. The "belong" group have made a new home in Alaska; they were highly motivated to come and genuinely enjoy Alaska without seeking external validation from others. They are actually less familiar with some terms and brands, possibly because they are living the local culture rather than examining it. The pattern of differences among these groups is consistent throughout the socialization variables studied here.

TABLE 7
Product Knowledge

	Product Knowledge		General Knowledge	
	Booster	Belong	Show	Reluct
Product knowledge				
F (3,90) = 4.60, p < .005	9.1 ^a	8.9 ^{a,b}	8.6 ^{a,b}	7.6 ^b
F(3,90)=5.52, p <.002	7.2 ^a	7.1 ^a	6.9 ^{a,b}	5.5 ^b

Limits

Some limitations of this study suggest directions for further research. First, the cross-sectional nature of the study requires reliance on self-report data. A longitudinal study would allow better examination of causal relationships suggested here. Second, this pilot study used rather small numbers and simple data analysis. A larger study is planned, using members from diverse parts of the community, to gain deeper understanding into socialization behaviors.

IMPLICATIONS FOR FUTURE RESEARCH

First, the research could be extended to other parts of the U.S. Stereotypes are associated with many regions of the US--tough Alaskans, laid-back Californians, old-fashioned southerners, and conservative or dull midwesterners. Because Alaska's image is more uniformly positive than many other regions, differences between "show" and "belong" groups may be easier to spot, but these differences will probably exist elsewhere. For instance, a person may enjoy identifying with the "sophisticated New Yorker" or "laid-back California" images yet dislike significant aspects of actually living in those places.

More generally, this study reflects findings from other research on adult socialization (Brim 1966; Campbell 1975; Schein 1968). As noted above, this literature suggests that adults will control much of their own socialization and will build on earlier socialization experiences. Thus, people who wanted to move to Alaska and who proudly accepted the Alaskan identity found ways to adjust and consume effectively. They sought out socialization agents and created their own anticipatory socialization experiences. Motivation may also be important for other forms of adult socialization. For example, various authors have emphasized the importance of socialization to service encounters (Goodwin 1987; Mills and Morris 1986; Solomon et al. 1985). In a given service or retail setting, people who are motivated and who welcome the identity associated with being a customer may be more likely to teach themselves to be effective consumers. For example, in a health club setting, one segment of customers may resemble the "show" group described above: they wear fashionable fitness outfits and enjoy telling others about their exercise program. Another segment

may genuinely enjoy participation in club activities and make a long-term commitment to a program.

Marketing managers can focus on enhancing the perceived value of the service and the attractiveness of identity associated with consumption. Different strategies may be required to motivate each segment.

Recovering From Drug Addiction: A Phenomenological Account

Elizabeth C. Hirschman, Rutgers University

ABSTRACT

This paper presents a phenomenological account of recovering from drug addiction through the support of Narcotics Anonymous. Themes such as opening and closing rituals, self-identification as an addict, the credo of identifying, not comparing, maintenance of the boundary 'clean' versus 'dirty' and the development of a surrogate family/community bond are discussed. In addition, the paper interprets the dynamics of group discussion. Recovering From Drug Addiction:

Drug consumption and drug addiction are two of the major social problems confronting consumers (Brister and Brister 1987). Every year thousands of consumers die from drug addiction, and thousands more enter detoxification and/or rehabilitation facilities (U.S. Department of Health and Human Services 1987). Detoxification and rehabilitation programs are designed to help the addicted consumer rid his/her body of the physical dependence on addictive substances. But they cannot live the recovering addict's life for him or for her. The recovering addict must somehow come to grips with the underlying emotional problems, issues, and inadequacies which compelled him/her to *become* an addict (Beattie 1989; Cermak 1986; Johnson 1980).

Many detoxification centers and virtually all rehabilitation facilities encourage their clients to enter a 12-Step program while in treatment and to continue in this program when formal treatment is completed (Johnson 1980; Hazelden Foundation 1985, 1974; Brownell, Marlatt, Lichtenstein and Wilson 1986; Gravitz and Bowden 1985; Wallen, Weiner, Mansi and Deal 1987). Twelve-step programs were originated in 1935 by the founders of Alcoholics Anonymous (A.A.). They are a system of emotional and spiritual recovery designed to help the recovering addict come to grips with the sources of his/her addiction (which generally lie in feelings of personal inadequacy and emotional disconnectedness), to make amends to those whom s/he harmed during addiction, and to provide a lifelong communal support group which accepts the recovering addict on his/her own terms.

There is a spiritual component to the 12-step system, which is derived in part from Christian theology, but, as will be described, this is not necessarily adopted in a theistic or religious sense by members. Currently, there are over 10 national programs derived from the original A.A. 12-step system. Among the most well known of these are: N.A. (Narcotics Anonymous), C.A. (Cocaine Anonymous), G.A. (Gambling Anonymous), S.A. (Smokers Anonymous), O.A. (Overeaters Anonymous) and Al-Anon and Ala-teen, which are designed for the families and children of alcoholics.

I chose to join N.A. because there were several meetings available, it was conveniently located, and there were people there I felt comfortable with. This

paper is based upon my experiences in N.A., both as participant and as an observer. It provides a phenomenological account of how recovering addicts relate to one another -- and to themselves -- within a communal support group.

The two N.A. chapters I attended (and still attend) are different in member composition. They are also different in structure, as well. One is what is termed a Step meeting, which means that each meeting we cover a particular step of the 12-step program. Hence, in 12 weeks, we have cycled through Steps 1 to 12 and are ready to begin again at Step 1. Not everyone in the meeting moves through the steps at that pace, however; in fact few do. Rather, each member moves at his/her own pace; further, some members drop out, and new members are continuously added, so that the group discussion of Step 4, for example, will be somewhat different every time that step is reached. There are usually between 10 and 25 people present at this meeting. The age range is from 17 to 55; it is predominately white and has a mixture of working class to upper middle class attendees. About one-third to one-half the attendees are female.

The other meeting I attend is what is termed a Speaker-Discussion meeting; in it a recovering addict (with at least two months' 'clean time') speaks for 20 to 30 minutes at the beginning of each meeting. This is termed 'sharing.' After s/he has spoken, the meeting is opened for all in attendance to share their thoughts, concerns, and feelings. This meeting usually attracts between fifteen and thirty attendees, approximately one-third are black or Hispanic and about one-fourth are female. The age range is from early twenties to mid-forties and the group is usually evenly divided between working and middle class.

Despite their differences in structure and composition, however, the two types of N.A. meetings exhibit some strong commonalities which are important for understanding how the fellowship functions. Among the most significant of these are (1) the opening and closing rituals, (2) self-identification as an addict, (3) the credo of identifying, not comparing, (4) maintenance of the boundary 'clean' versus 'dirty,' and (5) the development of a surrogate family/community bond. Each of these is described below:

Opening and Closing Rituals

Meetings of N.A. open with the Serenity Prayer¹, which may appear somewhat cliched to the non-addicted reader, but actually has substantial relevance to recovering addicts. Recovering addicts must accept the fact that they are not like other people -- they are compulsive (see O'Guinn, Faber and Krych 1987; O'Guinn and Faber 1989). They cannot change

¹God, grant me the serenity to accept the things I cannot change, the courage to change the things I can, and the wisdom to know the difference.

TABLE 1
Who Is an Addict?

Most of us do not have to think twice about this question. WE KNOW! Our whole life and thinking was centered in drugs in one form or another -- the getting and using and finding ways and means to get more. We lived to use and used to live. Very simply, an addict is a man or woman whose life is controlled by drugs. We are people in the grip of a continuing and progressive illness whose ends are always the same: jails, institutions and death.

TABLE 2
What Is the Narcotics Anonymous Program?

N.A. is a nonprofit Fellowship or society of men and women for whom drugs had become a major problem. We are recovering addicts who meet regularly to help each other stay clean. This is a program of complete abstinence from all drugs. There is only one requirement for membership, the desire to stop using. We suggest that you keep an open mind and give yourself a break. Our program is a set of principles written so simply that we can follow them in our daily lives. The most important thing about them is that they work.

There are no strings attached to N.A. We are not affiliated with any other organizations, we have no initiation fees or dues, no pledges to sign, no promises to make to anyone. We are not connected with any political, religious or law enforcement groups, and are under no surveillance at any time. Anyone may join us, regardless of age, race, sexual identity, creed, religion or lack of religion.

We are not interested in what or how much you used or who your connections were, what you have done in the past, how much or how little you have, but only in what you want to do about your problem and how we can help. The newcomer is the most important person at any meeting, because we can only keep what we have by giving it away. We have learned from our group experience that those that keep coming to our meetings regularly stay clean.

TABLE 3
Why Are We Here?

Before coming to the Fellowship of N.A., we could not manage our own lives. We could not live and enjoy life as other people do. We had to have something different and we thought we had found it in drugs. We placed their use ahead of the welfare of our families, our wives, husbands, and our children. We had to have drugs at all costs. We did many people great harm, but most of all we harmed ourselves. Through our inability to accept personal responsibilities we were actually creating our own problems. We seemed to be incapable of facing life on its own terms.

Most of us realized that in our addiction we were slowly committing suicide, but addiction is such a cunning enemy of life that we had lost the power to do anything about it. Many of us ended up in jail, or sought help through medicine, religion and psychiatry. None of these methods was sufficient for us. Our disease always resurfaced or continued to progress until in desperation we sought help from each other in Narcotics Anonymous.

After coming to N.A. we realized we were sick people. We suffered from a disease from which there is no known cure. It can, however, be arrested at some point and recovery is then possible.

this, but rather must accept it and learn to live their lives within certain boundaries. The most significant of these boundaries is that they must not resume the consumption of potentially addictive substances. Thus, N.A., as well as other 12-step programs, is premised upon *abstinence* from those things over which the consumer is believed to have no ability to control his/her behavior (e.g., drugs and alcohol). The text of the prayer also suggests that the recovering addict is responsible for changing aspects of his/her behavior that would improve the chances of

continued recovery and improved relationships with other people. In large part, this means taking responsibility for one's actions and making amends to those one has injured during addiction.

Following the Serenity Prayer, most groups read "Who is an Addict" [Table One], "What is the N.A. Program" [Table Two], "Why Are We Here?" [Table Three], and "How It Works" [Table Four]. These texts, consistent from one meeting to the next, provide the context within which the group will discuss the issues which are raised. They are very similar in function to

TABLE 4
How It Works

If you want what we have to offer, and are willing to make the effort to get it, then you are ready to take certain steps. These are the principles that made our recovery possible.

1. We admitted that we were powerless over our addiction, that our lives had become unmanageable.
2. We came to believe that a Power greater than ourselves could restore us to sanity.
3. We made a decision to turn our will and our lives over to the care of God as we understood Him.
4. We made a searching and fearless moral inventory of ourselves.
5. We admitted to God, to ourselves, and to another human being the exact nature of our wrongs.
6. We were entirely ready to have God remove all these defects of character.
7. We humbly asked him to remove our shortcomings.
8. We made a list of all persons we had harmed, and became willing to make amends to them all.
9. We made direct amends to such people wherever possible, except when to do so would injure them or others.
10. We continued to take personal inventory and when we were wrong promptly admitted it.
11. We sought through prayer and meditation to improve our conscious contact with God as we understood Him, praying only for knowledge of His will for us and the power to carry that out.
12. Having had a spiritual awakening as a result of these steps, we tried to carry this message to addicts, and to practice these principles in all our affairs.

the liturgy at a Protestant church service, setting forth common articles of faith and providing a ritualized entry into a communal mind-set in which the group will operate.

At the close of each meeting, the group members rise, form a circle, join hands and recite the Lord's Prayer. Although some members are uncomfortable with this practice intellectually and/or religiously (e.g., E.B., *N.A. Way Magazine*, 1990), most accept its textual *propositions*, if not its underlying Christian theology. The central idea is, as in the Serenity Prayer, not to attempt to control events that are beyond the recovering addict's ability; rather, the recovering addict is encouraged to make amends to those s/he may have damaged during addiction (i.e., "forgive us our trespasses"), as well as forgiving those who may have contributed to the addiction in his/her life (i.e., "as we forgive those who trespassed against us"). The textual portions concerning the avoidance of temptation and "deliverance from evil" are also significant to the recovering addict, who confronts a lifetime of resisting the desire to return to addiction.

Self-Identification as an Addict

After the opening texts are read, each attendee is asked to introduce him/herself. This is done on a first-name only basis, to maintain anonymity, and is always followed by the statement: "I am an addict." Whenever an attendee speaks, s/he must preface

his/her remarks by again stating a first name, followed by the declaration "I am an addict."² This public self-identification as an addict is very difficult for newcomers, many of whom are still struggling to come to terms with the stigma of being an addicted consumer. However, the verbal self-labeling *within the N.A. group* serves as a powerful source of achieving commonality and permits recovering addicts to come to grips with the reality of their condition, as well as reminding each one how easily recovery can be lost.

To Identify, Not Compare

One of the principal credos of the N.A. fellowship is to 'identify with other addicts, not to compare.' This is derived in part from a passage in the N.A. program statement: "We are not interested in what or how much you used, what you have done in the past, how much or how little you have, but only in what you want to do about your problem and how we can help" (*Narcotics Anonymous Handbook*, 1988, p. 9). The value expressed by this statement, and reiterated in the credo, is that all addicts share in common the *phenomenological experience of their addiction*. Each addict knows, regardless of what substances s/he used, no matter how long or under

²Or "I am an addict and alcoholic," "I am cross-addicted," etc.

what conditions, irrespective of socioeconomic status, race, age, gender or ethnicity, what it is to be addicted. And it is this existential knowledge that is their common bond. Non-addicts do not, and *cannot*, possess this knowledge, whereas all addicts do. In existential terms, this is the *dasein* of addiction: the *being there*. Addicted consumers, whether in recovery or still active, have all been there.

The credo, to identify not to compare, thus reminds members of the fellowship that their task is to empathize with what other members are sharing with them, and not to assume a critical, judgmental, or evaluative posture. Thus, within the dynamics of group interaction, criticism of what others have said is not permitted. Only supportive or suggestive comments are made. Within the N.A. tradition, it is not deemed appropriate (or functional) for one recovering addicted consumer to judge the thoughts, actions or words of another. It is believed that to do so would inevitably lead to cliques fragmented along drug-of-choice, economic, age, racial or gender lines.³

Clean Versus Dirty

In a phenomenological sense, perhaps the most important dialectic experienced by addicted consumers is clean versus dirty. Recovering addicts are *clean*; they have rid themselves of the substances, behaviors, attitudes and thoughts that contaminated (e.g., Douglas 1966) them during their addictions. Conversely, consumers who are still active in their addictions are viewed within this ideology as *dirty*; as profaned and polluted (e.g., Douglas 1966). In the phenomenological consciousness of the recovering addict, the world is full of potentially polluting contexts and substances that must be guarded against vigilantly. The boundaries of the body, in particular, are to be guarded from the entry of polluting substances; but the mind also is seen as a locus where potentially polluting thoughts and desires (termed 'wrong thinking') may enter and cause relapse.

Body Boundaries. There were several instances provided by the recovering addicts to whom I spoke of attempts to control body boundaries. Two (h, f, 27; w, m, 24) refused to permit novocaine injections during dental surgery, preferring to experience pain rather than "have drugs enter my body." Another recovering alcoholic (w, m, 25) is afraid to rinse his mouth with Scope mouthwash, because it contains 13% alcohol: "I'm just afraid that once that alcohol taste gets in my mouth, I'm a goner... I still have dreams where I wake up tasting bourbon in my mouth." Another recovering alcoholic (w, m, 24) reported refusing to eat some spaghetti sauce his mother had made because she had "poured some beer into it to kill the acid taste... She told me the alcohol was all cooked out, but it didn't matter. The beer was in there, and I wasn't eating it." Similarly, another recovering alcoholic (w, m, 29) became very upset when he learned the cake he had

eaten at a friend's house was flavored with Amaretto liqueur: "I just don't want alcohol to be in my body ever again." A recovering female addict (b, 27) "hates to get a cold, because when I do I won't take sinus medication. It makes me drowsy and reminds me of when I was using [drugs]."

Mental Boundaries. Just as recovering addicts seek to protect their bodies from polluting substances, they may also attempt to prevent polluting thoughts from entering their consciousness. The type of thinking which causes recovering addicted consumers the most concern is re-entry of the belief that they can control their consumption through willpower, as other (non-addicted) consumers do. One recovering heroin addict (w, m, 26) told me he had been having strong urges recently to "pick-up" (i.e., to use drugs). He kept "having fantasies that if I could just get my life where I wanted it -- a nice house, a great car, some money, a beautiful girlfriend -- then it would be o.k. for me to use again, 'cause I could control it." Sadly, he was not able to resist these thoughts and has now returned to heroin addiction. Another young woman (w, 28) has been clean for a year and is now "beginning to have thoughts that I could handle social drinking again. I see everybody else do it, and I think 'I bet I could do that too'; but I couldn't. When I was drinking I hurt myself very badly."

N.A. as Surrogate Family/Community

Consumers' addictions often originate in dysfunctional family life; and virtually all to whom I spoke had damaged or destroyed interpersonal relationships through their addictive behaviors. Thus, when they begin the process of recovery, many find themselves alone and friendless. N.A. provides them with a surrogate family and community which accepts them as they are, and serves as a source of nurturance, guidance, and support. As noted earlier, the opening and closing rituals, the concept of sharing one's thoughts and feelings, the credo of identifying/not comparing, and the establishment of a common bond through the phenomenological consciousness of addiction all serve to create a communal atmosphere within the group. One's sharing of oneself within the group generates a sense of self-transcendence closely akin to the Durkheimian notion of *sacredness* (Durkheim ed. 1961; Belk, Wallendorf and Sherry 1989; Csikszentmihalyi and Rochberg-Halton 1981).

However, the N.A. fellowship reverberates with a more religious form of sacredness, as well. Although explicitly non-denominational, it is fundamentally theistic; its textual materials make several references to a Higher Power, construed by many members to represent God. Some members are uncomfortable with these religious trappings (e.g., E.B., *N.A. Way*, 1990), and choose simply to find solace in the communal aspects of the fellowship, rather than in theism, per se.⁴

³It should be noted that there are some N.A. groups which are all-male or all-female, however, I am aware of none that are segmented along social class or racial lines.

⁴In response to the desire of some recovering addicts to attend non-religious support groups, several agnostic recovery networks are now available.

Theology aside, an N.A. meeting does rely upon Christian church metaphors and practices to help maintain a sense of sanctity for its mission. Meetings open and close with prayers, the meeting place itself is referred to as "these rooms" in metaphorical reference to a sanctuary, contributions are collected in a straw basket reminiscent of offertory practices in Protestant churches, and members in unison recite texts akin to liturgical passages in a worship service. All of this is in keeping with the central ideology underlying N.A., and indeed, all 12-step programs. That is that addicted consumers suffer from emotional and spiritual inadequacies, often springing from incomplete or absent bonding within their families as children.⁵ Their addictions will only be truly cured when these emotional and spiritual inadequacies are remedied. N.A. seeks to do this by providing a family, a community, and a spiritual outlet to which addicted consumers can belong without fear of rejection or abandonment.

Group Dynamics

The dynamics of the N.A. group are perhaps best understood by example. Partial summaries of group discussions for Steps One, Three, Nine, and Twelve are provided below, together with interpretive commentary.

Step One. This step requires addicted consumers to admit that they were powerless over their addictions, that their lives had become unmanageable. Cathy, a pretty, 25 year old, blonde woman is the first to speak. She states that she is "halfway through" this step. Her sponsor has encouraged her to "write it," and she is doing this. Writing down her experiences about drug use has made her realize how miserable her life was when she was using: "I used to do terrible things to myself, and I let other people do terrible things to me..." Now she feels "better about herself" and wants to regain her sense of self-worth and "do healthy things." She was at a wedding reception recently and her brother, who is still an active addict, tried to get her to do some drugs there. This made her feel very uncomfortable. She also had to watch many of her friends and relatives drink alcohol. She left the reception early, because she couldn't bear to be around so many people who were "using;" she was afraid she would give in to temptation. However, she now feels guilty that she left and was not doing the "socially appropriate thing" by staying.

Barbara (w, 40) comments on what Cathy had to say. She tells Cathy that she did a very healthy thing by leaving the reception and should not feel guilty about it. Her "self-preservation must come first," and "it took a lot of courage to leave and not give in to the social pressure" to conform by drinking. Barbara notes that there are many social occasions

where drinking is expected of people -- e.g., weddings, restaurants, cocktail parties -- and that it is made to seem normal, so that people who don't drink are made to feel abnormal. This makes life very difficult for recovering alcoholics. Barbara also states that "any friend who tries to entice a recovering addict to try drugs/drinks is certainly no friend," and Cathy should feel no guilt in refusing them.

Rod (b, 28) shares that he has been clean now for 6 weeks. He has been to N.A. before, but has relapsed each time. He feels much more confident about this attempt to stay clean, because he is now contributing to/and participating in the group. Before when he came to a meeting he would just "sit in the back like a shadow and never share anything... I had lots of good things to share, but I never did. Now, I've learned to speak up."

Another young woman (w, 25) relates how her mother, who was having memory problems, just underwent brain surgery that morning. The woman is very glad she is now sober so that she can deal responsibly with her mother's problems. Now that she is no longer drinking, she is able to feel appropriate emotions. When she was drinking, she was unable to feel -- in fact, she often drank "to escape from having to feel."

A young man (w, 30) has been clean for 16 days. He had been thinking about getting clean for 8 months, and finally entered a detox center. He had a difficult day yesterday. He was moving out of one house (where he had used drugs) to another residence. He had a hard time organizing his thoughts and deciding how to pack and what to take. Then his date for a concert fell through at the last minute. He was unsure if he wanted to go by himself, but he went anyway. A lot of people were drinking beer at the concert, but he was not tempted. He recalled a time a few months earlier when he had returned home from a party about 2 a.m. His roommates were doing lines of cocaine and invited him to have some. He was tired and wanted to sleep, but he did some anyway. By 4 a.m., he "was so wired I felt my heart was going to explode." This scared him and has helped him stay off drugs.

A woman (w, 35) shares that she was a drug abuser for 20 years but kept avoiding acknowledging it. She has been in psychotherapy for 4 years and only now is acknowledging to her therapist that she was an addict. As part of her therapy, he has had her write the story of her drug use in four chronological installments (5 years each). As she has done this, she has "revealed to herself the great extent and depth" of her addiction. Reading this chronicle helps to "keep her honest" about her earlier life on drugs and remain clean.

Michael (w, 50) comments that when he was in rehab, his counselor had him do the same thing. Michael found this very constructive, because when he talked with his counselor he would rely on the term "you know" to cover the undesirable details of his addictive behavior. For example, he would say "I would drink at a party and then... you know." Having to write down the details glossed over by "you know"

Among these are Rational Recovery and the Secular Organization for Sobriety (Gelman 1991).

⁵One knowledgeable reader commented, "Is it just lack of bonding? What about inadequate experience to enable learning of how to give emotional support to another human being?"

forced him to confront the most troubling and repressed aspects of his addiction.

Commentary. The themes surfacing in the group seem to revolve around two of the primary concerns among recovering addicted consumers: (1) maintaining abstinence from addictive substances in the face of their widespread availability, and (2) consciously confronting, acknowledging, and learning to accept the self-destructiveness of their earlier addictive behavior. Recovering addicts are often at risk of giving in to their own impulses and social customs to "use." They may feel self-conscious that they cannot have a drink at a celebratory ritual or social gathering like 'normal' people (often termed "normies"). The social awkwardness and emotional anxiety they experience in such situations often places them in the same frame of phenomenological consciousness they experienced during their addiction. Hence, the fear of relapse is very great -- and very real. Sharing these feelings with people who have had similar experiences helps greatly to restore a sense of commonness and normalcy. The recovering addict is reassured that it is better to 'stay clean,' than to give in to the impulse to fit-in socially by 'using.'

Often recovering addicts, even though aware of their earlier status as active addicts, experience difficulty in fully surfacing the extent and depth of their addictions. This is attributed to the remnants of the *denial* mechanism (e.g., Johnson 1980), which was in force during their active addiction and which, even in recovery, acts to protect them from having to consciously acknowledge the self-destructiveness of their earlier behavior. Many recovering addicts find that *externalizing* the story of their addiction by writing it down and telling it verbally to another person has an extremely cathartic effect.⁶

Step 3. This step states that addicted consumers must make a decision to turn their lives and wills over to God. Doris (b, 30) opens by sharing a story about herself and her cousin, the person who had originally introduced her to drugs (heroin). Her cousin had been in jail for drug-related crimes, during which time Doris had gone into recovery, gotten clean and joined N.A. Her cousin was released from prison last Monday and the first thing she did was call Doris up and ask if she could stay with her. Doris wanted to say no because she feared her cousin's negative impact on her own recovery, but she was afraid her cousin had nowhere else to stay and might end up on the streets. So she said yes.

When her cousin arrived at her house, she was already high on heroin ("noddin"), but Doris let her sleep on her living room couch. Her cousin's presence in the house made Doris nauseous and have diarrhea; she felt "just like I always did when I'd be shooting up the day before, but not have any stuff [heroin] the next day." Doris took this as a sign from her Higher Power that her recovery was at stake and that she must persevere in keeping clean. The next day her cousin left, but Doris is afraid she will return. She wants to tell the cousin no, but is afraid to offend her/not help

her. The next night Doris went to bed at 9:30 p.m., so that if her cousin came to her house, she would already be asleep and would not be tempted to get high. She is struggling with the dilemma of how to be supportive of her cousin and still maintain her own recovery.

Stuart, a handsome blonde young man (25), complains that since he has overcome his addiction he has become much more financially successful (he now makes \$45,000), but that instead of dealing with his emotional problems he "just throws money at them. If I'm having a bad day I can afford to just go see a movie to forget about it, rather than really working it out."

Tracy (w, 20) comments that she is having trouble with Step 3 because she does not believe in God in a religious sense. She does believe there is a power greater than herself ("than the human species"), but not in a traditional religious sense. She likes N.A., however, because she wants to be part of the group. She feels "comfortable and loved" here. Doris agrees that she too does not believe in God as her Higher Power. Her Higher Power is "the N.A. fellowship... the people who are here; that's who I believe in."

Lorie (w, 25) comments that she has just recently learned to understand what the phrase "one day at a time" means. "It means I only let myself worry about what's happening *that day*, not the next day, or next week, or next year. I only live this day and I can only do things that are happening this day... My father is having surgery on Friday and I was very worried about it, but I realized it's only Tuesday. My worrying today is not going to have any effect on what happens to my father on Friday. So I'm going to worry Friday about what is happening to my father on Friday... I used to carry the whole world's burdens on my shoulders, but I've learned to only carry one day's worth now."

Finally, Tim (w, 35) comments that he had a bad run-in with someone that day. A man had come down to the factory and yelled at him about something that was not directly his fault. However, although he had gotten in some "good [verbal] punches" back at the man, he did not lose his own temper. "I realized the guy had had a bad day himself, and he was going to tell somebody about it, so I figured it might as well be me." Tim reports that he is also struggling with co-dependency.⁷ "In my family, I was always the 'Fixer,' whenever something went wrong, I would always try to fix it. I still always try to fix things for my girlfriend... But a lot of times people resent it; they need to do it themselves."

Commentary. The discussion at a step meeting sometimes follows and sometimes digresses from the topic step. Doris and Stuart are using the meeting to

⁷Co-dependency refers to a behavioral syndrome in which one person (the codependent) attempts to control the actions and moods of another person by always seeking to please that person and anticipate his/her demands. Spouses of addicts, battered women, and even traditional housewives may exhibit the codependency syndrome (see Beatty 1989).

⁶These are steps 4 and 5 of the program.

externalize personal concerns and problems, the common subtext of which has to do with self-control and life management. Doris' problem is perhaps the most poignant in that it details vividly the difficulties which recovering addicts from lower SES backgrounds must face in maintaining their recovery. In Doris' social milieu, it is expected that she will provide shelter for her cousin. Yet, her cousin is not only an active addict, but the person who helped initiate Doris' own addiction. Doris' physical discomfort at her cousin's presence -- and her equating of it to her addictive experiences -- demonstrate her emotional upheaval at being placed in such a conflicted situation.

The subtext of Stuart's complaint that he now "just throws money" at his problems surfaces his concern that he is merely substituting a socially acceptable form of compulsive behavior (i.e., spending money) for a negatively sanctioned compulsion, drug addiction. The comments by Lorie and Tim relate more directly to the Step 3 topic, albeit in a somewhat discursive way. Both of these recovering addicts are trying to learn to "just let it go"; that is, to not attempt to exert control over all events/persons/situations that affect their lives. Tim is also still struggling with a tendency to not only attempt to control events in his own life, but also to control the lives of those with whom he has emotional ties. This is termed *co-dependency* (Beatty 1989; Cermak 1986); and is a dysfunctional psychological syndrome found in a segment of addicts -- most commonly those who had to care for (and attempt to control) substance-dependent parents when they were children.

Finally, as the comments by Tracy and Doris indicate, N.A. members do not necessarily subscribe to the Christian theology found in some N.A. materials. Note that both of these recovering addicts place the locus of the sacred aspects of N.A. within the *communality of the group*, rather than in a transcendent deity. Thus the bonding they rely upon resides at an interpersonal, not theistic, level.

Step 9. This step requires that the addict go to those people whom s/he has harmed and make amends to them. Maria (h, 30) begins the discussion by sharing that she has been trying to make amends to her sister from whom she is estranged due to her addiction. Her sister recently came by to see her, and Maria tried to be friendly and make amends, but her sister [in Maria's perception] was very rude and critical. This hurt Maria, but she is glad that she at least tried to make amends. Maria also tells us that her mother is opposed to her getting another job in a restaurant, fearing that it will set off her alcoholism again. Maria reluctantly agrees: "For me to work in a restaurant [where there is a bar] is like putting a junkie in a drug store."

Sarah (b, 23) is a graduate student at an Ivy League university. She feels under "extraordinary pressure" to study and do well. She is unhappy in the town in which she is living [to go to school] and seems to have made few friends. She wants to use drugs again. She began taking caffeine pills to study and work harder, and now finds she "can't stop taking them. I just take them to take them."

Barry (w, 22) says that "all this talk about graduate school has really got me worried... I'm still working on my G.E.D." This gets a big laugh from the group. Barry shares that he recently found a capsule of speed on the ground. He picked it up and smelled it. Fortunately, it no longer smelled like speed, for if it had "I'm afraid I would have taken it."

Jon (w, 24) shares that he has been feeling guilty about something. He was the liaison between two people, and he purposely manipulated the flow of information in such a way to serve his own selfish needs and purposes. "I was very manipulative of the situation, and it reminded me of how I acted when I was using [drugs]." He asked his sponsor what to do and the sponsor told him to "give the person you manipulated power back over his own choices." Jon did this and now he feels better.

Natalie (w, 25) is a new mother. She has been having difficulty adjusting to her new responsibilities and restrictions. She shares that her mind "wanders a lot" during the day when she is home alone with the baby. She feels she is not receiving enough appreciation from the baby and her husband, both of whom are at the meeting. The baby requires constant care and she is always anxious that something could go wrong: "In just one minute my baby could drown." She also feels that people [i.e., her husband] do not respect her opinion on things. "They just ask me hoping that I will agree with what they already think. If I don't, they disregard what I say or dispute it."

Ken (w, 25) shares that he is now at a new job. The past week he has been in the training program, but he is "somewhat paranoid" about the training instructor. He believes that the instructor may have found out that he is a former drug addict from his medical forms. "When the guy put on a training film about 'Don't Do Drugs,' he looked right at me... I know he knows I used to be an addict..." Ken says that "all my life most people haven't liked me... The only person that likes me now is my daughter [18 months old]; she's really happy when I go and see her, unless I am gone too long. Then she acts like she doesn't know me..."

Doris (b, 30) shares that her confidence is growing in her ability to advise other friends who are still on drugs, but that she still suffers from self-doubt. "I say to myself, who am I to tell this person how to live their life... I've only got 8 months clean time... But then I say, well, I am in recovery and I am working the program, so maybe I can help."

Commentary. The discussion by the group focuses upon two kinds of amends -- amends to others and amends to oneself. Maria and Jon are both struggling with re-establishing ties to other people. Maria still seems to need to see herself as the victim ("my sister was very rude"), even though she had originally estranged her sister through her addiction. Jon, conversely, fears that his old, manipulative behavior patterns may be resurfacing in his recovery. At a deeper level, he may also fear that this signals the possible return of his active addiction, as well. He is anxious to 'set things right,' again.

Maria, Sarah, and Barry are sharing with the group their anxieties about the ease with which they

could return to active addiction. For Maria, this would be signalled by her accepting another job as a restaurant manager. Sarah, who was on amphetamines as an active addict, has already compromised her recovery by consuming caffeine pills, another central nervous system stimulant. Barry's chance encounter with a discarded speed capsule has brought him right to the edge of resuming his addiction. He was "saved" by their lack of the distinctive scent, which served as an olfactory trigger for Barry.

Natalie and Ken are both facing common challenges imposed by the real world on recovering addicts. Natalie must learn to face the often overwhelming and thankless tasks of being a new mother. Now she is responsible not only for her own recovery, but for the well-being of her child, as well. Doubtless, this puts great pressure on her to return to her addiction. Ken fears being found out as a former addict. Now beginning a new career, he is fearful that his past may reach forward and destroy his chance of a normal life. Doris displays the ambivalent mixture of self-doubt and self-confidence that is found in many recovering addicts. She vacillates between feeling she is not even able to care for herself and feeling comfortable with assisting other addicted consumers to begin their own recoveries.

Step 12. The 12th Step deals with spreading word of the N.A. program to 'still-suffering addicts.' Doris (b, 30) opens the discussion by saying that although she is "nowhere near the 12th Step" in her personal program, she has already helped a few other addicts to obtain help by advising them and helping place them in appropriate rehab and detox facilities. This has "helped me feel good about myself." She repeats the N.A. adage: "We can only keep what we have by giving it away to others."

Next, Barbara (w, 40) shares her concern over a close female friend who is a binge drinker and drug user. This friend knows Barbara is in N.A. and has talked to her about addiction. Barbara has advised her to stop using alcohol and drugs completely, since the friend seems to be unable to use either (especially alcohol) in moderation. The friend told Barbara that she has been able to greatly curtail her drinking. However, last month Barbara learned that the friend is again binge drinking, experiencing blackouts, and driving while intoxicated. She is very concerned and conflicted over what to do for her friend. She does not know whether she should call and pressure the friend to begin attending N.A. meetings. She fears for the friend's safety and believes that the friend also might kill/injure someone else.

A newly recovered addict (w, m, 30) advises Barbara to help her friend as much as possible. He says at least four of his friends, plus his mother, had to "keep after him" for six months before he finally went into rehab. He had to be convinced by others that his drinking was abnormal, before he could recognize it himself. He is "very thankful his friends cared enough" about him to keep telling him he needed help; otherwise he believes he would have simply kept denying it to himself and making excuses to not change his behavior. A second man (w, 30) gives just the opposite advice. He fears that any attempt by

himself to help a still-active addict might threaten his own recovery. "I've only got enough strength to keep one life preserver afloat and that's mine. I don't want anyone else dragging me down."

A young woman (w, 28) advises Barbara that her friend may resent and resist her efforts to help. This young woman was arrested three times for DWI; each time she would tell the judge that she wasn't an alcoholic, but was only going through a particular crisis which had 'forced' her to drink: e.g., her parents divorced, she broke up with her boyfriend. Finally, on the third drunk driving arrest she was ordered into rehab. Once there, she realized that she was an alcoholic -- that she responded to virtually any problem by drinking. She advises Barbara that the friend must not only need to recover from addiction, but must also *want* to recover from addiction. Until the friend wants to help herself, Barbara's help will be rejected.

Tracy (w, 20) advises Barbara that it might be constructive not to force her friend to label herself as an addict; Tracy had felt "too weak and vulnerable" earlier to carry such a heavy label.

A final piece of advice comes from Jon (w, 28). He agrees that addicts must want to get better, but notes that they often need a great deal of support to be able to recognize their own addiction. They also can greatly benefit from suggestions as to what treatment alternatives are available and how they can get access to them (e.g., N.A. meetings). He, in essence, advocates what Doris has already been doing, i.e., helping to guide people into appropriate treatments.

Commentary. Perhaps one of the most significant acts a recovering addict can engage in is to assist a still-active addict into recovery. Besides being a socially beneficial behavior, these acts also help to reconfirm in the recovering addict his/her own decision to leave active addiction and lead a clean life. Every act of helping another addict, therefore, becomes a reaffirmation of one's own choice for recovery.

Recovering addicts are, in a phenomenological sense, perhaps the best equipped of the people an active addict comes into contact with to communicate the need for and possibility of recovery from addiction. The advice of friends and family may be dismissed by the active addict as irrelevant, because these people are seen as unknowledgeable about the experience of addiction and, in some cases, may even be viewed by the addicted consumer as causes of his/her addiction. Similarly, the warnings provided by medical and law enforcement personnel may be seen by the addicted consumer as infringements on his/her freedom to choose. Some addicts may see these persons as representing political values contrary to their own and, therefore, purposely attempt to counteract these efforts to curtail their addictive behavior.

However, it is much more difficult for an active addict to dismiss as naive, ignorant or misplaced the concern of the former addict. Phenomenologically, the recovering addict *has been* where the active addict now *is*, and chose to leave it. This simple phenomenological fact can be the most convincing

piece of evidence to active addicts that they should and can achieve recovery.

CONCLUSIONS

Recovering from addiction, like becoming an addict, is a process that involves a series of personal choices made over an extended period of time. In many ways recovery is like a voyage of discovery that seeks to reintegrate a self that has been in various stages of disintegration -- often for many years. The value of the fellowship of N.A., and other support groups like it, is that it provides both a haven and a testing ground for the reintegrating self. Often upon seeing the anxiety and uncertainty of newcomers to the group one is reminded of oneself earlier in recovery. Often upon hearing some particularly insightful words from an oldtimer one is inspired to keep going forward with one's life -- one day at a time.

Helping the Homeless: A Radical Consumer Behavior-Oriented Solution

Ronald Paul Hill, Villanova University

ABSTRACT

The purpose of this paper is to discuss a growing segment of the new homeless population in the United States using a consumer behavior approach. First, historical perspectives of the homeless are provided to establish the rationale for traditional thinking regarding this portion of society. Second, recent consumer research involving homeless persons is discussed in order to reorient our thinking regarding the homeless. Finally, a radical solution to solve part of the homelessness problem is provided based upon this revised understanding.

INTRODUCTION

The problem of homelessness has become one of the most urgent social and political issues of our time (King et al. 1989). Current estimates of the number of homeless persons on any given night range from 600,000 to 3 million (Whitman 1989). However, an additional 4 million to 14 million "nearly homeless" American families are living in crowded apartments with friends or family. The American Affordable Housing Institute projects that even a mild recession will disturb this precarious balance and cause homelessness in this country to double or triple overnight (Rich 1989).

Such a portrait is quite different from recent time periods. From the post-depression era to the 1970s, American homelessness declined dramatically (Rich 1989). Skid row areas reduced in size, number, and population, becoming the residence of mostly single, alcoholic, adult men. However, a number of factors, including sharp cutbacks by the Reagan administration in subsidies for construction of low-income rental housing, created a new, more diverse homeless population that is quite different from the past (Brown and Krivo 1989; Koegel, Farr, and Burnam 1986).

The purpose of this paper is to discuss a growing segment of this new homeless population using a consumer behavior approach. First, historical perspectives of the homeless are provided to establish the rationale for traditional thinking regarding this portion of society. Second, recent consumer research involving homeless persons is discussed in order to reorient our thinking regarding the homeless. Finally, a radical solution to solve part of the homelessness problem is provided based upon this revised understanding.

HISTORICAL PERSPECTIVES OF THE HOMELESS

In a recent literature review, Blau (1988) provides an excellent historical analysis of the ideology of the causes of homelessness in the United States over the last hundred years. In chronological order, six distinct categories of literature are identified: 1) Social Darwinism and the homeless, 2) Progressivism, 3) the on-the-road genre, 4) studies of homelessness during the Depression, 5) functionalist

sociological research, and 6) current perspectives of the homeless.

Social Darwinism and the homeless became popular in the last quarter of the nineteenth century in the wake of the 1873-1875 depression which left three million people unemployed. This ideology suggests that charity to the homeless was generally "indiscriminant almsgiving" and personal weaknesses, such as alcoholism, were the main causes of homelessness. For example, Wayland (1877), speaking at the 1877 Conference of State Charities, referred to able-bodied persons without homes as "tramps" and equated them with professional thieves. He recommended that tramps be provided only with the bare necessities, be segregated by sex to avoid their propagation, and be compelled to perform "useful" work. During this time period, even the ignominious funerals of these "paupers" came to signify their exclusion from the remainder of society, and marked them as failures (Laquer 1983).

Progressivism is a kind of Reform Darwinism based on a more compassionate view of the homeless (Goldman 1952). Anderson (1923), who was homeless for a period of time as well as a graduate student in sociology at the University of Chicago, viewed the homeless as individualistic and egocentric, as modern Ishmaels who resist social discipline and conventional social life. In a nonjudgmental fashion, he states that the reasons for homelessness include: 1) unemployment, 2) physical handicaps, 3) personality defects, 4) life crises, 5) discrimination, and 6) wanderlust. However, the establishment of labor colonies and work tests (a case work method that judged the homeless harshly) during this period suggests that the progressives were more lenient in their writings than in their recommendations or actions (see Hunter 1904).

The on-the-road genre contains two distinct groups: social activists as tramps and tramps as social activists. The former group usually was composed of members of the upper classes in society who went on the road to document the squalid conditions of the homeless (Anderson 1923; Chesterton 1926). While they often raised the public's consciousness, the reforms they advocated were mild at best. On the other hand, tramps as social activists tended to view homelessness as an opportunity for self-discovery and adventure, an almost spiritual experience (Mullin 1925; Jennings 1932). However, this approach provides little in the way of understanding of the possible causes of homelessness.

Depression era studies were a response to the tremendous economic and social consequences of the Depression which left millions of people out of work and homeless. Such studies posited two interrelated theories of homelessness: the economic theory and the demographic theory (Sutherland and Locke 1936). The economic theory is concerned with business failures, reduced wealth and incomes, and unemployment. The demographic theory attempts to

explain why, given these conditions, some individuals continued to work, have shelter, or accepted relief while others became homeless. While no blame is implied in these distinctions, value judgments based on traditional conservative thinking still were widespread among the public, resulting in typical negative stereotypes of the homeless.

In the late 1950s, the homeless became an area of research interest among functionalist sociologists. A positivist approach, functionalist sociology assumes a homeostatic social system, and the homeless aroused interest since they managed to survive outside of its boundaries. Merton (1957) suggests that the homeless adapt to the social environment through "retreatism", a condition where an individual is barred from success within society and subsequently retreats to drugs, psychosis, or skid row. Interestingly, the homeless often were viewed as a threat by functionalist sociologists precisely because they withdraw from society (Bahr and Caplow 1973). Their fear is that if a group can exist outside of the social system, the system itself may be in jeopardy.

The growth of homelessness in absolute size as well as visibility in the 1980s gave rise to a proliferation of reports on the homeless. This material can be categorized loosely as falling into two groups: original advocacy research and government-sponsored reports. Advocacy research often mixes moral witness and education in an attempt to change the stereotypical view of the homeless as weak-willed and at fault for their condition (Katz 1989; Ropers 1988). To accomplish this goal, it explores the structural factors in society that lead to homelessness, and describes the homeless as the "human waste of a disposable society" (see Hombs and Snyder 1983; Hopper and Hamberg 1985). Government reports take a different approach and tend to treat homelessness as a housing issue leading to a host of other social problems. Despite their diverse political purposes, most of these reports cite unemployment, deinstitutionalization, drug addiction, and the scarcity of low-cost housing as the primary causes of homelessness (National Mental Health Association 1988).

One major problem across these perspectives is the view of the homeless as helpless and unable to cope with personal or environmental circumstances. While recent research suggests that certain subpopulations such as the elderly, children, and the severely physically or emotionally ill may be unable to survive on the streets (see Hill 1991), other investigations identify a large and potentially growing segment that has developed quite extensive survival strategies. It is this group that we address in this paper.

THE HIDDEN HOMELESS AS SECONDARY CONSUMERS

In a recent *JCR* article, Hill and Stamey (1990) describe their ethnographic experience with the "hidden homeless," a subpopulation of homeless persons who choose to live on the streets, often beyond public scrutiny, rather than in shelters or public places such as subway stations (see *New York*

Times 1991 for an excellent example of this lifestyle). They collected data in a wide variety of settings including abandoned buildings, bridge abutments and tunnels, shantytowns, public parks, and automobiles used primarily for shelter. During this study, Hill and Stamey (1990) examined how possessions were acquired by looking at nontraditional employment strategies, scavenging activities (e.g., rummaging through public garbage containers), and why some products were purchased while others were scavenged. Further, they looked at the types of possessions consumed, and examined the approaches used by the homeless to obtain food, clothing, shelter, and personal hygiene/health care products as well as tools that were used to facilitate search, acquisition, storage, and consumption of these products. Finally, they considered how community among the homeless impacted consumption and its importance to protection of self and possessions, sharing of limited resources, and social interaction.

Three significant interpretive themes emerged from this research. In the first theme, the hidden homeless were portrayed as a "nomadic society," characterized by a reliance upon "nature" to provide the necessities of life, mobility to cover an area wide enough to provide sufficient quantities of needed items, and flexibility to adjust to changing opportunities as they are revealed within the environment (see Chris Drake 1990 for an additional source). The second theme centered around self-concept development by the hidden homeless. According to Hill and Stamey (1990), this segment of homeless persons is able to maintain some self-esteem by distancing themselves from the more dependent categories of their peers (e.g., "shelter dwellers"), and by living independently of welfare institutions. Finally, the third theme compared the meaning of possessions to the hidden homeless with middle-class Americans. The authors found that these homeless persons, when compared to average citizens, held different perceptions/lower expectations regarding what constitutes acceptable housing, and developed a sense of pride from the construction rather than purchase of their home (see Belk, Wallendorf, and Sherry 1989 and Wren 1991 for additional findings that parallel this interpretation).

One implicit theme that permeates these results is that the hidden homeless are a resourceful, determined, and capable group that proactively deals with the lack of available resources in their consumer environment. They often differentiate themselves from shelter users and feel that such facilities are used by the most destitute or the insane. Thus, this segment of the homeless tends to view themselves as surviving by their own wits and abilities.

SOCIAL AND PUBLIC POLICY IMPLICATIONS

The research by Hill and Stamey (1990) provides a sharp contrast with the work of Lewis (1966) by suggesting that many homeless persons take an active role in determining their life choices. However, this perspective of the homeless should not suggest that they are without need. Many go hungry

frequently and find themselves without shelter on a regular basis. Further, the most needy - for example, the mentally ill and the physically disabled - are the least likely to devise and employ the survival strategies described. Nevertheless, this study suggests that, as a society, we need to find methods of support that allow the homeless to maintain their dignity and independence (see Fabricant 1988).

One suggestion is to provide ways to help the homeless avoid the spiral down the housing chain from "housed" to "homeless." In order to halt this process, affordable housing should be made available in the communities where homelessness is most likely to occur so that people can escape this inevitable decline. The research of Hill and Stamey (1990) suggests that many homeless persons expect and require less in a shelter than the typical consumer. Nonetheless, the provision of basic shelter that provides a warm, safe, sanitary, and somewhat private refuge may help the homeless improve the quality of their day-to-day lives by allowing them to refocus their efforts on other important needs. The development of a "homeless village" with a first aid clinic, police mini-station, kitchen facilities, learning and training centers for youth and adults, shelter, and heated lean-tos for those unwilling to live inside has been proposed for the city of Philadelphia (Donald Drake 1990). Such a complex could be placed in resurrected abandoned buildings in the hearts of most cities, and could help the homeless cope with special problems that arise for families or the chronically ill.

Additionally, attempts by governmental agencies to encourage the homeless to accept "mainstream" employment opportunities generally have resulted in failure. One such program, Project Worth in Louisville, Kentucky, found that only five percent of the homeless who entered a special training program were employed one year after schooling (Kilborn 1990). Therefore, instead of seeking to change the patterns of behavior of the homeless, governmental authorities should actively encourage current alternative work such as the recycling performed by the subpopulation discussed by Hill and Stamey (1990). This form of nontraditional employment provides the homeless with a sense of independence and the city/town/suburb with a natural mechanism for dealing with their enduring problems with garbage. To facilitate such endeavors, the authorities should consider subsidizing redemption centers, providing convenient public buildings for the homeless to use as redemption sites, and equipping the homeless with the tools necessary to effectively scavenge.

Of course, such a program is not without problems. The vision of an army of homeless persons rummaging through public garbage containers would frighten most citizens (see Ablow 1991 for an example of fear of the homeless). However, procedures for successful and legitimate search could be established that limit such activities while still providing an opportunity to earn money. An alternative to recycling that may avoid some of these problems but also allow them to maintain their

independent lifestyle is the sale of the paper *Street News* by homeless persons (Adweek 1990; Donaton 1990). Started in New York City in late 1989, the paper is sold exclusively by homeless persons who are allowed to keep 55 cents per copy. In the first four months of operation, the newspaper's sales force grew from 125 to more than 1000 homeless men and women, and plans have been made to expand operations into 15 additional cities including Washington, D.C., San Francisco, Philadelphia, and Newark, NJ.

The provision of food and water requires different strategies. Such goods need to be made available on a regular basis if the homeless are to survive and continue to function in an independent capacity. The efforts of the government with food giveaway programs and soup kitchens are currently insufficient. Adequate supplies are rarely available in times of peak demand, and the variety or quality of these rations generally is poor. Thus, alternative methods of supply need to be considered.

One possible solution is to encourage private businesses to dispense excess foodstuffs to the homeless on a continuous basis. Many restaurants, bakeries, and grocery stores already engage in such activities. However, retailers may be concerned that the homeless will "invade" their establishments in search of food, and consequently frighten their patrons. One way around this problem is to have one or more central locations within a community where retailers can drop off food and the homeless can come to receive provisions. Second Harvest, which collects foodstuffs from manufacturers and grocers, distributes \$700 million worth of food annually through such a program (Schlossberg 1989). Local governments can enhance this distribution process by providing public buildings for storage and dissemination, and tax incentives to donating firms.

Obviously, not all of the homeless will be able to take advantage of these opportunities. As mentioned earlier, due to physical and/or mental illness as well as problems associated with substance abuse, some persons may require greater attention. Unfortunately, the current system of support through the municipal shelters and local mental and physical health clinics is inadequate. Many homeless persons would rather risk freezing to death on the streets than stay in the shelters. Further, many make use of community health facilities as a last resort rather than as a means to maintain or improve their functioning. Thus, more humane facilities that treat the homeless with dignity, reduce the "red tape" associated with utilization, safeguard cherished possessions, and facilitate physical and mental health through quality care are needed.

There are no easy solutions to the problems of the homeless. Clearly, more resources are needed. However, a more important change that may be necessary is perceptual (Gibbs 1990). Unless lawmakers as well as private citizens believe that all members of our society have the right to clean, safe, and sanitary shelter, nutritious and palatable food, and consistent and high quality health care provided in a dignified environment that allows for independent

living, the outlook for significant reform is doubtful (see Pear 1991 for a pessimistic look at the treatment of the homeless by public officials under a 1987 law designed to provide additional housing options).

Marketplace Estrangement and Consumer Theft

Anthony D. Cox, Indiana University
Dena Cox, Indiana University

In 1954, sociologist Gregory Stone showed that not all consumers' store patronage behavior was determined by utilitarian motives like price and convenience. Instead, he found that many consumers felt a sense of allegiance or kinship with stores owned by people from their own community and would patronize these stores out of ethical or social motives. In the 35 years since Stone's study, however, large corporate chains have increasingly displaced or acquired local family-owned stores: first in major cities, and more recently in small communities. Further, almost all of these mammoth retailers have eschewed the traditional personal contact between buyer and seller in favor of high volume, self-service operation.

During the same span of time, another change has occurred. The incidence of consumer theft and fraud from retailers has grown tremendously. Shoplifting alone has grown at twice the rate of consumer purchases and now results in retail losses of \$12 billion per year. Fully 60% of consumers now report that they have shoplifted.

This paper explores the possibility that these two trends are connected. We argue that the epidemic of consumer theft is not solely a security issue, but may reflect fundamental changes in the way consumers view the marketplace. We will examine sociological research showing a widespread tolerance toward crime against "socially distant" or abstract victims, particularly large corporations. We will also explore the relationship between some traditional marketing constructs (such as store "personality" and "loyalty") and consumer theft. Finally, the paper discusses how retailers might stem the tide of consumer theft - not by bolting down the merchandise, but by re-examining the way in which they interact with consumers and communities.

Consumer Behavior in Coping Strategies for Divorce

James H. McAlexander, Oregon State University

John W. Schouten, University of Portland

Scott D. Roberts, Old Dominion University

When considering the affect divorce might have on consumer behavior, scholars find themselves in surprisingly ill-charted territory. With notable exceptions in the "revised" family life cycle literature (Gilly and Enis 1982; Murphy and Staples 1979; Venkatesh 1980) our understanding of consumer behavior is almost entirely based on the intact family, with divorce being only observed as a variation from the norm. In fact, more than thirty percent of first marriages are affected by divorce (Berman and Turk 1981; Trafford 1982; Weiss 1975). The gap in understanding divorce and its impacts on consumer behavior is therefore something that demands more investigation (McAlexander 1991).

In an in-depth qualitative study of divorce and consumer behavior it is observed that divorce and consumer behaviors are interrelated in many important ways. This presentation explores one facet of that interrelationship, namely, how consumer behaviors appear to be used to assist in coping with the stresses of the divorce transition.

CONSUMING AS COPING

Recent work studying how consumer behaviors function as coping mechanisms during role transitions have offered some interesting early glimpses of the phenomenon. For example, McAlexander and Schouten (1989) identified how consumers maintain and manipulate personal appearance to assist them in coping with difficult life transitions. Roberts (1991) noted in a study involving laid off steel workers that consumption often played a major role in their adjustment to unemployment. Hill and Stamey (1990), in their examination of homeless consumers detail a number of consumer behaviors that assist the homeless in coping with the day-to-day struggle of living in a socially marginal and frequently perilous state.

In the present study, data analysis identifies a number of different ways in which consumer behaviors are integrated into strategies for coping with the stresses that accompany divorce. These strategies were identified as: personal stability zones, situational grouping, anticipatory socialization, and identity experimentation.

Anticipatory socialization is a strategy that allows a person to gradually bridge a discontinuity in advance to and in preparation for the full assumption of a new role. In our sample, examples of the use of anticipatory socialization as a coping strategy include a lawyer, who, while studying for the bar exam, spent extra energy investigating divorce law. Another example was provided by a husband who persistently pushed his wife to enroll in school. He was easing his unannounced departure by surreptitiously preparing her to become a self-supporting single parent.

A *personal stability zone* can be thought of as a familiar reference point in a time of stress (Hopson

and Adams 1976). For individuals involved in difficult transitions, personal stability zones include preserved vestiges of prior roles that are familiar and comfortable. Informants in our study used possessions like old furniture and photographs to connect them to a familiar point in their past. These possessions evoked feelings of connection to their former life structures and engendered a sense of continuity in their lives.

Situational grouping involves seeking mutual support among other people experiencing the same type of transition (Hopson and Adams 1976). For example, some informants in our study joined formal organizations like Parents Without Partners. Membership in such organizations provides opportunities for the divorced to meet and gain emotional support from people experiencing similar situations. In addition, informants found informal support groups within adult student associations, singles bars and their places of employment.

In divorce people sometimes experience a remarkable sense of freedom to experiment with personae and activities formerly unavailable to them within the structures and confines of their marriages. Through *identity experimentation* they try on and test possible selves (Markus and Nurius 1986) that may prove useful in the reconstruction of post-marriage identities. Such experimentation acts as a coping mechanism to the extent that it satisfies a need to consolidate an ambiguous or emergent identity and create a new, meaningful life structure. This appears to be especially important for informants who felt oppressed or overshadowed by their former spouses. Certain experimental behaviors also function in playlike fashion as an emotional release. Among the goods and services incorporated into the identity experimentation of our informants were illicit drugs, vacations, recreational equipment, new clothing and hairstyles, new automobiles, and new social activities.

CONCLUSION

Consumer behaviors play an important part in the divorce transition. Since neither the consumer behavior literature nor the divorce literature affords much insight into this topic, the interrelationship between divorce and consumer behavior would seem to be a fertile area for further research. For example, future research might explore how the tenor of the divorce affects and is affected by consumer behaviors, how individual roles played by spouses within the divorce affect consumer behavior. Future research might also offer a more processual examination of consumer behaviors through different phases of the divorce transition. Finally, a fuller understanding of consumer behaviors during the divorce transition may provide helpful insights for service providers, such as

lawyers and counselors, who may be interested in easing the divorce transition.

The Cigarette Advertising Controversy: Assumptions About Consumers, Regulation, and Scientific Debate

John E. Calfee, Boston University
Debra Jones Ringold, University of Baltimore

The U.S. cigarette market is surely one of the most thoroughly studied markets in history. The reasons are not hard to find. This market has been blessed with a conveniently short history (mainly since 1914) and copious data on production and sales (thanks to the tax system). A perennially fascinated advertising trade has provided data on advertising and promotion. Persistent market dominance by only six firms (four before the mid-1930s), repeated attention from antitrust authorities, and the prominent use of advertising as a competitive tool have made the cigarette market a natural target for studies of monopoly and competition. Finally, the periodic arrival of staccato bursts of health information, often followed by striking regulatory interventions, have had the effect of creating a series of fascinating natural experiments in oligopolistic competition and regulatory impact.

It is now apparent that the cigarette market has produced yet another natural experiment: the more or less overt adoption by consumer researchers of varied theories of consumer behavior, varied theories of regulation, and possibly, equally varied approaches to the use of scholarship in debate over public policy.

THEORIES OF CONSUMER BEHAVIOR: "SMART" CONSUMERS OR "DUMB"?

The recent literature on cigarette advertising and public policy reflects two distinct views of consumer behavior. One approach, well exemplified in the work of Cohen (1989a and 1989b) and Pollay (1989, 1990), views advertising as a powerful influence that consumers are ill prepared to resist. Let us call this the "dumb consumer" model of consumer behavior. In this model, consumers passively receive advertising messages and - if these messages are persistent and well crafted - passively succumb in large numbers to an almost unconscious impulse to purchase. A complementary role is postulated for public relations, which is seen as overcoming with ease the efforts of physicians and others to warn consumers of the dangers of smoking (Pollay 1990). Much of the potency of advertising and public relations is assumed to arise from fundamental deficiencies in consumer information processing. These deficiencies include short-sightedness or myopia, the discounting of small probabilities, and a reluctance to translate generalized risk information into personal risk. The result (according to this model) is that in the face of cigarette advertising and public relations, consumers systematically and drastically discount the health dangers of smoking, even if they routinely receive accurate health information from sources such as the United States Surgeon General. The dumb consumer model therefore predicts that regulatory interventions such as

mandated health warnings and limitations on advertising will have strong effects on the cigarette market.

We believe that the history of the cigarette market casts doubt on the validity of the dumb consumer model. The cigarette market has undergone a series of regulatory interventions that have focussed specifically on information. These interventions include a prohibition on health-related advertising in 1955, health warnings on cigarette packages in 1965, an end to broadcast advertising in 1970, health warnings in advertisements in 1972, and rotating warnings in 1984. These measures have apparently had little if any effect in reducing cigarette sales (cf. McAuliffe 1988; Calfee and Ringold 1990). The reason for this apparent lack of effects is almost certainly *not* that consumers systematically underestimate or ignore the health effects of smoking. Indeed, what seems likely is that from the very beginnings of the market (cf. *Consumer Reports* 1938 and citations therein) consumers have absorbed health information from many sources including parents, family, peers, physicians, the press, and popular culture ("coffin nails" is an old slang expression for cigarettes). As was pointed out when Congress prohibited broadcast advertising for cigarettes in 1970, there has never been strong evidence that advertising alone has carried significant weight in comparison to these other information sources, at least not when it comes to basic matters such as whether to smoke or how to rate the dangers of smoking (cf. Levitt 1970). Consumers have long since developed a deep appreciation of the potential dangers of smoking (cf. Calfee 1985). Data collected by the federal government's Office on Smoking and Health indicate that consumer awareness of the major health effects associated with smoking are now at extremely high levels, surpassing even governmental goals (Shopland and Brown 1987; U.S. Dept. of Health and Human Services 1990). Other work suggests that present-day smokers over-estimate (rather than under-estimate) the risk of lung cancer from smoking (Viscusi 1990).

Looking beyond the cigarette market to consumer markets generally, the dumb consumer model suggests that all sellers can routinely deceive consumers. The result should be a market-wide tendency toward deception, a tendency that should largely offset the otherwise beneficial nature of competition. This is an extremely powerful argument - too powerful, in fact. To claim that information processing deficiencies leave consumers helpless in the hands of sophisticated marketing is to imply that almost no market can work well, and that consumers will be subject to the whimsy of sellers in any market where advertising is prominent - and without broadcast advertising, cigarettes are well down on the "advertising-is-prominent" scale (cf. *Advertising Age*

1991, showing that in terms of advertising expenditures, the leading cigarette brand, Marlboro, ranks only 48th among all U.S. product brands, below such names as Tylenol, Ultra Slim-Fast, Circuit City, and Wrigley). The "dumb consumer" model therefore postulates a market process that cannot resemble efficiency, a market in which well established, vigorously advertised brands and products, however inferior, are nearly invulnerable to attack by new brands that (were it not for advertising) consumers would prefer to buy. But in fact, and contrary to the predictions of the dumb consumer model, markedly inferior products tend to succumb quickly to new and superior alternatives, as can be seen in markets ranging from automobiles to video games. The ancient aphorism, "nothing kills a bad product quicker than good advertising," would never have arisen from experience with dumb consumers.

In contrast to the "dumb consumer" model is what might be called the "smart consumer" model. This describes a world in which consumers use advertising rather than allow advertising to use them. Consumers instinctively mistrust advertising in the absence of supporting information such as experience with brands or retailers, and consumers must be "sold" before they buy. Thus consumers are simultaneously skeptical of advertising in general, yet willing to use advertising when it provides valuable information (cf. Calfee and Ringold 1988, 1992). Deficiencies in consumer information processing occur not in a vacuum but in a competitive environment. Sellers who find themselves placed at a competitive disadvantage by the oddities of consumer information processing have strong incentives to help consumers overcome their informational deficits. Sellers will be motivated to provide new information and to make it accessible - even if the new information is "negative" information that is likely to work to the disadvantage of the overall product market. This has happened in the cigarette market. During the 1950s, the combination of competitive instincts and new health information brought a wave of "fear advertising" about tar and nicotine and health effects of smoking generally. This advertising, which was spurred by competition and not by public health authorities, certainly scared smokers and probably reduced overall market sales. In the words of *Fortune* magazine, "Never before has an industry spent so much money trying to talk itself out of business. The 'commercials' keep reminding us that tobacco contains tars, resins, and other bronchial abrasives" (*Fortune* 1963; also see Calfee 1985, 1986; McAuliffe 1988; Ringold and Calfee 1990). Although the Federal Trade Commission has severely limited this kind of advertising since 1960, there are reasons to believe that in today's competitive environment, ad claims about tar and nicotine continue to remind smokers of the health dangers of smoking, as was pointed out some years ago by Schelling (1978).

Similar competitive dynamics have operated in connection with many other products, ranging from foods (where health claims about reduced fat and cholesterol have focussed consumer attention on what they do *not* want in foods; see Calfee and Pappalardo

1990 and Ippolito and Mathios 1990) to insurance (where claims about the financial security of certain firms can cause consumers to be alarmed about the safety of all insurance firms; see *New York Times* 1991). Over and over again, competitive forces have led advertising to highlight rather than suppress valuable information, even when that information reflects badly on the product being advertised.

There is a more general point: that consumers have always been vividly aware of sellers' incentives to exploit consumer ignorance, and that both consumers and sellers take these incentives into account when devising their marketplace strategies (Bauer 1958; Wright 1986). Buyers cast a skeptical eye on information from sellers. Sellers know this, and buyers know that sellers know it. So sellers realize they must eventually earn credibility in the marketplace, and lay plans accordingly. These insights can be combined with the large and growing literature on the economics of information, which describes how information courses through markets as a special kind of "product" (Stigler 1961; Nelson 1974; Ford and Calfee 1988 and references therein). The emerging result of these analyses is a vision in which competitive markets tend toward efficiency not only in the classic Adam Smith sense of production, distribution and pricing, but also in terms of information and consumer choices.

We believe that the smart consumer model is extraordinarily robust across cultures and through time. Perhaps what is most surprising is the degree to which this model applies to economies very different from that in the United States. If one looks at societies with amazingly weak consumer protection laws on, say, medicines, one finds that consumers who possess extremely little in the way of education or government information sources nonetheless carefully pick and choose among powerful drugs so as to avoid dangers that far more knowledgeable American consumers supposedly cannot deal with on their own (cf. Peltzman 1987, *Nigerian Hoechst Limited*, and *CIBA-Geigy Pharmaceuticals*). In Russia and Eastern Europe, where consumers have emerged wide-eyed from 40 or even 70 years of ceaseless anti-marketing propaganda, recent surveys show that these consumers are already equipped with attitudes toward markets and incentives that are essentially the same as the attitudes of American consumers (Shiller, Boycko, and Korobov 1991). Experimental studies of bargaining outcomes have also found striking similarities among citizens of nations as diverse as the United States, Israel and Yugoslavia (Roth, et al. 1991). It seems evident that wherever advertising is allowed, "smart" consumers - consumers who understand marketing incentives and use advertising to their own advantage - are the rule rather than the exception.

Thus there are two opposing views of how consumers respond to persuasive communications. The clash between these views is not new. Much the same dispute arose after World War I and its accompanying barrage of political propaganda. The dispute continued for decades, while the focus of debate slowly shifted from purely political advertising to commercial advertising. As described in the masterful

treatments by Bauer (1958, 1963), the depressing specter of hapless consumers victimized by organized persuasion is a vision that has often been described, but has never withstood scrutiny. Steady enhancements in the techniques of mass persuasion have not brought increasing commercial power over consumers, but instead have been met with increased sophistication and skepticism on the part of consumers. The effect is a market in which sellers must scramble to maintain credibility, rather than one in which consumers are simply victimized by whatever advertising claims come their way. These market dynamics should be taken into account when assessing the likely effects of advertising and promotion. Competitive advertising, like other competitive tactics such as price-cutting, can easily result in a stand-off between opponents, with little obvious change in market shares. If competitive dynamics are ignored, it is easy to fall into economic fallacies such as the commonly made argument that large advertising expenditures for individual brands necessarily cause either wholesale brand switching or an increase in total market sales (cf. Tye, Warner and Glantz 1987).

DOES REGULATION WORK? SHOULD WE CARE?

The cigarette market features unusually intense regulation of information (including warnings on labels and in ads, disclosure of tar and nicotine yield, prohibitions on broadcast advertising, and prohibitions on claims about health effects of smoking). Recent policy proposals argue that even stronger regulation (such as a ban on all cigarette advertising) would improve an otherwise defective market. We should therefore examine the topic of regulation itself, and in particular, the question of whether regulatory interventions improve markets. A natural companion to what we have called the "dumb consumer" model of consumer behavior is an optimistic model of regulation - a "dumb consumer/smart regulator" model, one might say. In effect, those who believe that consumers are bamboozled by advertising flim-flam are often prepared to supplant consumer judgments with the judgments of regulators. In making such recommendations, advocates of increased regulation typically treat regulation as if it were simply the rational result of disinterested public service, i.e., a well-crafted tool of enlightened public policy (American Medical Association 1986; Cohen 1989a and 1989b; Waxman 1991). That the result of increased regulation will be a net improvement for consumers is usually taken for granted, and the possibility that regulation will fail to improve the market is often ignored.

A second view of regulation is radically different. Regulation is viewed as the result of a political process, a process that begins with murky goals, meets pressure from numerous interest groups, undergoes intricate compromises, and finally achieves implementation in a form that may be entirely divorced from the original goals (to the extent that coherent goals existed in the first place). It is no wonder that analysts of the regulatory process refer to

the "law of unintended consequences," according to which the unintended costs of regulation outweigh the intended benefits. Hence regulatory failure is assumed to be more likely than regulatory success, unless and until contrary evidence emerges.

In the economic literature, these two approaches correspond roughly to the "public interest" theory of regulation, which assumes that regulation is wise and effective, and the Chicago school of regulation, which posits that the many interests served by regulation do not necessarily include those of the public at large (Stigler 1971). Debate over these opposing visions has given rise to a large empirical literature. This literature provides little support for a presumption that regulation is efficient or beneficial, and much support for the opposite view. In the history of major economic regulation at the federal level, for example, the gap between intentions and effects goes back at least to the renowned Interstate Commerce Act of 1887, which was designed to end the rapacious economic conduct of American railroads. Research has found that the ICC Act increased the stock prices of railroads, a result which strongly suggests that "the railroads welcomed regulation as a means for facilitating the enforcement of cartel-like agreements" (Prager 1989). Consumers were almost certainly losers under the ICC Act. Similar conclusions about more recent events have been reached by numerous studies of almost every major market in which regulation has been important (see Stigler 1975 or almost any issue of the *Journal of Law and Economics*, such as the one containing Coate, Higgins and McChesney 1990).

These remarks on the dubious benefits of regulation apply specifically to the cigarette market. Research has found that such major interventions as the 1960 FTC tar and nicotine ad ban and the 1970 broadcast ad ban strongly limited consumer benefits from informational competition, while often enhancing industry welfare (Hamilton 1972; Warner 1979; Schneider, Benjamin, and Murphy 1981; Calfee 1985, 1986, 1987; Schuster and Powell 1987; Mitchell and Mulherin 1988; Scheraga and Calfee 1991). Even the 1965 law that put warnings on labels has been criticized as worthless or worse (Drew, 1965). On the other hand, empirical documentation of benefits from these and other regulatory initiatives is scarce or nonexistent. It is clear that however one feels about the workings of the cigarette market in its present state, it would be foolish to assume without evidence that the next regulatory advance will improve the welfare of consumers.

PUBLIC ADVOCACY AND SCIENTIFIC DEBATE

Dispute among academics is inevitable whenever the spheres of science and public policy interact. The danger is that disputation will overwhelm science, to the detriment of scholars and consumers alike. Two problems are paramount. One is the substitution of *ad hominem* attack for reasoned argument - that is, attacks on scholars themselves (or on their ideology or their funding sources) rather than on the coherence of their arguments. The second

problem is the distortion of science itself. This more complex and more serious problem involves both misreading of research outcomes to support preconceived conclusions, and unreasoned attack on research for what it concludes rather than for its intellectual substance. These latter difficulties are simply too complex to deal with here, so we will stick with the first problem, which is more or less the personalization of academic debate.

Aside from being a sign of intellectual weakness (else why use this approach?), an *ad hominem* approach in debate about cigarette advertising would interfere with the process of arriving at better ideas and evidence. Three problems emerge. One is that the *ad hominem* approach - such as pointed inquiries into funding sources - will eventually stumble over itself. The process has no logical limit. There is always another suspicious factor to take into account. Large funding sources practically always have agendas, and policy evaluation research is therefore laden with the expectations of the funding source. For example, public agencies that advocate the printing of warnings on product labels surely hope that the research they support will find such labels to be effective. Of course, this expectation does not in itself eliminate the value of such research; rather, one must look at the substance of the research in order to assess its worth. The unfortunate result of ceaseless attention to researchers' motives is that all participants, targeters and targets alike, become distracted from the central issues whose resolution demands our full attention and more.

The second point is less obvious and more insidious. If one feels free to dismiss or discount arguments according to their source, a logical next step is to search for correlations between the content of arguments and the sources from which arguments emerge. Usually, such correlations will be found. Then, why not take a short cut? Why not simply assume that studies which reach certain conclusions are *likely* to have been funded by certain (suspect) sources, and therefore, *likely* to fall into a category that has already been judged as unworthy of attention regardless of content. One can then economize on intellectual effort by ruling out of the debate all research that reaches "incorrect" conclusions. The pernicious consequences of such an approach are too obvious to merit further discussion.

The third point, the simplest by far, is how to avoid the problem. We should all be judged by what we say, not by who we are or who we associate with or even whom we receive money from. Our own views on, say, "dumb" versus "smart" consumers, should be assessed according to the coherence of our argument and the quality of the evidence we have adduced. The same should apply, of course, to the arguments of those who take an opposing view. Unfortunately, there is reason to fear that this ideal state of affairs will cease to exist if and when the stakes in the debate (especially the financial stakes) become very large. Recent dispute over the health effects of exposure to asbestos, for example, suggests that when a product becomes engulfed in multi-billion dollar products

liability settlements, not to mention the prospect of government-mandated cleanup activities that will cost even more, the temptation to judge researchers by criteria other than the quality of their research becomes very great indeed; the courts have actually sought to prohibit certain experts from testifying purely because they participated in a certain academic conference (Stone 1991; *Wall Street Journal* 1991). Much the same thing is happening in connection with research on exposure to lead, where the financial stakes in terms of product liability and clean-up costs are also high (see *Science* 1991). Public debate based purely upon scientific merit remains an indispensable goal.

CONCLUSIONS

Consumer researchers of the cigarette market differ in their views of consumer competence and in their skepticism toward regulation. Much of the dispute resolves into a clash between confidence in regulation and confidence in market competition. This is not merely a matter of ideology, preconceived notions, or sources of funding. Different theories have different predictions. We believe the smart consumer model explains the dynamics of contemporary markets better than the dumb consumer model does. Market competition has proved to be more robust and beneficial - especially in connection with product information - than one might expect from a simple inventory of consumer information processing deficiencies. This is perhaps most striking in connection with information about the potentially adverse health effects of products, information that competitive advertising has repeatedly provided to consumers despite the potential to reduce overall demand for the product. Similarly, the optimistic view of regulation inherent in recommendations for increased regulation does not reflect the actual workings of regulation in either the cigarette market or in markets generally. Competitive advertising has consistently demonstrated its power to enlighten consumers without regard for the welfare of the industry doing the advertising, while regulation has tended to impede improvements in consumer information.

Sometimes, differences over science expand into a politicized attitude toward scientific debate. The result can be to judge research by its conclusions or by its source rather than by its quality. This is a self-defeating process that retards movement toward better understanding of both consumer behavior and the dynamics of the marketplace. The solution (not an easy one when vast amounts of money are involved) is to hold fast to the traditional academic focus on coherency of argument and quality of evidence.

Role of Affect and Need for Interaction in On-Site Service Encounters

Pratibha A. Dabholkar University of Tennessee

ABSTRACT

With the growing availability of computerized service delivery systems in on-site service encounters, customers are increasingly able to perform services for themselves. The issues for practitioners are whether customers will view such options favorably and what would determine their attitudes. A causal model drawing on information processing research and services literature is developed to address these issues. The model is tested and the data are analyzed using LISREL 7. A moderating effect of prior behavior is also hypothesized and is tested using a nested MANOVA and regression analysis. The findings support the hypothesized effects, contributing to theory development and providing implications for practitioners.

INTRODUCTION

In recent years there has been much innovation in service delivery and many service firms today offer customers the option to perform a service for themselves with the use of a machine. These options include services customers can perform for themselves from their homes, using a computer and/or telephone (e.g., home shopping or banking), as well as services they can perform for themselves on site, using a computerized service delivery system.

An early example of an on-site computerized service delivery system is the automated teller machine. Recent applications include computers in stores which customers can use to place their orders directly, ticketing machines at airports, closed-circuit check-out in hotel rooms, and touch screens for ordering in fast food restaurants.

A major issue to marketers who consider installing such service designs is whether or not customers would view such options favorably. Clearly, if they did view them favorably, service firms could experience substantial savings in labor costs (*Business Week* 1990; Lovelock and Young 1979).

Another issue is whether customers' familiarity with using similar systems has a bearing on how they view these computerized service delivery options (*The New York Times* 1989). If so, familiarity with computerized products could be used as a base for segmentation in providing such self-service options to specific targets.

A third issue relates to whether customers would be concerned about de-humanizing the service situation (Breakwell et al. 1986; Zeithaml and Gilly 1987). If this is a major concern, then marketers would be well advised to provide full service options alongside the new, computerized, self-service options.

This study investigates these practical issues in a fast food setting where touch screens are currently being tested as direct ordering options for customers (*Marketing News* 1990; *Nation's Restaurant News* 1991). A model is developed by drawing on information processing research and services literature and is tested with a student sample, a particularly

relevant sub-segment for fast food restaurants (*The Wall Street Journal* 1990). The data are analyzed using confirmatory factor analyses, nested MANOVA, and regression, and the results support the hypothesized model. The theoretical contribution of the study is discussed, as are implications for practitioners and for future research.

CONCEPTUAL FRAMEWORK

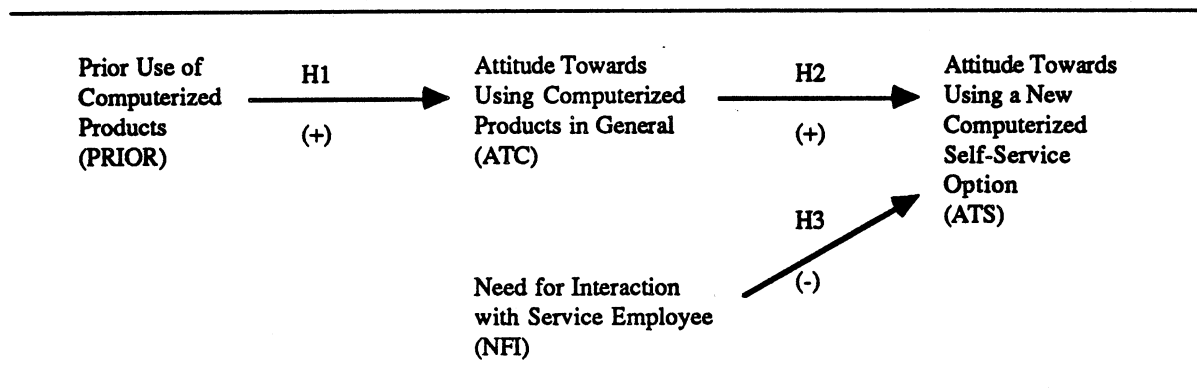

When faced with a new situation, people tend to draw on similar past experiences to make judgments about the new situation. This commonly observed phenomenon can be explained using the information processing paradigm (Johnson and Puto 1987; Bettman and Sujan 1987a), and the concept of category-based affect (Fiske 1982; Fiske and Pavelchak 1986; Sujan 1985).

Based on the information processing paradigm, individuals make and store cognitive representations (Lachman, Lachman, and Butterfield 1979; Johnson and Fornell 1987) about different situations, and also make judgments or overall cognitive evaluations about situations they encounter (Einhorn and Hogarth 1981). On confronting a new situation, they may recall earlier cognitive representations or judgments to evaluate the new situation. This is similar to stimulus generalization, an extension of Pavlov's classical conditioning theory. When an individual perceives a new stimulus, it is compared to similar stimuli in memory and is responded to on that basis.

Fiske (1982) and Sujan (1985) explain that prior behavior is associated with category-based affect. They propose that past behaviors are stored as an affective response and when a stimulus matches expectations, it triggers this category-based affect. The category-based affect is extended to the current behavior without a review of cognitive beliefs about the consequences of the current behavior (Bettman and Sujan 1987b). When the prior behavior is exactly the same as the current one, it can influence intentions or behavior directly; when the behavior is similar only in some respects to the current one, the affective response is likely to be triggered (Fiske 1982; Fiske and Pavelchak 1986; Sujan 1985). The new behavior will be viewed favorably or unfavorably depending on the nature of the category-based affect.

Prior behavior may be defined as the extent to which the individual has engaged in that behavior. For computerized service delivery systems, relevant prior behavior would include the use of products based on similar technologies (computers, ATMs, VCRs, etc.). People are more likely to have engaged in these activities than in using touch screens to order fast food, a relatively new option, with limited availability. Since these activities are similar to, but not the same as, using a touch screen to order fast food, prior behavior related to these activities is expected to influence some type of general category-based affect, such as attitudes towards using computerized products in general. The link between

FIGURE 1
Determinants of Attitude Towards New Computerized Self-Service Options

prior behavior and generalized attitude has been empirically supported as well (Dickerson and Gentry 1983). It is expected that a pre-conceived, positive, category-based attitude, in turn, would cause the individual to view a new, but similar, situation in a favorable way. Hence, the following hypotheses are proposed:

- H1:** Prior behavior with respect to using computerized products will have a positive effect on attitudes towards using computerized products in general.
- H2:** Attitudes towards using computerized products in general will have a positive effect on attitudes towards using a new computerized self-service option.

It would be interesting to consider whether a category-based affect exists towards self-service in general that could also affect attitudes towards using a new computerized self-service option. Although there is some evidence that people have different propensities to participate in service delivery (Langeard et al. 1981), it appears that this is largely situation-related (Lovelock and Young 1979). People may have a positive attitude towards certain forms of self-service such as filling your own gas or banking, but a negative attitude towards self-service in restaurants or home repair.

Researchers in services marketing (Bateson 1985; Langeard et al. 1981; Lovelock and Young 1979; Silpakit and Fisk 1985) have suggested that determinants of customer participation in self-service should be investigated in future research. A construct relevant to self-service versus full-service is the need for interaction. This refers to the need that some individuals feel for interacting with the service employee in a service encounter. Langeard et al. (1981) and Bateson (1985) found that the need for human contact in a service encounter was very important to some customers. Some people feel strongly that the use of machines in a service encounter dehumanizes the interaction (Breakwell et al. 1986). It is possible that these people may have a positive attitude towards using computers in their

homes, but may dislike the idea of using them in a service situation. Hence, it is proposed that:

- H3:** The need for interaction with a service employee will have a negative effect on attitudes towards using a new computerized self-service option.

These three hypotheses H1-H3 form a causal model indicating the antecedents of attitude towards new computerized self-service options. The model is presented in Figure 1 below.

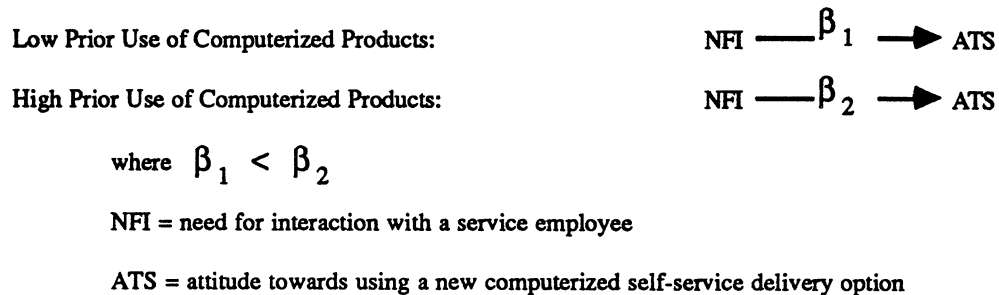

Attitudinal researchers (Ajzen, Timko, and White 1982; Oliver and Bearden 1985) recommend that in addition to developing attitudinal models, it would be worthwhile to explore moderating effects on linkages within these models. Researchers in information processing (Johnson 1989; Park, Iyer, and Smith 1989) also encourage investigation of moderating effects on relationships in information processing models.

On examining the variables in this study for possible moderating effects, it is noted that prior behavior would have a moderating effect on the relationship between the need for interaction and attitude towards the new option. This is based on the observation that greater familiarity with computerized products appears to make people comfortable with using them in any situation. Consequently, for these people, the need for interaction would become less important as a determinant of attitude towards new computerized self-service options (see Figure 2). Thus, the following hypothesis is proposed:

- H4:** Prior use of computerized products will have an attenuating effect on the relationship between need for interaction and attitude towards using a new computerized self-service option.

The literature does not suggest any gender differences in attitudes towards new computerized self-service options. However, two empirical studies did find gender differences that may be relevant for this study. Langeard et al. 1981 found that males showed a

FIGURE 2
Moderating Effect of Prior Use of Computerized Products

stronger preference for self-service options than did females. The authors linked this with the finding that males also tended to be more impatient and disliked waiting more. Breakwell et al. 1987 found that males had more positive attitudes towards new technology in general and believed technology would have more benefits for society. Based on these studies, two exploratory hypotheses are proposed:

- H5a:* Males will have more positive attitudes than will females towards using computerized products in general.
- H5b:* Males will have more positive attitudes than will females towards using a new computerized self-service option.

METHODOLOGY

Research Instrument

The research instrument is based on the scenario and questionnaire approach. The validity of scenarios and the equality of results between laboratory experiments and role playing studies have been well documented (Bem 1967) and this method has been advocated and applied by several researchers in consumer behavior (Bateson 1985; Belk 1974; Surprenant and Solomon 1987). The touch screen ordering option is clearly described in the scenario. It is also explained that price and menu are unchanged for this option. This is then followed by a questionnaire to measure the relevant variables.

The endogenous variables are attitudes towards using computerized products in general and attitudes towards using a new, computerized, self-service option, specifically using a touch screen to order fast food. Four, seven-point, semantic differential items, using endpoints such as good-bad and pleasant-unpleasant, are developed for each construct, consistent with the guidelines suggested by Fishbein and Ajzen (1975) for measuring attitudes.

The exogenous variables are prior behavior with respect to using computerized products and the need for interaction with a service employee. Four, seven-point, frequency items are developed for

measuring prior behavior with respect to using computerized products (e.g., home computers, automated teller machines). A four-item, seven-point, Likert scale for measuring the need for interaction with service employees is developed, after testing several versions for ease of understanding and face validity. Examples of items from this scale are "human contact in providing services makes the process enjoyable" and "I like interacting with the person who provides the service."

Analysis

The unidimensionality and reliability of constructs developed in this study are tested with confirmatory factor analysis, considered superior to conventional measure validation techniques (James, Mulaik, and Brett 1987). The analytical tool is LISREL 7 (Joreskog and Sorbom 1989). The model itself (comprising hypotheses H1, H2, and H3) is tested with a confirmatory design (using LISREL 7). Hypotheses H4, H5a, and H5b are tested using conventional multivariate analyses because the theoretical support for these hypotheses is not as strong as for the model, a condition necessary for meaningful application of confirmatory analysis and LISREL. Hypothesis H4 is tested using a combination of a nested MANOVA and regression analysis, while hypotheses H5a and H5b are tested using t-tests.

Sample

The respondents are students from a large urban university. Using a student sample increases homogeneity for theory development (Calder, Phillips, and Tybout 1981) and thus minimizes the problem of omitted variables and unforeseen interactions. In addition, college students are frequent consumers of fast food (*The Wall Street Journal* 1990) and hence this is a relevant sub-segment of the population of customers of fast food restaurants.

A total of 141 undergraduate students responded to the questionnaire. Sample size is linked with the method of analysis, and it may be noted that successful applications of LISREL have been conducted with about 100 respondents (Davis, Bagozzi, and Warshaw

TABLE 1
Confirmatory Factor Analysis and Construct Reliability
n=141

Scale	# Items	df	χ^2	p	GFI	AGFI	RMSR	Construct Reliability
ATC	4	2	2.12	0.35	0.99	0.96	0.02	0.90
ATS	4	2	5.92	0.05	0.98	0.91	0.03	0.89
PRIOR	4	2	8.41	0.02	0.97	0.85	0.06	0.77
NFI	4	2	1.85	0.40	0.99	0.97	0.02	0.82

ATC = attitude towards using computerized products in general

ATS = attitude towards using a new computerized self-service option

PRIOR = prior use of computerized products

NFI = need for interaction with a service employee

TABLE 2
Causal Analysis Results
n=141

Hypothesis Tested	Parameter	Estimate	Standard Error	t-value
H1	γ_{11}	0.22	0.08	2.71
H2	γ_{21}	0.67	0.15	4.46
H3	γ_{22}	-0.48	0.15	-3.13
Overall Model Fit:	$\chi^2 = 36.75$, $df = 31$, $p = 0.22$ GFI = 0.95, AGFI = 0.91, RMSR = 0.09, R^2 (ATC) = 0.21, R^2 (ATS) = 0.32			

1989, 1991) and an experimental design using LISREL was successfully executed with 60-70 respondents in each cell (Bagozzi and Moore 1991). The sample consisted of 72 males (age range of 21-45, mean age 25.79) and 69 females (age range of 21-44, mean age 25.65).

RESULTS

Study 1: Construct Development

The scales for the constructs in the study were developed as described and tested for face validity by three expert judges (faculty). Confirmatory factor analysis was conducted to check unidimensionality and compute construct reliability (see Table 1). It is seen from the chi-square values, probabilities, and goodness-of-fit indicators, that two of the scales (ATC and NFI) have excellent fits and one more scale (ATS) has an acceptable fit. The fourth scale (PRIOR) does not have as good a fit, but this is understandable because the scale measured frequencies of several

behaviors (e.g., using a home computer, using a VCR, etc.) that need not all be high or low for a given individual. Construct reliabilities were computed from the results of the confirmatory analysis and it is seen that reliabilities for all four scales are much higher than the acceptable 0.5-0.6 for theory development (Nunnally 1978).

Study 2: Causal Analysis

The causal model (see Figure 1) was tested with LISREL 7 (Joreskog and Sorbom 1989). The results of the causal analysis based on covariances are presented in Table 2. It is seen from the Table that the model has a good fit in terms of all the indicators. Furthermore, an examination of the t-values shows that all three hypotheses tested are supported. H1 is supported at $p < .01$, while H2 and H3 are supported at $p < .001$.

Thus, as hypothesized, prior behavior with respect to using computerized products has a positive effect on attitudes towards using computerized products in general, which in turn has a positive effect on attitudes towards using new computerized self-service

TABLE 3A
Nested Manova Results for Hypothesis H4
n=141

Dependent Variable	Independent Variable	Nested Groups	df	F (p <.001)
ATS	NFI	PRIOR (low & high)	2	18.41

ATS = attitude towards using a new computerized self-service option
 PRIOR = prior use of computerized products
 NFI = need for interaction with a service employee

TABLE 3B
Regression Analysis Results for Hypothesis H4

Group	n	Parameter Estimate (NFI → ATS)	Standard Error	F (p <.001)	Adjusted R ²
Low PRIOR	80	-0.42	0.07	19.44	0.32
High PRIOR	61	-0.33	0.08	7.84	0.19

options. Also, as proposed, the need to interact with service employees has a negative effect on attitudes towards using new computerized self-service options.

Study 3: Moderating Effect

The moderating effect (see Figure 2) was tested using a nested MANOVA and regression analysis. A nested MANOVA compares the slopes of the regression equations for the groups under consideration, and it is seen from Table 3A that a moderating effect was present (F=18.41, p <.001). Thus, the effect of the need for interaction with a service employee, on attitudes towards using a new computerized self-service option, was found to be significantly different for low and high prior use of computerized products.

To see if the moderating effect was in the predicted direction, regression analysis was conducted for low and high prior use groups (see Table 3B). Based on a comparison of the parameter estimates, F-values, and adjusted R² values, it is seen that hypothesis H4 is supported. Thus, as predicted, prior use of computerized products has an attenuating effect on the relationship between need for interaction with a service employee and attitude towards using a new, computerized, self-service option in on-site service encounters.

Study 4:

Gender differences (H5a and H5b) were tested using two t-tests. The results are presented in Table 4 and do not support either hypothesis. There was no difference between men and women in their attitudes towards using computerized products in general (t = -0.53, n.s.). Moreover, women had a more favorable attitude than did men (t= -2.91, p <.005) towards using new, computerized, self-service options.

DISCUSSION

Both information processing literature and attitudinal research have concentrated on product situations and largely ignored service situations. This study, drawing on the information processing paradigm, uses a service setting to investigate determinants of customer attitudes towards new options in service delivery. Thus, the model represents an extension of both streams of research to service settings.

The model is supported and validates the effect of prior behavior and category-based affect in service settings. The study also addresses issues of concern to services marketing researchers. It is found that attitudes towards new computerized self-service options are adversely affected by the need for interaction with a service employee, but that this effect is mitigated by greater familiarity with computerized products.

TABLE 4
T-Tests for Gender Differences in Attitudes

Hypothesis Tested	Gender	Mean	t-value	p
H5a	Male	5.83	-0.53	0.599
	Female	5.91		
H5b	Male	5.08	-2.91	0.004
	Female	5.62		

The findings that females have more favorable attitudes than do males towards new, computerized, self-service options, and that there are no gender differences in attitudes towards using computerized products in general, appear to contradict findings from the two earlier studies by Langerad et al. 1981 and Breakwell et al. 1987. One explanation for these results may be that the Langedard et al. study, which examined self-service versus full-service, used a sample from the general population, and students may not show gender differences for self-service options. The other explanation may lie in the fact that the Breakwell et al. study, which did use a student sample, examined attitudes towards the effects of new technology on society, rather than attitudes towards using products based on technology. It may be that females had a less favorable attitude in the Breakwell study because they were more sensitive to issues such as unemployment caused by technology. In this study, however, their attitudes towards using technology are measured, and it appears that women students, at least, seem to have more favorable attitudes towards using new service options based on technology, than do men.

The study provides several implications for practitioners as well. Those people (students, professionals, white collar workers), who are familiar with computerized products, are more likely to have favorable attitudes towards using new, computerized, self-service options. Therefore, it would be strategically sound to locate such service delivery options at sites frequented by these populations. In other words, familiarity with computerized products can be used as a basis for segmentation.

Firms may also wish to promote familiarity with computerized products in the general population as a long term strategy, since familiarity will positively affect attitudes towards these new service options. However, given that the need for interaction with a service employee does have a significant negative effect on attitudes, it may be prudent to provide full service options alongside these self-service options in locations frequented by the general public, so that customers can have a choice of service delivery.

Although the use of cross-sectional data implies that the temporal sequence of relationships cannot be guaranteed, cross-sectional data is commonly used in causal analysis, and appears to be

quite acceptable if there is theoretical support to suggest the causal paths for the hypotheses.

A student sample was considered appropriate for theory development, due to the relative sample homogeneity, and for the setting used in this study, as students are a relevant sample for fast food restaurants. The results may be generalized to other urban student populations, and to some extent, to populations with similar levels of familiarity with computerized products.

For future research, the study could be replicated with a sample from the general population to explore age and educational differences in attitudes. Older or less educated people, for example, may have a greater need for interaction with the service employee, as well as lower familiarity with computerized products. These differences, in turn, may be reflected in their attitudes towards new, computerized self-service options. Also, using a random sample from the general population would further validate the model developed in this study. Future studies could also test the model with different samples across the country to explore regional and cultural differences.

The results of this study should interest any firm that is interested in providing a computerized self-service delivery option to customers. Examples of such options would include airline ticketing machines at airports, computer ordering in catalog stores, closed-circuit check-out in hotel rooms, and touch screen ordering for photo processing. This study could be a starting point for future research that investigates customer attitudes towards using other innovative service delivery options.

The Role of Post-Experience Comparison Standards in the Evaluation of Unfamiliar Services

Ann L. McGill, Northwestern University
Dawn Iacobucci, Northwestern University

ABSTRACT

Previous research suggests that consumers evaluate service encounters by comparing them to prior expectations or other pre-experience comparison standards. The present research addresses the evaluation of services for consumers who lack the information or experience to construct detailed pre-experience comparison standards and so must rely on a more bottom-up approach to the evaluation. An exploratory study was conducted to examine the nature and content of consumers' expectations for unfamiliar services and on their post-experience evaluations. Results of the exploratory study indicate that consumers may indeed evaluate novel or unfamiliar services on "post-experience comparison standards" suggested by characteristics of the service encounter itself. The article considers differences in evaluations for consumers who rely primarily on pre- versus post-experience comparison standards.

In a recent article on models of consumer satisfaction, Tse and Wilton (1988) note that "it is generally agreed that post-consumption consumer satisfaction/dissatisfaction (CS/D) can be defined as the consumer's response to the evaluation of the perceived discrepancy between prior expectations (or some other norm of performance) and the actual performance of the product as perceived after its consumption" (p.204; see also Day 1984). Models of CS/D have emphasized the role of a pre-experience comparison standard (Beardon & Teel 1983; Cardozo 1965; Day 1977; Liechty & Churchill 1979; Miller 1977; Oliver 1977, 1980; Woodruff, Cadotte & Jenkins 1983) and the extent to which this pre-experience standard is disconfirmed (Anderson 1973; Beardon & Teel 1983; Cadotte, Woodruff & Jenkins 1987; Day 1977; Howard & Sheth 1969; LaTour & Peat 1979; Maddox 1981; Oliver 1977, 1980; Olshavsky & Miller 1972; Swan & Combs 1976; Swan & Trawick 1981; Woodruff, Cadotte & Jenkins 1983). Thus, a large body of research on consumers' satisfaction or dissatisfaction with products may be described using the so-called "disconfirmation paradigm".

The post-consumption evaluation of service quality is frequently asserted to be more difficult than the evaluation of products, primarily because of the intangibility of services, the heterogeneity across service encounters and the inseparability of production and consumption (e.g., Gronroos 1982; Lehtinen & Lehtinen 1982; Lewis & Booms 1983; Parasuraman, Zeithaml & Berry 1985; Sasser, Olsen & Wyckoff 1978). Nevertheless, the evaluation of services, like the evaluation of products, is said to involve a comparison of expectation with performance:

Service quality is a measure of how well the service level delivered matches customer expectations. Delivering quality service means conforming to customer expectations on a consistent basis (p.100, Lewis & Booms 1983).

The utility of this view of the evaluation process is demonstrated by the work of Parasuraman et al. (1985), which extends the notion of disconfirmation to a more general model of service quality. This model has direct managerial implications and also provides a structure for future research. Specifically, these authors propose five "gaps," including the gap between consumers' expectations and the actual service delivered, that determine service quality. For example, Parasuraman et al. posit that service quality may be influenced by the gap between management perceptions of consumers' expectations and the expectations themselves, between management perceptions of consumers' expectations and service quality specs, between service quality specs and the actual service delivered, and between service delivery and external communications to the consumer. Thus, the idea that consumers' evaluations are determined by the gap between consumers' expectations and their actual service experiences is intuitively appealing, provides a useful basis for additional research on the determinants of service quality, and carries with it the benefit of a large body of literature on CS/D that may be applied to understanding how people evaluate service quality.

A question that has not yet been addressed in the literature, however, and one that may become increasingly important as the size of the service sector continues to grow in the North American economy concerns how the disconfirmation paradigm may be applied to novel or unfamiliar service encounters. In particular, it is not clear how the notion that people compare their experiences to a *pre-experience* comparison standard may be applied to the evaluation of services for which the consumer has little information or experience to generate a meaningful expectation--i.e., when so little is known by consumers about the class of services that their expectations are imprecise and without much detail. Examples of such services may include consumers' initial experiences with visiting an attorney, seeing a therapist, getting a fitness evaluation, hiring a caterer, taking a marketing class, or visiting a career counselor. In each of these cases, novice consumers may have a general idea of what they hope to get out of the service and a vague sense of what the experience might be like. However, it is likely that consumers' expectations are quite impoverished relative to the actual experience, containing far fewer attributes than

consumers will in fact notice in experiencing the service.

Unfortunately, little information is provided in the marketing literature on the nature or content of consumers' expectations for unfamiliar services. Past studies have either manipulated subjects' expectations (e.g., Olshavsky & Miller 1972) or focused on relatively familiar services (e.g., Parasuraman et al. 1985; Cadotte, Woodruff, & Jenkins 1987). The question then is how do consumers evaluate novel service experiences? We draw on the marketing and psychology literatures, which suggest three possible answers to this question.

The first possibility is that consumers evaluate novel experiences on only those few attributes included in their expectations. For example, a novice consumer may expect attorneys to have nice offices, to dress in suits, and to use unfamiliar jargon. On visiting an attorney for the first time, the novice consumer may limit the evaluation to these three attributes. This view preserves the importance of the pre-experience standard of comparison as described in the literature on CS/D and carries with it the plausible assertion that novice consumers consider very few attributes in their evaluations because they simply don't know what to look for. This approach would keep the evaluation task simple for the novice.

A second possibility is that novice consumers cope with their inexperience by shifting to a higher level of abstraction. Research in marketing indicates that in choosing between so-called "noncomparable alternatives," which share few basic features, consumers shift to a higher level of abstraction to effect the comparison (Johnson 1984). Thus, in choosing between a stereo and a vacation, consumers may compare the alternatives on abstract features such as practicality, opportunity for self-improvement, or length of time over which the alternative will provide enjoyment. The application of this idea to the evaluation of unfamiliar services yields the suggestion that although novice consumers may not have any directly comparable experiences to help them construct an expectation for the service, they may have experiences that are comparable at a higher level of abstraction. For example, consumers who haven't been to an attorney might have trouble constructing expectations the way experienced people might--e.g., on detailed features specific to attorneys such as knowledge of relevant case law, education, and ability to predict the opposing attorney's strategy. Novice consumers may nevertheless construct expectations based on abstract features such as friendliness, self-confidence, and articulateness. It is possible also that this second approach based on abstract features may provide a way to reconcile Westbrook and Reilly's (1983) view of CS/D with the disconfirmation paradigm. Westbrook and Reilly suggest that people determine satisfaction not by comparing their experiences to a pre-experience comparison standard but instead by noting how well the alternative filled their needs or wants. At a very high level of abstraction, consumers may compare the outcome of their experience to the level of the utility or value that they had expected to receive.

A third possibility that we would like to propose is that people evaluate services by generating a comparison case after the fact. Novice consumers may be unable to generate detailed expectations in advance, but upon experiencing the service, they may see how it could have been otherwise. The service is evaluated as suggested by the disconfirmation paradigm--i.e., on the gaps between what was and what might have been. The difference is that the comparison standard is generated during or after the consumption experience, not before. Hence, this third view suggests a more bottom-up versus top-down approach to the evaluation of services.

Thus, we identify three possible approaches to the evaluation of unfamiliar services--i.e., based on a pre-experience comparison standard at a low level of abstraction, based on a pre-experience comparison standard at a high level of abstraction, or based on a post-experience comparison standard. Further, all three approaches may be present in a single evaluation. For example, consumers may evaluate the movie BATMAN on detailed features included in their expectations (e.g., "I expected Robin to be in it"), on abstract features derived from experiences with other action-adventure movies ("I expected it to be high-energy and fast-paced"), and on detailed features suggested after the fact ("It ruined it for me when they showed the Batmobile indestructible but the Batplane something you could shoot out of the sky with a handgun").

As this example suggests, evaluations based on post-experience comparison standards may be based on different types of attributes or features than evaluations based on pre-experience comparison standards. In particular, in contrast to the suggestion that consumers evaluate service encounters at a high level of abstraction, comparison to a post-experience standard suggests an evaluation based on specific details. An example may be student assessments of courses and instructors. Although frequently ingenuous in their expectations (e.g., "I hope to gain insights to make me a better manager"), student course evaluations often appear based on minute details (e.g., "use more subheadings in lecture outlines", "make more frequent eye contact with students"). Further, it would appear that these details are not likely to be those included in an expectation generated in advance, but rather appear available to the consumer only by virtue of having experienced the service. Thus, an important advantage of this third view, which proposes use of post-experience comparison standards, is its ability to explain how features that are not included in consumers' expectations influence the evaluation.

The purpose of the present research is to examine this third approach based on post-experience comparison standards in greater detail. An important goal first for this research was to gather evidence for the evaluation of services on features that were not included in consumers' expectations but which were suggested by the service encounter itself. To accomplish this goal, we conducted an exploratory study designed to examine the nature of consumers' expectations for unfamiliar services and the basis for

consumers' post-experience evaluations. In keeping with the three alternatives proposed for the evaluation of novel or unfamiliar services, we were particularly interested in determining whether these expectations and evaluations were based on many or few attributes and whether these attributes were expressed at a high or low level of abstraction.

After presenting results for the exploratory study, we interpret differences in the evaluation of services based primarily on pre- versus post-experience comparison standards in light of recent research by Kahneman and Miller (1986). These authors provide a theoretical basis for understanding a) how people may construct post-experience comparison standards and b) how evaluations based on post-experience comparison standards may differ from those based on pre-experience comparison standards. We present formal propositions regarding the nature of these differences and suggest methods for their examination.

STUDY

Method

Subjects. Subjects were 21 members of the Northwestern University community who had enrolled in an introductory workshop on a computer spreadsheet package. The workshop was conducted by the computer services division of the university and was designed for individuals with little or no prior computing experience. Subjects were given \$1.00 "as a small token of our appreciation" for agreeing to fill out the questionnaire.

Materials. Subjects answered a pre-experience and post-experience questionnaire. The pre-experience questionnaire asked subjects to describe the upcoming workshop in terms of what they expected to get out of the experience ("What are the main reasons you are planning to attend this workshop?") and in terms of how they expected to evaluate the workshop ("How will you evaluate this workshop? What factors will affect your satisfaction with this workshop?").

The post-experience questionnaire asked subjects to describe the workshop. Subjects were asked to "consider such things as what it was like to be in the workshop, how the instructor was, what you learned, and so forth" in describing the experience. Subjects were also asked to indicate, "What factors influenced your assessment of the workshop? What affected your satisfaction or dissatisfaction?" Finally, subjects were asked to evaluate *perceived performance* of the workshop ("...your objective assessment of the quality of the workshop, regardless of your personal level of satisfaction with the service..." on a 7-point scale ranging from "very poor" to "excellent" quality), *subjective disconfirmation* ("...how close the workshop came to satisfying your expectations for the service..." on a 7-point scale ranging from "very much poorer" to "very much better" than expected), and *satisfaction* ("...how satisfied are you with the workshop..." on a 7-point scale from "very dissatisfied" to "very satisfied"). These scales were adopted from Tse and Wilton (1988). Support for

these scales can also be found in Churchill and Suprenant (1982) and Oliver (1980).

Procedure. Subjects were contacted before the workshop and asked if they would be willing to fill out a questionnaire on the upcoming experience. Subjects were told that the purpose of the questionnaire was "to help understand how people evaluate experiences such as workshops and to assist the computing center in improving their services." Written instructions for the questionnaire were as follows:

Thank you for participating in this study. Please accept the dollar as a small token of our appreciation.

On the following pages, we ask you to describe your expectations for various services including the workshop in which you are about to participate. Please describe your expectations in as much detail as you can, noting both major and minor features. Also, try to include even "obvious" features in your description. For example, you might expect an optometrist to have a chart of letters on the wall and to evaluate your vision by asking you to read these letters. Even though this sort of thing may seem almost too common to mention, we ask that you please include such features in your description.

Please note that there are no right or wrong answers to any of these questions. For coding purposes, please write down the last 4 digits of your social security number: _____.

The post-experience questionnaire, which subjects were not told to anticipate, was administered at the end of the workshop. Instructions for the post-experience questionnaire informed subjects that "on the following pages we ask you to describe and evaluate the workshop you attended." Subjects were again asked to provide the last four digits of their social security number for coding purposes. Subjects spent roughly 10 minutes filling out each the pre-experience questionnaire and the post-experience questionnaire.

Results. Subjects' expectations and descriptions of the service in the pre-experience and post-experience questionnaires were coded as "abstract" meaning they could be applied to any workshop, class, or service or "specific" meaning they applied to the specific characteristics, outcomes, or content of the workshop on the particular spreadsheet program. Responses were further categorized as referring to a) the "outcome" of the service--i.e., what the person hopes to gain from the workshop--b) the "process" by which the service was delivered--i.e., the materials in the course, the behavior of the instructor, and so forth. Responses that could not be classified into any of the above categories were coded as "other." Figure 1 provides an example of each category of response. Table 1 displays the mean number and mean proportion of responses in each category for the pre-experience and post-experience questionnaires.

FIGURE 1

Examples of Features Provided on the Pre-experience and Post-experience Questionnaires by Category

Abstract

Process Pre "It's interesting to attend classes. I like it better than reading."
Post "I found the instructor courteous and energetic."

Outcome Pre "As a senior about to interview for jobs, I want to have the most up-to-date skills."
Post "I feel I learned a lot of new ideas and things."

Specific

Process Pre "It will matter if there is enough time to practice the new skills on the computer."
Post "I wasn't happy about the assistants walking around and the general noise level in the room."

Outcome Pre "I want to be able to sit down and program in [this package]."
Post "I learned some basic [program] commands."

Results confirm that subjects evaluated the workshop on attributes that were not included in their expectations but which were suggested by the service encounter itself. The first indication of this pattern is that subjects provided relatively more detailed descriptions in the post-experience questionnaire than in the pre-experience questionnaire ($t(19) = 3.77$, $p < .001$, matched t-tests). This difference in detail may also be attributed in part to a more general tendency to provide more detailed accounts for past versus future events (Bavelas 1973).

Additional evidence for the generation of post-experience comparison standards comes from examination of the nature of subjects' expectations and post-experience evaluations. We consider first the pre-experience questionnaire. When asked to describe their reasons for attending the workshop (Q1--see Table 1), subjects overwhelmingly provided reasons related to the outcome of the service ($t(20) = 14.06$, $p = .000$, matched t-tests). Further, subjects tended to mention specific outcome features in greater proportion than abstract outcome features ($t(20) = 2.74$, $p = .013$). That is, subjects for the most part indicated their reasons were related to how they would use the specific course material, for example, "everyone else in my office uses [this spreadsheet package] and I need to be compatible."

When asked how they expected to evaluate the upcoming workshop (Q2), subjects provided a different mix of features. Subjects again mentioned outcome features in greater proportion than process features, but for this question the difference was only marginally significant ($t(20) = 1.77$, $p = .092$). The decrease in proportion of process features was due to relatively more frequent mention of abstract process features ($t(20) = 3.15$, $p = .005$) and relatively less frequent mention of specific outcome features ($t(20) = 2.67$, $p = .015$) compared to the preceding question on reasons for attending the workshop. The proportion of abstract outcome and specific process features did not change significantly (p 's $> .25$). Thus, although subjects emphasized specific outcome features when asked how they would evaluate the workshop, they

described their evaluation standard more frequently in terms of abstract features, particularly abstract *process* features. This outcome suggests that subjects intended to evaluate the workshop using general cues to quality that could be applied across service encounters of this sort--e.g., on the professional manner of the instructor or the general appearance of the handout material.

Whatever subjects' expectations or intended evaluation standards, the post-experience questionnaire indicated a wholly different response to the experience. In contrast to the pre-experience questionnaire, subjects described the workshop (Q3) primarily in terms of process features ($t(20) = 6.17$, $p = .000$), dividing their comments almost equally between abstract and specific process features ($t(20) = .90$, $p = .377$).

Subjects' listing of features that ultimately influenced their satisfaction with the experience (Q4) revealed a similar pattern. Process features were more commonly mentioned ($t(19) = 5.78$, $p = .000$, with specific process features (e.g., "the assistants were distracting when they walked behind me") mentioned in somewhat greater proportion than abstract process features (e.g., "there was plenty of time for questions"), although this difference was not significant ($t(19) = 1.59$, $p = .13$).

In contrast to what might have been expected from the literature on the disconfirmation paradigm, comparison of subjects' listing of features that affected their level of satisfaction in the post-experience questionnaire (Q4) were not entirely consistent with the listing of factors that they *expected* to affect their level of satisfaction in the pre-experience questionnaire (Q2). The proportion of abstract process features did not change significantly ($t(19) = .32$, $p = .756$). However, the proportion of abstract outcome features and specific outcome features dropped significantly (abstract outcome features, $t(19) = 2.28$, $p = .034$; specific outcome features $t(19) = 2.85$, $p = .01$), while the proportion of specific process features increased significantly ($t(19) = 6.61$, $p = .000$). The increase in proportion of specific process features is

TABLE 1

particularly noteworthy; whereas the proportion of these features was not reliably greater than zero in the pre-experience questionnaire ($Q2-t(21) = 1.00, p = .17$), specific process features assumed a strict majority in the actual evaluation ($Q4--53\%$). The frequency of mention of specific process features in the post-experience questionnaire indicates that the inexperienced consumers who participated in the present study were satisfied or dissatisfied with the workshop because of small details--details that they did not mention as part of their expectations for the

service and which it would be difficult to imagine them able to mention before experiencing the service given the particular nature of these features.

We also examined the relationships among the perceived performance, subjective disconfirmation, and satisfactions scales for evidence for the use of pre-experience and post-experience comparison standards. As the current CS/D literature would predict, subjects' ratings of their satisfaction with the workshop were highly correlated with their ratings of the extent to which their expectations were met by the workshop--

i.e., their ratings of subjective disconfirmation ($r = .599, p < .003$). Furthermore, ratings of subjective disconfirmation were only partly related to their ratings of perceived performance ($r = .360, p < .064$), a result that is sensible if confirmation is a function of the objective assessment and subjects' expectations. However, we also note that ratings of perceived performance were an even better sole predictor of satisfaction ($r = .696$ vs. $.599$) than was the subjective disconfirmation rating. That is, while theoretically the perceived performance and the expectation together are expected to predict satisfaction better through the disconfirmation process, the perceived performance ratings alone predict satisfaction more clearly, and expectations as evidenced through the disconfirmation rating add only noise to the prediction of satisfaction.

Discussion. One of the most striking aspect of the exploratory study was the difference in features mentioned in the pre-experience and post-experience questionnaires. Subjects' post-experience evaluations appeared influenced primarily by specific process features, although these features were rarely mentioned in the pre-experience questionnaire. This pattern of results suggests use of a post-experience comparison standard in which consumers' satisfaction is determined by first experiencing the service and then imagining how it could have been otherwise. The implication of this finding is discussed in the following sections.

However, instead of viewing the large proportion of specific process features in the post-experience questionnaire as inconsistent with the pre-experience questionnaire, we also considered the possibility that specific features were cited merely as examples of the abstract. For example, we considered the possibility that subjects mentioned specific process features (e.g., "the instructor told stupid jokes") in the post-experience questionnaire as evidence for the abstract standard articulated in the pre-experience questionnaire (e.g., "professionalism of the instructor"). Future research is needed to evaluate this view further, but it is our belief that the specific process features affected the consumers' satisfaction directly and not as evidence for a more abstract standard. This belief is based on the previously stated theoretical concerns and on closer scrutiny of subjects' post-experience questionnaires wherein subjects appeared to describe their satisfaction as a direct consequence of the specific process features (e.g., "I was annoyed because the instructor told stupid jokes"). Subjects did not articulate any relationship between specific process features and an abstract standard, for example in comments of the form "the instructor told stupid jokes which just didn't seem professional."

Results of the exploratory study also suggest that consumers may experience considerable difficulty in translating their reasons for purchasing a service into an effective evaluation standard. Subjects in the present study articulated their reasons for attending the workshop primarily in terms of specific *outcome* features. However, subjects based their evaluations of the workshop more frequently on specific *process* features. Subjects may have adopted this approach

because while process features were immediately available, outcome features may be more difficult to assess until some later date. This reasoning suggests that consumers may evaluate services on different classes of features at different points in time. Nevertheless, the scant proportion of outcome features in the post-experience questionnaire is surprising given the importance of these features in the pre-experience questionnaire. One might have expected relatively more frequent comments in the post-experience questionnaire of the form, "I liked (disliked) the workshop because I think I learned a lot (very little)." The particulars of the experience appear, however, to have dominated subjects' evaluations.

DIFFERENCE IN EVALUATION FOR PRE-VERSUS POST-EXPERIENCE STANDARDS

While previous research posits that consumers evaluate services by comparing their actual service experiences to pre-experience comparison standards, results of the exploratory suggest that consumers may in some cases evaluate the actual service experience relative to a standard of comparison that is generated after the fact. In this section, we examine differences in the evaluation of services for subjects who compare the experience to a pre-experience comparison standard versus those who rely primarily on a post-experience comparison standard.

Attribute Importance

Differences in the evaluation may derive from how post-experience comparison standards are constructed versus expectations or other pre-experience comparison standards. Research by Kahneman and Miller (1986) suggests the likely characteristics of a post-experience comparison standard. These authors note that in constructing an alternative to a stimulus, people will hold some features constant while they let other features vary. Kahneman and Miller propose that "the mental representation of a state of affairs can always be modified in many ways, that some modifications are much more natural than others, and that some attributes are particularly resistant to change" (p.142-43).

Kahneman and Miller further suggest the sorts of features that are likely to be held constant ("immutable features") as opposed to those which are likely to be let vary ("mutable features"): "a plausible hypothesis is that the essential features that define the identity of the stimulus are most likely to be maintained as immutable. This hypothesis has surprising consequences: it entails that judgments of a stimulus evaluated in isolation will tend to be dominated by features that are not its most central" (p.141). The implication of this proposal for the present research is that when a service encounter is evaluated in isolation, for example when the consumer has no previous experience or does not have the ability or inclination to produce a well-formed expectation, the consumer may construct a comparison standard post hoc. The post-experience comparison standard is proposed to resemble the

service experience on its more central, more important attributes but to differ on its less central, less important attributes thereby affording the less important attributes greater influence in the evaluation. By contrast, when the service encounter is evaluated in context, for example, when it is compared to an expectation, prior service encounter, or other pre-experience standard, evaluations should derive primarily from differences on the more central, more important attributes (LaTour & Peat, 1979; Tse & Wilton, 1988). The following proposition reflects this reasoning:

- P1: Evaluations of a service relative to a post-experience comparison standard will tend to be influenced by less central, less important features as compared to evaluations relative to a pre-experience comparison standard.

Thus, in evaluating an attorney, for example, consumers who rely on a post-experience comparison standard may evaluate the attorney relatively more on how they were greeted at the office, which they imagine could have been more cordial, than on the attorney's level of experience, which they took for granted (and so treated as immutable). However, these same consumers may independently concede that the level of experience of an attorney is more central and more important to assessing overall quality than the attorney's manners. By contrast, consumers who approached the experience with a pre-experience comparison standard, although put off by the attorney's manners, may nevertheless evaluate the attorney to a greater extent according to his/her level of experience as prescribed by the relative importance of these attributes.

Attribute Type

Our second proposition concerns the types of features that are likely to influence the evaluation. As noted above, researchers have made the distinction between "process features," which concern how the service is delivered, and "outcome features," which concern the benefits for which the service is purchased (e.g., Parasuraman et al. 1985). For example, process features for dental service may concern the pleasantness of the interactions with the dentist and hygienist, the promptness and cleanliness of the office, and the comfort or discomfort of procedures. Outcome features might concern, for example, clean teeth, filled cavities, and a sense of well-being.

We propose that process features may be further decomposed into two types. "Dynamic process features" refer to the behavior of the service provider toward the consumer--e.g., courtesy, friendliness, and responsiveness. "Static process features" refer to fixed or semi-fixed characteristics of the service provider that do not vary from customer to customer--e.g., age, gender, education, level of knowledge of the dentist--and to the fixed characteristics of the production process itself--i.e., the formal steps or procedures involved in the delivery of the service. An

example of the latter would be the use of a dental assistant to take x-rays and to perform the initial examination.

We propose that dynamic process features may be treated as relatively more mutable in constructing imagined alternatives to an experience than static process features. For example, in constructing a post-experience comparison standard for a visit to the dentist, novice patients (for example, those who haven't been to a dentist since, say, childhood) may be more likely to imagine the dentist less gruff in response to their questions than to imagine the dentist and not the assistant responsible for the x-rays. Patients may be similarly disinclined to imagine the dentist with different traits, for example, younger or a different gender. Thus, patients may base their evaluations more on the behavior of the dentist than on the specific traits of the dentist or on the structure of their visit:

- P2: Evaluations of a service relative to a post-experience comparison standard will tend to be influenced more by the interpersonal behavior of the service provider than by traits of the service provider or characteristics of the service itself as compared to evaluations relative to a pre-experience comparison standard.

Number and Consistency of Attributes

Two other differences concern the consistency with which a standard of comparison is applied in the evaluation of a service and the number of attributes that are used across different evaluations. A pre-experience comparison standard implies, by definition, that the attributes used in the evaluation will not shift depending on the features of the particular service encounter. In addition, the attributes used in the evaluation should not shift markedly from service encounter to service encounter. By contrast, a post-experience comparison standard implies, by definition, a standard that is constructed in response to the features of a given service encounter. Thus, each service encounter creates its own standard of evaluation and the standard may shift from service encounter to service encounter. For example, students who rely on post-experience comparison standards may not evaluate instructors on a consistent set of attributes such as knowledge of the course material, organization, and preparedness, but instead may evaluate each instructor on a separate set of attributes depending on the alternatives that were available for each experience. Thus, consumers with less experience, who generate standards of comparison after having experienced the service, may be especially difficult to please or to predict because their evaluations are based on largely inconsistent and varied sets of attributes.

A similar view is offered by those concerned with the cognitive complexity of individuals. Research in this area suggests that when subjects are asked, for example, to make pairwise similarity judgments, more sophisticated processors may be better able to produce and use consistently the

dimensions required to accommodate a set of objects (Scott, Osgood, & Peterson, 1979). Less sophisticated processors, by contrast, may not be able to generate the general dimension needed to accommodate the entire set and so instead make do with a series of fractionated similarity judgments on less general dimensions (Malholtra, Pinson, & Jain, 1989). Thus, evaluations by those who generate a pre-experience comparison standard may differ from evaluations by those who generate the comparison standard post hoc on the number and consistency of attributes:

P3: Variability in the attributes used to evaluate service encounters will tend to be greater among consumers who rely on a post-experience comparison standard compared to consumers who rely on a pre-experience comparison standard; and

P4: Consumers who evaluate services relative to a post-experience comparison standard will tend to base their evaluations on a larger set of attributes than groups who evaluate services relative to a pre-experience comparison standard.

Quality of the Evaluation

Finally, differences in the quality of the evaluation are expected for consumers who rely on pre-versus post-experience comparison standards. Past research indicates that in constructing an alternative to a stimulus, people are more likely to change negative features to positive rather than positive to negative; the goal appears, at least, to contrast the actual stimulus with an ideal (Kahneman & Miller, 1986; Read, 1985). This method of constructing a post-experience standard of comparison implies a typically harsh evaluation, the stimulus must always be less desirable than the post-experience standard. By contrast, when the actual experience is compared to a pre-experience standard of comparison which is not an ideal, the evaluation may be positive, negative or neutral, depending on the relative values of attributes of the experience and the standard (e.g., Woodruff, Cadotte & Jenkins, 1983). Hence, this reasoning implies that evaluations by consumers who construct the comparison standard after the fact will differ from those by consumers who construct the standard in advance:

P5: Evaluations of a service relative to a post-experience comparison standard will tend to be less favorable as compared to evaluations relative to a pre-experience comparison standard.

CONCLUSION

Results of the exploratory study suggest that in some cases, people may evaluate services in a more bottom-up ("data-driven") approach than has been suggested previously in the literature. The present research has focused on those who find it especially difficult to develop a detailed top-down strategy for

evaluation because they lack the necessary information and experience. It seems plausible, however, that even knowledgeable customers would sometimes rely on bottom-up processing, for example, when they are pressed for time or when they are not motivated to consider the service much in advance because it is not perceived as very important. Although research in marketing is frequently sensitive to the use of bottom-up processing, for example, in discussing the effectiveness of advertising and promotional messages, there is little discussion of this sort of processing in post-purchase evaluations. The present research on the generation and use of post-experience comparison standards addresses this gap in the literature by identifying the phenomenon and by suggesting how so-called "data-driven" evaluations progress. Four of the propositions presented describe differences in the evaluation for top-down versus bottom-up processors and concern the number, importance, type, and stability of attributes that may be used in the evaluation. The fifth proposition concerns the nature of the evaluation and suggests that bottom-up processors may be more difficult to please in their evaluations.

Recent research in marketing has focused on the importance of managing what consumers learn from experience (e.g., Hoch & Deighton 1989). Consistent with this literature, the propositions detailed in the present article suggest that service providers may benefit by helping consumers to develop pre-experience comparison standards instead of allowing consumers to construct evaluations after the fact. Future research should test these propositions and develop additional propositions on the differences between top-down and bottom-up processors.

Determinants of Word-Of-Mouth Communications During Product Consumption

Paula Fitzgerald Bone, West Virginia University

ABSTRACT

Word-of-mouth (WOM) communications which occur during product consumption have received little attention from consumer researchers. In this paper, factors which may "spark" WOM during consumption are examined. Findings from a field study show that WOM can be partially explained by: (1) social tie strength, (2) the presence/absence of an individual taking a committed decision maker role, (3) consumer satisfaction and, (4) perceived novelty.

Foods, sporting goods, musical concerts, and videotaped movies all have one thing in common--they are often consumed in groups. And, when products are consumed in groups, there is the possibility that word-of-mouth communications (WOM) may occur. Indeed, Belk (1971) found that WOM is most likely to occur when individuals are in close proximity to a product. In this study, several factors which may influence the amount of WOM during consumption are examined.

The traditional notions of information seeker and information receiver seem to be inappropriate when studying WOM which occurs during product consumption since individuals in this situation are simply sharing thoughts--they are not necessarily providing and requesting information. For this reason, WOM communication is conceptualized herein as a group phenomenon--an exchange of comments, thoughts, and ideas among two or more individuals in which none of the individuals represent a marketing source.

Several factors may "spark" WOM during the consumption experience. This paper examines aspects of the social environment, objective characteristics of the situation, and individuals' perceptions of the consumption experience as determinants of how much WOM about the product/service occurs (cf. Yale 1987a). In the next section of this paper, these potential determinants of WOM are discussed. Then, an empirical investigation of these factors is presented.

THE SOCIAL ENVIRONMENT OF A CONSUMPTION GROUP

Two aspects of the social environment of a consumption group are of interest here: social ties and the social role of committed decision maker. Social ties represent the strength of a consumer's relationship to the people accompanying him/her. Since relationship strength has been shown to influence information flow from consumer to consumer (Brown and Reingen 1987), it is also likely to affect discussions during consumption. Rumor researchers suggest that persons in a new social relationship spread rumors in order to learn more about each other (Fine and Rosnow 1978). Taking this concept further, individuals who are simply acquaintances or casual friends (i.e., have weak social

ties) may attempt to strengthen friendships. They may look for safe, uncontroversial topics of discussion that can be used to get to know each other better (Yale 1987a). Discussion about products/services consumed may meet consumers' needs to learn more about their companions. Thus, it is suggested that the weaker the social ties that exist among group members, the more WOM will occur.

A second component of the social environment is whether one or more of the group members takes on the role of a committed decision maker. Conceptually, a committed decision maker is an individual who selects the product/service to be consumed *and* is enthusiastic about sharing this consumption experience with his/her companions. For instance, assume John lives in New York City and has friends coming to visit for the weekend. John wants to show off New York, so he carefully chooses a restaurant that he particularly likes. He has taken the role of committed decision maker.

The committed decision maker makes a choice that is visible and affects other people. This situation is likely to create some psychological dissonance for the decision maker, so, s/he will seek confirmation of the choice from her/his companions (Stuteville 1968). In fact, Dichter (1966) proposes that group members are motivated to report their experiences and opinions to the decision maker and that the decision maker expects such reports. This suggests that whenever there is a committed decision maker in a group, WOM is likely to occur.

OBJECTIVE SITUATIONAL CHARACTERISTICS

Belk (1975a, 1975b) suggested five categories of objective situational variables, two of which are examined in this paper: temporal perspective and task definition. Temporal perspective deals specifically with the concept of time. Belk (1975a) proposes that the time elapsed since last purchase may be an important part of the consumption situation. This situational factor suggests that the greater the time between consumption experiences, the more attention the consumer pays to it. Attention will be maximized whenever it is a consumer's first experience with a particular product or service. Thus, greater WOM is expected to occur whenever the consumer has his/her first experience with a product or service.

Task definition explores the reason behind a particular consumption experience (Belk 1975a). The gift-giving situation is of interest here, since it may spark conversation during consumption. The gift-giver(s) is motivated to please the recipient(s); therefore, situational involvement is heightened. Additionally, the gift-giver is likely to want feedback from the recipient concerning his/her opinion regarding the product. Finally, the receiver may have questions about the product/service which would be addressed to the giver.

INDIVIDUAL'S PERCEPTIONS OF THE CONSUMPTION EXPERIENCE

The final set of variables considered is individual's perceptions of the consumption experience. Three such factors, satisfaction, dissatisfaction and perceived novelty, are discussed below.

Satisfaction and dissatisfaction affect an individual's mood and increase the amount of WOM. In fact, much research shows that satisfaction and dissatisfaction lead to WOM after product experience (Dichter 1966; Richins 1983; Yale 1987b). Satisfaction and dissatisfaction may begin as a response to a situation (Belk 1975a) but then become part of the situation. This is possible because product consumption occurs over time, so satisfaction and dissatisfaction can occur early in the consumption experience and then influence WOM during the latter part of the consumption experience. Extreme levels of satisfaction and dissatisfaction heighten the consumer's awareness of the consumption experience and increase his/her likelihood of discussing the experience. Indeed, such discussions may reduce emotional tension created by a very pleasing or displeasing product/service (Dichter 1966).

A novel consumption experience is one that is perceived as out of the ordinary by an individual. This may be a function of the consumer's lifestyle and experiences, characteristics of the product/service, and/or the manner in which the product/service is presented. A situation which is perceived as novel will receive the consumer's attention, making product conversation more likely.

FIELD STUDY

A restaurant setting was used in this investigation since individuals often consume restaurant food in groups and the consumption experience has a clear beginning and ending. A wide variety of restaurants participated in the study ranging from fast-food chains to expensive "atmosphere" restaurants. A total of 321 people participated, representing 153 groups of restaurant patrons. Forty-three percent of the respondents were male, 72% were under the age of 45, and 46% had incomes over \$30,000.

Interviewers were instructed to approach every group of two or more individuals after they had completed their meals and ask all group members to participate in the study. Respondents were asked to complete the questionnaire individually without consulting the other group members.

Hypotheses

The following hypotheses are of interest. *The amount of WOM in a group is expected to increase:*

- H1: As the number of weak social ties among group members increases.
- H2: When a group member takes on the role of committed decision-maker.

- H3: As the number of individuals in the group who are experiencing the restaurant for the first time increases.
- H4: As the number of individuals in the group who are experiencing a particular entree in the restaurant for the first time increases.
- H5: When the consumption experience represents a gift-giving situation.
- H6: As the number of people in the group who experience extreme satisfaction increases.
- H7: As the number of people in the group who experience extreme dissatisfaction increases.
- H8: As the number of individuals in the group who perceive the consumption experience as novel increases.

Measures

Word-of-mouth. An index of the amount of WOM was developed for this study since the usual dichotomous measures could not adequately test the hypotheses. Three items measured the amount of WOM. The first was an eleven-point graphic rating scale anchored with "we did not talk about the food at all" and "we talked about the food a lot." A seven-point Likert-type item asked whether the food eaten was a large part of the mealtime conversation. Finally, a seven-point item asked how much of the table conversation dealt with the food being eaten. Responses ranged from "nothing was said about the food" to "the biggest topic of conversation was our food." These measures were standardized and summed to yield a reliable index ($\alpha=0.79$).

Social Ties. Participants indicated their social relationship with each person sitting at their table using a seven-point item. Responses ranged from "not very close--casual acquaintances" to "so close it's hard to imagine life without him/her" (Johnson and Reingen 1987).

Committed Decision Maker. This social role was measured by three items. First, participants were asked who chose the restaurant. Only respondents who indicated they had made the decision were considered for the committed decision maker role. The psychological dimension of this role was measured using two seven-point Likert-type items. The first stated, "I was very excited to bring my companions to this particular restaurant." The second stated, "I encouraged my companions to come here today because this is one of my favorite places to eat and I wanted to share this restaurant with them" ($r=0.69$).

Gift. Respondents were asked whether they were purchasing the meal as a gift for their companions.

Satisfaction/Dissatisfaction. These states were measured using two scales. The first was a seven-point delighted to terrible scale (Westbrook 1980b). The

TABLE 1
Group Variable Determination

Word-of-mouth	Average of the individual WOM scores given by group members
Social Ties	Total number of weak ties indicated by group members. Weak ties were relationships characterized as "recently met", "casual acquaintance", and "new friend"
Committed Decision Maker	At least one group member's committed decision maker score exceeded the mean committed decision maker score plus one standard deviation <i>and</i> stated that s/he decided where the group would eat
New Restaurant Patronage	Total number of group members who stated they had never eaten at the restaurant before
New Entree	Total number of group members who stated they had never eaten that entree at that restaurant before
Gift	At least one group member stated that he/she was purchasing the meal as a gift for his/her companions
High Satisfaction	Total number of group members whose satisfaction score exceeded the mean satisfaction score plus one standard deviation
Low Satisfaction	Total number of group members whose satisfaction score fell below the mean satisfaction score minus one standard deviation
Perceived Novelty	Total number of group members whose novelty score exceeded the mean novelty score plus one standard deviation

second asked respondents how satisfied they were with the food. Responses could range from 0% (not at all satisfied) to 100% (completely satisfied; Westbrook 1980a). These two items were standardized and summed ($r=0.70$).

Restaurant Patronage and Entree Purchasing Frequency. Respondents indicated how often they ate at the restaurant and how often they ordered the entree selected on six-point items. A response format ranging from "at least once or more a week" to "never before today" was used.

Perceived Novelty. Perceived novelty was measured by three seven-point Likert-type items asking whether the food was presented in a different manner than expected, whether the food was presented in an interesting or unusual manner, and whether the food was out of the ordinary for the respondent ($\alpha=0.64$).

Data Analysis

Several issues had to be addressed during data analysis. Some groups had incomplete data. Groups were only included if the majority of the members completed the questionnaire. Respondents who did not complete more than 3 items were excluded from the analysis as were individuals who did not complete all three of the WOM items. This eliminated persons who did not thoughtfully complete the questionnaire. Missing data were handled by substituting the mean

value for the missing data point. This conservative procedure may have attenuated the results since it treats an individual as average when, in fact, s/he may have possessed one of the critical characteristics. Thirty-nine groups were dropped from the analysis due to the above procedures, resulting in usable data from 114 groups.

In order to test the hypotheses, information from the individual questionnaires was combined to provide group data. Table 1 provides the rules used in determining the value of the independent group variables used in the final analysis.

Results

A regression model was used to investigate the hypotheses. The condition index for the data set was 9.27, indicating that multicollinearity is unlikely to be a problem (Belsley, Kuh and Welsh 1980). In order to control for group size, the analysis was conducted using the residual WOM scores after the effects of group size were taken into account. Hypotheses were tested using the residual group WOM score as the dependent variable and the weak ties, committed decision maker, new restaurant patron, new entree, gift, high satisfaction, low satisfaction, and distinctiveness group scores as the independent variables. The overall model was statistically significant ($F=4.54$, $p<0.01$, adjusted $R^2=0.20$). Table 2 contains the regression coefficients. (Note

TABLE 2
Regression Results

Variable	Beta	Probability
Weak Ties	-0.610	0.027
Committed Decision Maker	1.245	0.028
New Restaurant Patron	0.334	0.311
New Entree	0.380	0.172
Gift	0.229	0.538
High Satisfaction	0.615	0.029
Low Satisfaction	0.132	0.587
Perceived Novelty	0.562	0.088
R^2		0.257
Adjusted R^2		0.201

that several potential interactions were examined; however, none were statistically significant.)

The results indicate that four of the variables are significant. It appears that having (1) a committed decision maker in the group, (2) highly satisfied group members, and (3) group members who perceive the consumption experience as novel creates greater product discussion. Thus, H2, H6, and H8 are supported. The relationship between weak social ties and WOM is significant but in the opposite direction than hypothesized. Four of the independent variables are not statistically significant: (1) a new restaurant patron, (2) new entree consumed, (3) gift-giving situation, and (4) low satisfaction. Thus, H3, H4, H5, and H7 are not supported.

DISCUSSION

This field study suggests that the social environment and individuals' perceptions of the consumption experience play a role in determining the amount of product discussion during consumption, explaining 20% of the variance in WOM behavior. Additionally, it appears that WOM during consumption is a common phenomenon since more than 80% of the respondents indicated that at least one or two comments were made about the food during the meal. Given that WOM can have a strong effect on performance perceptions (Bone 1990), creating positive WOM during consumption should be an important part of a marketing strategy.

The variables found to spark WOM can be used to create positive WOM during consumption. Marketers may wish to create group consumption situations which include a committed decision maker. Many firms have "regulars" who are likely to be

psychologically committed to the establishment. Special promotions can be used to entice these customers to bring their friends and associates along as well. The finding that high satisfaction leads to greater WOM emphasizes the importance of providing quality products and services. Quality which exceeds a consumer's expectations will be rewarded by positive WOM. Finally, offering novel products via unusual presentations or unique product/service offerings can also increase the amount of WOM during consumption.

A few of the findings from the field study were surprising. Most surprising was the inverse relationship between social ties and WOM. It is possible that individuals who have weak social ties spend more time talking about each other's past experiences and interests in an effort to find common interests and to learn more about each other. On the other hand, individuals with strong ties may spend more time talking about the present since they already know so much about one another. Their conversations may focus on daily events (e.g., How was the office today? What do you want to watch on TV tonight? Do you like what you ordered?).

Also surprising is the fact that high satisfaction led to more WOM during consumption, but low satisfaction did not. One problem may be that the vast majority of the respondents in the study were relatively satisfied with the food they received. Only one subject indicated that the food was terrible and only three indicated that they were mostly dissatisfied (out of 321 respondents). Thus, even though individuals identified as dissatisfied had satisfaction scores well below the mean, it is possible that they experienced only moderate dissatisfaction.

This study reveals that WOM during product consumption is a rather common event which can be partially explained by only a handful of variables. Of course, findings may be limited to the respondent population and environments examined herein, but the study does open a variety of issues for further investigation. For instance, only a small portion of the factors which may affect WOM were investigated. Other characteristics such as the consumption atmosphere (e.g., upscale vs. downhome environments), the structure of the consumption group (e.g., family vs. business), mood states, time of day/year, and product consumption with the purpose of determining adoption of the product/service by a group may also affect the amount of WOM during consumption.

In the future, other product consumption situations should be examined. Specifically, alternative product such as movies, compact disks, sporting equipment, video games, etc. can be examined to determine how frequently conversations occur and what variables spark such conversations. In addition, we can examine product trial situations and shopping experiences to determine the frequency and content of such discussions.

Given the high levels of satisfaction reported by the respondents, it is probable that the majority of the conversations held were positive in nature. Yet, future research should examine the content of product conversations--the valence of the conversations, common themes which run through conversations, the demographic and psychological characteristics which play a role in the content of WOM, and the effect of these conversations on repurchase decisions.

In sum, this study shows that several variables (social ties, committed decision maker role, satisfaction and perceived distinctiveness) systematically influence the amount of WOM during consumption. In addition, the paper offers a multi-item measure of the amount of WOM which appears reliable. Given that WOM conversations can explain over 20% of the variance in product judgements (Bone 1990), it is clear that this topic is deserving of further research.

Buying More than We Can Use: Factors Influencing Forecasts of Consumption Quantity

Mary Frances Luce, Duke University

ABSTRACT

This paper develops a process description of consumer forecasts concerning the optimal quantity of repeatedly consumed goods. The case where limited availability necessitates a forecast over an unusually long time period is of particular interest. It is hypothesized that extension of the forecast period will induce upward bias in quantity forecasts. It is further hypothesized that reliance upon current preferences in the absence of the ability to predict future preferences is a primary factor underlying this bias. The roles of confidence in current preferences, of safety stock, and of forecast heuristics are also discussed.

There has been recent interest in individuals' ability (or lack of ability) to understand their own preferences. For instance, theoretical (March 1978) and empirical (Kahneman and Snell 1990; Varey and Kahneman In press) work suggests that people are unable to accurately predict their future preferences. The related issue to be discussed in this paper is how, and with what degree of accuracy, individuals forecast their utility maximizing purchase quantity. Little work has been done to date investigating the processes by which individuals decide *how much* of a good to buy. Instead, research has concentrated on the manner in which consumers decide *what* to buy. However, the quantity decision is a very important part of the purchase process. Many sellers, notably those handling food and clothing, rely on consumers to make large, repeat purchases. Therefore, encouraging multiple purchases is often one of the seller's major goals. The quantity forecasting issue will be examined primarily within a special case. This case is that of a relatively long forecast period caused by limited availability of the good under consideration.

It may seem that the quantity decision made during any particular shopping trip is unimportant; one may simply correct a suboptimal quantity decision on the following trip. This would be true if consumption rate were exogenous to inventory level. However, there is some evidence that consumption rate is a function of inventory level (Folkes, Gupta, and Martin 1991). This indicates that each quantity decision may play a role in the determination of total consumption.

It seems that forecasts of consumption quantity will generally display upward bias, especially when limited product availability extends the forecast period. Several cognitive processes which may contribute to this effect are discussed below. This paper does *not* discuss the effect of limited availability upon preferences, and, therefore, upon *optimal* purchase quantity. The enhancing effect of limited availability upon preferences is important, but has been well documented elsewhere (e.g., "the rule of the few," in Cialdini 1985). Instead, this paper concerns

the effects of scarcity upon consumption forecasts *holding preferences constant*.

There is anecdotal evidence for the hypothesis that limited availability results in higher forecasts of consumption quantity. The Wall Street Journal reports that Warner-Lambert Co. enjoyed an impressive sales increase in three flavors of gum once the company limited their availability to two months a year. Sales rose from \$3.2 million in 1986 to \$10.5 million in 1988. Pam Goyette, a Warner-Lambert senior product manager, attributes this success to the fact that consumers "really load up" on the gums as a result of their limited availability (Alsop 1989, p.B1).

There is also intuitive appeal to the notion that limited availability will produce overestimation of one's optimal consumption amount. In general, it seems that people overestimate when consumption forecasts are necessary. The cognitive processes and biases which are investigated below seem to produce a behavioral theme of unfounded optimism concerning one's enjoyment of any item under consideration. Further, this optimism seems to be accentuated when forecasts of optimal quantity must be made in advance. We tend to take more food than we can possibly eat when later access to the buffet table is limited. We consistently forget that we will be tired after the first week of vacation. We do not realize that we will not wear the clearance shoes that we buy in three colors.

Implications resulting from this work will generalize to two classes of marketing situation. First, this analysis is directly relevant to the case of limited product availability. Some consumer items are routinely offered on a restricted basis. For example, many clothing products are available for only one season. Food items, such as beer and candy, are commonly offered seasonally or in limited editions. Many collectibles are offered "for a limited time only." Exclusive distribution restricts a good's availability for consumers who live far from a store which carries the good. Tourist items are of limited availability to the traveler. Any insights as to how consumers make quantity decisions under limited availability should aid marketers of the above product classes. Likewise, this theoretical development provides a rationale for the somewhat counter-intuitive practice of making one's products difficult to obtain.

The second, and more common, case to which these ideas apply is that of sale items. Most products are constantly available, but are periodically available at a sale price. Sales may induce customers to estimate optimal consumption levels over relatively long time periods. In fact, some consumers refrain from buying certain items unless those items are on sale. Thus, periodic sales may cause the consumer to behave as if an item is not continually available. The ideas in this paper may, therefore, be valuable to marketers who use price discounts as a promotional tool. This paper

provides a rationale, beyond inducement of trial or switching, for the offering of periodic price discounts.

What follows is a discussion of several processes which may contribute to bias in the forecasting of consumption quantities. The bulk of this paper discusses a process by which difficulty in forecasting preferences may cause biased quantity forecasts. Additional, complementary processes and biases are also discussed. The major goal of this paper is to apply knowledge concerning cognitive functioning to a relatively ignored problem in consumer research.

PROCESSES INVOLVED IN FORECASTING QUANTITY

Forecasting Preference

Previous Research. It seems that forecasting one's future preferences is a difficult task. March (1978) theorizes that future preferences are fuzzy and capricious. Therefore, he states, decisions concerning future outcomes must reflect guesses, not certainty, about one's preferences for these outcomes. Furthermore, he hypothesizes that current theories of choice, which do not acknowledge irregularities in preference, are inadequate for the description of human decision making.

Kahneman and his colleagues (Kahneman and Snell 1990; Varey and Kahneman In press) offer experimental evidence indicating that individuals cannot accurately predict their own preferences. For instance, subjects in Kahneman and Snell's (1990) experiments were asked to predict, after an initial sampling, their own preference fluctuations during repeated exposures, over several successive days, to food and music. Correlations between actual and predicted changes in tastes were minimal, even for this relatively simple preference forecasting task.

Further, subjects do not consistently incorporate information about fluctuations in the quality of a class of experiences into decisions concerning these experiences. Kahneman and his colleagues demonstrate that subjects choose risk seeking alternatives when deciding among probabilistic strings of increasingly unpleasant experiences. Risk seeking decisions are inconsistent with the increasing marginal disutility reported by the majority of these same subjects. For instance, subjects did *not* consistently prefer a probabilistic (in the number of treatments necessary) medical treatment which offered a reduction from ten to eight treatments for one outcome in exchange for an (equally probable) increase from two to four treatments for another outcome. However, the same subjects indicated that treatment side effects would worsen with time, implying that the reduction from ten to eight is more "valuable" than the reduction from four to two (Kahneman and Snell 1990; Varey and Kahneman In press). Varey and Kahneman (In press) conclude that "responses to questions eliciting intuitions about global utilities [for a series of experiences] are unaffected by people's beliefs about the changes in the experience over time" (p.19).

Why might people be insensitive to trends in a series of hedonic experiences? Kahneman and Snell (1990) hypothesize that people commonly fail to conduct separate evaluations of each experience. They propose that individuals simplify decisions by using an "instantaneous representation" to evaluate temporally separated sets of outcomes. An instantaneous representation is simply a projection of the relevant time period onto a single moment. Consultation of the instantaneous representation results in neglect of the unique aspects of each experience. For example, instead of integrating the predicted utility of each of a set of experiences, people may use "news utility" as a simplification allowing evaluation of the set. News utility consists of the individual's prediction of his own emotional reaction to learning that he will undergo the experiences in question (Kahneman and Snell 1990). To foreshadow, it seems that news utility will be evaluated against current preferences. For instance, it seems that the news that one will consume three chocolate bars in the future will be less favorably evaluated if one has just consumed two.

Preference Forecasting. The above theoretical development may be directly applied to the quantity forecasting process. To make optimal quantity decisions, the consumer must consider the hedonic quality of several, temporally separated, consumption experiences. Each consumption experience will likely be unique due to preference fluctuations. The empirical work discussed above indicates that the consumer will be unable to accurately incorporate these preference fluctuations into her decision. Instead, she may collapse the forecast period and use one measure of preference. This will most likely be current preference since evidence suggests that people cannot estimate future preferences very well. In other words, current preference may be used to represent preferences throughout the forecast period.

Quantity forecasts, therefore, will be biased to the extent that current preference is not representative of future preference. Hence, one must investigate the likely nature of preference fluctuations in order to determine the nature of the bias, if any, induced by reliance upon current preferences. McAlister (1982) offers a useful model of preference fluctuation. She proposes that individuals hold inventories of recently consumed attributes (such as "fruit flavor") and that preference is inversely related to inventory levels. In her model, attribute inventories continually deplete, with individual- and attribute-specific parameters determining the depletion rate. Preference is at its highest when attribute inventories are at their lowest. Preferences continually fluctuate, lowering with consumption and then gradually rising. Satiation, or the degree to which a preference deviates from its highest level, is included in current preferences to the extent that the relevant attributes have been recently consumed.

The work of Kahneman and his colleagues (Kahneman and Snell 1990; Varey and Kahneman In press) suggests that satiation will only affect the preference forecast process to the extent that current preferences are moderated by satiation. Absence of

recent consumption, and therefore absence of satiation, is almost guaranteed at the beginning of a restricted availability period. Obviously, an individual cannot consume a good which is not available. Preferences throughout the forecast period will, however, be moderated by consumption. Therefore, with limited availability, preferences during purchase are very likely to be higher than average preferences over the forecast period. If these abnormally high preferences are used as a proxy for preferences during the forecast period, upwardly biased quantity forecasts should result.

The likely level of preferences at the time of purchase is less certain with sale items. However, if the individual buys more than he normally would because an item is on sale, and consumption elevates as a result, preferences over the period should be more moderated by satiation than are preferences at the time of purchase. This implies that the manager should allow time for inventories (real and, hence, attribute inventories) to become depleted between sales. Further, it implies that a strategy of restricting availability will work best for distinctive goods. Otherwise, attribute inventories may be maintained by consumption of similar goods.

In general, abnormally high preferences at the beginning of an availability period should result in overestimation of the average hedonic quality of consumption of the good in question. Thus, the following is proposed:

P1a: Consumers will rely on current preference as a proxy for preferences throughout the consumption period when determining purchase quantity.

P1b: Forecasts of optimal consumption quantities will become upwardly biased as the time horizon of forecast is extended.

The above analysis implies that the individual generally cannot adequately forecast satiation or incorporate anticipated satiation into his forecasts. This hypothesis follows from the empirical work of Kahneman, Snell, and Varey. Of course, this does not imply that satiation can never be anticipated. An individual may eventually learn to recognize that she typically overestimates preference for a certain item; this seems most likely with frequently purchased items. However, the difficulty individuals display in predicting preferences should preclude the general finding of accuracy in predicting satiation. This is, of course, an empirical question:

P2a: Individuals will not adequately consider satiation when making consumption forecasts.

Although it may be impossible for the individual to incorporate satiation into her quantity forecast, manipulation of attribute inventory levels should alter preferences, affecting quantity forecasts:

P2b: Forecasted quantity will decrease with recent consumption of the item under consideration.

The Role of Certainty. Subjective certainty in one's current preference may contribute to bias in quantity forecasts. Certainty is not typically correlated with accuracy in decision making, with overconfidence being the norm (e.g., Lichtenstein, Fischhoff, and Phillips 1982). Recent evidence suggests that overconfidence is caused by people's tendencies to overweight the strength or extremeness of evidence relative to its weight or credence (Tversky and Griffin In press). Individuals tend towards overconfidence in decisions when the evidence upon which they are deciding has high strength but low weight. For instance, an extreme proportion (high strength) based upon a small sample (low weight) may produce overconfidence. Extreme preferences are high in strength but low in weight; they are noticeable, like the extreme proportion, but unreliable, like the small sample. Thus, a high preference level may actually *cause* overconfidence. Subjective certainty may, therefore, operate to exacerbate bias from reliance upon abnormally high current preferences. (Of course, this overconfidence may also operate on abnormally low preferences, but in this case the individual will simply not buy the good in question.)

P3a: Individuals should show a significant, positive correlation between preference level and certainty.

P3b: Individuals should show an insignificant correlation between certainty and accuracy when forecasting quantities.

Thus far, we have discussed cognitive processes which may cause individuals to *inadvertently* buy more than their optimal amount of a good. Other cognitive mechanisms may cause individuals to *intentionally* buy more than they believe is optimal. This possibility is discussed below.

Purchases Above Forecasted Optimality: Safety Stock

One could conceptualize the task of forecasting optimal quantity as an inventory problem. A possible contributor to large quantity forecasts, evident from the inventory framework, is the purchase of excess inventory or safety stock. These are simply items purchased, in addition to the quantity forecasted as optimal, in order to lower the risk of a stockout. Both normative solutions to inventory problems (i.e., the newsboy problem) and intuition dictate that safety stock depends upon the costs of overestimation and underestimation of optimal quantity. The individual should buy exactly the forecasted amount if both costs are equal. As underestimation of optimal quantity becomes relatively more costly, the individual should purchase increasing amounts of safety stock.

The human value function is such that the perceived cost of underestimating consumption may consistently dominate that of overestimating. People

tend to value the disutility associated with goods of which they are deprived more highly (i.e., against a steeper value function) than they value the disutility of forfeiting the purchase price of those same goods. In general, goods of which one is deprived are valued as a loss while money spent on goods is not, and value functions are typically steeper for losses than for gains (e.g., Tversky and Kahneman *In press*). Even *anticipated* consumption is thought to shift the individual's reference point, so that not having an anticipated item will be valued as a loss (e.g., Hoch and Loewenstein 1990). Thus, people may evaluate the cost of having one too few of the item under consideration by a steeper disutility function than that by which they will evaluate the cost of buying one unnecessary item. If so, the cost of underestimating consumption will routinely dominate the cost of overestimating consumption. Hence, the consumer will be prone to consistently buy at a level above his forecasted optimal quantity.

Forecasting Consumption Opportunities

This section will briefly discuss a second estimate which must be made before purchase quantity can be determined. Specifically, the individual must forecast the number of opportunities he will have to use the product class in question. Note that this forecast is very likely made simultaneously with one's preference forecast; the processes are separated for clarity. The general form of the heuristic used to forecast consumption opportunities may influence the amount of bias in one's final quantity forecast. An estimate of consumption opportunity must, in general, be based upon either a rate or a whole number. When using a rate-based strategy, the individual may be less likely to consider satiation because the focus is upon "one-at-a-time" (i.e., once a day) consumption. Therefore, bias should generally be at its worst when this form of heuristic is utilized. Alternatively, a holistic (i.e., based upon determination of a total number of opportunities) heuristic seems likely to cause the decision maker to focus on a large amount (i.e., 30 items monthly) of consumption. Therefore, satiation seems more likely to become salient. Use of a holistic heuristic may therefore lead to moderation of the proposed bias.

- P4: Forecasted consumption quantity will be larger with a rate-based heuristic than with a holistic heuristic.

It would be helpful to determine factors influencing the type of forecasting heuristic which is used. Some related research, involving estimates of past behavior, exists (e.g., Blair and Burton 1987). For instance, there is some suggestion that a (holistic) "recall and count" strategy is less likely, and a rate-based strategy is more likely, as the estimation period is extended (Blair and Burton 1987). Thus, rate-based strategies may be more likely once the forecast period is extended. This may be yet another contributor to the expected upward bias in quantity forecasts with lengthened forecast periods.

However, several factors unrelated to the length of the forecast period may influence what sort of heuristic is adopted. The heuristic may be influenced by a firm. For instance, some forms of packaging (i.e., soda in separate cans) may promote a rate-based heuristic, while others (i.e., two liter bottles) may promote a holistic heuristic. Other factors, such as experience with the product class, may influence which heuristic is chosen and may also directly influence the magnitude of the bias observed. For instance, experienced users of a product class may be more likely to use a rate-based heuristic, but, due to their experience, they may also be less likely to arrive upon a biased forecast. Thus, the relationship between rate-based heuristics and forecasting bias may be attenuated by the effects of factors such as experience.

CONCLUSION

This paper begins investigation of a problem which has been neglected by consumer researchers, namely the manner in which a consumer forecasts optimal purchase quantity for a repeatedly consumed good. This paper has further focused upon the special case of limited product availability. However, some of the factors discussed above may impact quantity forecasts of goods which are of unlimited availability. For instance, individuals may have a general propensity to purchase safety stock. Thus, the process description offered above may apply to more than just this special case.

Research promoting understanding of the forecast process could have detrimental as well as beneficial effects on the consumer. It almost certainly is just as easy to "help" the consumer add bias to his estimates as it is to help the consumer remove this bias. However, future research efforts may uncover or develop techniques for avoiding overestimation of purchase quantities. For example, consumers may reduce bias in their forecasting decisions by variety seeking. It may simply be easier to generally restrict oneself from buying too much of one thing than it is to make accurate forecasting decisions. An individual may learn to curtail his tendency to overestimate optimal quantity by developing variety seeking rules.

Finally, note that the specific processes and events described above may operate in a complementary- or a contradictory- manner. Returning to our Warner-Lambert gum example, several processes may have combined to create the observed sales increase. Consumers' preferences may become enhanced with limited availability; perhaps the gum is now seen as a novelty item. Deficits in forecasting satiation with the gums' distinctive flavors may occur, leading to upwardly biased forecasts of preference over the forecast period. The cost of underestimation of consumption is likely to dominate that of overestimation, so that individuals purchase safety stock. Finally, individuals may tend to overestimate the possible opportunities for chewing gum. For instance, one may use a rate-based heuristic and forget to adjust downward for occasions when gum chewing is not appropriate.

When Are Higher Social Class Consumers More and Less Brand Loyal Than Lower Social Class Consumers?: The Role of Mediating Variables

Rajesh Kanwar, San Diego State University
Notis Pagiavlas, San Diego State University

In this study we investigated the extent to which perceived risk mediates the influence of social class and purchase experience on brand loyalty. We found that the relationship between social class and brand loyalty is far more complex than previously thought. This study's results indicate that depending on the mediating variables and causal paths involved, brand loyalty can both increase and decrease with social class.

INTRODUCTION

Soon after Brown (1952) first published his findings on brand loyalty, researchers quickly identified its theoretical and managerial importance. Investigators realized that since brand loyalty (the repeated acquisition of a brand because of a distinct preference for it (Jacoby and Chestnut 1978)), or its absence, represented the final outcome of consumers' decision processes, it was seminal to understanding consumer behavior. And brand loyalty's managerial importance was indelibly established when researchers found that loyal customers account for most of a brand's sales (McConnell 1968).

Because brand loyalty is so central to consumer behavior and a brand's profitability, much research has been conducted on identifying the environmental (e.g., marketing) and individual factors that influence the amount or level of brand loyalty consumers develop towards brands. Thus, researchers have investigated the influence of individual factors such as social class (e.g., Carman 1970), demographic characteristics (e.g., Prasad 1975), personality (e.g., Carman 1970), prior experience (e.g., Tucker 1964), and perceived risk (e.g., Roselius 1971) on brand loyalty. In a similar vein, researchers have also examined the influence of environmental variables such as perceived product quality (McConnell 1968), price activity levels, and the number of brands available (Farley 1964), on consumer brand loyalty.

Of all these influences, one factor--perceived risk--seems to consistently influence brand loyalty across diverse products and consumer populations (e.g., Derbaix 1983; Sheth and Venkatesan 1968). Thus perceived risk has been found to influence brand loyalty or choice for disparate products and services such as drugs (Bearden and Mason 1978), consumer goods outlets (Prasad 1975), fabric softeners, laundry detergents, coffee, ice cream (Dunn, Murphy, and Skelly 1986), and automobiles (Peter and Ryan 1976). However, even more impressively, perceived risk has also been shown to influence brand loyalty across diverse consumer groups. For instance, despite the general paucity of cross cultural research (Albaum and Peterson 1984), perceived risk has been shown to influence brand loyalty in culturally and economically heterogeneous countries such as Mexico (Hoover, Green, and Saegert 1978), and India (Kanwar 1989), in addition to the U.S.

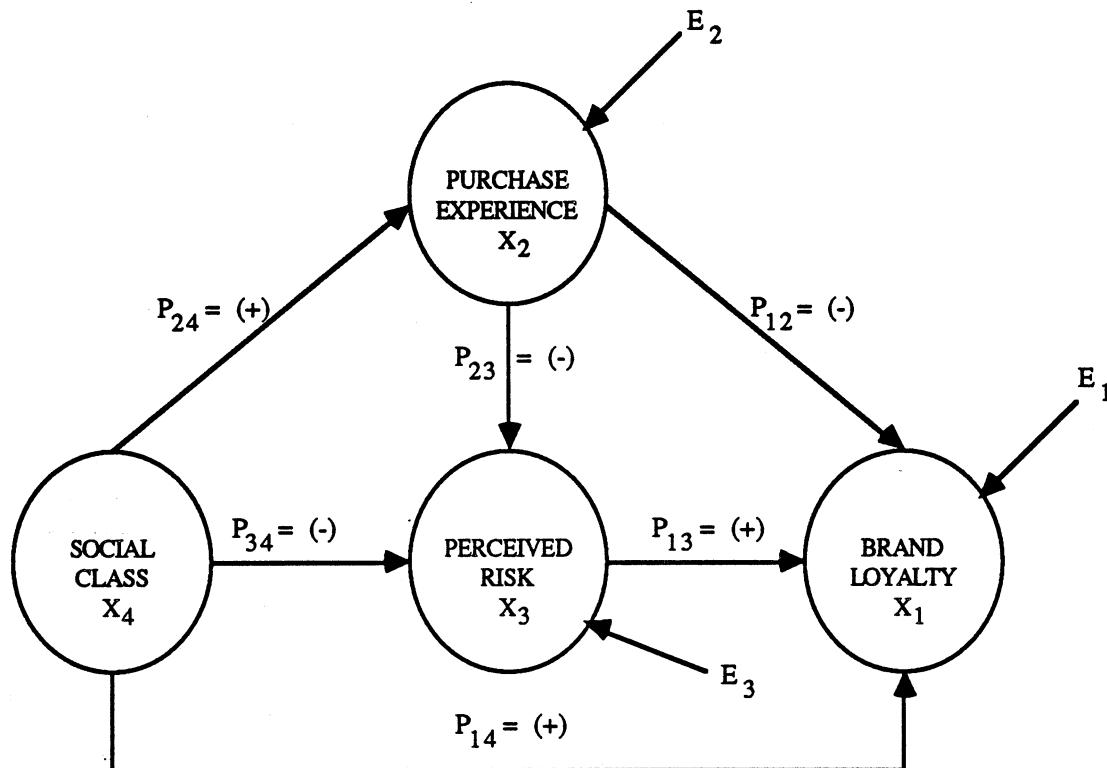

In fact, because perceived risk influences important consumer behaviors beyond brand loyalty, it has emerged as a significant aspect of consumer behavior in its own right. For instance, perceived risk has been shown to influence consumers' store choices (e.g., Potter and Coshall 1985), information search behaviors and information sources (e.g., Garner and Thompson 1986), new product adoption (e.g., Popielarz 1967), and involvement levels with products and decisions (e.g., Laurent and Kapferer 1985). Consequently, just like for brand loyalty, much research has been conducted on the factors that influence consumer risk perception levels. Thus substantial research has been conducted on exploring the influence of such individual and environmental factors as social class (Dash, Schiffman, and Berenson 1976), demographic characteristics (Schiffman 1972), personality (Schaninger 1976), product experience (McConnell 1968), and nature of the product (Dunn, Murphy and Skelly 1986), on risk perception. However, as prior discussion shows, many of the same factors have also been used in research on the factors that influence brand loyalty. For example, Schaninger (1976) and Carman (1970) investigated the influence of personality on perceived risk and brand loyalty respectively.

Thus, this extant research consists of three streams (i) the perceived risk-brand loyalty relationship, (ii) the influence of individual and environmental factors on brand loyalty, and (iii) the influence of individual and environmental factors on perceived risk. But, this research has ignored a related issue. To what extent does perceived risk mediate the influence of individual and environmental factors on brand loyalty? For example, we know that social class influences perceived risk as well as brand loyalty, and that perceived risk influences brand loyalty (e.g., Carman 1970; Chance and French 1972; Dash, Schiffman, and Berenson, 1976; Sheth and Venkatesan 1968). But, we do not know the extent to which perceived risk mediates the influence of social class on brand loyalty.

Thus, in general, in this study we are interested in determining the extent to which perceived risk mediates the influence of individual or environmental factors on brand loyalty. In specific, as Figure 1 shows, this study investigates the extent to which perceived risk mediates the influence of social class and purchase experience on brand loyalty.

We chose to investigate the affects of these two individual variables because of their theoretical and managerial importance. For instance, because social class and purchase experience influence a variety of important consumer behaviors (other than brand loyalty and perceived risk), such as shopping behavior, information search, store choice, and media exposure (see Rich and Jain 1968), they are among the

most powerful methods of segmenting markets (e.g., Myers, Stanton, and Haug 1971; Schaninger 1981).

HYPOTHESES

As we discussed above, the purpose of this study is to explore the extent to which perceived risk mediates the influence of social class and purchase experience, on brand loyalty. As we mentioned before, brand loyalty increases with perceived risk (e.g., Roselius 1971; Sheth and Venkatesan 1968). That is, as perceived risk increases, consumers minimize or reduce the probability of, financial, social, or other losses by repurchasing products that they know perform satisfactorily. We could thus conclude that since the higher social classes perceive less risk (Dash, Schiffman, and Berenson 1976), they should also be less brand loyal than consumers who belong to the lower socioeconomic groups. But, research results do not support this conclusion. For example, Carman (1970) and Chance and French (1972) found that consumers from the higher social classes were more brand loyal than consumers from the

lower social classes. We thus have seemingly contradictory findings.

In fact, some other research too suggests that consumers from the higher social classes should be less brand loyal than consumers from the lower social classes. As Bell (1964) and Hayes (1959) suggest, consumers from the higher social classes have a higher tolerance for risk (and may in fact seek out risk), than consumers from the lower social classes. Thus, because of their tolerance for risk, the higher social classes should be less brand loyal than consumers from the lower social classes. But, again, other research suggests that because the lower social classes are usually more concerned about preserving limited resources, they are more likely to switch brands than higher social class consumers (Dash, Schiffman, and Berenson, 1976). That is, because of a need to preserve resources, consumers from the lower social classes are less likely to be brand loyal than consumers from the higher social classes. Consequently, there seem to be competing and contradictory hypotheses regarding the relationship

between social class and brand loyalty. However, as we discuss below, it may be possible to resolve this contradiction, by assuming that social class has several separate and contradictory influences on brand loyalty.

First, because measures of social class often include financial resources (see Ellis 1975), there is what we could call the direct affect of social class on brand loyalty (P_{14} in Figure 1). As we mentioned above, Dash, Schiffman, and Berenson (1976) suggested that consumers from the lower social classes are likely to switch brands when doing so helps them conserve resources. That is, social class should be positively related to brand loyalty. But, social class also has a second, indirect, affect on brand loyalty that is mediated by perceived risk.

As we mentioned earlier, people who belong to the higher social classes not only have a higher tolerance for risk (often seeking out risk), but because they are also more self-confident, they tend to perceive less risk than their counterparts from the lower social classes (Bell 1964; Hayes 1959; Prasad 1975). That is, if we consider the path:

social class → perceived risk → brand loyalty

in Figure 1, social class should be inversely related to perceived risk (i.e., a negative P_{34}), while brand loyalty should of course increase with perceived risk (i.e., a positive P_{13}). Thus, the net impact of social class on brand loyalty, through perceived risk, should be negative ($P_{34} \times P_{13}$), resulting in two related hypotheses regarding the affects of social class on brand loyalty. First:

H(1): In the causal diagram shown in Figure 1, when we consider the direct path between social class and brand loyalty, indicated by P_{14} , brand loyalty should increase with social class (that is, P_{14} should be positive).

and second,

H(2): When we consider the causal path social class → perceived risk → brand loyalty in Figure 1, brand loyalty should decline with increases in social class (that is $P_{34} \times P_{13}$ should be negative), since perceived risk should decline as social class increases (a negative P_{34}), while brand loyalty increases as perceived risk increases (a positive P_{13}).

However, in addition to the above affects of social class, we are hypothesizing that social class has two other indirect affects on brand loyalty that are mediated by purchase experience. Research indicates that consumers who belong to the higher social classes not only consume a wider variety of products and services, than lower social class consumers (Myers, Stanton, and Haug 1971; Schaninger 1981),

but that they use or buy these products more often too (Hirisch and Peters 1974). Consequently, people who belong to the higher social classes are much more experienced as consumers than people from the lower social classes. Because of this greater breadth and depth of purchase experience, the higher class consumers should possess highly developed consumer and decision-making skills that enable them to make consumption decisions, and evaluate products and marketing communications, with confidence and relatively little risk. They should, therefore, both perceive less risk, and also be more willing to switch brands, than consumers from the lower social classes. In other words, both perceived risk and brand loyalty should decrease with experience. However, since purchase experience increases with social class, we are hypothesizing that when we consider the two paths:

social class → purchase → perceived risk → brand
experience experience loyalty

and,

social class → purchase experience → brand loyalty

in Figure 1, brand loyalty should decline as social class increases because:

H(3): As purchase experience increases, both the amount of perceived risk and brand loyalty should decline (negative P_{23} and P_{12}). Thus, the overall impact of social class on brand loyalty along the two paths should also be negative (both " $P_{24} \times P_{12}$ " and " $P_{24} \times P_{23} \times P_{13}$ " should be negative), since purchase experience increases with social class, and brand loyalty increases with perceived risk (both P_{24} and P_{13} are positive).

METHODOLOGY

In order to test our hypotheses, we conducted a study with Asian Indian women. As we briefly indicated earlier, most consumer behavior studies have been conducted with U.S. consumers (Albaum and Peterson 1984). Consequently there is a great need for cross-cultural research that replicates and extends the results of studies conducted with U.S. consumers, to other cultures and economies. Conducting this study with women from India makes just such a contribution. But, such a strategy carries the risk that the study's results may be culturally driven. Although possible, we feel that such concerns are at least somewhat ameliorated by a variety of factors. First, as mentioned earlier, prior research found that perceived risk produces similar consumption behaviors across diverse cultures and economies, including India (Hoover, Green, and Saegert 1978; Kanwar 1989), somewhat alleviating the concern that this study's results may be culturally driven. In addition, as Figure 1 shows, our causal model includes, indeed builds on and extends, some previously established

relationships (e.g., the perceived risk-brand loyalty relationship). Thus, we can test whether our study replicates these established relationships. If it does, we would have added confidence that this study's results are not culturally driven. And, we would have also made an incremental contribution towards establishing the cross-cultural validity of prior findings related to perceived risk, and meeting the need for more cross-cultural research.

Sample

Altogether 222 women, residing in a major city in Southern India were used as subjects in this study. A two-stage sampling plan was used to select these women. In order to recruit women from the middle and upper social classes, we randomly selected three residential areas where middle and upper middle class families were known to reside in the city of interest. Then residential maps of these three areas were used to randomly select 150 single family homes for participation in the study. One of three women investigators then visited each home, and administered the questionnaire used in the study to the "lady of the house." If the "lady of the house" was not available, up to two call backs were made to contact the selected respondent. Because of the high call back rate, the non-response rate was only 4%, resulting in the final sample of 144 women from these areas.

Exactly the same procedure was used to recruit women belonging to the lower social classes, except that these women were recruited from two randomly chosen lower social class residential areas. Although we had randomly chosen ninety single family homes, from these areas for participation in the study, only seventy-eight of these women participated in this study because of the slightly higher refusal rate in these areas.

Respondent Characteristics

The average middle and upper social class woman was married (98%), 36 years old, and had two children. Ninety-six percent had completed high school, and 81% had undergraduate or higher degrees (in comparison the country's literacy rate is 36%). However, only 11% of the women worked outside the home, 89% classifying themselves as housewives. The average family income was about \$2400 per year, as compared to the national average household income of about \$1200. Thus, as desired, the women in the sample belonged to India's middle and higher social classes, with higher than average education and incomes.

In contrast the average woman from the lower social classes was 35 years old, married, and had 2.4 children. Not only did a much lower proportion have undergraduate degrees, but the average family income of \$1250 was almost half that of the higher social classes. Less than 10% worked outside the home, more than 90% classifying themselves as housewives.

Procedures

Each subject answered an interviewer administered questionnaire designed to measure demographic characteristics and perceived risk for

twenty non-durable consumer product categories such as personal care products (e.g., hair removers), over-the-counter drugs (e.g., headache remedies), and household and food products (e.g., detergents and instant coffee).

Perceived risk for these product categories was measured with scales similar to those used by other researchers (e.g., Dean, Engel, and Talarzyk 1972). Two five-point scales were used. Although four-point scales have been more commonly used to measure perceived risk (e.g., Dean, Engel, and Talarzyk 1972; Hoover, Green, and Saegert 1978), five-point scales were used in this study because pretests indicated that these were more suitable, than the four-point scales, for Indian consumers. The first scale measured the degree of perceived similarity between brands in each product category (1 = very similar, 5 = not at all similar). The second scale measured the amount of risk the consumer associated with trying new products in each product category (1 = no chance at all, 5 = very high chance). The scores on the two scales were then summed to produce the amount of risk each subject perceived for each product category. In addition, we used a similar five point scale to measure brand loyalty towards each product category, requesting consumers to estimate the likelihood that they would try brands that they had not tried before. Since subjects only responded to the perceived risk and brand loyalty scales for the products that they used, we then constructed mean indices of perceived risk and brand loyalty for each subject by averaging across these scales for the products respondents used.

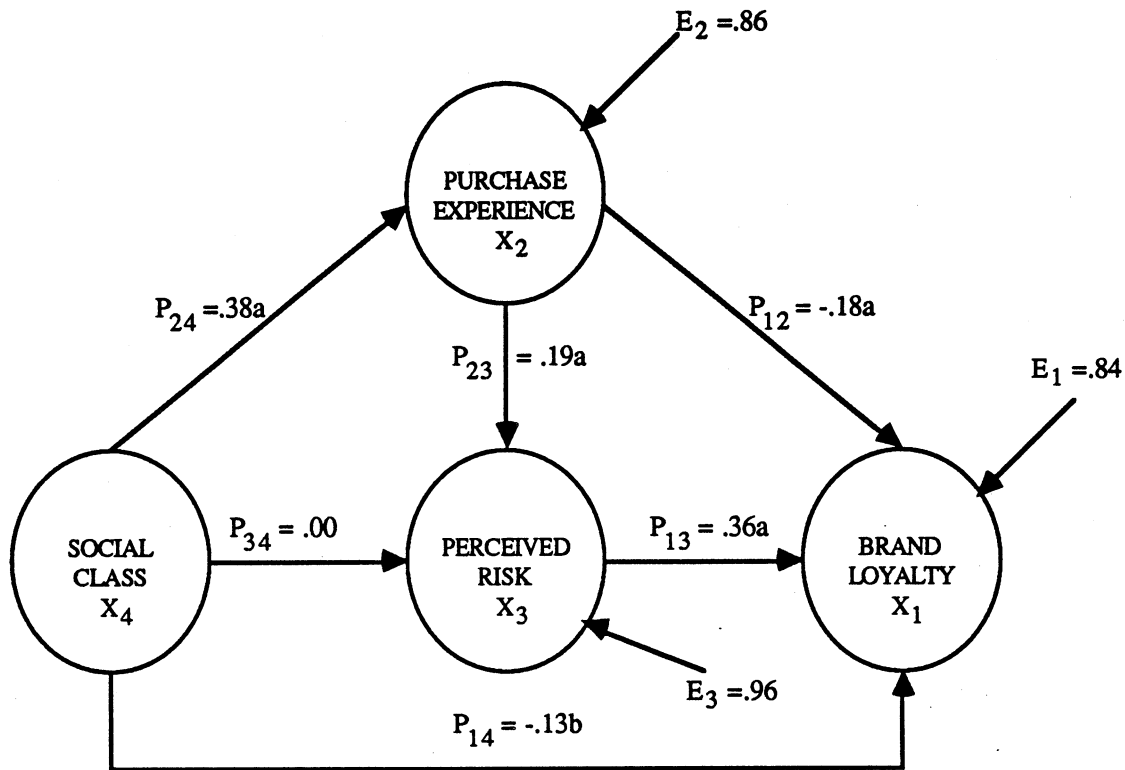

We also computed an index of social class for each respondent by summing the scores on two four point scales measuring each housewives level of education, and the family's income. Although previous research has generally included occupation with income and education to produce indices of social class (Ellis 1975), we did not include occupation in our index because our sample consisted of women, who usually do not work outside the home in India (as shown by the high percentage of the women in the sample who considered themselves housewives).

Finally, we counted the number of different products each woman used, and used this count as an indicant of the breadth of each consumers' purchase experience.

RESULTS

As discussed earlier, we had hypothesized that the direct influence of social class on brand loyalty would be positive, but that the indirect affect, mediated by perceived risk, would be negative. That is, P_{14} would be significant and positive, but that P_{34} would be negative while P_{13} was positive, so that the overall impact of social class on brand loyalty would be negative ($P_{34} \times P_{13}$). We had also hypothesized that while consumers purchase experience would increase with social class (a positive P_{34}), consumers perceived risk and brand loyalty would decrease with increasing purchase experience (negative P_{23} and P_{12}), so that the overall influence of social class on

FIGURE 2
Solutions of the Structural Equations and Causal Model Shown in Figure 1

a. Significant at $p < .01$
b. Significant at $p < .10$

brand loyalty, that was mediated by perceived risk and purchase experience, would be negative.

We tested these hypotheses by using regression analyses to solve the structural equations shown in Figure 1. Figure 2 presents the results we obtained when we solved these equations.

We had earlier expressed our concern that because this study was conducted with Asian Indian women, its results could be culturally driven. As we had then mentioned, such concerns would be somewhat reduced if our study replicated previously established findings. As Figure 2 shows, our study clearly does so.

First, like previous researchers (Hirisch and Peters 1974; Myers, Stanton, and Haug 1971; Schaninger 1981) we too found that consumer purchase experience increased with social class ($P_{24} = .38, p < .01$). That is, just like in the U.S., Indian consumers who belong to the higher social classes consume a wider variety of products, than consumers from the lower social classes. Similarly, as expected, we also found that perceived risk was positively related to brand loyalty ($P_{13} = .36, p < .01$). That is, just like U.S. consumers, Indian consumers too use

brand loyalty as a method of reducing risk. Thus, since our study replicates both these established relationships, we can be at least somewhat confident that the results and test of hypotheses we report below, are not culturally bound.

As figure 2 shows, our hypotheses were only partially supported. Contrary to expectations, social class only influences perceived risk indirectly. When purchase experience is included in the causal model, social class does not directly influence perceived risk ($P_{34} = 0$). However, we did find that social class had a significant affect on perceived risk, that is mediated by purchase experience ($P_{24} \times P_{23}$). Although contrary to expectations, this relationship was positive rather than negative, that is perceived risk increased with social class, it does suggest that prior research (e.g., Dash, Schiffman, and Berenson 1976), may have overlooked the mechanisms thorough which social class influences risk perception.

Second, and perhaps more important, we found that social class had both positive and negative influences on brand loyalty. For example, we found that as expected, people who are highly experienced consumers are less likely to be brand loyal than

consumers with lower levels of purchase experience ($P_{12} = -.18, p < .01$). Consequently, since purchase experience increases with social class, the overall affect of social class on brand loyalty is negative ($P_{24} \times -P_{12}$). That is, when one considers the causal path:

social class → purchase experience → brand loyalty

brand loyalty decreases as social class increases. People from the lower social class are likely to be more brand loyal than people from the higher social classes. Similarly, although only marginally significant ($P_{14} = -.13, p < .10$) it also seems that when no mediating variables are involved, brand loyalty decreases as social class increases. Perhaps factors such as higher education act to reduce brand loyalty. Because well-read or educated consumers are less likely to be influenced by marketing communications (Levy 1966), consumers from the higher social classes may perceive fewer differences between brands, and are thus more willing to switch brands than lower class consumers.

However, if we consider the causal path:

social class → purchase experience → perceived risk → brand loyalty

it seems that brand loyalty increases with social class, since the sequential relationships between these variables are all positive (P_{24}, P_{23}, P_{13} , are all positive). Thus it seems that depending on the causal path or intervening variables involved, like we had expected, social class had both negative and positive influences on brand loyalty.

Finally, we should also mention here that our finding that perceived risk increases with purchase experience was contrary to expectations. Perhaps, as purchase and product experience increase, consumers perceive greater and greater differences between brands and products, increasing their level of perceived risk. However, only future studies can test the validity of this explanation, since our study does not have the data to allow such a test.

CONCLUSION

Our findings indicate that the influence of social class on brand loyalty is far more complex than previously thought, perhaps explaining the often inconsistent results of previous studies. For instance, as we had discussed earlier, some studies have indicated that perceived risk decreases as social class increases (Dash, Schiffman, and Berenson 1976). Since brand loyalty is high when perceived risk is high, these results suggest that consumers from the higher social classes should be less brand loyal than consumers belonging to the lower social classes. But, studies that directly investigated the relationship between social class and brand loyalty did not support this conclusion. For example, Carman (1970) and Chance and French (1972) found that brand loyalty increased with social class. Our results seem to explain these inconsistent findings. The relationship between social class and brand loyalty is far more complex

than previously thought. Because of intervening or mediating variable such as purchase experience, and perceived risk, both positive and negative relationships between the two variables are possible.

This study's results also indicate that current understanding of the relationship between social class and perceived risk may be oversimplified. The relationship between these two variables seems to be entirely explained by intervening variables such as purchase experience. When this variable is considered, the direct relationship between social class and perceived risk simply disappears.

However, in addition to uncovering the complexity of the relationship between social class and brand loyalty, this study also made another important contribution. By conducting this study with women from India, we not only provided further evidence on the cross-cultural validity of previous research on social class, perceived risk, and brand loyalty, but we also extended this research. Thus, the study made an incremental contribution toward fulfilling the great need for cross-cultural research that validates and extends the findings that have emerged with U.S. consumers.

Playing with Pictures: Postmodernism, Poststructuralism, and Advertising Visuals

Linda M. Scott, University of Colorado, Boulder

ABSTRACT

The postmodern environment in consumer research has led to a diversity of approaches to consumer culture. As is typical of many postmodern enterprises, the new ethic of research has often resulted in recasting consumption and its culture as "texts" to be read and interpreted. Within this framework, several interpretive essays on commercial art have appeared, but all have used structuralist/semiotic theory. This essay explores the advertising visual as a postmodern text, proposing that poststructuralist theory offers particular promise as an appropriate strategy for interpreting graphic signification in consumer culture.

"Our advertising is fed by postmodernism in all the arts and inconceivable without it," writes Fredric Jameson in his landmark essay, "Postmodernism and Consumer Society" (1983, p. 124). The postmodern critique has reached a momentous level among cultural theorists (compare Gitlin 1989; Hassan 1980; Hebdige 1989; Jameson 1983, 1984; Kellner on Baudrillard 1989; Lyotard 1984; McRobbie 1986; Morris 1989). Although there is disagreement about postmodernism's meaning, political orientation, and artistic effects, there is a consensus that the postmodern aesthetic comes from the marketplace. Postmodernism, it is argued, is the artform of the consumer society, an outgrowth of mass production, mass media, and mass marketing (Hebdige 1989; Jameson 1984; Gitlin 1989). Critics assert that postmodernism represents the rise of the visual at the expense of the verbal, and the archetypal example is often the advertisement (McRobbie 1986, p. 54-56). Yet the textual, technological, and historical developments in commercial art that point to the postmodern aesthetic have not been traced.

As this academic kettle was brewing in the humanities, a paradigm shift occurred in consumer behavior that brought us into a "postmodern" period (Lutz 1989, Sherry 1991). This new ethic of research welcomes multiple voices and pluralistic methods for their diversity, richness, and new insights--and mirrors similar moves toward intellectual pluralism in fields like literary criticism and anthropology. As is typical of postmodern enterprises, initial efforts have often recast consumer culture, indeed the act of consumption itself, as a form of text (Stern 1989 is just one example). The study of advertising texts has drawn specific interest, including several essays on advertising visuals (Durand 1987, McQuarrie 1989, Mick and Politi 1989). So far, however, all the new work on commercial art in our own discipline has adopted the mantle of semiotics/structuralism as its theory. My purpose in this essay is to introduce poststructuralist thought as a new framework for studying advertising visuals, particularly within the context of the postmodern aesthetic. This is an exploratory piece, presenting concepts along with

historical illustrations as a way of suggesting the potential and parameters for a different way of thinking about advertising images. I am motivated to do this by the uncanny confluences among certain poststructuralist concepts, the formal and historical characteristics of advertising texts, and the marks that are generally agreed to typify postmodern style in graphics.

POSTMODERNISM: A SHOPPER'S GUIDE

"The entire elusive phenomenon that has been characterized as postmodernism is best understood not just as a style but as a general orientation, as a way of apprehending and experiencing the world and our place, or placelessness, in it" (Gitlin 1989, p. 101). Postmodernism has been notoriously hard to define. Part of this difficulty is traceable to one of its most characteristic traits, a tendency to embrace diversity. As in our own field, postmodernism in art, literature, and everyday life is often seen as a fundamental multiplicity of viewpoints. To some, this is a democratic characteristic; to others, this multiplicity is seen as a cynical inability to commit, a jaded lapse of conscience, a vision that is hopelessly "fragmented," or simply the absence of viewpoint caused by the tolerance of many views (Donoghue 1986, Gitlin 1989, Jameson 1984, Lyotard 1984). Postmodernism in intellectual discourse is often also relativistic and historicist, distrustful of transcendent principles or underlying structure (see, for example, Anderson 1986). Thus, for those who prefer hierarchical orders, traditional art, and absolute truths, postmodernism can be quite threatening.

"Postmodern" and "postmodernism" are terms that are used to describe a philosophy, an aesthetic, and the conditions of living in a certain period of history, much as the terms "Renaissance" or "classical" are used for the same purposes. This overlap in terminology is not peculiar to the discourse on postmodernism. However, our awareness of the overlap of these forces in social experience is a rather salient feature in postmodern thinking. In the current practice of cultural criticism--influenced as it is by neomarxism and the cross-fertilization between anthropology, "high theory," and the arts--it has become a truism that philosophy and aesthetics are produced by the conditions of living and, in turn, affect the conditions of living via their influence upon values, beliefs, and perceptions. So, although we are primarily concerned in this paper with a visual style and aesthetic, both the conditions of living and the philosophical orientations of the twentieth century will be constant subtexts.

In cultural works, a certain constellation of styles and tones are generally thought to characterize postmodernism: pleasure in the play of surfaces; allusion; mimicry; irony and parody; formal self-consciousness; fragmentation; repetition; mixtures of

forms, periods, and styles (Gitlin 1989, Hassan 1980, Jameson 1983). Although postmodernism occurs in music and literature, it is frequently characterized as profoundly visual, and thus a death threat to the culture of the word (Donoghue 1986, Hassan 1980, McRobbie 1986). Since postmodern artifacts frequently allude to other artifacts in a visual way, postmodernism has been called (pejoratively) an art that quotes "images already man-made" (Donoghue 1986, p. 36; see also Benjamin 1968). These allusive exchanges are often between mass media texts--the print ad that "quotes" a TV sitcom, for example, as in Figure 1.

Postmodernism is bashed by both political extremes. The New Left reviles postmodernism as the culture of "Thatcherism"; high art traditionalists bemoan it as the degenerate voice of popular culture (Hebdige 1989). Nevertheless, if one observes postmodernism as it exists in everyday life--those things in ads, album covers, table settings, magazine layouts, and music videos that are "pointed to" as being postmodern--a number of other social aspects become clear. One is that the postmodern is a popular style in both senses of the word: it is a mass form and it is well-liked by many people (Gitlin 1989; Lyotard 1984, p. 76). Indeed, the positive reception given postmodern culture appears to be one of its greatest sins in the minds of intellectuals (Jameson, p. 124; Lyotard 1984, p. 76). In the forms it takes and the allusions it makes, postmodernism is an art of the every day; for example, its text and context is often television ("that mongoloid medium," Hassan, p. 124). Postmodernism is often identified, explicitly or implicitly, as a peculiarly American phenomenon; descriptions often focus on sites of mass consumption, like shopping malls and fast food restaurants (see Gitlin 1989). Postmodernism shows a penchant for the retro and the tacky, as well as a preference for the imaginative recombination of everyday forms over the exaltation of the rare, privileged, or expensive. Thus, postmodernism is an aesthetic that is accessible to the many and not just the few. Further, the ability to broadly communicate is a mark of postmodern cultural artifacts that distinguishes them from modernist works--and raises the ire of the critics (Lyotard 1984, p. 76; Merquior 1986, p. 17). Taking advantage of the shared discourses of television, radio, films, and mass magazines, the postmodern style can tap into a world of artifice and allusion that is easily as sophisticated as the world of gentlemen literary critics--but with a much wider audience. The knowing audience implied by postmodernism challenges both the elitist assumptions and anti-empirical methods of the culture of modernist criticism (McRobbie 1986, p. 55-56). Thus, in many ways, the thrust of postmodernism works against "modernism's relentless hostility to mass culture" (Huysen, qtd. in McRobbie).

POSTSTRUCTURALISM: THE TRIAL-SIZED VERSION

As both a philosophy and a theory of language, poststructuralism exists in opposition to structuralism and its contemporary manifestation, semiotics (Davis and Schliefer 1989, pp. 147-148, pp. 205-213;

Eagleton 1983, pp. 127-150; Newton 1988, pp. 147-148). Poststructuralism was introduced by French philosopher Jacques Derrida in 1966, and gained rapid acceptance, notably among famous structuralists like Roland Barthes and Jonathan Culler (Davis and Schliefer 1989, pp. 205-213; Eagleton 1983, pp. 135-145; Lentricchia, pp. 157-210; Newton 1988, p. 171). Using Saussure's principle that a sign has distinctive meaning by virtue of its difference from other signs, Derrida built the poststructuralist argument that all gestures signify according to their present place in a web made of the existing universe of signs (Eagleton 1983, pp. 127-134). The locus of meaning, then, is not an immutable, ideal structure of language that acts as a "center" for signification--and thus knowledge and life. Instead, meaning inheres in the surface of an ever-changing web of signs, making all language acts essentially provisional and allusive. Each signification is seen as being constructed of fragments of prior significations, being meaningful by virtue of the traces that each fragment carries of previous uses (Derrida 1972). These already-used words and images are then reassembled, in an act and form that Derrida calls *bricolage*, and they come to mean in the way that they shimmer against each other and against their previous context. This "play" among the fragments is what is known as the *freeplay of the signifiers*. Since each fragment means by virtue of association with other fragments, meaning is said to be always deferred to another chain of signifiers. This constant deferral of meaning is known, in a play on Saussure, as the *différance* (Derrida 1972; Eagleton 1983, pp. 127-135).

A primary interpretive strategy of poststructuralists has been to reveal the constructed nature of texts by unravelling the associations upon which they are built, a technique called *deconstruction* (Abrams 1977, Miller 1976). Indeed, this technique is so famous and controversial that poststructuralism is often called "deconstruction" or "deconstructionism." In particular, the deconstructive strategy often aims to subvert the binary oppositions presumed by structuralists, showing the text to be *undecidable* in binary terms, due to the freeplay of the signifiers (DeMan 1979, Eagleton 1983, pp. 132-134). As the text is unravelled, poststructuralists assert, one catches a glimpse of the absence of an immutable structure, or philosophical center, underlying the utterance. This momentary insight into the chasm underlying language is known as the *mise en abyme* (Abrams 1977, p. 560). The work of the critic toward the moment of the abyss has given poststructuralism a bleak metaphysical aspect (Abrams 1977; Gitlin 1989, pp. 106-107), and led to a reputation for the theory as, ironically and at once, both playful and nihilistic (Derrida 1972, pp. 243-246; Lentricchia, pp. 160-163).

For our purposes here, we must note that poststructuralism also differs from semiotics in another important way. While structuralism is a speech-based theory of language, or *phonocentric*, poststructuralism is a writing-based theory, or *graphocentric*. Everything in poststructuralism is a text, and there is nothing that exists outside the text

FIGURE 1 (CONTINUED)

...which Formica® Brand surface to choose.

When it comes to countertops, there are only three possibilities. Each has its own special advantages. And Formica Corporation is the only company that makes them all.

1

LAMINATE. There's only one Formica brand laminate. Although other people now make laminate, we invented it, and we're still the best at it. Which you'll realize when you see the amazing variety of patterns, colors and textures we offer. You can be wildly—or even not so wildly—creative with it. If you're planning on doing a kitchen or bath and quality is important, ask for Formica brand laminate by name and accept no substitutes.

2

COLORCORE. For a customized look, you should look into ColorCore surfacing material. Color is what ColorCore is all about—color that goes all the way through, so its beauty isn't interrupted by the dark edge of regular laminate. ColorCore gives you the look of a solid surface at less cost, as well as the option to do distinctive custom edge treatments like the one shown. And there are over a hundred ColorCore colors to choose from.

3

SURELL. The newest and unquestionably the most exciting solid ever introduced, SURELL solid surfacing material has a timeless, sculpted look. It gives you the beauty and elegance of marble and granite in a choice of countertops, vanities with molded backsplashes, lavatory bowls and showers, all with the assurance of Formica brand quality. Solid color choices are available, as well as several remarkably realistic granites. If you're doing a kitchen or bath to match a lifestyle that's here to stay, SURELL solid surfacing material is your design solution.

For the name of the kitchen and bath dealer nearest you, call 1-800-FORMICA.

The Name Brand in Surfacing.

(Derrida 1972, Davis and Schliefer 1989). Among other things, this difference opens poststructuralism to the differences in how images, as a form of writing, are portrayed, as opposed to focusing on or assuming their referentiality, as has been the case with structuralism (for example, Barthes 1982). The effect of poststructuralism is specifically to divide the signifier from the signified, as well as to decenter the privileges of the word over the image (Eagleton 1983, p. 128; Morris 1989).

ADVERTISING AS POSTMODERN BRICOLAGE

Given its preoccupation with fragments, allusion, playfulness, surfaces, and the work of bricolage, poststructuralism predictably has become nearly synonymous with postmodernism in cultural critical discourse (Gitlin 1989; McRobbie 1986; Morris 1989). Poststructuralism, seemingly the most suitable analytical tool for postmodern artifacts (though by no means the only tool), has become identified with them, much the same way New Criticism became identified with Modernist poetry and fiction (Davis and Schleifer 1989, p. 15). Consequently, it seems likely that poststructuralism would have much to offer our own scholars in their desire to analyze that prime mover of postmodernism, advertising.

In the remainder of this essay, I wish to suggest how advertising came to exhibit the distinguishing characteristics of postmodern artifacts and show the suitability of poststructuralist concepts to the explication of ads-as-text. We will look first at the historical basis and ground for pictorial allusion in advertisements, thus sketching out the symbolic web and the trajectories of the *différance*. Then, practices of signification typical of advertising, the reuse of images and mimicry of styles, will be analyzed as overt acts of bricolage. Target audiences will be discussed as the coin of which one side is fragmentation and the other, multivocality. The development in television advertising of story-telling and character description as a progression of broken images will be examined. Finally, the changing relationship between image and word will be explored in order that the question of an emergent pictographic culture may be raised.

THE PICTORIAL WEB

The history of advertising as a visual discourse, as opposed to its verbal history, must be traced from retail signboards to the popular printed poster to the magazine ad (Hornung and Johnson 1976, Presbrey 1929). Key to the momentum is the ability of printing technology to reproduce visual forms in an increasingly accurate and full-bodied way--with line, color, half-tones, and so on. Both the reproduction of pictures and the growing vocabulary of typefaces have been of central interest to advertisers throughout graphics history (Hornung and Johnson 1976). Advertisers, however, were precluded from running elaborate pictures in newspapers and, later, in magazines, for decades after pictures were routinely

included in editorial (Hornung and Johnson 1976, Presbrey 1929). Once allowed to use fully the pictorial capability of a medium, advertisers frequently appropriated the styles of the contextual vehicle. For example, the cover of the *Saturday Evening Post*, the most popular early-century magazine and the most aggressive in soliciting advertising, was mimicked in advertising layouts as early as 1905 ("Pro-phy-lact-ic Tootpaste" ad 1905) and continues today ("Durolast" ad 1989). As the "Golden Age of Illustration" progressed, more illustrative styles and layouts were both known and mimicked, not only in advertising but in other cultural forms as well. Furthermore, once the technology was sophisticated enough to reproduce high art forms in quantity, the practice of visually alluding to famous paintings and sculptures became common. Typical of this genre is the current ad for Minolta (Figure 2), which alludes to the works of Rene Magritte. The sense of this ad, like others of its type, is based on a sufficient reproduction of the original, graphically altered for the purposes of rhetoric. Thus, it signifies through partial allusions, recombined in fragments, that "shimmer" against each other in a new message. Such ads often result in a visual parody of high art, like the 1970 Levi's ad that simply showed Michelangelo's David dressed in a pair of "cut-offs" (Goodrum and Dalrymple 1990, p. 170).

In the 1930s, growth in two other cultural forms, comic strips and radio, is mirrored in advertising pictures. Throughout the magazines of the thirties are examples of comic characters or strip styles being adapted for commercial use. Advertisers, apparently trying to effect synergy between the new medium of radio and the more mainstream medium of popular print, also tended to announce their sponsored radio offerings in the corners of print ads, often signalled by an appropriate picture, like a drawing of an orchestra conductor ("Coca-Cola" ad 1936). In the 1936 ad for Campbell's Tomato Juice reproduced in Figure 3, we see a full-blown example of this kind of intertextual allusion: the visual convention of the comic strip is used to evoke the sponsored radio show by making a box-and-balloon recreation of the comic antics of Burns and Allen. Eventually, similar practices would be used to announce sponsored television shows, as well. The main visual in Campbell's Soup advertising of the 1950s is usually a photograph of Timmy and Lassie or Donna Reed's TV family, since both *Lassie* and *The Donna Reed Show* were sponsored by the soup-maker ("Campbell's Soup Print" 1900-1985).

Given this pictorial past, then, it is perhaps easier to see how the TV allusion in Figure 1 came to be. The headline does not refer exclusively to *I Love Lucy*, nor to the characters of Fred and Ethel Mertz, nor to Vivian Vance and William Frawley, though certainly the advertiser is banking on the viewer making those connections. The headline's allusion, however, is more general than that. It gestures toward all the domestic squabbles that typify the genre of television situation comedy. The headline is aided by a graphic screen over the photograph, a convention that we know signifies "television." Thus, both the

THE SATURDAY EVENING POST

EDUCATING GRACIE

HERE'S A TOAST TO YOUR GOOD HEALTH!

People drink Campbell's Tomato Juice first of all for the fun of it. The strong, tangy flavor, drinking it with pleasure is its natural and best tomato taste. It honestly tastes as lively and full as the most sun-ripened tomatoes do fresh from the garden in August.

25 Years of Improving the Flavor

Campbell's have taken great care to get such a rare, fine flavor for this drink. For twenty-five years they have been carefully cross-breeding tomato plants to improve their luscious flavor and their tangy taste. And today Campbell's tomatoes are such leaders as you have never dreamed of. These Campbell's press lightly, so as to secure only the best and finest juice and thick pulp. Then this keen, tangy juice is canned by a special process which minimizes heat and exposure to air, and thus keeps it at the true fresh tomato tang. So people drink Campbell's Tomato Juice for fun, and there are real reasons too why they should drink it for reason.

An 8-ounce Glass a Day for Health

One of Nature's main suppliers of vitamins A, B and particularly of the important vitamin C is fresh tomatoes.

Vitamin C is the element that helps change ordinary, listless, lackadaisical health into vigorous, alert, buoyant health. The same special process which protects the fresh flavor of Campbell's Tomato Juice retains the vitamins to the very maximum degree. So one 8-ounce glass of Campbell's Tomato Juice is an important step toward the pep and vigor that all of us desire.

Keep Plenty in Your Refrigerator

Drink Campbell's Tomato Juice! Drink an 8-ounce glass a day, for health! A second, and a third, for fun! Keep several cans on hand always. *A better drink is better health!*

10c a can (14-oz.)
The family size 16-oz. can
is even more economical.

Campbell's
TOMATO JUICE
TASTE THE DIFFERENCE!

textual referent and the manner of "writing" are important to the allusion. The graphic style is not empty mimicry, as is often claimed by critics of postmodernism, but a purposive, meaningful gesture.

Looking at the "flip side," if you will, we also find allusions to and parodies of advertising in other media forms. *Saturday Night Live* is but one in a long history of late-night TV shows that have used advertising parody as a staple comic gimmick. But new forms such as *Nick at Nite*, which reruns old TV shows but parodies them in the promos, have made such allusions even more complex. In Figure 4, *Nick at Nite* pretends to offer a ceramic sculpture of the graphic sign of a classic sitcom, *My Three Sons*. In so doing, it parodies "mail-away" ads like those of the Franklin Mint, ending with the send-up, "Not available anywhere, even from us." This ad's picture must be understood, therefore, as *both* the intertextual referent and its parody. We can see, then, the web of signs being altered by this use, refabricated in the current play of signification. Our sketch of the pictorial web is now more or less complete: we have seen the interaction of the advertising visual with popular magazines, high art, radio, comic strips, television, and, ultimately, with itself. This formal consciousness of self is, in many opinions, the essence of postmodernism.

REUSING IMAGES AND MIMICKING VISUAL STYLES

The ability to accurately reproduce and mimic other images also led quickly to the reuse and repetition of the advertiser's own signs. For example, in 1897, Colgate paid Maxfield Parrish twenty-five dollars for the painting of a Dutch boy for the purposes of advertising Cashmere Bouquet. Once in possession of the painting, Colgate had other artists copy it, adapt it, and reconfigure it in various forms, large and small, in line art and halftones, as a female and a male, in multiple repetitions and for many other products. Consequently, it became one of the best known advertising signs of the turn of the century, constantly reappearing in new incarnations (Ludwig 1975, pp. 105-106). The Dutch boy image itself--like thousands of others that would follow--became meaningful specifically through the mechanism of graphic reconstitution and repetition and referring always to its string of previous appearances.

Using unknown artists to mimic the visual styles of well-known popular illustrators in the production of new images became a common strategy among advertisers. By borrowing certain visual styles, the advertiser alluded to the associations that the known artist had come to have (Scott 1991). Thus, the style of rendering itself came to signify. Beginning in the late 1920s, advertising art directors also appropriated the styles of high art, as they were articulated both pictorially and typographically, often to lend an air of authority or prestige to their campaigns (Marchand 1985, pp. 140-148). This taught the conventions of Cubism, Vorticism, Impressionism, Bauhaus, and other styles to an audience that might never have otherwise been

exposed to them (Marchand 1985). Over time, the social and historical associations of these styles could be invoked through their reproduction to create an ethos or a sense of period. Ultimately, the profusion of popular and high styles that could appear and be meaningful within the context of a single magazine issue comes to constitute a kind of visual heteroglossia (Bakhtin 1981); that is, cultural multivocality stated in visual terms.

As it appears in a magazine, the Jello Jigglers ad in Figure 5 has a noticeable all-over yellow cast, similar to that caused by the color print-production technologies of the 1950s. The headline is set in a typeface popular in the 1950s and the graphic recipe cut-out is much more typical of that decade than the present one. The consumption texts, both the little boy's pajamas and the recipe itself, are also evocative of the baby boom years. For all appearances, this is an ad from the 1950s; however, it actually ran for the first time in 1989. This ad is thus a particularly good example of the postmodern genre of *pastiche*. The pastiche is a form of historical parody that Jameson criticizes as one text aping another without the humor or affection characteristic of "real" parody (Jameson 1983). Yet if we think of all the signs here as fragments coming together to signify through their associations with prior symbolic gestures, as well as their appropriateness for the task at hand, then this pastiche is merely using visual forms to communicate in much the same way words do under the poststructuralist model. Notice also that the graphical *manner* of signifying in this ad is as important as *what* objects are pictured--perhaps more so. Thus, the structuralist principle and practice of brushing aside the surface manifestations of pictures in search of the underlying structures or the apparent referents would obscure much of what is being said here (see Leymore 1987, Barthes 1982). And, surely, though the literary critics may not view these pajamas as an affectionate allusion, most of the rest of us would. Using these affectionate allusions, the Jigglers ad visually evokes a fondly-remembered historical period as a means of building the ground for mutual confidence that is necessary to persuasion.

FRAGMENTATION, MULTIVOCALITY, AND PRACTICAL UNITIES

In ways similar to the work of the Jello ad, various visual strategies may be used to appeal to and create alliances with certain groups of readers, or target audiences. Targeting audiences obviously is further achievable through the channels and vehicles of media. For example, in the current Toyota ads, different pictures rendered in the same style target the typical readers of various magazines: a youthful, male sportscar driver for *Rolling Stone*; a young woman for *Mademoiselle*; a family around the fireplace for *Metropolitan Home*. The pictures and the placements carve out various audiences, while the consistent visual style creates formal campaign unity.

As a consequence of this use of pictures and styles to carve out smaller groups from the larger society, however, consumer texts are often charged

Make Jell-O® Gelatin
you can eat with your hands.

Try our Jigglers recipe.

Jell-O® Gelatin Jigglers

- 2 family-size pkgs. (8 serv. size) or
- 4 small pkgs. (4 serv. size)
- Jell-O® Brand Gelatin
- 2½ cups boiling water or apple juice

Completely dissolve gelatin in boiling water or juice. Pour into 13 x 9-inch pan. Chill until firm, about 3 hours. To unmold: dip pan in warm water about 15 seconds. Cut into squares or use cookie cutters. Lift from pan.

THEY'RE A HANDFUL OF FUN.

with "fragmenting" culture (Gitlin 1989). This is a specious argument, in my mind, which is best refuted by considering the textual alternative. Opposing this kind of fragmentation in the media can only be done by homogenizing both the approaches to society and the channels for reaching it, as well as the depictions of its members, thus denying its diversity and multivocality on all levels. Recently, Dick Hebdige, has argued in support of the multivocality--and implicit democratic impulse--behind such postmodern developments, and, taking his cue from Raymond Williams, suggests the worthiness of "demassifying the masses," even unto the point of forging alliances between Marxism and market research (1989, especially p. 52-53).

A further source of criticism falling under the general heading of "fragmentation," is the convention of visual collage or montage, particularly in television. This convention was begun by advertisers in the early 1960s as a means of telling stories and evoking characters in the short time frame allowed for television commercials (Haber 1989, Levine 1984). Since there wasn't time in a TV spot for the careful plotting and revelation of character allowed by traditional dramatic forms, advertising producers experimented with stringing together multiple visual moments--an action, a facial expression--that would, together, constitute a narrative, describe a character, or evoke a mood. Television programming itself has generally continued to use a much more traditional form of dramatic exposition--essentially the "naturalistic theater" form of storytelling--while the commercials have become increasingly composed of vignettes and montages, especially as lengths shortened. Even so, such "fragmentation" is constrained by the achieved unity of story or character comprehension, as intended by the advertising author (Haber 1989, Levine 1984). In other words, the composition of the fragments is not open-ended, but constrained by normative strategies of seeing, storytelling, and inference. It is often argued, on the other hand, that the poststructuralist model avoids the issue of interpretive norms that circumscribe the play of associations and therefore make communication possible (Abrams 1977).

THE IMAGE AND THE WORD

The community of criticism, being heavily invested in the culture of the word, has traditionally viewed pictures as atavistic icons, powerful implements that bypass our rational faculties to drag us back to more primitive times, while the word is the very heartbeat of civilization (Mitchell 1986, p. 3 and 7-46). There is thus a thoroughgoing antivisual bias in cultural criticism that nearly always lies just beneath the discourse on popular culture. The tendency toward verbal imperialism in structuralist theory plays well to this disposition; the impetus of poststructuralism is directly against it (Saussure 1959, p. 16; Mitchell 1986, pp. 53-74; Morris 1989). Further, the gestures of postmodernism, particularly in advertising, have tended to change and subvert

assumptions about the relationship between word and image.

In Western culture, verbal literacy has long been equated with power. Access to the skill to read has been the goal of the oppressed, as in the heroic efforts of the American black community to attain literacy in the 19th century, as well as the means to keep the oppressed in their place, as in reading requirements for voting rights. It is important to understand that the rise of the mass media substantially changed the role of reading in several ways. First, popular fiction, as published in mass magazines or cheap books, made reading a pastime of the masses for the first time (Darnton 1987). Secondly, the growing hegemony of the visual and aural cultures of television and radio, have threatened the preeminence of the written word. Finally, the ever-widening visual vocabulary caused by the practices I have described here has changed the interaction between pictures and words in popular texts. Whereas pictures in a written work have traditionally illustrated or elaborated the text in a subordinated fashion, the postmodern work is more likely to show a meaningful interaction--a free-playing--*between* image and word. And, the use of communicative styles of typeface, as well as purposive layouts, have come to mediate the word in a profoundly visual way.

For example, in Figure 6, the meaning of the ad must be inferred by holding the picture and the headline in semantic tension. The headline, which uses a typical diplomatic phrase that normally occurs in situations of conciliation, "strengthens our ties," is contradicted by the visual, a caricature of Ayatollah Khomeini dangling Uncle Sam by a string. Together, they form an ironic trope. Neither picture nor headline alone can produce the trope, a proposition you can easily test by covering one while "reading" the other. *Both* must be present to constitute the irony. So, the meaning occurs precisely in the space of interaction not only between two signs, but between two sign systems (see also Foucault 1983).

The inability of structuralism to account for meanings that must be inferred in a state of ambiguity has been one of its weakest points, and a place frequently attacked (Davis and Schliefer 1989; Eagleton 1983). In poststructuralist theory, this argument is further articulated in the demonstration of the *undecidability* that occurs in a text between binary categories of structurality (see De Man 1979). For a demonstration of this phenomenon occurring on both a visual and verbal level, look at the J & B advertisement in Figure 7. Here we see a messy representation of the alphabet that looks like it was brushed hastily in black paint. The letters "B" and "J," however, have been set in a neat, Garamond typeface, in red. They contrast succinctly, but not overly, with the surrounding alphabet and they are not in the order of the product's name. The legend is simply, "J & B neat," simultaneously a play on "J & B straight up" *and* on the contiguous representation of the messy alphabet with the neat letters "B" and "J." The meaning here is created by both a metaphor (the

FIGURE 6

IMPORTED OIL STRENGTHENS OUR TIES TO THE MIDDLE EAST.

Last year, almost 40 percent of all the oil we used came from foreign countries. Much of that from the unstable Middle East. And this dependence on foreign oil is growing.

The more we use nuclear energy, instead of imported oil, to generate electricity, the less we have to depend on foreign nations.

The 110 nuclear electric plants in the U.S. have cut our foreign oil

dependence by over three billion barrels since the first Arab oil embargo. And they have cut foreign oil payments by over 100 billion dollars.

But 110 nuclear plants will not be enough to meet our growing electricity demand. More plants are needed.

If we are going to keep our energy future in our own hands, we need to rely more on energy

sources we can count on, like nuclear energy.

For a free booklet on nuclear energy, write to the U.S. Council for Energy Awareness, P.O. Box 66103, Dept. AY02, Washington, D.C. 20035.

Nuclear energy means more energy independence.

FIGURE 7

pun on "straight up") and a metonymy (the letters)--and is thus undecidable. It is also undecidable whether the joke inheres in the letters themselves or the *visual representation* of the letters. Therefore, *neither* a paradigmatic (metaphorical, rhetorical) model nor a syntagmatic (grammatical, metonymic) model is sufficient by itself to decide the meaning. It is found, instead, in the shimmering surface between each binary opposition.

M. H. Abrams has explicated the Derridean notion of language as a graphocentric system in which we constitute meaning from black marks and spaces that have been estranged from our usual prior model of speech acts. These marks and spaces, however, are signs we have seen before, not random markings, and as they are reused to make new meanings, they carry with them the disembodied traces from previous uses. Thus, any act of interpretation or attempt at definition ties one to the never-ending, ultimately meaningless chain of deferral. By breaking down each text into an endless chain of associations, synonyms, and etymological roots, purposely working across those places where the possibilities are generally narrowed and guided by norms, the poststructuralists interpret their texts into oblivion. This action is intentional; its purpose is to lead to the aforementioned moment of the abyss. The deconstructionists claim that all linguistic configurations are ultimately undecidable, or, as Abrams puts it "more bluntly: 'All reading is misreading'" (1977, p. 560). Thus, though the Derridean concept of language is grounded in shared knowledge and past experience as the source (indeed, the only source) of meaning, the poststructuralist activity of deconstruction finally denies the way that social experience and norms constrain the limitless possibilities presented by the text. In this way, the Derridean concept has led to a model of language that does not communicate. Poststructuralist critics, by exploding shared practices, knowledge, and historical events, ultimately reject the possibility for either communication or action in a way that many feel is cynical (Abrams 1977, Gitlin 1989, Hirsch 1976).

Figure 8 provides a surprising play on this cynical model of language. This is a recent advertisement for Cointreau that appears only in hip, upscale, postmodern magazines like *Spy*, *Details*, and *Vanity Fair*. The visual is a very artificially dressed and made-up woman. Tinted purple, and superimposed slightly to the left of her image, is the partial face of a man, who seems to be the speaker. (Perhaps he is the human equivalent of a "fragment.") The backdrop for the copy block is even marbled, like the world of these readers, hopelessly hip.

But it is the copy that is remarkable in its strangeness. It is an odd French-based patois, at once Gallic and pidgin. A second headline and copy block appears at the bottom of the ad, but it is cut off, as if the run of the press was crooked. (Freeplay in the machine?) It is as if to indicate that the next signification, the next *différance*, is already in the process of being formulated. When we are first confronted with it, this language has all the strange and threatening appearance of the innovative text

described by Poststructuralist J. Hillis Miller: "...the terror or dread readers may experience when they confront a text which seems irreducibly strange, inexplicable, perhaps even mad" (1989, p. 567). The traces of French and pidgin are even a bit offensive, implying a cruel, long-ago, but still destructive colonialism. We may, perhaps, despair of understanding this ad, considering ourselves not qualified to aspire to the hipness demanded by postmodern society. Maybe we turn the page.

But maybe we try reading this out loud. The language, it turns out, is completely phonetic. A minimal knowledge of French makes the sense of these lines come rolling out when they are spoken. The primacy of speech reasserts itself in a wonderful little joke; the closed graphic presentation is opened by a phonetic key. In a playful gesture between writing and speech, the word reasserts its communicative power.

Conclusions

I have tried to draw here the outlines of a visual history in which images have come to communicate in abstract, allusory, and stylistic ways that challenge verbal language. We have seen several instances in which the visual presentation of words impinged heavily on meaning, conflating the traditional separation between image and text. We, as collective viewers and readers, have moved and continue to move beyond a past in which pictures largely confined themselves to referentiality or ritual, and toward a culture in which pictures demonstrate, exhort, explain, allude, and, above all, play. What we are making here, it seems to me, is a full-blown pictography that can both speak to and represent a wide, diverse audience. Unfortunately, it appears that a mistrust of consumer society, a vested interest in the culture of the word, a thinly-veiled contempt for the "masses," and an unwillingness to support art as communication, have led cultural critics to greet this development in human ability as the death knell of civilization.

The role of advertising in this development appears to be direct. Many developments discussed here grew out of the desire to address people in an attractive and economical way, taking advantage of technology, channels of discourse, and cultural history, as opportunities presented themselves. It seems logical to me that in harnessing pictures to the service of rhetoric, a subtle and complex language of the visual would be born.

The appropriateness of poststructuralism for research on consumer culture lies in its awareness of the dynamic nature of signifiers and their inherent intertextuality. It also seems possible that poststructuralism offers much in its ability to deal with pictures and graphics without subordinating them to referentiality or to the "structure" of another sign system. The overall concern with the constitutive effect of surfaces is also peculiarly relevant to advertising. Advertising makes much of its meaning by borrowing from other texts and altering them on the surface to make new meaning. Ultimately,

FIGURE 8

however, our own disciplinary concerns with communication and persuasion would find poststructuralism lacking. For concepts of the norms that guide practice, we would need to return to theories of grammar, such as structuralism. To evaluate persuasion and social effects, we must continue to develop the tools of history, ethnography, and rhetoric. In other words, to truly accommodate the multivocality of consumer culture, we must be multivocal ourselves, recognizing language theories and methods as strategic efforts to get at particular kinds of knowledge, just as in science. The current postmodern climate promises to provide a welcoming environment for this kind of effort.

Remembrance of Things Past: Music, Autobiographical Memory, and Emotion

Hans Baumgartner, Pennsylvania State University

ABSTRACT

It sometimes happens that a piece of music becomes associated with an event from a person's life so that hearing the piece of music evokes memories of the original experience. The purpose of this paper is to examine this phenomenon empirically. More specifically, the study investigates what kinds of autobiographical episodes are triggered by music that respondents self-selected as examples of this phenomenon, what characterizes these instances, and what is the relationship between the emotions descriptive of the original experience and the emotions aroused by hearing the piece of music.

And before Swann had had time to understand what was happening, to think: "It is the little phrase from Vinteuil's sonata. I mustn't listen!", all his memories of the days when Odette had been in love with him, which he had succeeded, up till that evening, in keeping invisible in the depths of his being, deceived by this sudden reflection of a season of love, whose sun, they supposed, had dawned again, had awakened from their slumber, had taken wing and risen to sing maddeningly in his ears, without pity for his present desolation, the forgotten strains of happiness.

Marcel Proust (1913/1956),
Swann's Way, p. 496

INTRODUCTION

Music is sometimes called the language of emotion, but it is not at all clear how music expresses, or is expressive of, the emotions. In order to elucidate the issues involved and to set the stage for the main focus of this paper, it might be helpful to briefly discuss two distinctions.

The first distinction is between what Pratt (1931) calls autonomous and heteronomous music. Adherents of the view that music is (or should be) autonomous argue that the "essence of music lies wholly within the borders of sound" (Pratt 1931, p. 205) and that the character of a piece of music is due entirely to intrinsic properties of the music itself. Those who regard music as heteronomous, on the other hand, argue that music possesses "content which is non-tonal" (Pratt 1931, p. 212) and that the character of a piece of music is often a function of extramusical associations. Drawing on the work of Charles Peirce, Dowling and Harwood (1986, Chapter 8), in their discussion of the relationship between music and emotion, make a similar distinction between iconic and indexical representation in music, where iconic representation (of emotions) refers to "patterns within the music itself ... of tensions and relaxations ... [which] mirror the form of emotional tensions and relaxations" (p. 205), whereas indexical representation refers to "direct association of a

musical event with some extramusical object or event, so that emotions previously associated with the extramusical object come to be associated with the music" (p. 204).

The second distinction is between what Kivy (1989, Chapter XIII) calls musical emotivism and musical cognitivism. Proponents of musical emotivism argue that music arouses (or induces) emotions (e.g., sad music actually makes you sad), whereas adherents of musical cognitivism (such as Kivy) suggest that music merely embodies (or represents) emotions (e.g., sadness in music can be recognized because sad music has characteristic qualities). While the distinction between musical emotivism and musical cognitivism centers on whether music actually induces or merely represents emotions, the difference between autonomous and heteronomous music refers to whether music per se or extramusical objects or events associated with the music induce or represent emotions.

It is possible to arrange the concepts of autonomous vs. heteronomous music and musical emotivism vs. musical cognitivism in a two by two table and to distinguish four cases of expressiveness in music. The topic of interest in the present paper is heteronomous music which arouses emotions, or the indexical induction of emotions (cf. Dowling and Harwood 1986, p. 204). The excerpt from Swann's Way by Marcel Proust quoted at the beginning is a well-known literary example of this phenomenon. Most readers, however, will probably have had a similar experience in which a piece of music conjured up images of some past autobiographical episode.

Writers on musical aesthetics, even those in the cognitivist camp, generally agree that a piece of music may acquire the capacity to arouse emotional reactions through association with significant personal experiences, but the expressiveness of music, it is argued, is then due to an accident of association and has (or may have) nothing to do with the "real expressive character of the music" (Kivy 1989, p. 157). For example, a happy piece of music could come to arouse sadness because of its association with a sad event. Furthermore, if expressiveness in music is a consequence of its indexical function, music is stripped of any special status as the language of emotion because any other object (a photo, a gift, even a smell) could also become associated with a significant personal experience and thus induce emotional reactions.

Although it is quite understandable why aestheticians would not get too excited about instances in which idiosyncratic associations endow music with emotive meaning, it nonetheless seems an interesting question to investigate this phenomenon empirically. The study reported below was designed as an initial examination of some of the issues involved. Specifically, the objectives of the study were (1) to assess how readily people can bring to mind personal

experiences that have become associated with a piece of music, (2) to explore what characterizes these autobiographical episodes, the music that triggers them, and the instances in which the phenomenon occurs, and (3) to examine the relationship between the emotions descriptive of the original experience and the emotions aroused by hearing the piece of music.

METHOD

Subjects

Seventy-three undergraduate marketing majors (43 males, 30 females) participated in the study as part of a course requirement. The data were collected in one 45-minute session in which other experimental tasks unrelated to the present study were also administered. Participants were run in groups of at most 8 people in 12 experimental sessions.

Procedure and Measures

Subjects received a questionnaire and were told to complete it at their own pace. On top of the first page they were given the following instructions:

"Sometimes a piece of music becomes associated with an autobiographical episode from a person's life so that every time the person hears the music, (s)he is reminded of the original experience. Please take a minute and think about instances in which this has happened to you. Select the instance that is most salient in your mind and briefly describe the piece of music and the personal experience that the music reminds you of every time you hear it."

After subjects had answered this question, they were asked to rate their feelings toward both the piece of music and the personal experience on two seven-point scales (pleasant-unpleasant and favorable-unfavorable). The coefficient alphas of the two sets of measures were 0.93 and 0.99, respectively.

Subjects were then asked approximately how long ago the personal experience recalled had originally occurred, how vivid the recollections of the personal experience brought about by the piece of music were (seven-point scale from 'not at all vivid' to 'extremely vivid'), how emotional the recollections were when they occurred (seven-point scale from 'not at all emotional' to 'extremely emotional'), to what extent they relived the original experience when they heard the piece of music (seven-point scale from 'not at all' to 'a great extent') and to what extent the recollections were accompanied by imagery (visual images, sounds, smells, etc.) descriptive of the original experience (seven-point scale from 'not at all' to 'a great extent').

Finally, an attempt was made to capture in more detail the affective qualities characteristic of the original personal experience and the emotional tone descriptive of the piece of music associated with it. The question, however, was which instrument to use

for the measurement of emotions (cf. Plutchik and Kellerman 1989).

In recent years, mainly through the work of Plutchik (1980, 1989) and Russell (1980, 1989), circumplex models of affect have become popular. In Russell's version of the model, 28 affect terms are arranged in a circular order, and their relative positions around the circle are described with reference to two underlying bipolar dimensions labeled pleasure-displeasure and degree of arousal (see also Mehrabian and Russell 1974).

It is interesting to note that as far back as the 1930s, Hevner (1935, 1936) proposed what is essentially a circumplex model of emotional epithets to describe music. In Hevner's scheme, 66 adjectives are classified into 8 groups arranged in a circular order. Even more interesting, the two dimensions underlying Hevner's circumplex structure correspond remarkably well to Russell's dimensions of pleasure-displeasure and degree of arousal.

Since one of the goals of this research was to investigate how well the affective qualities descriptive of the personal experience corresponded to the emotional tone ascribed to the piece of music, it was decided to measure the two sets of emotions with the Russell (1980) and Hevner (1936) instruments. Russell's 28 affect terms, arranged in circular order from high arousal/pleasure to high arousal/displeasure, are: aroused, astonished, excited, delighted, happy, pleased, glad, serene, content, at ease, satisfied, relaxed, calm, sleepy, tired, droopy, bored, depressed, gloomy, sad, miserable, frustrated, distressed, annoyed, afraid, angry, alarmed, and tense. Hevner's list of 66 adjectives was shortened to 24 by selecting three items from each of her 8 groups. The eight groups of three items, arranged in the same order as the Russell terms, are: majestic, vigorous, exalted; passionate, triumphant, exhilarated; merry, joyous, cheerful; light, graceful, playful; quiet, tranquil, soothing; sentimental, dreamy, longing; mournful, tragic, doleful; and serious, dignified, solemn.

To assess the emotional qualities of the personal experience recalled by a participant, subjects were asked, "Now we would like for you to tell us which of the following feelings are characteristic of the personal experience that you described on the previous page. Please tell us how much you felt each of the feelings listed below when the episode that the piece of music reminds you of first occurred?" Subjects responded on nine-point scales with endpoints of 'did not feel this feelings at all' and 'felt this feeling very strongly.' Similarly, to assess the emotional tone of a piece of music, subjects were asked, "The last thing we would like to know is how hearing the piece of music that you named on the first page makes you feel. Please tell us how much you feel each of the following feelings when you hear the piece of music?" Again, subjects responded on nine-point scales with endpoints of 'do not feel this feeling at all' and 'feel this feeling very strongly.'

The emotional descriptors selected from the Russell and Hevner instruments to measure the affective qualities of personal experiences and the emotional tone of pieces of music do not overlap and,

TABLE 1
Classification of personal experiences

	Unpleasant	Pleasant	Total	Percent of all memories
Current romantic involvements	0	18	18	26%
Past romantic involvements	6	6	12	17%
Times spent with friends	0	15	15	21%
Vacations	0	6	6	9%
Other	5	14	19	27%

for purposes of data collection, were listed in random order, but they supposedly tap the same two-dimensional structure of pleasure-displeasure and degree of arousal. The fact that the two sets of affect terms are distinct should reduce the problems associated with collecting all ratings at the same time, while the similarities in the underlying structure should make it possible to test whether the emotional tone ascribed to a piece of music is a function of the affective characteristics of the personal experience with which the music is associated.

RESULTS

Subjects apparently had no difficulty bringing to mind an instance in which an autobiographical episode had become associated with a piece of music. Only three of the 73 participants (2 males, 1 female) did not report a piece of music and an associated personal experience, although they evidently had thought of one because they completed the rest of the questionnaire. However, these subjects were excluded from further analysis.

In what follows, the written responses to the open-ended question will be analyzed first, then subjects' descriptions of the personal experience and the piece of music which were collected with the standardized questions are discussed, and finally the self-report measures of emotion are examined.

Analysis of Verbal Responses

One question that can be addressed by looking at subjects' verbal protocols is what kinds of personal experiences become associated with pieces of music. Table 1 shows that the majority of episodes reported by subjects (64 percent) relate to past or current romantic involvements and times spent with friends. Past and current romantic involvements refer to recollections of times spent with a past or current boyfriend or girlfriend (e.g., memories of the first date, sexual experiences, etc.). Times spent with friends is similar to romantic involvements in that another person or other people are at the center of the recollection, but no romantic relationship is implied (e.g., parties, concerts, special events, and segments of one's life in which friends played a significant role, etc.). Vacations refers to recollections of past holidays spent with family or friends. Finally, the category of other experiences includes episodes which did not fit into any of the previous groupings and which were not mentioned frequently enough to

warrant a separate classification (e.g., movies or concerts with no mentions of friends, a victory in a boxing match, the death of one's grandfather, childhood memories, etc.).

Table 1 also indicates that most personal experiences recalled by subjects (84 percent) were of positive valence. All recollections in the categories of current romantic involvements, times spent with friends, and vacations were positive, and only 6 out of 19 episodes in the other category were negative. Interestingly, memories of past romantic involvements were just as likely to be negative as positive.

There was a great deal of variation with respect to the pieces of music that subjects had memories attached to. In 15 of the 70 cases the piece of music or the composer/interpreter were not named, although people generally mentioned what kind of music it was. With the exception of Gustav Holst's *The Planets*, Russian Christmas Music, and the National Anthem, all named musical selections were of the pop/rock/folk variety. Only one song was mentioned twice, and subjects mentioned 47 different singers or groups.

Phenomenological characteristics of indexical association

Table 1 indicates that 59 of the 70 personal experiences recalled were evaluated positively and 11 were evaluated negatively. Not a single person provided a neutral rating. More importantly, most recollections were strongly affectively charged. When the extremity of evaluations (i.e., the absolute value of the deviation from the midpoint) was analyzed, 49 of the subjects (70 percent) scored the maximum value of 6 (44 positive deviations and 5 negative deviations of 6 from the midpoint).

The picture is similar for the evaluation of music that triggers personal memories. Most ratings cluster around the endpoints of the scale, although only two musical selections were rated below the midpoint of the scale, and 41 subjects (59 percent) attain the maximum deviation from the midpoint.

The median time interval that had elapsed since the personal experience first occurred was 2 years, but for some people it was as short as a week and for others as long as 14 years. Subjects also indicated that the recollection of a personal experience brought about by the piece of music was rather vivid and emotional (means of 6.0 and 5.6, respectively, on seven-point scales). Furthermore, subjects tended to

TABLE 2
Correlations among phenomenological characteristics

Feelings toward music	1.00						
Feelings toward experience	0.68	1.00					
Pastness of experience	-.20	-.06	1.00				
Vividness of recollections	0.20	0.13	-.15	1.00			
Emotionality of recollections	0.44	0.32	-.40	0.35	1.00		
Reliving of original experience	0.39	0.22	-.24	0.34	0.56	1.00	
Imagery during recollections	0.15	0.14	-.16	0.54	0.39	0.41	1.00

Note: Correlations greater than 0.20 are significant at $\alpha=0.05$ (one-tailed).

relive the original personal experience when they heard the piece of music (mean of 5.2) and reported that the recollection was often accompanied by imagery descriptive of the original experience (mean of 5.8).

Correlations among the various measures discussed in the foregoing paragraphs are presented in Table 2. Subjects' evaluations of the piece of music and of the personal experience associated with it are strongly correlated at 0.68, which lends some preliminary support to the notion that feelings aroused by listening to music may sometimes derive from feelings associated with an autobiographical episode that the piece of music evokes. Table 2 also indicates that the more vivid and emotional the recollections triggered by a piece of music are and the greater the extent to which people relive the original experience, the more positive the evaluation of the piece of music will be.

Analysis of Experiential Emotions

Correlations were computed among Russell's 28 affect terms on which subjects rated the affective qualities of the personal experience they had recalled, and the resulting correlation matrix was subjected to a nonmetric multidimensional scaling analysis using the program KYST (Kruskal and Wish 1978). The stress values for one-, two- and three-dimensional solutions were 0.16, 0.11, and 0.06, respectively; the two-dimensional structure yielded the most interpretable solution, however, and it is depicted in Figure 1.

It can be seen that the 28 affect terms fall roughly into a circular order. With the exceptions of tired and bored, whose positions do not fit the hypothesized pattern, the structure proposed by Russell (1980) is replicated quite well. The horizontal axis reflects pleasure-displeasure and the vertical axis indicates degree of arousal.

Analysis of Musical Emotions

Correlations were also computed among the 24 emotional descriptors of music, and the resulting correlation matrix was subjected to a nonmetric multidimensional scaling analysis. The stress values in one, two, and three dimensions were 0.17, 0.11, and 0.06, respectively, and the two-dimensional structure yielded the most interpretable solution. The results are shown in Figure 2.

The hypothesized circular order is not obtained as clearly for the musical emotions as it was for the experiential emotions, but the arrangement of the 24 musical adjectives corresponds roughly to prior expectations. The horizontal axis again reflects pleasure-displeasure and the vertical axis indicates degree of arousal.

Correspondence between Experiential and Musical Emotions

In order to assess the degree of correspondence between the affective qualities descriptive of a personal experience and the emotional tone ascribed to a piece of music, it was necessary to reduce the number of experiential and musical emotions to a more manageable number. Principal components analysis was used to accomplish this.

For the experiential emotions, five factors had eigenvalues greater than one and together accounted for 72 percent of the total variance. After performing an oblique rotation (PROMAX), the five factors were defined by the following items: EXPPEMOT-I (aroused, excited, delighted, happy, pleased, glad, satisfied); EXPPEMOT-II (serene, content, at ease, relaxed, calm); EXPPEMOT-III (sleepy, droopy); EXPPEMOT-IV (tired, bored); and EXPPEMOT-V (astonished, gloomy, miserable, frustrated, distressed, annoyed, afraid, angry, tense, alarmed). The items defining a given factor were summed up and the reliabilities of the five composites are shown in the appropriate diagonal of Table 3. The items 'sad' and 'depressed' were not included in any of the composites because they had large negative loadings on the first factor and did not load very highly on any of the other factors.

For the musical emotions, four factors had eigenvalues greater than one and together accounted for 71 percent of the total variance. After performing an oblique rotation, the four factors were: MUSEMOT-I (vigorous, majestic, triumphant, exhilarating, graceful, dignified); MUSEMOT-II (exalted, merry, joyous, cheerful, light, playful, longing); MUSEMOT-III (passionate, tranquil, soothing, sentimental, dreamy); and MUSEMOT-IV (quiet, mournful, tragic, doleful, serious, solemn). The items defining each factor were again summed up and the reliabilities of each composite are shown as the diagonal entries in Table 3. It is apparent that the five experiential and the four musical emotion factors correspond closely to

FIGURE 1
Multidimensional Scaling Solution for 28 Experiential Emotions

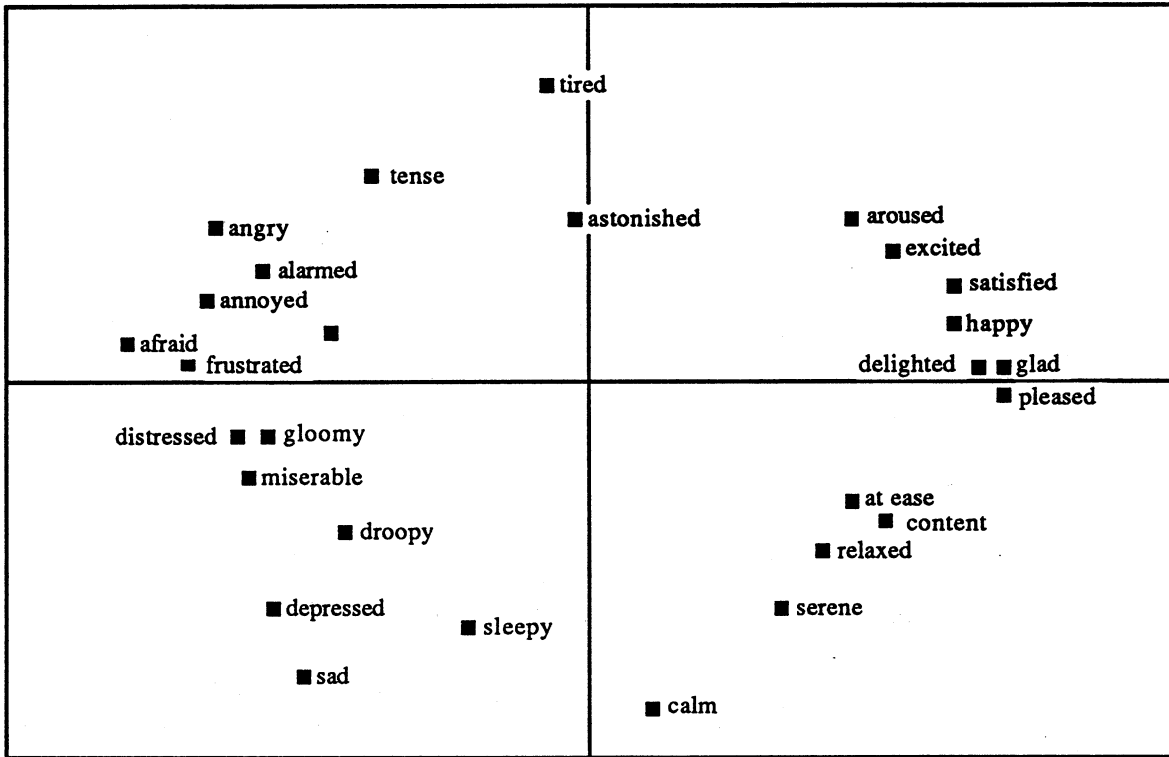

FIGURE 2
Multidimensional Scaling Solution for 24 Musical Emotions

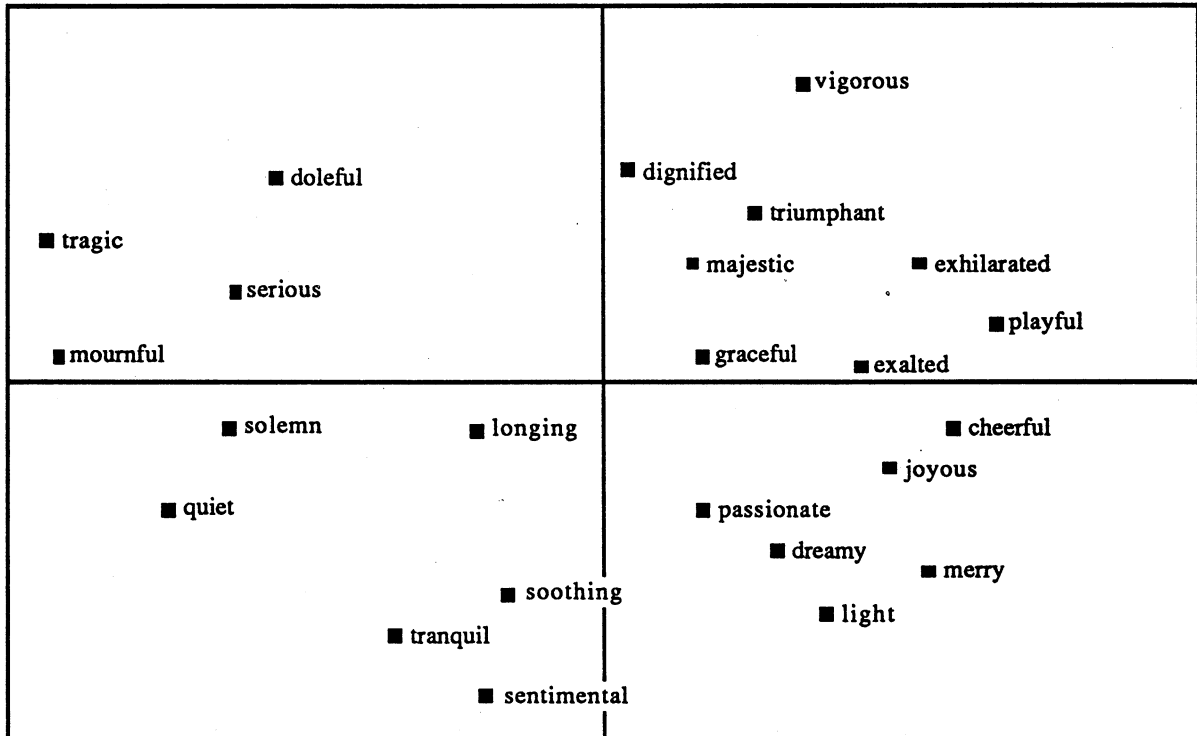

TABLE 3
Correlations among the five experiential and the four musical emotion factors

	EXPEMOT					MUSEMOT			
	I	II	III	IV	V	I	II	III	IV
EXPEMOT-I	0.95								
EXPEMOT-II	0.55	0.81							
EXPEMOT-III	-.22	-.06	0.76						
EXPEMOT-IV	-.04	-.05	0.48	0.70					
EXPEMOT-V	-.42	-.24	0.43	0.33	0.91				
MUSEMOT-I	0.59	0.45	0.03	0.09	-.06	0.90			
MUSEMOT-II	0.81	0.52	-.14	-.11	-.28	0.70	0.89		
MUSEMOT-III	0.53	0.71	0.04	-.09	-.23	0.55	0.60	0.85	
MUSEMOT-IV	-.36	0.16	0.46	0.15	0.57	0.04	-.23	0.31	0.88

Note: Correlations greater than 0.23 are significant at $\alpha=0.05$ (two-tailed).

the way affect terms cluster together in the multidimensional scaling solutions.

Besides the correlations among the five experiential emotion factors and the four musical emotion factors, Table 3 also exhibits the cross-correlations among the two sets of factors. It is apparent that the emotional tone ascribed to a piece of music follows the affective characterization of the personal experience that the music evokes. If the autobiographical episode was described as exciting and happy (using the items with the highest loadings to define a factor, in this case EXPEMOT-I), subjects tended to characterize the music primarily as merry and longing (MUSEMOT-II), but also as majestic and triumphant (MUSEMOT-I) and tranquil and soothing (MUSEMOT-III). If the original experience was perceived as serene and calm (EXPEMOT-II), the piece of music was described predominantly as tranquil and soothing, but also as merry and longing and majestic and triumphant. Finally, if the affective qualities of the personal experience were called sleepy and droopy (EXPEMOT-III) or alarmed, astonished, and distressed (EXPEMOT-V), the music that triggered such recollections was characterized as mournful and doleful (MUSEMOT-IV).

Although the terms 'sad' and 'depressed' did not define a separate factor or load highly on EXPEMOT-IV, the two items were correlated 0.74 and had a correlation of 0.55 with EXPEMOT-IV. Furthermore, the composite of sad and depressed was correlated 0.68 with MUSEMOT-IV.

DISCUSSION

The results of this study suggest that the subjects who participated in this research had experienced a situation in which a piece of music had become associated with an event from their lives so that hearing the piece of music evoked memories of the original episode. Most of the instances of this phenomenon reported by undergraduate marketing majors involved relationships with past or present lovers or experiences with family and friends, and

although some people described unpleasant episodes, overall there was a significant bias toward remembering happy events. Most personal experiences for which the phenomenon occurred were strongly affectively charged, and the recollections triggered by the music were described as vivid and emotional and as involving a reliving of, and being accompanied by imagery descriptive of, the original episode.

The results of the study also indicate that the emotional tone ascribed to a piece of music is a function of the affective characteristics of the personal experience with which the music is associated. First, there was a fairly strong correlation between a person's evaluation of the piece of music and his or her evaluation of the autobiographical episode. Second, there was more specific evidence that people's ratings of the affective characteristics of the personal experience corresponded to the feelings induced by hearing the piece of music.

How does the research reported in this paper relate to similar work in consumer behavior? There has recently been a flurry of research on the effects of music on consumer behavior (see the review by Bruner 1990 and the more recent papers by Alpert and Alpert 1991, Kellaris and Kent 1991, Scott 1990, Wallace 1991, and Yalch 1991). These papers deal with a variety of important issues relating to the use of music in marketing (music as an affective background in ads, music as a mnemonic device, music as a communicator of meaning, etc.), but they are not particularly pertinent to this study.

Two other streams of research are more relevant to the present concerns. One is the work by Baumgartner, Sujan, and Bettman (in press) on the role of consumers' autobiographical memories in information processing (see also Thorson and Friestad 1989). In a series of studies, Baumgartner et al. (in press) show that consumers' autobiographical memories involving products and product usage experiences are affectively charged and that the retrieval of these memories influences ad and brand

evaluations. The present study indicates that some pieces of music may be rather effective in cuing autobiographical memories and that the recollections triggered by music are strongly, and generally positively, affectively charged. This suggests that music in advertising may impact ad and brand evaluations through the retrieval of autobiographical memories. Although there was a lot of diversity with respect to the pieces of music for which subjects reported recollections of autobiographical events, the present study does not allow drawing conclusions about how frequently associations with popular pieces of music are formed. A fruitful avenue for future research would thus be to investigate whether the inclusion of well-known tunes in ads triggers memories of past personal experiences which arouse emotions beyond what would be predicted from the mere popularity of a piece of music.

A second area of research that deals with issues similar to the present concerns is the work of Holbrook and Schindler (1991) and Havlena and Holak (1991) on nostalgia. Nostalgia is often defined as a "yearning for the past" and refers to the "bittersweet" memories people have of past personal experiences (frequently from the period of adolescence and early adulthood). As noted by Havlena and Holak (1991), there has recently been a boom in the use of nostalgia in marketing, and advertisers often try to evoke nostalgic feelings through music, jingles, and other stimuli. In a study dealing with the development of musical tastes, Holbrook and Schindler (1989) found that subjects expressed the strongest liking for music that was popular when they were in their early twenties. The authors argue that one reason for this peak in preference in early adulthood might be that people associate pieces of music from this time with emotionally powerful events such as fraternity parties, school dances and other social gatherings. Many of the associations reported by subjects in the present study may be classified as nostalgic recollections of past events, and the results show that most memories are "sweet" rather than "bitter." Furthermore, the participants in the study were all juniors or seniors and thus in their early twenties, and most of them (78 percent) described pieces of music that had been popular, and experiences that had occurred, during the previous four years. Given that the music tended to take on the emotional tone of the personal experience with which it was associated and given that most episodes recalled were happy events, the present findings suggest that preference for popular music, especially when tracked over time, may not be a function of the music per se, but a consequence of the personal associations people have with the music.

The research reported in this paper only scratches the surface of many of the issues raised. Furthermore, several limitations of the study should be kept in mind. First, the findings that emerged are based on data from a relatively small sample of undergraduate marketing majors, they are correlational in nature, and they may not generalize to other segments of the population. Second, instances of the phenomenon of indexical induction of emotions through music were self-selected, and the ratings of

both the affective qualities of the personal experience triggered by music and the emotional tone of the piece of music associated with the personal experience were collected at the same point in time, which could have increased the correspondence between the experiential and musical emotions. One way of overcoming this deficiency would be to obtain ratings of the emotional tone of the piece of music at a later point in time and to mask the connection to the earlier study by gathering data on several pieces of music. Third, the structure underlying Hevner's (1936) shortened instrument for the measurement of musical emotions was not very clear-cut and more research seems necessary to refine the list of adjectives. Furthermore, since the Russell (1980) and Hevner (1936) instruments probably do not measure the emotions associated with a personal experience and a piece of music equally well, the correlations reported in Table 3 should be interpreted with care. If the research were conducted in two waves, the same scale could be used for the assessment of the affective quality of a personal experience and the emotional tone of the piece of music and this problem could be circumvented. The present findings are preliminary, but the results thus far look encouraging and the phenomenon of indexical induction of emotions through music is interesting so that further investigation of the topic seems warranted.

A Framework Providing Direction for Research on Communications Effects of Mental Imagery-Evoking Advertising Strategies

Laurie A. Babin, University of Southern Mississippi

Alvin C. Burns, Louisiana State University

Abhijit Biswas, Louisiana State University

ABSTRACT

The authors review mental imagery research related to advertising strategy and observe that both within- and across-strategy research is lacking. A framework positing predictor, criterion, mediator and moderator variables is proposed as an appropriate frame of reference. The mediating role of mental imagery between advertising strategy alternatives and communications effects is highlighted, and while some scale development has taken place, a rigorous scale development process, along with the recommended framework, could lead to much better understanding of the consumer information processing dynamics involved with imagery-evoking advertising strategies.

INTRODUCTION

Much of the research into the methods by which consumers process information has concerned itself with what is termed "discursive processing" (MacInnis and Price 1987). This style of processing inquires into how language and symbols are manipulated in memory to perform some function such as solve problems, create or change attitudes, or be stored for later retrieval. Recently, however, there has been interest in mental imagery as a provocative method of information processing (See MacInnis and Price 1987; Lutz and Lutz 1978; Childers and Houston 1982, for example). Lutz and Lutz (1978) have defined imagery as "a mental event involving visualization of a concept or relationship." On the other hand, MacInnis and Price (1987) describe imagery as a "conceptually distinct way of representing information." They further stress that imagery is: "...(1) a process...by which (2) sensory information is represented in working memory." Childers and Houston (1982) state that various forms of imagery can be experienced, including stimuli represented by each of the five senses: hearing, touch, taste, smell, and visualization.

While the research on the conceptual and applied aspects of imagery theory is embryonic, initial theoretical implications and empirical findings indicate a rich domain for consumer research, especially in an advertising context. MacInnis and Price (1987) recently reviewed research on imagery as it relates to information processing. They indicate a need for further work on imagery's role in a marketing context stating that although imagery is pervasive, little is known about its impact relative to consumption. They further recommend that factors controlled by marketers to influence consumer imagery should be investigated due to their potential effects on product information processing and purchase behavior.

The general purpose of this paper is to review imagery research that relates to advertising and to provide directions for future consumer research in this area. Specifically, imagery-evoking strategies that can be used in advertisements are reviewed and gaps in our knowledge are revealed. We posit an appropriate framework which identifies the categories of factors which should be addressed in future empirical research, and we discuss the variables in each category which pertain to advertising strategy. Based on this framework and our review of prior mental imagery research, we propose a systematic program of research which should lead to enlightenment in this area.

IMAGERY-EVOKING ADVERTISING STRATEGIES

MacInnis and Price (1987) discuss four imagery-evoking strategies: pictures, concrete words, instructions to imagine, and guided imagery. These were gleaned from Lutz and Lutz (1978) and Alesandrini and Sheikh (1983), and the first three were advocated as advertising strategies by Rossiter (1978). These works, in turn, were compiled primarily from the psychology literature. For example, Paivio (1970) enumerates the typical types of imagery manipulation as concrete stimuli, instructions, and the selection of subjects based on individual imagery capability, and Wollman (1981) discusses the use of guided imagery in studying social psychological phenomena. In sum, there is a substantial base of literature that holds there are different types of imagery-evoking strategies. However, with the exception of Slee (1978), no studies have examined whether there are differences between these strategies. Slee examined the differences among the use of concrete words, instructions to imagine, and individual differences as imagery-evoking strategies and found that each type of strategy caused different effects on memory.

Guided imagery is an intrusive, clinical method of stimulating mental visualization and does not fit an advertising context well; however, the remaining three strategies enumerated by Rossiter (1978) and MacInnis and Price (1987) are viable alternatives for both print and broadcast media and could be compared separately and/or in combination to determine differential impacts on (e.g.) memory and brand attitudes. Although scant empirical evidence exists, practitioners continue to design advertisements with these components. In fact, in a normative paper, Rossiter (1978) states, "high imagery visuals work far better than instructions to imagine" (p. 102). Thus, it is apparent that empirical investigation seems warranted to address the question of the relative efficacy of alternative imagery-evoking strategies.

Pictures

Pictorial material is defined as "any two-dimensional representation in which the stimulus array contains at least one element that is not alphabetic, numeric, or arithmetic" (Lutz and Lutz 1978, p. 611). As such, photographs, drawings, and illustrations fall under the rubric of pictures. It is believed that pictures influence the process of mental imagery (Bugelski 1983; Paivio 1971; Rossiter 1978; Shepard 1967). The picture superiority effect, which contends visual information is remembered over verbal information, has been explained through imagery by Paivio's (1986) dual code theory. The theory posits that not only do pictures activate a visual encoding process, but they also activate a verbal encoding process. Moreover, the visual code is thought to be qualitatively superior to the verbal code. So two retrieval paths can be activated at the time of recall. Words, on the other hand, activate only a verbal encoding process, resulting in poorer recall. (However, certain words can also stimulate mental imagery as is discussed under concreteness of wording.)

Pictures can be classified according to the level of concreteness and the degree of interaction depicted. Concreteness can range from very concrete and realistic to abstract (Rossiter and Percy 1983). A concrete picture is one that is easily identifiable of a person, place, or object; whereas, an abstract picture is one not easily identifiable (Rossiter and Percy 1983). For example, an advertisement containing a picture of a product is more concrete than one that contains a silhouette. Moreover, the elements within a picture can also be interactive or noninteractive in nature (Lutz and Lutz 1977, 1978). An interactive picture is one in which persons and/or objects are figurally integrated in such a manner as to be associated in some mutual or reciprocal action; whereas, a noninteractive picture depicts the items side by side (Alesandrini and Sheikh 1983).

While studies have analyzed the impact of concrete, abstract, or no pictures (e.g., Mitchell 1986; Mitchell and Olson 1981) and interactive versus noninteractive pictures (e.g., Lutz and Lutz 1977), no study has examined the impact of a range of pictures. For complete disclosure, it is necessary to examine the relative effect sizes of all types of pictures, concrete/interactive, concrete/noninteractive, abstract, and no pictures, on imagery processing.

Words

Compared to abstract words, concrete words are more likely to elicit a mental image in the mind of the viewer/listener because of their higher "imagery value." By asking individuals to rate words with respect to their ease of arousing sensory images, imagery values have been established for nouns (Paivio, Yuille, and Madigan 1968), for verbs (Lippman 1974), and for 1,000 frequently-used words (van der Ver 1975). For example, it is easier to form an image given the concrete word "dog" than it is given the abstract word "justice." There is evidence indicating the positive effects of concrete words on memory (Paivio 1969). The effectiveness of concrete

wording on memory and attitudes has been well-substantiated in the literature (see Lutz and Lutz 1978 for a review). In a normative paper, Rossiter (1978, p. 101) states, "High imagery words should be used in advertising," and it has also been shown in an advertising context that ads containing concrete versus abstract wording resulted in more positive attitudes toward the ad and brand as well as greater behavioral intentions (Burns, Biswaw, and Roach 1991). Still, the comparative or combined impacts of word types with picture types and/or instructions to imagine remain elusive.

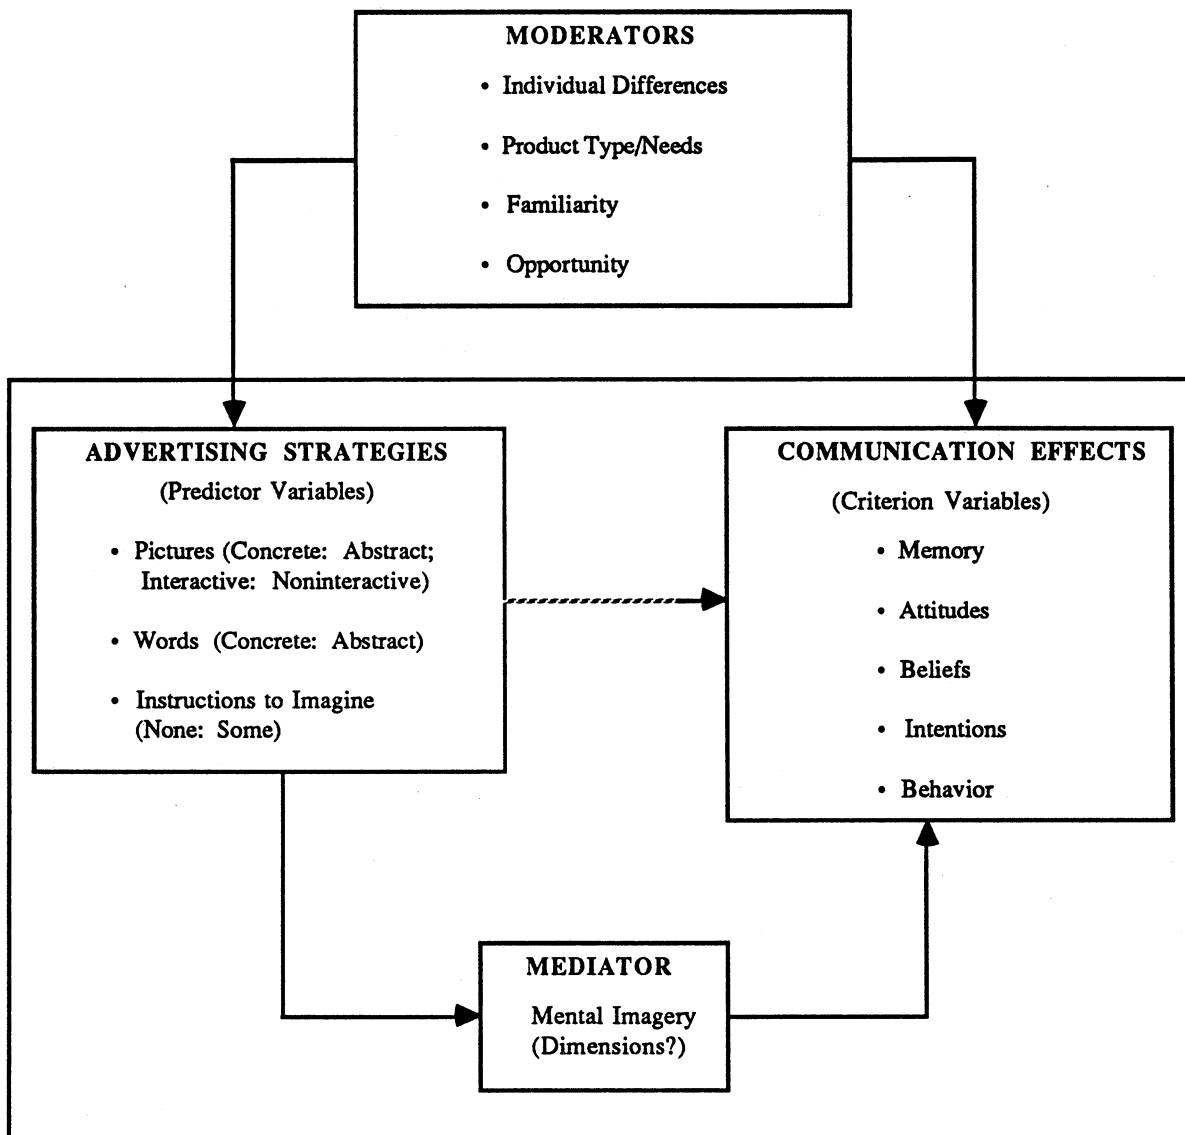

Instructions to Imagine

This imagery-evoking strategy is the most direct way to encourage imagery processing. Typically, instructions to imagine have involved the experimenter giving instructions to the subject to form mental images, especially in studies in psychology. Subjects are told to "form a mental picture..." or to "picture yourself in the situation."

Embedding instructions to imagine within a message stimulus is a viable alternative for advertising. A few researchers have analyzed the effects of embedding instructions to imagine within a promotional message, but results have been mixed. For example, Wright and Rip (1980) manipulated instructions to imagine included within a message stimulus given to high school sophomores concerning colleges. However, they failed to achieve significant differences on attitudes. The lack of effect could have been due to subjects' inability to imagine the scenarios described because they did not possess adequate knowledge structures about colleges to facilitate imagery (MacInnis and Price 1987). In a study by Gregory, Cialdini, and Carpenter (1982), subjects were given information concerning cable television, and the experimental group received a message with instructions to imagine included in the message. The experimental group exhibited more positive attitudes, greater behavioral intentions, and had a greater subscription rate than the control subjects. However, one factor other than the instructions to imagine may have caused the results. In the information-only condition the message did not target the respondent in the scenario, while the imagery-only condition did. Thus, the imagery condition was also self-related, while the information condition was not. It has been found that self-relatedness of an imagery-inducing message influences responses such as likelihood (e.g., Anderson 1983), attitudes, and intentions (e.g., Bone and Ellen 1990). Therefore, the messages were not equivalent with respect to self-relatedness, and this could have been the casual factor for the differences found.

Paivio (1971) reviewed several studies on experimenter-provided mental imagery instructions and concluded that such instructions facilitate learning. Another advantage of instructing the viewer to form his/her own mental image as opposed to providing a picture for them is that the self-generated mental imagery will probably be more personally relevant. This could result in self-generated persuasion and stronger attitudes (MacInnis and

FIGURE 1
 Framework for Imagery-Evoking Advertising Strategy Research

Jaworski 1989). While Rossiter (1978) states, "high imagery visuals work far better than instructions to imagine," no wholly adequate empirical study has been performed to test this proposition. Thus, there is need to assess the mental imagery-generating potential of instructions to imagine embedded within an advertising message.

A FRAMEWORK FOR IMAGERY-EVOKING ADVERTISING STRATEGY RESEARCH

A fundamental shortcoming of almost all studies to date is that instead of assessing imagery processing, researchers have relied on criterion-based responses (MacInnis and Price 1987). Typically, an imagery-evoking strategy is manipulated, and imagery processing is inferred from the results such as memory

differences. Thus, it is assumed that imagery processing was the causal factor in the positive responses for the imagery-evoking condition. While pragmatic, this approach affords little with regard to insight and understanding. Figure 1 offers a research framework to overcome the inherent shortcomings of prior research. The Figure draws conceptually from comments by Baron and Kenny (1986), who distinguish between moderator and mediator variables in social-psychological research. As can be seen, the three classes of imagery-evoking advertising strategies are cast as independent variables. Communications effects such as recall, attitude, brand beliefs, and intentions are posed as the dependent variables, while mental imagery itself is positioned as mediating the effects of predictors on criterion variables.

A mediator functions by accounting for some or all of the relationship between a predictor and a criterion. Thus, mental imaging serves as a cognitive process bridge between independent and dependent variables. Moderators, on the other hand, affect the direction and/or strength of the relationships between predictor, mediator, and/or criterion. As just noted, no research to date has posited mental imagery as a mediator of advertising strategy on communications effects variables, nor have most studies utilized a moderator designation to investigate conditions under which empirical relationships do or do not hold. (See Baron and Kenny (1986) for complete discussion of mediators, moderators and recommended analytical procedures.)

COMMUNICATION EFFECTS

Given this framework, it is useful to briefly discuss the criterion variables of interest to those experimenting with the various imagery-evoking advertising strategies described earlier. While memory plays an important role in brand awareness, beliefs, attitudes, intentions, and purchase behavior are also major communication effects for advertising research (Rossiter and Percy 1983). Some studies in marketing have examined the effect of an imagery-evoking strategy on recall and recognition of brand names (e.g., Childers and Houston 1984; Childers et al. 1985; Houston et al. 1987; Lutz and Lutz 1977; Robertson 1987) or message recall (Gardner and Houston 1986). Other studies have examined the impact of some imagery-evoking strategy on attitude toward the product or brand (e.g., Bone and Ellen 1990; Burns et al. 1991; Gregory et al. 1982; Kisielius and Sternthal 1984; Mitchell 1986; Mitchell and Olson 1981; Oliver et al. 1990; Rossiter and Percy 1978, 1980; Wright and Rip 1980), attitude toward the ad (e.g., Bone and Ellen 1990; Burns et al. 1991; Mitchell 1986; Mitchell and Olson 1981), behavioral intentions (e.g., Burns et al. 1991; Gregory et al. 1982; Kisielius and Sternthal 1984; Mitchell 1986; Mitchell and Olson 1981; Rossiter and Percy 1978, 1980; Oliver et al. 1989), and actual behavior (e.g., Gregory et al. 1982).

Whereas awareness, attitudes, and intentions have been studied in imagery applications, only a handful of studies have investigated imagery and product beliefs (e.g., Mitchell 1986; Mitchell and Olson 1981), and these have primarily manipulated pictures as the imagery-evoking strategy. It can be speculated that different imagery-evoking strategies will result in differential beliefs about the brand advertised. Furthermore, one imagery-evoking strategy may result in a greater number of beliefs as well as different brand belief strengths. This is an area that needs further research, and, as with all other criterion variables, there must be increased concern for comparisons across imagery-evoking strategies.

MEASURING IMAGERY PROCESSING

Researchers familiar with this area will readily agree that the measurement of mental imagery has been a major hinderance. There have been various approaches to measuring imagery processing, but

only one holds good promise. From psychology, one method involves interrupting an individual involved in imagery processing, which is referred to as "thought sampling" or "event sampling" (Klinger 1978). Another, called Experiential Analysis Technique (EAT), involves videotaping individuals as they are imagining and later having them interpret the video (Sheehan et al. 1983). Physiological measures have also been used to assess imagery processing. Finally, pencil and paper assessment of imagery processing has also been attempted, which incorporates manipulation checks and scales.

In general, research in psychology has not really succeeded in measuring imagery processing. The attempts are, at best, performed as manipulation checks and can be classified into three groupings: (1) asking subjects to rate the vividness of their imagery (e.g., Rigney and Lutz 1976); (2) asking subjects what learning strategy they had used (e.g., Elliott 19733); or (3) checking the subject-provided written or verbal record of what they had done (e.g., Anderson 1983).

In marketing, measurement attempts can be grouped into: (1) manipulation checks (e.g., Lutz and Lutz 1977); (2) protocols (e.g., Rethans and Hastak 1982; Smith et al. 1984); or (3) scales (e.g., Bone and Ellen 1990; Ellen and Bone 1990; MacInnis and Price 1990; Oliver et al. 1989). Except for Ellen and Bone (1990), however, useful conceptualization and scale development of imagery processing has been lacking.

Ellen and Bone (1990) provide the only systematic attempt to develop a scale to measure stimulus-evoked imagery processing. They proposed that communication-evoked imagery may be reflected in five dimensions: vividness and/or clarity, quantity, ease, and links experienced from the message, but they empirically determined four dimensions in which the quantity and ease dimensions were considered as one. However, careful review of their work reveals they did not adhere to rigorous scale development methodology such as that set forth by Churchill (1979). First, the authors did not generate a large inventory of items to begin with; indeed, they started and ended with 19 items. Second, they used radio ads from a previous study as stimuli (see Bone and Ellen 1990), which may have resulted in demand characteristics since six out of the seven ads were high imagery-evoking ads beginning with the statement "Imagine this." It may be more appropriate to use a spectrum of stimuli that range from high to low imagery-evoking characteristics. Finally, the authors only collected data once to develop the scale (although they did use two studies with one data collection each). This procedure is inconsistent with the framework proposed by Churchill (1979) in which new data is recommended to purify the measure and assess validity.

Nonetheless, the work of Ellen and Bone (1990) provides an excellent starting point. They propose reasonable dimensions derived from the conceptual and empirical literature from which to begin proper scale development. Because it is a pregnant mediator construct, assessment of imagery processing is necessary in any study, particularly those in an advertising context. Thus, there is a need

for an acceptable scale to measure mental imagery processing, and the best method for developing one involves a rigorous and systematic effort.

MODERATORS

Not only are the effects of different imagery-evoking strategies on imagery processing and advertising communication variables an area for future research, but the moderating natures of several variables have yet to be explored satisfactorily. Variables such as individual differences in imagery processing and knowledge structures (i.e., familiarity with the product or brand advertised), needs tapped by the advertisement and/or product, and the opportunity for imagery processing may influence the effectiveness of an imagery-evoking strategy.

Individual Differences in Imagery Processing

Individual differences in imagery processing have received attention in a number of studies. The areas of interest are studies of individual differences in (1) spatial ability, (2) imagery ability, (3) imagery content, and (4) processing style. These dimensions of individual differences have been studied both for their direct and indirect roles on the processing of information, but the majority of studies have treated individual differences in imagery ability, imagery content, and/or processing style as predictor variables. Several scales exist to measure individual differences in imagery processing (for a review, see MacInnis (1987) and Sheehan et al. (1983)).

Imagery ability refers to the vividness and controllability of an individual's mental imagery (MacInnis 1987). Vividness refers to clarity of the mental imagery, while control implies an individual's ability to perform manipulations such as mental rotations (Childers et al. 1985). These dimensions focus on one's cognitive ability as the determinant of the type of processing strategy evoked. Ability has typically been treated as a predictor variable (e.g., Childers et al. 1985; Marks 1973; McKelvie and Demers 1979; Oliver et al. 1989; Slee 1978) or as a covariate (e.g., Childers and Houston 1984; Sheehan 1966), but results have been mixed. Thus, no conclusions can be drawn regarding the moderating effect of imagery ability on the relationship between imagery-evoking strategies and imagery processing or communication effects.

Individuals also differ with respect to the general content of their images and fantasies as well as their use of imagery in everyday life. This construct reflects individual tendencies to engage in vivid imagery, to use imagery to plan the future, and to engage in fantasy (MacInnis and Price 1990). Very few researchers, however, have studied this individual difference variable, and those who have (e.g., MacInnis and Price 1990), have found disappointing results.

Similar to imagery ability, style of processing (or processing preference) has been examined in several marketing studies. In contrast to imagery ability, however, it has received more support as being effective as a predictor variable (e.g., Childers

et al. 1985; Gould 1990; Holbrook et al. 1984; Oliver et al. 1989; Rossiter and Percy 1978). While imagery ability and style of processing may appear to be similar constructs, Richardson (1977) argues that they are independent dimensions, and Childers et al. (1985) provide support for this argument. Ability refers to an individual's basic cognitive ability, but preference for using a specific processing style (i.e., verbal) or imagery (i.e., visual) reflects one's tendency to utilize one type of processing style more than others. More specifically, Childers et al. (1985, p. 130) conceptualize processing style "as a preference and propensity to engage in a verbal and/or visual modality of processing." Thus, while an individual may possess a strong imagery or verbal ability, he/she may be indifferent as to the style of processing preferred. Indeed, Betts (1909) found that most, if not all, individuals possess some imagery ability and can image when asked to do so. Therefore, processing preference may be the superior, differentiating individual difference moderating variable.

Product Type and Needs

The type of product advertised may well influence imagery processing. Some products may be considered as strictly utilitarian in nature, and may discourage imagery processing. This could have been the reason Oliver et al. (1989), who used a high-tech computer printer, failed to find significant results. This type of product may have a low imagery-evoking ability, and using an imagery-evoking strategy may be disappointing unless unusually creative. Thus, a typology of products based on their imagery-evoking potential would be useful to advertisers and researchers alike.

The type of need evoked by an advertisement may enhance or dampen imagery processing. MacInnis and Jaworski (1989) posit that needs, either utilitarian or expressive, may moderate the relationship between exposure to the ad stimulus and the level of brand processing. If rather concrete in nature, a product advertised through strictly utilitarian benefits may not generate the elaborative processing necessary for mental imagery to be effective. On the other hand, a product advertised through more emotional, expressive needs may encourage mental imagery. Both product type and need configuration are potential moderator variables deserving attention.

Knowledge/Familiarity

Familiarity with the stimulus affects the quality of imagery. MacInnis and Price (1987) contend that imagery processing relies on prior knowledge for both the ability to visualize and the vividness of such visualization. This claim is also made by Smith et al. (1984) and alluded to by Wright and Rip (1980). The point here is that mental visualization requires some prior knowledge of the stimulus being imagined, and the more familiar one is with the stimulus object, the richer is the base from which images will spring. Scant research (Burns et al. 1991) has addressed this factor. It remains unknown as to what extent familiarity moderates mental imagery.

Opportunity

Another moderating variable that may influence the effect of imagery-evoking strategies is the opportunity to image (MacInnis and Jaworski 1989). While many studies have used print ads as stimuli (Burns et al. 1991; Childers and Houston 1984; Childers et al. 1985, 1987; Lutz and Lutz 1977; Rossiter and Percy 1978, 1980; Wright and Rip 1980), only one has used radio ads (Bone and Ellen 1990). Though it has been pointed out in the literature that, *ceteris paribus* (i.e., involvement in processing the medium), imagery strategies presented aurally may be more effective than written imagery strategies (Alesandrini and Sheikh 1983; Lutz and Lutz 1977), no study has examined this issue empirically. This assertion was based on the interference work done by Brooks (1967), in which two visual tasks interfered with each other. Experiments performed by Salthouse (1975) also indicate an interference effect when two simultaneous tasks both involved either verbal information or spatial information but not when one task was verbal and the other spatial. Clearly, because mental imagery requires some degree of effort, the opportunity factor should be factored into future research designs.

DIRECTIONS FOR FUTURE RESEARCH

Several avenues for future research are apparent from this review. First, the relative efficacy of different imagery-evoking strategies has yet to be explored satisfactorily. Both intra-strategy and across-strategy comparisons must be assessed. For example, while it is well-known that including pictures in an advertisement is more effective than not including pictures, the type of picture included has not been examined. Based on past studies, it would seem that a concrete/interactive picture would be more effective than an abstract picture. Not only are pictures useful for eliciting imagery in advertisements, but instructions to imagine should elicit imagery processing and influence communication effects. However, only a few studies have included instructions to imagine within a message stimulus, and results have been mixed. Additionally, it would be interesting to examine whether or not instructions to imagine could supplant pictures, thus making the use of pictures unnecessary. If this could be done, then costs associated with the advertisement could be reduced by not including pictures.

Second, whereas awareness and attitudes have been widely examined as dependent variables, beliefs, behavioral intentions, and actual behavior have not. Although a hierarchy of effects implicitly underlies most advertising strategy, the nuances of mental imagery may obviate a smooth progress. In short, until a complete array of communications effects is investigated, the total consequences of these strategies will not be properly researched.

Third, the examination of imagery processing as a mediating variable between imagery-evoking strategies and communication effects is an area for future research. To examine the effect of imagery-evoking strategies on imagery processing, an

acceptable scale to assess imagery processing is necessary. Scale development could begin with the dimensions proposed by Ellen and Bone (1990), and then the mediating role of those dimensions could be examined. Only by measuring the quality and quantity of mental imagery can we hope to understand how criterion variables are affected.

Fourth, the effect of several moderating variables should be explored. Individual differences in imagery processing, particularly processing preferences, may moderate the effectiveness of an imagery-evoking strategy. If so, identifying individuals with different processing preferences would be of interest to advertisers. Thus, demographic and psychographic profiles of these individuals will provide insight into whether or not it would be profitable to segment based on this individual difference variable. Needs expressed in the advertisement or inherent in the product itself may also moderate the effectiveness of an imagery-evoking strategy. Furthermore, from a research point of view, a typology of products based on perceived need, and hence imagery-evoking value, would be useful when designing experiments to examine the effect of imagery-evoking strategies on imagery processing and communication effects. Researchers and advertisers must also be aware that familiarity with the product stimulus plays a moderating role. Asking audiences to imagine using a product may be not be effective if they are not sufficiently familiar with the product class. Finally, the opportunity to imagine may be another moderating variable that holds implications as to the appropriate medium for a given imagery-evoking strategy. For example, instructions to imagine may be more effective for radio advertisements because there is no interference from other visual tasks such as reading a print advertisement.

While not exhaustive, this paper has presented several fruitful areas of imagery research in an advertising context. In our view, imagery research, regardless of the context, must adopt the proper framework, and it desperately requires the development of an acceptable scale to assess imagery processing. Conceptualization of relevant dimensions of imagery processing is necessary, followed by rigorous scale development to measure those dimensions. Once done, the "black box" can be opened to provide insight into the processes that mediate the relationships between imagery-evoking strategies and communication effects. Though numerous input-output studies have been performed indicating the effectiveness of imagery, there is a dearth of literature regarding explanations. From a practitioner's perspective, knowing that one strategy is effective may be sufficient, but from a consumer researcher's point of view, understanding why a strategy is effective is the goal.

Examining Alternative Operational Measures of Internal Reference Prices

William O. Bearden, University of South Carolina

Ajit Kaicker, University of South Carolina

Melinda Smith de Borrero, University of South Carolina

Joel E. Urbany, University of South Carolina

ABSTRACT

Both Winer (1988) and Klein and Oglethorpe (1987) have noted that consumer internal reference price (IRP) is a multi-dimensional construct. Internal reference prices can either be estimated indirectly using scanner data (Winer 1986; Lattin and Bucklin 1989; Kalwani et al. 1990) or measured by asking consumers directly (e.g., Zeithaml and Graham 1983; Bearden and Urbany 1989; Urbany and Dickson 1991). The current paper considers the latter, with a focus on defining different reference price concepts, discriminating between indicators of transaction utility and acquisition utility, and examining how well those indicators explain purchase intentions.

Since first proposed by Emory (1970) and Monroe (1973), the notion that consumers use internal reference prices (i.e., price information stored in memory) in judging product value has become well established. This notion has strong theoretical (cf. Helson 1964; Kahneman and Tversky 1979) and empirical (Winer 1986; Lattin and Bucklin 1988; Kalwani, Rinne, Sugita, and Yim 1990) support, in spite of the fact that many consumers may hold expectations with uncertainty (Urbany and Dickson 1991).

The idea that consumers have and use internal reference prices is neither new nor revolutionary. The more important question currently is *which* kinds of reference prices exist, are measurable, and have the most impact on purchase decisions (see Winer 1988; Klein and Oglethorpe 1987). Internal reference prices have been used in the prediction of consumer brand choice by comparing the price the consumer sees in the current market to the price that s/he expected to be offered (i.e., by calculating price discrepancies). The current research examines how different types of reference price discrepancy terms perform in predicting purchase intentions. We first consider the notion of price discrepancy in more detail.

Price Discrepancy and Consumer Choice

The classic term "sticker shock" may best describe how internal reference prices can influence consumer decision-making. That is, a price that is surprisingly high (higher than the consumer expects) creates disutility and reduces the probability of purchasing that particular brand. Likewise, a price which is lower than expected produces positive utility and increases the likelihood of purchase. These effects have been demonstrated empirically, most impressively in studies using reference prices estimated from scanner data to predict brand choice (Winer 1986; Lattin and Bucklin 1988; Kalwani, Rinne, Sugita, and Yim 1990). In such studies, internal reference prices are estimated as a function of actual previous market prices and, therefore, represent

the prices that panel consumers expect to see charged in the market on a particular purchase occasion.

The price discrepancy terms used in these and other studies (Urbany and Dickson 1991; Bearden and Urbany 1989) have most likely represented what Thaler (1985) calls *transaction utility*. Transaction utility represents the "value of the deal" reflected in a given asking price and is based upon a comparison of the asking price and P^* , an expected or "just" price. Two issues are raised in the current paper:

1. Are certain measures of P^* better than others?
2. Do discrepancy terms based upon reservation price concepts add significantly to the prediction of purchase intentions?

Acquisition Utility

While price discrepancy terms which reflect transaction utility have been found to be significant predictors of purchase intentions and behavior, it seems that transaction utility itself is a fleeting (if important) source of utility for consumers. For example, positive transaction utility often is simply a perceived windfall which either encourages a consumer to enter the market or to choose one brand over another. However, the consumer's choice is ultimately based upon some evaluation of the product's ability to produce value and create utility relative to the price to be paid (e.g., "get" relative to "give") (Ahtola 1984). Thaler (1985) proposed that the construct *acquisition utility* captured this value concept. Acquisition utility is the surplus of utility (in dollar terms) over price paid (Thaler 1985, p. 205) or, alternatively, the ratio of perceived benefits to perceived sacrifice (Monroe 1990, p. 74). Further, Monroe (1990) suggests that acquisition utility, like transaction utility, can be represented in a price discrepancy term: $(P_{\max} - P)$, where P_{\max} represents reservation price (see also Thaler 1985, footnote 6).

In the present research, we consider the relative explanatory power of separate price discrepancy terms representing transaction and acquisition utility. Before presenting the research methodology, we consider various operational measures of the internal reference price concepts which can be used in calculating transaction utility and acquisition utility.

Potential Estimates of P^*

P^* is the internal reference price concept designed to reflect the price the consumer expects to be charged or believes is just or fair (Thaler 1985). The current study asks subjects to estimate internal reference prices for a particular apartment, using a

variety of approaches. The measures of P^* and P_{max} are presented below in verbatim form.

Perceived Price. Winer (1988) includes a number of internal reference price concepts under this category, although "perceived price" appears to relate primarily to the consumer's expectation of the price that sellers will charge for a given product on a given purchase occasion. We use three alternative (and probably substitutable) measures for this construct. These estimates have been used as well in a number of advertised reference price studies (e.g., Biswas and Blair 1991; Lichtenstein and Bearden; Urbany, Bearden, and Weilbaker 1988).

- NORMAL:** What do you think is the NORMAL rent for this apartment?
- EXPECTED:** What is the rent you would EXPECT to pay?
- AVERAGE:** Overall, what do you think is the AVERAGE rent for apartments like this?

"Just" or "Fair" Price. Winer (1988) separates fair prices from perceived, noting that the definition of fair price is slippery. The fair price is apparently based in part upon the consumer's perceived price, but also seems to require judgment against some standard of fairness (see Thaler 1985; Kahneman, Knetsch, and Thaler 1986). As such, the previous estimates of perceived price (i.e., shown above) may be different (and possibly higher) than those for the fair price measure:

- FAIR:** What do you think is a FAIR total monthly rent?

Potential Estimates of P_{max}

Conceptually, P_{max} is intended to indicate utility in dollar terms -- that is, the dollar amount the consumer would be indifferent to in choosing between cash and the product or the most one would be willing to pay. Operationally, we use three measures:

- MOST:** What is the MOST you would pay and still consider the apartment worthwhile to rent?
- INDIFFERENT:** From the price range given on the right, identify that price at which you would be INDIFFERENT between renting the apartment or looking further for an apartment.
- HIGHEST TO SEARCH:** Let's assume that you are currently living and settled in this apartment and it meets your needs. Assume that the rent is expected to change. If

the apartment owners/managers actually decided to change apartment rents, what is the HIGHEST monthly rent that would make you SEARCH FOR AND MOVE to another apartment?

Research Expectations

Our research attempts to discriminate between price discrepancy measures which should indicate transaction utility (TU) and those which should indicate acquisition utility (AU). In addition to measuring price expectations, we also measured respondent perception of TU and AU using several scaled items. As such, we expect that the TU price discrepancy variables will correlate most strongly with the TU scale and that the AU price discrepancy variables will correlate most strongly with the AU scale.

We also examine below how the TU and AU discrepancy terms perform in predicting purchase intentions. Our original expectation was that the AU construct, in reflecting the more permanent "utility" that the consumer would obtain through the purchase, would have a stronger impact on purchase intentions.

METHOD

Data were collected from 125 graduate student subjects via an interactive computer simulation. Seventy-six of the participants were male; the average age for the sample was 25.2 years. The research was conducted under the guise of research involving the evaluation of residential and apartment properties for university students. Prior to exposure to several apartment descriptions, data were collected regarding prior renting experience, rents paid, and related search experiences. One hundred and eighteen of the subjects (94 percent) were current renters; half the sample rented two bedroom apartments. Seventy percent of the respondents rated their general familiarity of apartments in the University area as at least "4" on a seven-place scale. The critical apartment (i.e., the location for which the various price estimates and judgments were elicited) was described as: having two bedrooms; being close to campus; in a safe, nice area; within a new building; and having a dishwasher. Using the operational statements reviewed above, the various price estimates were obtained in the following fixed order: NORMAL, MOST, EXPECTED, INDIFFERENT, AVERAGE, FAIR, and HIGHEST TO SEARCH. Following these estimates, the respondents were exposed to similar questions for another but different apartment. These latter tasks served also to separate the initial estimates from subsequent scaled-item judgments of perceived acquisition value, transaction value, and willingness-to-rent.

After providing price estimates for the second apartment and an additional set of filler questions, the study participants were provided with the initial apartment description in the context of a newspaper advertisement, including a monthly rent. Subjects were asked to assume they were in the market for an apartment and noticed this advertisement in the

Acquisition Utility	3	12.78	4.96	.81
Willingness-to-Rent	4	16.69	7.69	.94

Sunday newspaper. The advertised prices were manipulated to vary across seven conditions. These conditions were configured in a 1X7 design to represent prices either 15, 30, or 45 percent above or below or equal to the average of each subject's initial NORMAL and EXPECTED price estimates. As such, the prices were varied at the individual level based upon each subject's initial expectations. The cell sizes ranged from 17 to 19.

Operational Measures. Again, the "raw price estimates" were obtained using the question wording as previously described. Difference scores, in which the individual price is subtracted from the respondents' price estimates, were computed to represent the price based estimates of acquisition value and transaction value. That is, the advertised price was subtracted from the estimates of EXPECTED, AVERAGE, NORMAL, and FAIR to reflect four alternative price-based estimates of transaction value ($P^* - P$). Likewise, the advertised price was subtracted from the initial estimates of MOST, INDIFFERENT, and HIGHEST TO SEARCH to obtain three price-based individual estimates of acquisition value ($P_{\max} - P$). A series of four, three, and four seven-place scaled statements were also included to operationalize transaction value, acquisition value, and willingness-to-rent, respectively. The responses to the indicators for the latter three constructs were summed to form an overall index for each variable. The wording of the statements was varied in direction to inhibit response bias; each scale position was labeled to suggest equal intervals across response alternatives. The four transaction scaled statements were each worded to prompt the respondent explicitly to compare the expected price to

the advertised amount. For example, the items were prefaced by: "Compared to what I expect this apartment normally rents for, the advertised price appears to be..." These statements were then followed in the computer exercise on separate screens by the following bipolar adjective sets: high-low, outrageous-reasonable, expensive-inexpensive, and overpriced-underpriced. The summated scale version of acquisition value was operationalized as the response to three items: 1) Overall, the offer for this apartment is ...Very Poor Value-Very Good Value; 2) Overall, this apartment is a good value for the money...Agree-Disagree; and 3) The apartment is an excellent buy for the money...Agree-Disagree. Willingness-to-rent (cf. willingness-to-buy) was measured as the sum of four items similar to the following two examples: 1) "How willing would you be to rent this apartment...Very Unwilling-Very Willing"; and 2) "Given the offer described, the likelihood that I would rent this apartment is...Very Low-Very High". As shown in Table 1, the coefficient alpha estimates of internal consistency reliability were 0.94, 0.81, and 0.94 for the scaled measures of transaction value, acquisition value, and willingness-to-rent, respectively.

RESULTS

The means and standard deviations for the seven price estimates along with the means for the three scaled measures are presented in Table 1. Three of the initial estimates of P* (i.e., NORMAL, EXPECTED, and AVERAGE) have essentially the same mean and standard deviation. The fairness measure produced a numerically higher mean and variance than the other three measures--suggesting a wide range of

interpretations of the term "fair." There is a fairly wide range between the three reservation measures of Pmax. The lowest estimate came from the "indifference" measure for which respondents were placed in a search context. For the "highest to search" estimate (and the estimate that possessed the highest mean), subjects were asked to assume they were already renting. Of interest also, the "most" estimate was not that different from three of the P* estimates.

Intercorrelations among the initial estimates of the "raw" scores along with the intercorrelations among the difference scores are summarized in Table 2. For the raw score estimates (shown above the diagonal in Table 2), some very modest evidence of discriminant validity of the P* estimates versus the Pmax estimates was provided. Additional evidence regarding the very different effects captured by the fairness measure was also provided. The high correlations among the discrepancy scores for (P*-P) and (Pmax-P) clearly show that, while the Pmax estimates may be higher (see Table 1), the Pmax or reservation price difference scores are closely correlated with the P* estimates.

Correlations of the price-based estimates of transaction value [i.e., (P*-P)] and acquisition value [i.e., (Pmax-P)] with the scaled measures of transaction value, acquisition value, and willingness-to-rent are depicted in Table 3. In support of the general research procedures employed in the study and as would be expected, the initial estimates (which were obtained prior to the provision of the apartment rent) were not correlated with the scaled variables. In contrast, and as expected, all of the discrepancy variables were significantly correlated ($p < .01$) with the scaled measures of acquisition and transaction value. However, all the results were not as anticipated. Specifically, the acquisition value estimates [i.e.,

(Pmax-P)] were not more highly correlated with the scaled measure of acquisition value, but were actually more strongly related to the four-item scaled measure of transaction value. It is possible that the respondents were unable to get or develop a solid feel for the overall utility of the apartment that might be obtained with a more complete description or a picture.

The relative predictive ability of the various measures of acquisition value and transaction value were further examined in a series of simple and multiple regression analyses. These results are presented in Table 4. In these tests, the measure of willingness-to-buy was used as the dependent variable throughout. The Table includes both standardized regression coefficients and simple correlations along with estimates of the amount the variance explained decreased when each variable was omitted from its corresponding two predictor variable multiple regression equation. These latter estimates assist in interpreting the relative importance of predictor variables when multicollinearity problems are likely.

These regression results present a number of interesting findings. The scaled measures of acquisition value and transaction value explain a considerable amount of the variance in willingness-to-rent (i.e., adjusted R-square = 0.73). However, the scaled measures shared considerable similarity in measurement methods, despite the items being interspersed among a larger number questions and the varied direction of the item wording. As shown, analysis of the three scaled variables revealed that acquisition value appeared to be the most important correlate with willingness-to-rent as anticipated. A different conclusion emerges when the price-based predictions are evaluated. That is, the discrepancy estimates of transaction value [i.e., (P*-P)] appear

^aAll correlations involving difference scores are significant.

most important. In other words, the relative importance of TU and AU differ somewhat depending upon the types of measures used.

A number of other findings appear noteworthy as well. First, there was considerable overlap among the predictors. Little incremental variance was explained by the addition of a second variable in most of the equations. And, for the price discrepancy estimates, the fairness estimate contributed very little to the overall judgments of the advertised apartment. This finding is surprising in view of Thaler's (1985) suggestion that "fairness" represents a primary measure of P*.

DISCUSSION

This paper presented results from a simple experiment which examined the correlations between a series of price discrepancy variables and willingness to buy. In the research, the advertised price was subtracted from seven price estimates to form four and three price discrepancy measures of transaction value (P* - P) and acquisition value (P_{max} - P), respectively. Relationships with scaled measures of transaction value and acquisition value were also investigated. Caveats are in order regarding the use of student

subjects, the simulated nature of the research, and the failure to separate in time the initial estimates from the overall scaled measures. [Our intent for future research is to vary the order of estimate elicitation.] Efforts were made, however, to use a plausible context for which subjects were familiar and a number of filler tasks did separate the initial estimates from the advertisement exposures.

The most obvious result is that, except for the FAIR estimate of P*, the TU and the AU price discrepancy terms are relatively indistinct, especially in their influence or correlation with intentions. We would argue that previous research has operationalized price discrepancy terms which seem to represent transaction utility primarily (e.g., Kalwani et al. 1988; Lattin and Bucklin 1988; Winer 1986). To the extent that P* and P_{max} overlap or are highly correlated, however, the (P* - P) term may be sufficient. That is, adding the AU term may not add incrementally to explained variance. While these studies have referred to their price expectation measures generally as "reference prices," they may be capturing elements of reservation price as well as price expectations.

^ap<.01

The above conclusion is drawn from our correlational analysis. However, limited incremental gain from adding the AU term to the prediction of willingness to buy may hold even when P^* and P_{max} are conceptually and empirically distinct. All that is required is that P^* and P_{max} be highly correlated. In this study, the "highest-to-search" measure produced the highest estimate of P_{max} (and, therefore, was the most distinct from P^*), yet was still highly correlated with the estimates of P^* .

Situations can be envisioned when P^* and P_{max} are identical, and hence, the price discrepancy terms of AU and TU would be identical. For example, any situation in which a consumer believes that the most s/he is willing to pay is equal to the market price (i.e., there is no need to pay more) would equate P^* and P_{max} . Even if this is not the case, it is still likely that the expected market price provides a foundation for judging P_{max} , and as a result, the two will be highly correlated. To the extent this is true, operationalizations of Thaler's model using price discrepancy terms may be accomplished most effectively using just the TU discrepancy terms.

To understand whether $(P^* - P_{max})$ will always be highly correlated, however, we need to make sure

that P_{max} is being properly measured. It seems that the measure of P_{max} should allow for maximum distinction between itself and P^* . Clearly, future research is warranted. For example, we are not certain what the respondents were considering in their responses to the "fair" estimate. The unexpected relatively high estimate for FAIR and the very large variance indicate differences in judgments for this internal reference price estimate.

Lastly, the results are derived from a single study for a single alternative evaluation, and hence, our findings are offered only as an initial effort. And, even if the conclusion were eventually reached that the AU price discrepancy term adds little to the "easier to measure" TU price discrepancy term, this would not suggest that the AU concept itself is not useful. In fact, although, intercorrelated, the scaled measures of AU which measure perceptions of the "value for the money" directly were correlated with purchase intentions.

Transcendent Benefits of High-Risk Sports

Richard L. Celsi, California State University, Long Beach

In recent years, there has been a dramatic increase in the number of participants in high-risk leisure activities such as mountain and rock climbing, SCUBA, skydiving, extreme skiing, white water rafting, and aviation sports (Lyng and Snow 1986). Not only are more people experiencing these activities, but their demographics include a widening age range and a growing number of female participants (Celsi, Rose, and Leigh 1991). Further, through increased media coverage and word-of-mouth, vicarious consumer participation also flourishes, as scenes of parachutists, hang gliders, and white water rafters capture our imagination.

For instance, recall recent TV ads, including a parachutist on a slalom ski skimming over the top of a body of water with the voiceover "life is short, play hard," or skydivers on surfboards free falling for a Coca Cola, or the countless images of both male and female extreme skiers, mountain cyclists, and rock climbers. These scenes are breathtaking, as each image captures and reflects a growing fascination with the excitement of high-risk sports. The attraction is visceral and the message clear: "experience the thrill and live life to the fullest." But beyond experimentation and thrill, what is it about playing on the edge that attracts and sustains the interest of those few who continue and become veterans of these sports? What additional benefits sustain their continued participation? That is, beyond thrill, what motivates experienced participants to continue to risk their lives?

The objective of this paper is to briefly examine benefits that are realized by many individuals through prolonged participation in and consumption of high-risk sports. My intention is not to present a comprehensive review of benefits and outcomes that accompany and motivate participation in high-risk sports, but rather to focus on a specific set of abstract benefits that appear to be common to experienced participants across many high-risk sports. Thus, the interpretations presented in this paper are not intended to encompass the entire high-risk experience, but only those experiences that I will refer to as "transcendent." These are (1) self realization and the flow experience, (2) *communitas*, and (3) self-change. I classify this set of outcomes as transcendent because they are commonly described by participants as having properties capable of altering one's perceptions in terms of self, context, and others. Moreover, participants' descriptions of these experiences are often accompanied by expressions of wonder and bemusement, often associated with profound experience.

METHODS

The data for this paper are gained primarily from three high-risk sports: (1) mountain climbing, (2) BASE jumping, and (3) skydiving (see Celsi et al. 1991 for an ethnography of skydiving). Mountain climbing refers to the skills and experiences

associated with negotiating a mountain with the goal of summiting. Skydiving refers mainly to free fall parachute jumps from an aircraft. BASE jumping is the use of a parachute to jump from a fixed object such as a Building, Antenna, Span (bridge), or Earth (cliff). All three activities are risky. In combination, approximately 100 Americans die each year while participating in these three sports (Society of Actuaries 1982).

The conclusions and inferences drawn in this paper are based on participant observation, interview data, and secondary data sources in all three high-risk sports except BASE jumping which is based on non-participant observation. Direct experience includes over 650 free fall skydives and mountain climbs to altitudes of 19,000'. In addition, over 70 hours of in-depth interviews with participants in these activities have been conducted and analyzed. This experience and data has been collected during the past five years at over 20 sites in the United States, Europe, and Mexico.

Data collection and analysis procedures were emergent and iterative and based on prolonged engagement (Kvale 1983; Wallendorf and Belk 1989). Multiple methods, multiple sites and contexts, as well as member checks, were used to ensure triangulation and credibility (Lincoln and Guba 1985; Werner and Schoepfle 1987).

TRANSCENDENT EXPERIENCE

Mountain climbing, BASE jumping, and skydiving are similar in that participants willingly risk injury or death to experience their sport's benefits. Each requires the development of specific physical skills along with the ability to handle specialized equipment. For example, skydivers and BASE jumpers must manage parachutes and develop aerial skills, while climbers learn to use ice axes and crampons, and to hone their balance. Yet, each physical context is descriptively different. A BASE jump from a 50 story building is a blur that lasts just seconds, and is reduced largely to a series of survival actions in the face of extreme and immediate conditions. In contrast, the context of climbing a mountain is drawn out over days or weeks and encompasses many levels of risk and conditions. Skydiving, although of relatively short duration when compared to mountain climbing, occurs over a much longer time frame than BASE jumping. Skydiving typically includes a minute of free fall (or *skydiving*) before the participant must take survival action and activate his or her parachute which then takes about four or five minutes to land.

However, when participants describe the more abstract qualities of these activities, they use a common language. For example, BASE jumpers, skydivers, and mountain climbers all reflect on camaraderie, timelessness, involvement, and a sense of freedom as benefits of their respective sports. My description and interpretation of transcendent

experience is based on these abstract commonalities that are reported and observed across all three of the high-risk sports that are examined.

Specifically, I use the term *transcendent* to describe those person/context interactions that are experienced by the individual as producing either altered temporal experience (e.g., a sense of timelessness), special understanding (*camaraderie*), or personal change that is considered to be profound by the participant. These commonalities are most evident when these individuals describe (a) their involvement with the context in which their high-risk sport occurs, (b) the sense of community and special communication that they feel, and (c) the sense that they are changed by engaging in the activity. These themes are described in the following sections as (1) the flow experience, (2) *communitas*, and (3) felt self-change.

The Flow Experience

When BASE jumpers, skydivers, and mountain climbers discuss the primary activities of their sports, for instance, the actual act of "making a bridge jump," of being in free fall, or traversing a glacier, they speak in terms of the absolute involvement that is demanded, as well as the sense of release, timelessness, and freedom that coincides with those peak experiences. For example, a BASE jumper describes the total commitment of a leap from a 55 story building.

After reaching the top, you had to step up onto a ledge. My knees felt weak and, I think, were shaking. I needed a hand to step up there... But when I jumped into the darkness, all of that left me. I was perfectly calm and clear. There is no sense of time, other than you know you don't have much of it, but it almost seems as if everything is in slow motion, if you have any sense of it at all. But it's only when I look back on it that it seems that way. At the time I was completely engrossed in what I was doing (BASE jumper, wm 44, Los Angeles, California, 5/91).

A similar state of involvement while mountain climbing is recorded in the following field note excerpt.

At 13,000' I encountered a 75° cornice. It wasn't that big a deal, I mean it didn't overhang and it was only about a 15' wall. However, it was at the top of a glacier that averaged 50° and was 2000' vertical feet and I was solo... I had been more conscious of time than usual as I felt it necessary to clear this drainage before the summer sun softened the snow, and the sun was now 20' to my left. However, when I turned into the cornice and front-pointed over it (with crampons and ice axe) everything was reduced to the feel of the snow on my hand. I don't remember the sun hitting me until I was up, but it must have. There was no time, no consciousness, no effort that I recall, everything in retrospect seemed reduced to that

tactile memory. The sun then became a reward (field notes, Mt. Shasta, California, 7/91).

A skydiver describes this involvement as a sense of freedom experienced while falling two miles through vertical space:

Freefall is a ...free feeling. It's one time in my life when I think of nothing else. I mean, there's nothing on my mind. There's nothing I'm thinking about other than what I'm experiencing. Everything else is totally out of my mind and I am free. There is nothing to hold me down, to hold me back. There's just nothing there... (wf 27, 100 jumps, South Carolina, 1989).

Csikszentimihalyi (1974, p. 58) describes person/context interactions such as these as "flow" experiences. He defines flow as a

state in which action follows upon action according to an internal logic which seems to need no conscious intervention on our part. We experience it as a unified flowing from one moment to the next in which we are in control of our actions, and in which there is little distinction between self and environment; between stimulus and response; or between past, present, and future.

Csikszentimihalyi and Csikszentimihalyi (1988) believe that flow signifies the emergence of an individual's true self, which is free of self-limitation and self-awareness. As such, flow is a fluid state that seems atemporal, where one moment flows into the next as personal action and situational demands synchronize and become one. Self-consciousness, as evaluator and commentator, is replaced by a seemingly less obtrusive awareness that is typically recalled only after the flow experience has ended. This state of personal freedom is reflected in the above verbatims, in which the depth of involvement in the activity is described as overriding the participant's self-awareness. Thus, flow represents a release from conscious constraints, such as self-doubt and socially imposed limitations, and therefore results in at least a temporary realization of an unencumbered self.

For flow to occur, situational demands must generally approximate the coping abilities of the participant, thus allowing for a potential state of absolute involvement. That is, a context must exist in which the individual is neither "underwhelmed" or overwhelmed by the situation's demand characteristics, as the former is boring, and the latter quickly becomes terrifying. Neither produce flow.

Mitchell (1983, p. 154) states that ideal conditions for flow exist when an individual is both free to enter a situation and has autonomy over his or her behavior once engaged. Similarly, Goffman (1967, p. 185), referring to such a context as "action," says that it must allow for creative freedom and be sought out and embraced solely as an end in itself. Writing about heightened experience, Caillois (1961)

adds that this context must also allow for fantasy in terms of imagined outcomes and scripts, and produce a sense of vertigo, or altered consciousness that accompany the purposefully sought uncertainties encountered in activities such as skiing, skydiving, and mountaineering... (in Mitchell 1983, p. 154).

High-risk sports are and remain attractive to individuals because they meet these criteria. They (1) are freely engaged as an end in themselves, (2) present a context that tests abilities, and (3) provide the potential for imaginative and heightened experience. Moreover, high-risk sports provide these opportunities to virtually all participants because these activities are not absolute in their risk and degrees of difficulty, and thus can be engaged by individuals in a manner that approximates their respective skill levels. For example, a twenty-one year old with relatively little experience expresses this benefit when describing a rock climb.

This [climb] was only about 20', but it was Denali to me [Mt. McKinley], I was so in to it...! (field notes, 9/90; Joshua Tree National Monument, California).

Thus, in high-risk sports the stimulus field can be intentionally delimited (Mitchell 1983). For instance, routes up mountains can be chosen that challenge individual abilities, skydives can be planned to match the skill levels of the divers, and BASE jumps can be made from various altitudes and stances. In this manner, high-risk sports offer an infinite variety of contexts that provide flow opportunities and possible transcendent rewards to all participants who choose to interact with the context. Because of such rewards, individuals are motivated to return often to the risk context in order to "re-create" or "replicate" the experience (Csikszentimihalyi 1975).

Scott, who retired from BASE jumping after suffering a serious injury in a near fatal BASE jump, and whose retirement was reinforced by marriage, says with increasing frequency that he can feel the urge to BASE jump again. "It's something that will never leave me." He began skydiving again six months after his accident (Conversation, Long Beach, California, 4/91)

Communitas

Whereas flow, as described above, is experienced at the individual level, another form of transcendence occurs at the communal level in the form of shared experience. Turner (1977) defines this social bonding as *communitas*. Belk, Wallendorf, and Sherry (1989, p. 8) believe that *communitas* is a kind of "shared flow." They state that flow and *communitas* are not distinguished "so much in the nature of the experience [but] in whether it is a group or individual phenomenon." Clearly, the flow experience is a key aspect of *communitas*, but to view *communitas* as "shared flow" is limiting. *Communitas* is a function and sense of *shared experience*, stemming as much from the shared boredom of a sleepless night at

altitude or the grief shared at a friend's funeral, as from the highs of flow and camaraderie. Often *communitas* may be experienced as a feeling of flow, but just as often it is a conscious sense of "team," common language, and shared responsibility. As such, *communitas* is inclusive of, but not limited to, feelings of shared flow (see Celsi et al. 1991). BASE jumpers, climbers, and skydivers reflect this group involvement which stems from common experience.

...when we are out here climbing on these rocks, nothing else matters to us, not school, work, or anything... All of that is gone. All there is is the climbing, the sun, and the people I want to be with... Everybody I know feels the same way... (wm 27, Joshua Tree National Monument, California, 9/90).

It's almost like a family out here [at the parachute center]. There is a certain kind of camaraderie among skydivers that you just don't get anywhere else (wm 40, 1100 jumps, skydiving photographer, South Carolina, 1989).

Communitas, as interpreted by Belk et al. (1989, p. 7), "is a social antistructure that frees participants from their social roles and status and instead engages them in a transcending camaraderie of status equality" (also see Turner 1977). High-risk participants often talk of the common bond that they have with one another and the suspension of everyday social order. This status equality, which is pervasive in high risk sports, is described by two skydivers:

The sport has a special kind of camaraderie [so] that it doesn't matter what kind of background [you come from], in any category, be it religious, educational, or whatever... there is still a common bond that exists and draws people together (wf 34, 1600 jumps, Chester, South Carolina, 1989).

...jumpers have a special kind of bond... you have your doctors, professors, lawyers, but you also have your truck drivers, brick layers, and masons. Out here on weekends, none of that is a factor. What people do and how much money they make just doesn't play any part (wm 25, 325 jumps, Charlotte, North Carolina, 5/88).

This type of social leveling and bonding is most likely to occur when an individual is in a liminal state "between two statuses such that may occur on a religions pilgrimage," or, in other words, among layman when they seek acceptance into a subculture (Belk et al. 1989, p. 8; also see Turner and Turner 1978). In the following field note, this "pilgrimage quality" is observed in passing by a solo climber. Here, many groups of individuals, who are essentially inexperienced "mountain climbers" (or in a sense liminal members of this high-risk sport) have embarked on a "once in a lifetime" climb. In the

process, they are observed to be transformed and bonded by the experience.

I had camped at about 7500' near the trail head of the "normal" route up the mountain. As it was summer, there was an enormous number of "climbers" of various abilities and experience who were going to attempt this standard route up the mountain. I was amazed at how many there were. Most were clearly here for a once-in-a-lifetime experience. Some had hiked the switch-back trails of Mt. Whitney and thus felt they were up to this mountain because of its comparable altitude. All expectations were high, as climbers camped on the side of this Volcano that rose an additional 7000' in only 4.1 miles. The mountain was still snow and ice covered, but the standard route, this time of year, was little more than a walk-up to someone experienced with altitude, crampons and ice axe. I would climb a different, somewhat steeper route, but for the first 2000' the next morning, I shared the same route with this column of over 100 climbers, who looked as if they were laying siege to the mountain as they snaked up its side! For four hours I passed many of these climbers, and in a strange Chauceresque way collected many of their "stories" in exchange for mine. To some this mountain was a life-long ambition, to others an uncertain experience. However, all were under the spell of the mountain and shared a look of intentness that made an impression on me. It was clearly religious. All differences seemed dwarfed by the mountain, which had become some kind of shared Grail. However, perhaps because I planned to climb a different route, I felt more an observer than member. At 11000' I climbed solo, and in stark contrast, saw and heard no one until I traversed the top of a west facing glacier at about 13,500' and gradually rejoined the normal route near the summit plateau. Only a handful of the climbers had made it this far. One, who was the only person out of five in his group who summited (and whom I had seen earlier), said with a quiet excitement that it had not been at all like he had expected. It was so much more. It had been a pilgrimage, he said. He laughed a kind of half laugh to himself looking past me, and said again, with that same half laugh, that it had been a pilgrimage -- nothing else could describe it... (field notes, Mt. Shasta, California, 7/91)

In contrast, the pilgrimage quality of *communitas* may not be as overt with experienced climbers, BASE jumpers, and skydivers, as these participants often are more process, as opposed to "Grail" or outcome orientated. Nevertheless, the sense of *communitas* remains strong and unifying, as this experienced BASE jumper and skydiver indicates:

...these people are my brothers. I trust them with my life all the time... they do what I do and know essentially what I know... (wm 24, Zepherhills, Florida, 3/89).

This shared understanding and experience often translates into a common language that is also a central aspect of *communitas*. That is, a combination of common experience and specialized technical vocabulary, which is little understood by outsiders, ties together the cultural community, thus reinforcing the uniqueness of the group (Celsi et al. 1991). For example, climbing and skydiving terms, such as "rappeling" (a way of descending with the aid of rope), and free fall, are only understood at all levels of meaning by participants who share the experience of these terms beyond their linguistic translation.

This inability to translate non-common experience is expressed by one skydiver:

Well, first of all, I can't really go on and explain to somebody who has never jumped, OK? That's one thing that if you've never done something, you can't really share it with someone else (wm 22, 300 jumps, Columbia, South Carolina, 1990)

Malinowski (1923) refers to this cabalistic aspect of a shared language, which transcends direct translation, as *phatic communion*. As such, *phatic communion* is a special set of verbal and non-verbal cues, which are well-understood by insiders, and allows them to both create and communicate their special world view. Thus, language which describes shared experience becomes, in itself, a central aspect of *communitas* as it gives cohesion and a sense of pride to the subculture.

This sense of language, group membership, and pride is reflected in the words of a young hang-gliding enthusiast.

It's like a different language, like French; I love it when my brother can't understand what I'm talking about... (Brannigan and McDougall 1983, p. 45).

In sum, *communitas* is a special sense of community that emanates from shared and often unique experiences. It is manifest at the levels of camaraderie and language, and like flow, often transcends ordinary experience.

Felt Self-Change

Feelings of self-change and personal growth are also rewards of peak experience, as most mountain climbers, skydivers, and BASE jumpers feel that they have been changed, often in profound ways, by their respective sports. This personal change is manifest at many levels and essentially evolves relative to the individual's experience level. Initially, for example, feelings of self-confidence and self-efficacy accompany the success of high-risk undertakings, as this young woman who had just completed her first parachute jump announced.

I've done it. And it's nothing anybody can ever take away from me... (overheard conversation at a skydiving meet in Lidkoping, Sweden, 5/89).

Then, as experience is gained, most, who go on to push the limits of their context and ability, also feel that their overall lives have been changed in significant ways. To these individuals, who have experienced *communitas* and the intensity of flow, and who have most likely confronted death or injury in some form, feelings of increased confidence and self-respect are accompanied often by changes in perspective and world view.

...it has changed me, as far as, you know, [pause] ...I've been doing it for so long now, it almost seems like a way of life (skydiver, wm 25, 1400 jumps, Columbia, South Carolina, 1988).

However, in addition to, and highly related to the personal growth described above, is an actual *experience* of self-change, a feeling that sometimes follows profound peak experience. It is an experience of self-change that is palpable and *phenomenologically felt*, as if the change that occurs incrementally in ordinary life were temporally compressed resulting in an acute self-awareness of differences between old and new self. This feeling is expressed in the following field note recorded in the days immediately following a mountain climb.

...it's powerful, like the sensation of experiencing someone else's body and mind, only you know it's you, but the novelty of the feeling is real and tangible. It's like having many years of life's experience compressed into a short period... like the feeling of falling asleep a 12 year old and waking up 16. It's a very special kind of high, because not only have you changed, but you can *directly experience* and feel the change. You can look through new eyes and experience for a short while the prosaic in your life as novel (field notes, El Popocatepetl -- 17,887', Mexico, 12/90).

This feeling of self-change is experienced as a "high," but not as an adrenalin or excitement high, but rather more like the infinitely intensified feeling of wearing a new suit of clothes. Like flow, the feeling is transcendent in that perceptions are somehow altered, but unlike flow, it is a state that is *self-consciously* experienced and immediately available to introspection. In fact, it is the intensified self-awareness of the change in itself that seems to provide, or is the high.

This feeling is like being "allowed" to experience the *transition* from one self to another, like overtly observing a deep-seated psychological process (field notes, Mount San Antonio, California, 11/90).

This feeling can be described, internally, as the sensation of experiencing a new or changed self, and externally, as perceiving life, including the mundane, as new and meaningful. An analogy may be found in Dostoyevsky's (1866) "Crime and Punishment," wherein the protagonist and murderer, Raskolnikov, is finally caught and is being taken away for life to prison. Conveying the abrupt and fully perceived change that this brings to Raskolnikov's life, Dostoyevsky focuses on Raskolnikov's perception of a street sign. Raskolnikov, who has passed this street sign every day of his life, thinks how profoundly strange and uniquely different the sign now appears to him in its complete detail as he passes by it on the way to prison. He thinks not only that the sign's meaning has changed for him, but that his very perceptions of the sign's physical characteristics and context have been altered. Clearly, Raskolnikov's life has changed for the worse, but the analogy of altered perception following sudden and intense perceived self-change is highly applicable.

Similarly, journalist Claudia Dowling (1991) reflects on the positive nature of this self-change after her unsuccessful Mount Everest attempt. She also notes the ephemeral nature of the feeling.

And yet -- I have climbed a bit of Everest... And the world seems great and magnificent that it could have such a mountain in it. "It changes you," English [who also had climbed Everest with Dowling] had told me. "It make you a better person. But it [the feeling] only lasts about two weeks. That's why you keep going back" (p. 56).

The experiential quality of self-change does seem to diminish in a few weeks as English says. Yet, it's not likely that the self-change is temporary, but rather that the change is assimilated and the contrast is no longer felt. One is clearly left with the feeling of permanent and positive change, and the desire to experience this unique high again. As English had told Dowling, "it changes you for the better" (p. 56).

The ephemeral and addictive quality of the high is expressed by a skydiver.

...the skydiving, it just calls you back every time... it was my love and lust (wm 34, 1038 jumps, Chester, South Carolina, 1989)

In theory, felt self-change in high-risk sports appears to be a function of the entire high-risk experience punctuated by flow, or more likely, a *series* of flow episodes such as typically occurs, for example, on a mountain climb. In this sense, flow, as a peak experience of absolute involvement, acts as a crucible where the manifestation of extant self is tempered through a process of repeated *actualization*. This process likely forges personal change that is felt later when the absolute involvement of flow gives way to self-awareness and the contrast between old self and new self is phenomenologically experienced. Thus, felt self-change is likely, in part, an outcome of flow, with flow a crucible that forges change through total

involvement. As such, felt self-change and flow are separate but related experiences. Flow is the experience of absolute involvement, marked by the absence of self-consciousness, while felt self-change is an acute and transcendent experience of self-awareness.

CONCLUSION

High-risk sports offer extensive benefits, most of which are beyond the scope of this paper. However, it is experiences such as flow, *communitas*, and self-change which are gained from intimate interaction with these activities that provide individuals with a sense of transcendence, personal identity, and ongoing motivation. In sum, while qualities such as thrill and excitement are always desired and enjoyed, it is the ability of high-risk sports to produce both individual and shared transcendent experience that elevates them most of all to the realm of the "sacred" (cf. Belk, Wallendorf, and Sherry (1989)).

Discussant's Comments on Competitive Papers Presented Session 8.6 - Services

Michael A. Belch, San Diego State University

The following review of papers in this section will involve a brief summary and discussion only. Methodological and other issues considered in the review process will not be commented upon.

COMMENTS ON CONSUMER AND EMPLOYEE ROLES IN SERVICE ENCOUNTERS

This is a very interesting research study which explores the personal interaction between consumers and employees in the sale of services. The research adds a new dimension to previous research by exploring the consumers' role in this process.

Prior to discussing the contribution of the research and some of the implications, it is necessary to discuss some of the limitations. While these limitations do not severely qualify the results and conclusions, future research that was designed to overcome these limitations would further our knowledge significantly. There are really three limiting factors:

1. *The sample selection*--the sample used in this research is limited both in size and demographic composition. Twenty-eight undergraduate students enrolled in an introductory marketing class, unfortunately, do not represent a very broad-based view of society and/or consumers. As one would expect, their limited backgrounds and consumption experiences narrow the perspectives that they bring to the research. This fact is reflected by the limited domain of experiences discussed--restaurants and retail stores.
2. *The lack of some quantitative information*--it would have been extremely helpful if at least some preliminary information -- hopefully of a quantitative variety -- was obtained prior to conducting the interviews. As will be seen, some of this information may have direct impact on the roles that the consumer assumes in the dyadic communication. This information might have included factors such as the situation in which the consumption took place, the level of involvement of the consumers and/or the relative competence (confidence) of the consumer in making the purchase decision.
3. *The interpretative process*--from the information available to me, it appears that interpretation of the interviews was the sole responsibility of the researcher. If this is true, the opportunity for bias and lost information is high. I would suggest a

panel of judges/interpreters to be used in much the same way that cognitive responses are interpreted. This process would allow for a broader range of interpretations, as well as a measure of consistency.

Again, let me reiterate that these criticisms are meant in a constructive manner. As an academic, I am quite aware of the budgetary constraints imposed, and the difficulty in accessing respondents for conducting research. On the other hand, if advances are to be continued to be made, ways to improve the research studies should be considered.

As noted earlier, one of the contributions of this research is that it includes the perspective of the consumer in the service exchange process. A role-theoretical perspective is assumed, in which the consumer and the employee are perceived as actors in a consumer setting. Consumers are eventually classified as *dependent, autonomous, and/or mutual*.

Without rehashing each of these roles (they are well described in the paper), it can be seen that determinants of which of these three roles will be assumed include consumers' involvement, perceived self-competence and confidence. In addition, the situation in which the setting is taking place will have a significant impact. In respect to the first of these, dependents, the consumer is perceived as wanting assistance, seeking help, and somewhat uncomfortable in the purchase setting. In autonomous settings, the consumer "wants to be left alone," while mutuality lies in between.

I would suggest that the roles that the consumer wishes to assume will essentially be predetermined by the above factors. In fact, I think that these assessments of the self and the situation will determine even the context in which these interactions will occur. For example, envision a situation in which I know the part for the car that I am looking for. I will be more likely to choose a store in which I can get in quickly, find the part (hopefully at an affordable price) and get out. I have little or no use for the employee, and may never even have a service interaction. Now imagine that I am trying to fix the car, but have little knowledge of what is required. In this case I will select a different store, and a different service encounter is anticipated and sought. As can be seen, not only do the roles change, but so too does the entire decision process.

In respect to the roles assumed by the employee--*indifference, dominance, and co-operation*--again, a number of factors should be taken into consideration. The author cites some of these including competence, training, sales requirements, etc. In addition, I would argue (and hope) that the selection of the employee again is made with the needs and requirements of the consumer in mind. Restaurants with a variety of fine wines will typically have

employees more knowledgeable about the choices. Parts stores for serious mechanics will have more informed employees that are able to answer difficult and involved questions.

The point that I am trying to get at here is that while the model presented in this paper is an excellent start, a number of additional factors must be considered. The role that the consumer assumes in the service situation, at least in part, has been predetermined by the aforementioned factors--that is, the situation, the level of competence, involvement, etc. Thus, the consumer has essentially "self-selected" the role that they will be in, and the role that they expect the employee to assume. The model, then needs to consider these antecedents, and should also attempt to incorporate some additional situational factors that may be taking place during the exchange as well. For example, what happens if role expectations are not met? How do role adaptations take place, and so on.

Finally, what takes place after the interaction takes place? It has been noted that the level of consumer satisfaction will be directly influenced by these interactions. If this is true, what impact will this have on attitudes toward the service provider, future shopping behaviors and the consumer's own preparations for future encounters?

COMMENTS ON ORGANIZATIONAL CHARACTERISTICS AND EMPLOYEE EXCUSE MAKING: PASSING THE BUCK FOR FAILED SERVICE ENCOUNTERS

As noted in the previous paper just reviewed, much of the research on service encounters has focused on the employee's role in this exchange. This paper follows along that line, using attribution theory and role theory to pose propositions as to when employee excuse making will be likely to occur. The paper goes on to discuss the importance of employee excuse making and suggests additional research that might be considered.

While this paper itself does not provide empirical support for the propositions, significant and plausible research from other sources is cited to lend credence to the propositions.

What the propositions seem to say in a nutshell is that the more involved the service being provided--involved as in time required to administer, complexity, number of persons involved, etc.--the greater the likelihood of employee deflection activity (excuse making). Other factors such as role conflict and ambiguity and the organization's span of control will also contribute to this process.

What appears to be missing from these propositions are factors similar to those that may have likewise improved the former paper just discussed. That is situational factors, employee involvement, and employee expertise. Most, if not all, of the factors presented here tend to be focused on the service provided, the number of employees, and other work factors. (Role ambiguity does mention the expertise, but needs to be developed in more detail).

Once again, I would argue that the employee's involvement in the service exchange is a critical determinant in their actions. For example, one might expect the service provider who takes pride in his/her work and/or who's income depends upon the customers' satisfaction to approach such deflection strategies differently than a college student that is using the job only as a part-time source of income. Further, the service provider that has both confidence and expertise in his/her abilities may be less likely to make excuses than one with less confidence or knowledge. In the latter instance, the employee may have little choice but to deflect to someone else with more knowledge and/or authority. Finally, the situational factors in operation will also come into play. One of the examples cited in the paper was that of the employee waiting on tables. The amount of time available to the employee, the number of customers waiting, the absence or presence of the boss are just a few of the many situational characteristics that will impact the employee's actions.

In sum, I think this paper offers a contribution in that it poses a number of tangible propositions about excuse making, and suggests a variety of topics for future research.

IMPLICATIONS

Both of these papers raise some interesting managerial issues. For example:

- *hiring practices*--at issue here is the question as to what type of employees should be hired. These reports would suggest that cordial, understanding, and communicative service providers should be sought. In addition, competence, confidence and interpersonal skills are obviously required. Given that everyone doesn't have such attributes, the issue that is raised is where do I find them? How do I keep them?
- *training*--again, both papers indicate the need for formalized training programs. These programs should involve indoctrination as to the channels of authority, how to handle complaint behaviors, etc., as well as instructions on improving interpersonal skills. (How many times have you been to a restaurant when a minor problem is not addressed, or goes unresolved?)
- *establishment of rules and procedures*--many of the problems that may arise in the service exchange process could be avoided or overcome by the establishment of definitive rules and procedures to be followed. While many organizations now have such guidelines, most do not. Developing such rules is not difficult, and would go a long way in providing employees direction.

Incorporating Consumer Judgments into Aggregate Choice Models

W. Steven Perkins, Pennsylvania State University¹

ABSTRACT

Consumers' judgments about choice alternatives are incorporated as covariates in aggregate multinomial logit choice models. Hypothetical multiattribute choice alternatives were presented to consumers in two formats: first as sets of choice alternatives and second as conjoint profiles. Aggregate choice models were estimated for the multiattribute alternatives using an ANOVA formulation, and also estimated using the conjoint profile ratings as a covariate in an ANCOVA formulation. Including the covariate provides a measure of the overall preference for the alternative after taking into consideration its attributes. Implications of including covariates in choice models are discussed.

INTRODUCTION

In aggregate consumer choice models, respondents' choices are gathered by survey, then analyzed in an effort to understand the factors affecting those choices. Consumer choices are modelled as a function of either the utilities for the choice objects themselves or the utilities for the attributes comprising the objects. Parallel to traditional conjoint analysis, these utilities are often estimated with dummy variable regression or ANOVA, using categorical independent variables. Aggregate level models of consumer choices typically do not consider the simultaneous effects of choice objects and choice attributes. In addition, they do not consider the effects of continuous variables, as in logit models used with scanner data. Thus, the applicability of these models is restricted in terms of the choice phenomenon which can be modelled realistically and in terms of the types of data which can be included in the model. These two limitations can be addressed by including choice related covariates in a new model which draws concepts from market share analysis and from hybrid conjoint analysis.

This paper outlines previous models used in consumer choice and market analysis, then investigates the advantages of combining elements from both. A model which might be termed an aggregate hybrid choice model is proposed and its application illustrated in a transportation context. Implications for including covariates in aggregate consumer choice models are discussed.

DEVELOPMENT OF THE MODELS

All of the models addressed in the present research stem from Luce's (1959) choice axiom, which states that the probability of choosing one alternative

from a set of alternatives can be modelled as the utility for that alternative divided by the sum of the utilities for all the alternatives in the choice set. Often formulated in marketing as the multinomial logit (MNL) model, this approach has been used extensively for both studies of consumer choice and studies of market share.

Consumer Choice Models

Batsell and Lodish (1981), Mahajan, Green, and Goldberg (1982), Louviere and Woodworth (1983), and others have applied the MNL model to the analysis of consumer choices derived from experiments and surveys. An alternative's share of choices is modelled as the utility for that alternative divided by the utility for all alternatives in the set.

The design of consumer choice studies will be briefly outlined. Typically, the respondent's task in such research is to choose one alternative from each set of available alternatives (e.g., Louviere and Woodworth 1983), or to allocate fixed resources to the alternatives in each set (e.g., Mahajan, Green, and Goldberg 1982). Parallel to traditional conjoint analysis, multiattribute alternatives can be constructed from a factorial design. Alternatives could also represent wholistic objects, such as actual soft drinks. One approach to constructing the choice sets is to consider each alternative as a factor in a second factorial design, with two levels on each factor: include the alternative in the set or exclude it. Unique sets of alternatives will be generated from this two step process. Besides the alternatives, Louviere and Woodworth (1983) suggest that each choice set contain a "none of these" option which serves as a baseline for comparison.

The data are often aggregated across respondents, resulting in the frequency with which each alternative was chosen from each set. Louviere and Woodworth (1983) sum discrete choices across respondents; Mahajan, Green, and Goldberg (1982) average subjects' allocations across alternatives. Batsell and Lodish (1981), on the other hand, present an individual level choice model.

One model employed in analyzing aggregate consumer choice data is the analysis of variance (ANOVA) formulation operationalized by Louviere and Woodworth (1983) as:

$$\ln(m_{is}) = \mu + \mu_i + \mu_s + \epsilon_{is} \quad [1]$$

where

m_{is} = number of times alternative i was chosen from set s

μ = intercept

μ_i = main effects for alternatives ($i=1,2,\dots,I$)

μ_s = main effects for choice sets ($s=1,2,\dots,S$)

ϵ_{is} = error term

¹The author would like to thank Gary Graley, Director of Market Research at Greyhound Lines, Inc., for his assistance in conducting this research. Frank Mulhern and Kate Searls provided helpful comments on a previous draft of the paper.

The dependent variable is the log of the number of times alternative i was chosen from set s , across respondents. The μ_s control for the influence of choice set and are usually not of interest. When the "none of these" option is included in the choice set, then the effect of each alternative $i = \mu_i - \mu$. Parameters representing the utilities for the alternatives could be estimated by dummy variable regression. Mahajan, Green, and Goldberg (1982) discuss a related ANOVA formulation of the problem.

Louviere and Woodworth (1983) and Louviere (1988a) illustrate several variations on this basic model. For example, if the μ_i represent multiattribute alternatives constructed by the analyst, then alternatives could be examined at the level of the attributes comprising the objects. In this case Model 1 could be re-written as:

$$\ln(m_{is}) = \mu + \sum_{k=1}^K \beta_k Z_{ik} + \mu_s + \epsilon_{is} \quad [2]$$

where all terms are as defined before except the Z_{ik} are dummy variables denoting the level of alternative i on attribute k , and the B_k are the estimated parameters for each attribute k .

Proposed Models

Cooper and Nakanishi (1988), among others, illustrate the use of the MNL model in analyzing market shares. Often labelled the attraction model, the market share for a brand is modelled as its attraction relative to the attraction of all the brands in a market. The attraction for a brand is, in turn, seen as a function of its marketing efforts. This model has been used to examine the effects of promotions, for example, on market shares (Guadagni and Little 1983). The data usually come from scanner data or panels. Cooper and Nakanishi (1988, p 118) point out that the MNL formulation of the attraction model is equivalent to the analysis of covariance model (ANCOVA), which can be expressed as:

$$\ln(m_{is}) = \mu + \mu_i + \mu_s + \gamma * X_{is} + \epsilon_{is} \quad [3]$$

Parallel to the consumer choice equation shown in Model 1, the effects of brands (alternatives) and time periods (choice sets) are captured by μ_i and μ_s , respectively. In addition, the market share model includes the marketing effort (e.g., promotions) for brand i at time s , X_{is} , as a covariate.

The proposed models to be investigated in this study apply this ANCOVA formulation, typically seen in market share analysis, to aggregate consumer choices. Using Model 3, the effect of a covariate could be investigated in conjunction with the utilities for the choice alternatives. A covariate could also be included in Model 2, resulting in:

$$\ln(m_{is}) = \mu + \sum_{k=1}^K \beta_k Z_{ik} + \mu_s + \gamma * X_{is} + \epsilon_{is} \quad [4]$$

Note that the covariate, X , is indexed by i and s indicating that it varies by alternative and choice set. One possible variable to use as the covariate is a measure of the consumers' overall rating judgments about the alternatives chosen from a set. These judgments could come from a traditional, profile at a time, conjoint task. To calculate the covariate, consumers' judgments about the alternative chosen from a set can be aggregated by:

$$X_{is} = \left(\sum_{r=1}^R X_{ir} * C_{irs} \right) / \left(\sum_{r=1}^R C_{irs} \right) \quad [5]$$

where $C = 1$ if respondent r chose alternative i from set s , and zero otherwise. And where X_{ir} is respondent r 's overall judgment about alternative i . Mathematically this is simply the mean rating given for the choice object by all people who chose it from that set. Note that as in hybrid conjoint, the X_{is} and the Z_{ik} could be correlated, resulting in biased estimates. We can test this by comparing Models 2 and 4.

This covariate would be analogous to the use of self-explicated judgments in hybrid conjoint (e.g., Green 1984, his equation 2). In hybrid, responses to conjoint profiles can be modelled as a combination of respondent level utilities for the alternatives and group level utilities for product attributes. In Model 4, the choices are a function of the set level preference for the alternative, X_{is} , plus the "market" level utilities for attributes, Z_{ik} . Thus, both the decompositional aspects of Model 2, breaking the choice object down to its component attributes, and the total compositional aspects of Model 1, considering the choice object as a whole, are incorporated. On the other hand, including the judgmental covariate into Model 3 may have a small effect on the explanatory power of the equation because the ratings, X_{is} should be somewhat redundant with the estimated alternative utilities, μ_i .

THE STUDY

From an applied point of view, the objective of the study was to determine consumer preferences for different modes of public transportation at given prices and given levels of scheduling convenience. Transportation has often been studied in choice analysis (Ben-Akiva and Lerman 1985, Louviere 1988b). The sponsor of the project, an inter-city bus line, was interested in comparing consumer preferences for bus and train trips, and also for bus and plane trips. This marketing problem provided an opportunity to compare aggregate consumer choice models estimated in the more common ANOVA multinomial logit formulation with those estimated by the proposed ANCOVA model. In particular, does the inclusion of a consumer judgment covariate improve the explanatory power of the models?

Materials and Procedure

To generate the multiattribute alternatives considered in this study, 3 attributes, each having 2 levels, were selected after consulting with corporate management and reviewing previous research. The

first attribute, Z_1 , mode of transportation, could be a bus or one other mode. One group of respondents chose between bus and plane alternatives; the other group, between bus and train alternatives. The second attribute, Z_2 , price, could be low or high, with the high prices approximating the actual cost of taking a 350 mile trip, and the low price about 1/3 less. Finally, the third attribute, Z_3 , arrival and departure scheduling convenience, could be either "very convenient" or just "convenient." Eight alternatives were then generated based upon all the combinations of the 3 attributes at 2 levels each.

Developing the choice sets entailed a double conditional design, as explained in Louviere (1988a). First, 4 of the multiattribute combinations were selected. Specifically the following multiattribute alternatives were of interest:

- Alternative 1: bus, low price, convenient
- Alternative 2: bus, high price, very convenient
- Alternative 3: other mode, low price, very convenient
- Alternative 4: other mode, high price, convenient

Second, these 4 alternatives were then treated as factors in a 2^4 factorial design, in which each alternative was either included or excluded from the choice set. The design generates 15 choice sets with 1 to 4 alternatives, plus the "none of these" option, in each set. Respondents considered each set then circled the one alternative they preferred the most.

In addition, consumers' gave their overall judgment about the 8 multiattribute alternatives created from the 2^3 design. Each alternative was presented in a traditional conjoint profile format. Respondents judged how likely they were to take the trip described in each profile and circled a number ranging from 0 to 100.

In terms of administration, every respondent received a 4 page questionnaire which started with an explanation of the nature of the project (but no identification of the sponsor) and a brief statement asking respondents to think about a trip of 350 miles when answering, then the 15 choice sets, the 8 conjoint profiles, and several demographic questions.

Samples

Using a convenience sample, interviewers completed usable questionnaires with a total of 100 travelers from three locations: an inter-city bus terminal, a train station, and an airport. Group 1 respondents consisted of 26 inter-city bus riders and 26 plane riders; variable Z_1 could be a bus or a plane. Group 2 respondents consisted of 24 inter-city bus riders and 24 train riders; variable Z_1 could be a bus or a train.

Analysis

The input data for the analysis consisted of the number of times each of the 4 alternatives, plus the "none" option, was chosen from each set, and the ratings for those same 4 alternatives. The rating for

the "none" option was assumed to be zero; the ratings for the other 4 alternatives not involved in the choice task were not analyzed.

To analyze the data, multiple regression equations were estimated for Models 1 through 4 for Group 1, the bus and plane riders, and estimated again for Group 2, the bus and train riders. Dummy variable coding of the categorical independent variables follows Louviere (1988a); in particular for Models 2 and 4, the low values for each attribute (and "bus") were coded as -1 and the high values as +1. In all cases, the equations were estimated by a weighted least squares method because choice frequencies are often heteroscedastic (Louviere and Woodworth 1983). The observed frequency of choices, m_{aj} , were used as weights in the general linear models procedure of SAS (SAS Institute 1979).

RESULTS

The results of estimating Models 1 and 3, which consider the alternatives as wholistic objects, appear in Table 1. The estimated utilities for the alternatives are presented, both without and with adjustment for the judgment covariate. Note again that the regression estimated parameters for the l_j should be interpreted as the difference between the alternative and the intercept. (The intercept term and set effects are not presented.) The mean judgmental ratings of the alternatives, X_{js} , should be highly collinear with the estimated utilities for the alternatives. In fact, including the covariate decreased the level of significance of the utilities. Evidence for this collinearity is also seen in the fact that the R^2 values do not increase from Model 1 to Model 3 when the covariate is included. For the bus and train group the covariate has only a marginal ($p < .10$) level of significance, and was not significant for the bus and plane group.

The more interesting case considers including the covariate in the estimation of the utilities for the attributes which comprise the alternatives. Table 2 presents the results of Models 2 and 4 where attribute utilities are estimated both without and with the judgment covariate. In both groups of respondents, the covariate is significant. As a result, the R^2 values increase over 20 points with the inclusion of the covariate, up to the same levels found with Model 1. The fact that the explanatory power of Model 2, based on attributes, is below that of Model 1, based on alternatives, could be interpreted to mean that respondents were choosing on the basis of the whole object rather than simply on its component attributes. This interpretation is also encouraged by the large increase in R^2 with the inclusion of the covariate in Model 4 because the covariate is again a wholistic representation of the choice alternative.

The signs and relative magnitudes of the attribute utilities in Table 2 do not change from Model 2 to Model 4, because the covariate affects the intercept more than the attribute slopes.

There does not seem to be a problem with multicollinearity between the covariate and the attributes. In every equation, price, Z_2 , had the largest

absolute impact on choice. Bus and train respondents were more sensitive to mode of transportation, Z₁, than to convenience, Z₃; but the opposite occurred in the bus and plane case. Interpreting the coefficient for the covariate requires considering the choice elasticity with respect to the judgment rating, $\gamma^*X_{is} (1 - m_{is})$. In other words, the impact of the covariate is in part a function of the share of choices (Cooper and Nakanishi 1988).

DISCUSSION

This paper has investigated the inclusion of a covariate in aggregate consumer choice models, in contrast to previous applications in marketing which have typically involved only categorical independent variables. Model 4 in particular presents some interesting possibilities because it allows for simultaneous estimation of the utilities of the

attributes and the estimation of an overall alternative effect. There are both substantive and methodological advantages attained from including a covariate. First, the model avoids the assumption that each choice alternative must be considered only as one whole object (i.e., Model 1) and, on the other hand, avoids the assumption that a choice alternative must be considered as simply the sum of its parts (i.e., Model 2). Both alternatives and attributes are represented in the model. If the covariate is insignificant, indicating that the choices depend on the attributes alone, then the formulation reduces to Model 2, the more typical approach. In this study, however, the covariate was highly significant, pointing to the conclusion that consumers' choices involve both overall judgments of the object and weighting of its attributes. In a sense, the covariate captures the "brand equity" effect for the choice alternative above and beyond its attributes. Essentially, we can partition the aggregate choices

into the effects due to attributes and the effect due to the object itself. Second, drawing upon previous concepts in market share analysis and in hybrid conjoint analysis, the ANCOVA formulation extends the applicability of aggregate consumer choice models based on survey data to situations involving continuous variables. Thus, the model provides a more flexible approach statistically and what may be a more realistic approach conceptually.

There are several avenues for improvement upon the model and for future research. This project was limited in terms of the number of respondents and in the number of alternatives considered. More interesting designs could have been employed in the construction of the alternatives and choice sets. The focus of the research was instead on the effect of the covariate. Future research could consider using other variables such as income or age as covariates, as well as self-explicated data. Also other methods of calculating the covariate could be devised, though it must vary by both alternative and set, or its effect will be absorbed by the dummy variables. Though it was not a problem with these data, the covariate could be related to the choice attributes. The structure of the model is limited to the extent that these are correlated, biasing the estimates. It is often assumed that the utilities for alternatives should not differ by choice set, following from the independence from irrelevant alternatives (IIA) property of Luce's individual choice axiom. According to Ben-Akiva and Lerman (1985), however, this property need not hold at the group level. They suggest that logit models should incorporate socioeconomic variables, for example, to capture market place heterogeneities. Further study is needed in marketing on the effect that including covariates has on the IIA property.

There have been relatively few published research studies in marketing using aggregate choice modelling based on consumer surveys or experiments, particularly when compared to the number using conjoint analysis, its close relative. Even a recent review of the commercial use of conjoint (Wittink and Cattin 1989) and a recent overview of new directions for research in conjoint (Green and Srinivasan 1990) have little to say about the aggregate choice approach. The models investigated in this project may expand the applicability of the aggregate approach to more marketing problems.

Validating Realtime Response Measures

Thomas C. Boyd, University of North Carolina, Chapel Hill
G. David Hughes, University of North Carolina, Chapel Hill¹

Realtime measures provide a rich source of information regarding consumer attitudes, feelings, and judgements about stimuli. Television advertisements are particularly well suited to this form of measurement. Although popular with practitioners, realtime measures have not received much attention from researchers who struggle with important issues regarding their reliability and validity. The authors report on the results of a validation study using the Multitrait-Multimethod matrix first proposed by Campbell and Fiske (1959). They find evidence of construct validity and make suggestions that will facilitate future assessment of the validity of real time measures.

Consumer researchers have traditionally had to deal with limitations when collecting consumer responses to audio/visual stimuli. Most methods of data collection require either interruption in the stimulus to elicit a response, or subject response after exposure. When the subject is responding to a stimulus, such as a TV ad, interruptions can be intrusive and post exposure responses make it difficult to measure dynamic responses over the period of the exposure, making process tracing difficult. One way to overcome these problems is to use data collection methods that allow subjects to respond continuously over the course of an exposure. One such method is realtime response measurement.

Realtime response measurement has become the generic term for techniques that allow subjects to respond whenever they wish to continuous stimuli such as television commercials, speeches, sales presentations, lectures, presentations to mock juries, and television programs. Systems used recently by commercial researchers required subjects to push buttons, turn dials, or move sliders (Porado 1989). The methods can be traced to the 1930s when George Gallup used his method to help edit *Gone With the Wind* and Frank Stanton and Paul Lazarsfeld developed a system to test CBS programs. The equipment was bulky and analysis of the output was limited. The few studies reported in the marketing literature have been consulting reports (e.g., Polsfus and Hess 1989). Microcomputer and video technology in the last decade made the equipment portable and extended the methods of analysis, providing new opportunities for academic research.

Figure 1 shows an example of the output that can be generated from realtime measures. It shows results from a control group that watched eleven thirty-second commercials and a weather report. Subjects watched the entire set twice, first dialing for

affect (favorability of feelings) and then dialing for cognition (usefulness of information), each time using a continuous rotary dial with a range of 1-100, where 50 is considered 'neutral'. As can be seen from the figure, subjects sometimes showed no similarity between judgements of usefulness and favorability-as in the first ad for Budweiser, and sometimes showed a high correspondence between the two, as in the second ad for Upjohn. Realtime measures can provide a rich source of information regarding consumer attitudes, feelings, and judgements about stimuli. Television advertisements are particularly well suited to this form of measurement. Although popular with practitioners, realtime measures have not been subjected to tests for reliability, validity, and replication of findings using other measures. An exception is Hughes and Lennox (1990), who reported high week-after retest reliability. Our purpose here is to explore these issues using the Multitrait-multimethod matrix (MTMM) first suggested by Campbell and Fiske (1959). But first, we give an example of how realtime measurement methods can contribute to an existing area of research.

AN APPLICATION

Brand Attitude and Ad Attitude Relationships

One area where realtime methods can contribute to consumer research is the study of the mediating role of the attitude toward an ad (Aad) on the attitude toward a brand (Ab) (e.g., Burke and Edell 1989; MacKenzie and Lutz 1989; MacKenzie, Lutz and Belch 1986). Aad is usually a single measure or scale administered after exposure to the ad. Such measures are subject to errors in recall and tell us nothing about the processing of the ad that produced the final attitude. While some researchers are beginning to note the need to measure processing directly (e.g., Heath 1990), consumer research tends to rely on analysis of variance or path analysis to infer process.

If we measure each subject's processing directly we can examine consumer decision processes more simply. We can then examine how prior brand attitudes affect ad processing and how ad processing revises brand attitudes. This results in a modification of the traditional model which might look like this:

$$Ab_{t1} \rightarrow \text{Processing Ad}_{t1} \rightarrow Ab'_{t1}+$$

where processing Ad has replaced the traditional Aad as the mediating factor.

Realtime measures can help us capture data that reflects the processing of the ad. Instead of a single post exposure measurement of, say, how the ad made subjects feel, we can have up to 150 measures taken at equal intervals over the course of a thirty second commercial. Because consumers will see an ad many

¹The authors gratefully acknowledge the assistance of MSI in providing support for subjects and two anonymous reviewers for their helpful comments and suggestions.

FIGURE 1
Sample of Realtime Curves Showing Affect and Cognition

times, we must expand the traditional model for additional exposures.

$$Ab_{t1} \rightarrow \text{Processing } Ad_{t1} \rightarrow Ab'_{t1+} \rightarrow \\ \text{Processing } Ad_{t2} \rightarrow Ab'_{t2+}$$

This approach suggests not only that the processing of the ad is important, but also that processing of ads may change over the course of multiple exposures. Understanding how processing changes may provide valuable insights into how and why brand attitudes change over the course of an ad campaign. Further development of this model is beyond the scope of this paper, however, it illustrates one application of the realtime method and shows why we will benefit from its use, provided validity can be demonstrated.

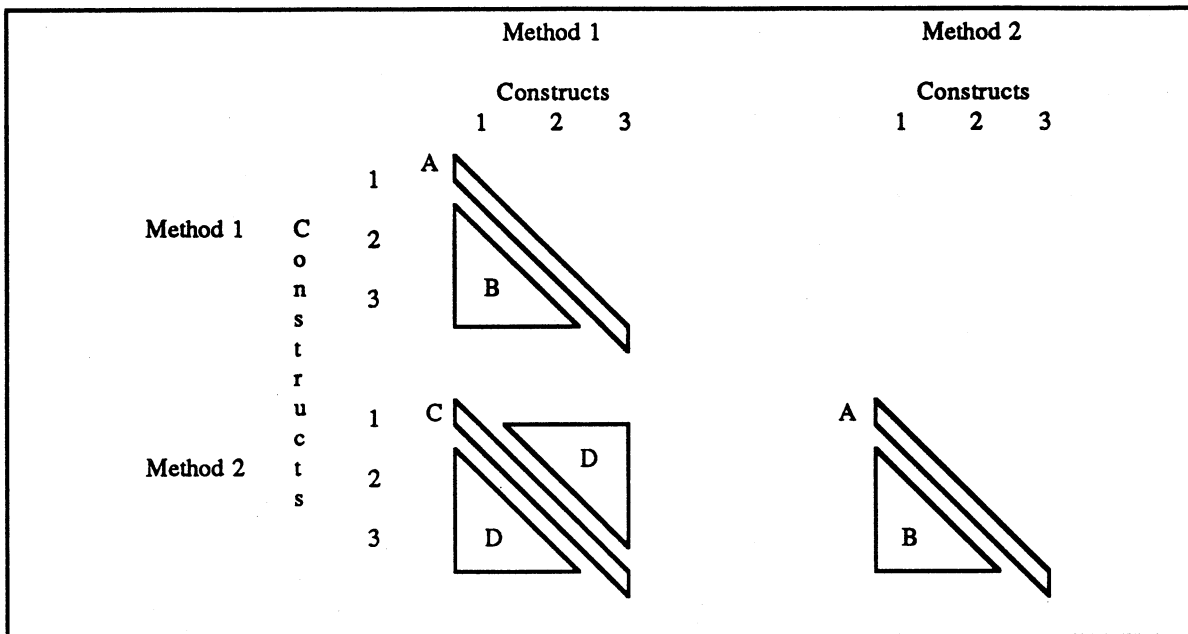

Construct Validation

If realtime measures are to prove helpful in academic research, we must have confidence in their

value. Our focus here is on construct validity, specifically, the measurement issues of construct validity that require that measures of a construct must reflect levels of, and variations in, that construct only. Peter (1981) described two ways of viewing construct validity. The first is whether the construct is appropriate and helpful for examining the concepts which underlie the behavior of interest. In this case we must consider whether the constructs of interest in our study, affect and cognition, are appropriate for studying subjects' reactions to advertisements. There is a significant body of work that uses affect and cognition as key constructs in the study of attitudes and attitude change, (e.g., Mackenzie, Lutz and Belch 1989; Petty and Cacioppo 1982) while others have focused on related concepts such as the hedonic and utilitarian components of attitude (Olney, Holbrook and Batra 1991). These works have established evidence that the constructs of interest here are valid and appropriate to the field of study.

The second approach to construct validity mentioned by Peter (1981) asks whether the measures

FIGURE 2
The Multitrait-Multimethod Matrix

being used are actually measuring the constructs of interest. We focus on this definition of construct validity throughout the remainder of this paper. We are concerned with demonstrating whether realtime response measures of affect and cognition are actually providing us with measures of the constructs of interest. Peter points out that this task is difficult because we cannot directly assess this form of construct validity, rather we can only infer it from evidence provided by testing our measures.

Churchill (1979) details eight steps for the improvement of marketing measures. Included are the assessment of reliability and the assessment of validity of measures. For these purposes he recommends the use of multiple measures of constructs in order to perform tests of reliability and validity. Churchill recommends against using test-retest measures of reliability, however, the continuous responses from realtime measures are not likely to suffer from the same effects as scale items with discrete response choices. For a discussion of these issues see Hughes and Lennox (1990), who demonstrated reliability using test-retest realtime measures. Our focus here is on validation using multiple measures.

Campbell and Fiske (1959) provide guidelines for the examination of issues of validity. Their description of the Multitrait-Multimethod (MTMM) matrix and its application to the validation of constructs has been widely used and is still central to validation studies today (e.g., Bagozzi and Yi, 1991). In this case, the MTMM matrix examines reliability and two dimensions of construct validity, discriminant validity and convergent validity.

Campbell and Fiske advocate measuring multiple concepts using multiple methods - and computing the correlation matrix between the different

concepts (traits) as measured by each method. Three components of construct validity are reflected in these correlations. They are the trait component, reflecting the interdependence between two traits; the method component, reflecting the interdependence between two methods; and error. In examining validity we focus on the convergence of 'maximally independent' methods and therefore hope for evidence of a low method component. Ideally, we should find evidence that the correlation between measures of a single trait using two methods is due to the trait, not because the methods have covariation in their responses.

Traditional methods of validation use single values for comparison with other measures. For example, if we wish to examine the validity of a Likert scale item we might compare it to other Likert scale items intended to measure the same construct, or compare it to a semantic differential scale item. Each of these methods, including the MTMM matrix, uses a measure of the construct taken at some point in time. For dynamic data, such as that provided by realtime measures, the problem is one of adapting the realtime measure to a static measure for comparison. This issue is addressed in the methods section.

The Multitrait-Multimethod Matrix

The MTMM matrix is based on the comparison of multiple measurement methods measuring a set of constructs. Figure 2 shows an example of a MTMM matrix. The example shows a comparison of two methods, each measuring three constructs. Entries in the matrix are the correlations between the measures of the constructs using the method indicated for each quadrant. For example, the value in the upper left hand corner of the top region labeled B is the correlation

between construct 1 as measured by method 1 and construct 2 as measured by method 1.

The matrix provides three primary forms of validation: reliability, convergent validity and discriminant validity. The diagonals in the upper left and lower right quadrants, labeled A, represent measures of test-retest reliability. These test-retest correlations should be examined within and across groups (Churchill 1979). The test-retest results are not of primary interest in this study, although they are reported in the results section for completeness.

Convergent validity occurs when two or more different measurement methods produce similar results for the same construct. Region C in Figure 2 shows what Campbell and Fiske (1959) call the validity diagonal. Correlations in this region compare different methods of measuring the same construct and should be significantly different from zero.

The MTMM matrix provides three criteria for the determination of discriminant validity, the ability of a method to reflect the variation in the construct being measured and not other constructs that are separate and distinguishable from it. The upper and lower triangles, labeled B and D in Figure 2, are compared with the values in the validity diagonals to evaluate discriminant validity. Discriminant validity is interpreted using the following comparisons:

1. Values in the validity diagonal (C) should be larger than the values that appear in the regions labeled D. This is the most basic requirement in that it simply means that different measures of the same variable should have a higher correlation than correlations that have neither trait nor method in common.
2. Values in the validity diagonal (C) should be larger than the values that appear in the regions labeled B. These regions represent correlations between measures of a single method taken on different traits, which should be smaller than the correlations between different measures of the same trait.
3. The pattern of correlations in the heterotrait triangles, labeled B and D in the Figure, should be similar in each triangle. This criteria requires that at least three traits (constructs) are measured so cannot be applied to our work here.

One of the weaknesses of many validation methods is that they provide no decision rules for determining when validity is demonstrated (Bagozzi and Yi, 1991). Rather, patterns of correspondence are interpreted, and may provide justification for further examination of the methods being evaluated. An alternative method for evaluation is structural equation modeling, however, it cannot be used with only two methods and traits. In a future study we plan to add a third method and/or trait and compare the results from the MTMM and a structural model.

We examine the validity of realtime measures by interpreting the patterns of correlations in the

MTMM matrix. We measure two traits, affect and cognition, using two methods, realtime measurement and Likert scales. We are looking for patterns of correlations, rather than perfect correlations, because we don't believe that a realtime curve measures exactly the same dimensions of the constructs as the Likert scale. The MTMM matrix is well suited to this situation because it focuses on the correspondence in patterns of measures rather than absolute correlations.

RESEARCH METHODS

One hundred and six paid subjects were recruited from a large university in the south. Four subjects were dropped when they failed to appear for the second session of data collection. While student subjects would not normally be used in tests of advertisements, it is appropriate in this case since our interest is the method of measurement. Subjects were randomly assigned to two test groups that saw the same ads. Each group saw the series of ads four times, twice each in two sessions that were one week apart.

The one-hour procedure included an instructional videotape, so all subjects received the same instructions. The video-taped instructions help to ensure that all subjects used the same standards when dialing and used fifty as their neutral point throughout an ad. They then responded to demographic and attitude questions that appeared on the television screen by pushing buttons on the keypad they each had in front of them. Next they dialed continuously as they watched the stimuli. The test stimuli reported here consisted of four television commercials embedded in a series of eleven thirty second television ads and a weather forecast. Some commercials came from cooperating companies while others were taken off the air. Subjects saw all 11 commercials and the weather forecast for a total time of ten minutes. The test ads were shown in the third, seventh, eighth and ninth positions and were chosen from among three sets of ads that represent low, medium and high levels of involvement for subjects. The high involvement ads were for a pizza chain, the moderate involvement ad was for a local bank and the low involvement ad was for homeowner's insurance. Involvement was considered a potential alternate explanation for the variance in correlations. An F test showed that involvement did not have a significant main effect ($F=.00$) on the correlations in the validity diagonals and so is not considered in further analyses.

The system used for this research is a fourth generation system that has both a 1-to-100 dial for continuous stimuli and a keypad for discrete responses to categorical questions. The first time subjects saw the stream of commercials they dialed for affect on the 100 point scale. Subjects were instructed to start their dial at fifty and dial 'up' when their feelings about the ad were favorable and dial 'down' when their feelings about the ad were unfavorable. The second time they dialed for cognition, evaluating the uselessness-usefulness of the information in the ads. After seeing the stimuli, subjects used their keypads again to answer questions that included the Likert scale criterion measures. The commercials were then played back to them for discussion and debriefing. The same

procedure was followed one week later, using the same commercials in the same order, to minimize alternative sources of variation in the test-retest measures.

There are many ways to reduce the realtime curve to a single point so that we can compare them to Likert measures. We want to choose a method of reduction that gives a measure that provides the same information given by the criterion measures. The criterion measures used for validation are retrospective assessments using Likert scale items measuring overall affect and cognition. The scale items were as follows: For affect, subjects responded on a five point scale ranging from very unfavorable to very favorable to the question, how did the ad make you feel? For cognition subjects answered the question, how useful was the information in the ad? They responded on a five point scale which ranged from very useless to very useful. We therefore hypothesize that the Likert items are most similar to an overall evaluation of the ad, represented by the average of the realtime curve values. If this is true, the average of the realtime values should be more highly correlated with the Likert items than any single point from the curve, which represents a response at only one particular moment. We should stress there are other possible summarizations of the realtime curve values and more examination is required before we can be confident what summary statistic best corresponds to a post-exposure scale item.

To test our hypothesis we computed correlations between the Likert item for affect and the four quartile points (i.e., the values at 7.5, 15, 22.5 and 30 seconds) on the affect curve, as well as the average value for the entire curve. The same process was repeated for cognition. As expected, the average of the curve was consistently more highly correlated with the criterion measure than the single values. This provides evidence that the most appropriate value, of those considered for use in the MTMM matrix, is the curve average. The problem here is that our criteria says the best single summary measure should be the one which correlates most highly with our criterion measures. But this also assures us of the best possible results, namely the highest possible correlations in the MTMM. For this reason it is important to stress that this work must be extended with other measures and methods before results can be considered conclusive.

RESULTS

MTMM matrices for the four test commercials were computed for subjects from week one and week two. Due to coding problems the insurance ad from week one had to be dropped. The seven matrices appear in Tables 1 and 2. They consist of correlations between the two measurement methods, Likert scale and realtime, and the two constructs measured, general affect for the ad and a rating of the usefulness of the information in the ad, or cognition. The first MMTM matrix in Table 1 has been partitioned to correspond to the regions shown in Figure 2 to aid interpretation.

In the test of convergent validity there are seven validity diagonals, one for each ad, each with

two values, for a total of 14 possible correlations between measures of a construct under the two methods. Eleven of 14 correlations are significant at the .05 level. As can be seen in the Tables, the values ranged from .16 to .73 with an average validity diagonal value of .50. We interpret this as moderately strong evidence of convergent validity and as strong support for the further examination of the realtime method.

The first criterion for discriminant validity involves a comparison of the values in the validity diagonals with the row and column elements in the hetero-method matrix (the values in regions labeled D in Figure 2). Of the twenty-eight possible comparisons, twenty-five were in the correct direction, the validity diagonal elements were higher than the off diagonal elements in the same matrix. Although, in some cases, such as Pizza #3 week 2, the values were very close.

The second criterion for discriminant validity requires comparison of the validity diagonal values with the relevant hetero-trait measures. For example in the first MTMM matrix in Table 1 this means that the .16 and .65 values in the validity diagonal would each be compared with the .24 in column one and .78 in column three. Under this criterion measure seventeen of the twenty-eight relationships are in the desired direction. Of the eleven relationships that are not in the right direction, nine of them are the result of very high correlations between the Likert items for affect and cognition. In six out of seven ads the correlation between Likert measures of affect and cognition were higher than realtime measures (e.g., .78 versus .24 in the Pizza #3 ad, table 1). This indicates a higher covariation between measures of different traits using the Likert method than with realtime. There are several possible reasons for this: First, it may be because subjects are less able to separate affective and cognitive reactions to an ad after exposure - seeking instead for a consistent reaction that combines both. Second, it may be because the Likert scale suffers from an inability to separate affective from cognitive responses. Third, it may reflect demand artifacts or the desire to appear consistent on the Likert items. Finally, it may be the result of the limited number of responses available with a Likert scale. In contrast, realtime measures have previously been demonstrated to discriminate between affect and cognition in Hughes and Lennox (1990).

The third test for discriminant validity was not performed because only two constructs were measured, affect and cognition. In the future we plan to add a third construct, purchase intentions. This addition will allow us to use the third method for evaluating discriminant validity.

Test-retest measures of reliability are included in the Tables for information. The average test-retest correlation is .53. This low number is caused in part by the low scores for the realtime measures of affect, average .25. Without these, the average correlation is .64. There are several possible reasons for the low scores: First, they represent a first and second exposure to the stimuli, and as such are not

representative of the same test. Second, test-retest of realtime measures will be more accurately reflected in a point by point matching of subject responses, rather than a comparison of averages. The point by point comparison was used by Hughes and Lennox (1990). Finally, wearout may be a factor.

DISCUSSION

The results provide evidence that realtime response measures display both convergent and discriminant validity. These findings are strongly consistent with the recommendations of the MTMM model and give direction for future research. Researchers using realtime methods of measurement

should consider the following recommendations to allow additional validation studies to be done. First, multiple scale items should be used for the criterion measures as a comparison with the realtime measures. This is important for two reasons: 1) Multiple items with demonstrated reliability will provide a better measure of the underlying construct. 2) If we believe that the realtime response captures many aspects of the construct being measured, then we would expect that multiple scale items should more accurately reflect what we believe the realtime method to be measuring. Second, future designs should be balanced to account for possible order effects. This would apply to the order of measures of affect and cognition as well as the

order of the ads seen. Third, at a minimum, we should add a third method or construct to the MTMM matrix. This would provide additional validation criteria and also permit the use of Campbell and Fiske's (1959) third test for convergent validity. Finally, we should also explore other means of validation, including the use of verbal protocols and trained judges or raters to evaluate realtime measures.

Other applications of realtime methods provide additional opportunities. Processes other than reactions to advertisements such as political speeches, sales presentations or other interpersonal communications are well suited to measurement via realtime. Realtime measures are also appropriate for examining issues of primacy versus recency effects.

Realtime methods provide rich, process oriented measures of subject reactions to dynamic messages. They provide us with the opportunity to perform individual level diagnostics on the process of

interest. They are also preferable to post exposure measures in that individuals are unable to provide retrospective responses about early points in a communication without bias due to having seen the rest of the message (Hughes 1991). With realtime measures we have responses to the communication, up to that point, every fifth of a second. This is useful to researchers who are interested in the process by which attitudes toward messages are formed.

We have provided a demonstration of how methods of evaluating reliability and validity can use measures taken at a point in time to provide evidence of reliability and validity of realtime measures over time. The Multitrait-Multimethod matrix provides evidence that research using realtime measures can have construct validity. We must now explore other methods of validation, ideally with measures that allow us to use all the data in the realtime curve.

Deriving Attribute Utilities from Consideration Sets: An Alternative to Self-Explicated Utilities

David B. Klenosky, DePaul University
W. Steven Perkins, Pennsylvania State University

ABSTRACT

Questions have arisen concerning the use of self-explicated utilities as an element in conjoint analysis. This research proposes an alternative method by deriving utilities from consideration sets. Fifty subjects screened conjoint profiles into groups of alternatives they would accept for consideration, put on hold, or reject. They then completed traditional conjoint and self-explicated tasks. Attribute utilities derived from their consideration sets differed markedly from their self-explicated utilities, apparently reflecting a different aspect of the consumer choice process. In subsequent hybrid conjoint analyses, including the consideration set utilities in place of the self-explicated utilities resulted in a higher R^2 and alleviated the bias in the parameter estimates representing the attribute-level effects.

INTRODUCTION

Researchers attempting to study and predict consumer preferences frequently rely on attribute importance weights and attribute-level desirabilities that are directly elicited from respondents. The collection of such "self-explicated" data, as it is commonly called, is recognized as a useful and relatively efficient approach for modeling consumer choice behavior (Leigh, MacKay and Summers 1984; Srinivasan 1988; Green and Helsen 1989). Interest in self-explicated data has become particularly important recently with the development of "hybrid" conjoint models that combine the data-collection efficiencies of the self-explicated approach with the generality and power of regression-like conjoint preference models (see Green 1984 for a review of hybrid conjoint models). One popular conjoint software package even includes a self-explicated task before respondents evaluate profiles (Johnson 1987). Recent research, however, has noted possible drawbacks to the use of self-explicated data. First, the information-processing assumptions underlying the self-explicated approach may be violated by consumers' actual choice behavior. Second, estimates of attribute parameters may become biased when self-explicated data are included in a regression equation. This paper presents an alternative method for generating attribute utilities that addresses both of these issues.

Choice Behavior Inconsistent with Underlying Assumptions

Fundamental to the self-explicated approach is the assumption that respondents can accurately state which levels within an attribute are acceptable versus unacceptable. Furthermore, it is assumed that respondents use a conjunctive evaluation procedure in which alternatives possessing unacceptable attribute levels will be rejected from further consideration,

while those possessing acceptable levels may be considered depending on the levels of other attributes.

Previous research, however, indicates that people do not always adhere to the conjunctive implications of the self-explicated procedure. In particular, Klein (1986) found that respondents often fail to reject alternatives with attribute levels which they themselves had previously designated as unacceptable. More specifically, she found that 15 percent of the alternatives chosen as best by the respondents in her study possessed an attribute level that was supposedly "completely unacceptable." In a later study, Green, Krieger and Bansal (1988) demonstrated that the tendency to consider alternatives with "completely unacceptable" levels can be somewhat reduced by strengthening the instructions used to rate the attribute-level desirabilities. Interestingly, however, these researchers found that there is still a 47% chance, at best, that respondents will fail to adhere to the conjunctive implications of the completely unacceptable level. In sum, researchers rely on the self-explicated approach, despite the fact that its assumptions are often violated by actual choice behavior.

Bias in Parameter Estimation

Several studies have compared the predictive accuracy of self-explicated models, traditional conjoint models and hybrid conjoint models (Akaah and Korgaonkar 1983; Cattin, Hermet and Pioche 1982; Green, Goldberg and Wiley 1982; Moore and Semenik 1988). Although the results of these studies have been somewhat inconsistent, the traditional conjoint and hybrid conjoint models typically outperform the self-explicated model on a number of cross validation measures (i.e., adjusted R-squared, percent of first-choice predictions and average holdout sample correlations). Interestingly, however, the hybrid conjoint model's improvement over the traditional conjoint model is often not very substantial. According to Green, Goldberg and Montemayor (1981), the variation captured by the self-explicated component of the hybrid model may fail to increase the amount of variance accounted for by the conjoint component. In other words, the information captured by the self-explicated component of the hybrid model may be partially redundant with the information captured by the "conjoint" component.

This problem can be seen by analyzing the effect of adding the self-explicated component to the other terms in the hybrid conjoint model, i.e., the terms reflecting the attribute-level dummy-variables. Adding the self-explicated term to the hybrid model may have an adverse, biasing effect on the parameter estimates of the dummy variables. In particular, dummy-variable parameter estimates that were

previously significant may become insignificant when the self-explicated term is added to the hybrid model. Interestingly, this problem has yet to be addressed in published studies of the hybrid conjoint model.

Given the above problems with the self-explicated approach in general and in its use in hybrid conjoint analysis in particular, it is important to consider alternative approaches for estimating attribute-level desirabilities.

An Alternative to the Self-Explicated Approach

One alternative to the collection of self-stated attribute utility estimates is to derive those estimates based on actual choice behavior. In this paper we describe such an approach, called the "screening" approach, in which respondents are shown full-profile choice alternatives (like those used in traditional conjoint studies) and are asked to decide which of three groups each alternative belongs in: (1) those the respondent would definitely consider selecting, (2) those he might consider selecting and (3) those he would definitely reject from further consideration. As shown below, these "screening decision" responses can then be used to derive utility estimates representing the desirability of each level of each attribute for each respondent.

Study Objectives

In general, one would expect that these screening-derived attribute-level utilities would be somewhat similar to the attribute-level desirabilities obtained using the self-explicated approach. One purpose of this research is to determine whether this is in fact the case. Thus, our first objective is to assess the convergent validity of the self-explicated approach with an alternative approach based on actual screening-decision behavior.

As noted above, the information reflected in the self-explicated term is often redundant with the other terms of the hybrid conjoint model, resulting in biased dummy-variable parameter estimates. Using an alternative term based on the screening-derived attribute utilities may be one way to get around this problem. Thus, the second objective of this study is to assess the extent to which a screening-derived utility term (used in place of the self-explicated term in an alternative hybrid model) reduces the amount of bias in the parameter estimates typically found in hybrid conjoint models.

BACKGROUND

Typically in hybrid conjoint, self-explicated utilities are gathered by having the respondent rate the desirability of each level of each attribute. These utilities are denoted as u_{ij} for the utility of level i on attribute j . Though scales of varying lengths have been employed, a simple three point scale--best, acceptable, unacceptable--is not uncommon (e.g., Green 1984, Figure 3). The respondent notes which single level of the attribute is best, then marks the remaining levels as either acceptable or unacceptable. Then the analyst assigns a score to each point on the

scale, such as best=3, acceptable=2, and unacceptable=1. (Respondents may also be asked to state their self-explicated importance weight for attribute j , but to keep the focus on the attribute level, all attributes in this study were unit weighted.) For the estimation phase of the project, the self-explicated utilities are summed by profile according to the corresponding attribute levels in the profile. This sum represents a holistic, compositional estimate of the utility for that profile. (In some studies, the utilities are not summed; instead weights are estimated for each attribute, though calculating the summed utility appears often, as in Moore and Semenik 1988).

In contrast, this project investigated a different approach to generating the u_{ij} 's, though the ultimate use of the summed utility in estimation was the same. Specifically, the respondent's task differed from the rating approach seen in most hybrid studies. To derive the utilities, respondents screened each profile by assigning it to one of three categories--accept for consideration, hold (undecided), or reject from consideration. Then working from those observed screening decisions, utilities were developed by calculating the probability of accepting, holding, or rejecting, for each level on an attribute. For example, a respondent might screen four profiles with attribute j at level i , rejecting three of the profiles and putting one on hold. The derived probability of rejecting equals 75%, with a 25% chance of holding, and a 0% chance of accepting. A utility value for that level could be calculated by weighing the score for each category by the probability of that category occurring. Thus for an attribute j :

$$u_{ij} = \sum_{k=1}^K p_{ik} s_k$$

where: p_{ik} = the probability that a profile at level i (of attribute j) will be screened into category k

s_k = the numeric desirability score for category k

Note that the typical rating task employed in gathering self-explicated data can also be expressed in these terms; however, the scale value marked by the respondent receives a probability of 100% while all other scale values for that attribute level equal 0% probability.

A brief numeric example should make the steps in deriving the utilities more clear. Assume that a respondent screens twelve profiles, four profiles at each of the three levels on attribute j . The results might be as in Table 1. These same steps would be followed for each attribute. The screening derived u_{ij} could then be treated in the same manner as self-explicated utilities in the estimation phase.

Though mathematically parallel to the self-explicated utilities, the screening derived utilities capture a different aspect of the judgment process. In

TABLE 1
Screening-Based Approach for Deriving Attribute Utilities

		Accept	Hold	Reject	Total
Level 1	(low)	0/4= 0%	1/4=25%	3/4=75%	100%
Level 2	(medium)	1/4=25%	2/4=50%	1/4=25%	100%
Level 3	(high)	2/4=50%	2/4=50%	0/4= 0%	100%
	Score	3	2	1	
	u_{1j}	$= (.00*3) + (.25*2) + (.75*1) = 1.25$			
	u_{2j}	$= (.25*3) + (.50*2) + (.25*1) = 2.00$			
	u_{3j}	$= (.50*3) + (.50*2) + (.00*1) = 2.50$			

this project, the subjects' task was specifically to screen the profiles for consideration, not to choose one. In a later task they rank ordered the same profiles and completed the self-explicated utility ratings. Thus the screening derived utilities represent the weights subjects placed on attribute levels during consideration set formation, not during final evaluation and choice. Several researchers have hypothesized that at this earlier consideration set stage subjects would exhibit more non-compensatory behavior, compared to more compensatory behavior at a later evaluation stage (Roberts and Lattin 1991; Wright and Barbour 1977). That is, at an earlier stage in the process, subjects would be more likely to use a conjunctive rule and reject a choice alternative (profile) if any of its attribute levels were below an acceptable level. Whereas, in a later stage those alternatives that have passed screening would be evaluated in a more compensatory manner.

THE STUDY

The data for this research was collected as part of a larger study designed to investigate the consumer consideration set formation process (Klenosky 1990). The study involved a simulated decision-making task in which subjects were asked to select a restaurant, from a pool of available restaurants, for a hypothetical restaurant choice situation. (Though not relevant for the present study, subjects were randomly assigned to one of two situations: (1) choose a restaurant to go to when you're feeling too lazy to cook and (2) choose a restaurant to go to for dinner with your boy/girlfriend and his/her parents).

Subjects

A paid convenience sample of 50 university students were recruited for the study. Subjects were selected based on a screening questionnaire to ensure they had some familiarity and interest in the choice domain involved.

Stimuli Used as Choice Alternatives

The stimuli used in the study consist of descriptions of hypothetical restaurants constructed to simulate condensed restaurant reviews. Based on a literature review and a series of pilot studies, six attributes were selected to describe the restaurant

alternatives (see Table 2 for a summary of the attributes and attribute levels used in the study). As a starting point, the three levels of the four most important attributes (Atmosphere, Food Quality, Service Quality and Price) were fully crossed to create a base set of 3^4 , or 81 profiles. Profiles with unrealistic attribute level combinations were then discarded reducing the available set to 63 profiles. Finally, the levels of two additional attributes (Food Variety and Waiting Time) were randomly assigned to each profile to create 63 restaurant alternatives described on a total of 6 attributes. The orthogonality of the attributes in these profiles was a concern. However, a subsequent analysis indicated that the degree of correlation among the attributes used in the profiles was low, indicating the design was still relatively orthogonal.

Procedure

Each subject participated individually in a session whose average time was 45 minutes. Subjects were first shown a brief description of the choice situation and then began to examine the profiles. The profiles were not in any particular order and were drawn at random by the experimenter. Subjects were allowed to examine as many or as few profiles as they wanted or needed to in order to make their choice. Subjects were instructed to indicate what they wanted to do with each profile by placing those that they wanted to consider for the situation in a pile to their left and those that they wanted to reject from consideration in a pile to their far right. They were also told they could use a middle pile if they liked as a "hold" pile for alternatives they were unsure of. Subjects indicated when they were ready to stop examining profiles and make their choice. They then ranked each of the profiles examined from their most preferred to their least preferred. (Note that the 50 subjects participating in the study examined an average of 6.4 profiles, with a range of 1 to 22. Of the 306 profiles screened, 21% were accepted, 15% put on hold, and 64% rejected).

Once the process of examining profiles ended, subjects completed the self-explicated task by indicating the desirability of each attribute level using the simple three-point scale described earlier. That is, they first indicated, for each attribute, which level was

TABLE 2

the best or most preferred, and then rated the remaining levels as either acceptable or unacceptable.

RESULTS

As noted above, the first purpose of this research was to assess the convergence between self-explicated utilities and screening derived utilities. Table 2 presents these results by attribute level; the means across attributes appear at the bottom of the table. There are noticeable differences between the two approaches. In particular, on average the unacceptable level was chosen 27% of the time but 64% of the profiles were rejected. On fourteen of the seventeen attribute levels, respondents rejected the profiles at a higher rate than they rated the attributes as unacceptable. The differences between the two approaches are quite large on some attributes, such as "casual atmosphere" where none of the respondents rated that as unacceptable, but 60% of the time profiles at that level were in fact rejected. Of course, such differences are understandable since our methodology for deriving utilities based on screening behavior

enforces a strict conjunctive rule that if a profile is rejected, all the attribute levels for that profile are considered rejected.

The deviations between the self-explicated and screening derived utilities can also be examined by correlating the two sets of utilities produced by each individual. The mean correlation coefficient across the 50 subjects equalled .40 (after a Fisher Z transformation) with a range from +.90 to -.73. For 46% of the respondents the two sets of utilities were significantly correlated; or conversely, for 54% the two sets were not related using a 1 tail test at $\alpha = .05$. There is one caveat: the observations within an individual's set of utilities are not completely independent. Thus, while these correlation results indicate some lack correspondence between the two utility measures, they are not definitive.

Table 3 summarizes the extent to which subjects violated the conjunctive implications of the self-explicated procedure by crossstabulating the outcome of the screening decisions by the presence of unacceptable attribute levels in the profiles. If any

TABLE 3
 Frequency of Violating Conjunctive Decision Rule and Median Profile Ranking by Screening Decision Outcome and Profile Type

Profile Type	Screening Decision			Total
	Accept	Hold	Reject	
Profiles Containing at Least One Unacceptable Attribute Level	n=26 .89	n=33 .68	n=186 .31	n=245 .42
Profiles Containing No Unacceptable Attribute Levels	n=38 .94	n=14 .80	n=11 .48	n=63 .83
	n=64 .92	n=47 .71	n=197 .32	n=308 .50

attribute level in a profile had been rated as unacceptable by the respondent, then the profile was classified as "unacceptable" (see Green, Krieger, and Bansal 1988, Table 4). We might expect that all unacceptable profiles should have been rejected, and in fact of the 245 profiles classified as "unacceptable," over 75% were rejected. On the other hand, however, respondents failed to reject 25% of these supposedly "unacceptable" profiles. Note also that of the 64 profiles that were accepted by the respondents, 40% contained at least one unacceptable attribute level, indicating once again a moderate level of inconsistency.

The median rank orders for the profiles which fell into each screening by self-explicated cell are also presented in table 3. (The ranks were rescaled by respondent such that the most highly ranked profile equalled 1 and the least highly equalled 0.) The rankings monotonically decline from accept to reject decisions and from acceptable to unacceptable attribute levels, as expected. Respondents' rankings were congruent with their screening and self-explicated results. Thus, the screening and self-explicated utilities should be useful in predicting preferences, even though the respondents were not always consistent in following the conjunctive rule.

The second purpose of the research was to assess the effect of including a summed screening derived utility term in a hybrid conjoint regression equation in place of the typical summed self-explicated term. In previous studies the inclusion of the self-explicated term, along with the traditional dummy variables representing the levels on the profile attributes, has improved the predictive ability of the equation (e.g., Green 1984). However, this increase may come at the cost of introducing some bias into the estimation of the regression parameters because the self-explicated term can be redundant with the attribute levels. Thus, the coefficients for the dummy variables will be altered if the self-explicated utility term is included.

Using the rescaled respondents' rankings of the choice alternatives as the dependent variable, three equations were estimated with the CONJOINT macro in SAS which performs monotonic regression (SAS 1985). All equations were estimated at a total group level, $n=308$. As a baseline for comparison, the first equation included only the dummy variables for the profile attribute levels. The estimated parameters appear in Table 4, along with the R^2 of .35. Note that seven of the eleven attribute level parameters are significant.

A second equation included the self-explicated utility term, summed by profile, along with the dummy variables, following the same formulation shown in Moore and Semenik (1988, their equation 3). The R^2 increased to .46 as might be expected, but in this case four of the attribute level parameters which had been significant in the dummy variable equation are now insignificant. Only four parameters are significant when the self-explicated term is included. This is important from a managerial perspective because the meaning of the parameters changes between the two

equations. Considering the self-explicated term alone, without dummies, results in an R^2 of .39.

Finally, a third equation substituted the summed screening derived utility in place of the self-explicated term in the second equation. In this case the R^2 improved to .50, but more importantly the attribute parameters remained as they were in the first dummy variable equation. The same seven which had been significant previously, remain significant in this equation indicating that the screening-derived term is bringing in new information, uncorrelated with the profile dummy variables. An equation with the screening derived term alone, without dummies, produces an R^2 of .36.

DISCUSSION AND CONCLUSIONS

This research has merged aspects of consideration set formation with the modelling of consumer preferences. Previous research has noted the consideration set formation as an essential step before product evaluation (Roberts and Lattin 1991), but many models ignore that step and focus only on the final step of the process: choice. Obviously if a product is not included in the consumer's consideration set, it cannot be chosen. To model choice more realistically, the earlier processes should also be included.

The typical self-explicated utility task asks consumers to declare whether any levels of an attribute are unacceptable. Thus, if a product had that level, it would not be considered for choice. The method described in this paper seeks to obtain the same information from the consumer; however, in this method, attribute utilities are derived by screening profiles for consideration. Our approach entails a less direct task from the consumer's perspective--they do not overtly rate attribute levels. On the other hand, this approach may provide a more direct, behaviorally-based measure of attribute utilities.

Summarizing the research results, we find noticeable inconsistencies between the screening decisions and the self-explicated utilities. For example, over 40% of the profiles respondents accepted for consideration contained at least one "unacceptable" attribute level, while 25% of the profiles with "unacceptable" levels were not rejected from consideration. We also find that, compared to a summed self-explicated utility term, a summed screening-derived utility term is less redundant with the dummy variables in a hybrid conjoint equation.

These results suggests that the utilities generated by the screening task differ from those generated by traditional self-explicated methods. These differences may arise from both our mathematical formulation as well as the respondent's task. First, our formulation calculates the utility of a profile by weighing the desirability scores for an attribute level by the probabilities derived from the screening decisions. This probabilistic formulation of utility may be a more realistic representation of the respondent's behavior, but further research is needed on this point. To improve the comparability of utilities across subjects, future research could require

all respondents to screen the same set of, say 18 factorially designed, profiles. An additional possibility would be to substitute a profile screening task for the self-explicated task now built into the Adaptive Conjoint Analysis (ACA) software program (Johnson 1987). Green, Krieger, and Agarwal (1991) have recently questioned several aspects of ACA, and a screening task may help resolve some of those issues.

Second, in addition to differences due to our mathematical formulation, differences between the screening derived and self-explicated utilities may also result from the task the respondent is asked to perform. The screening task captures the consideration set formation stage of the choice process. Thus, the weights placed on attribute levels during consideration set formation may well differ from those associated with the final choice stage. Future research could explore the factors which increase or decrease the differences between the weights used in the two stages, including factors related to product class, respondents, purchase situation, and task instructions.

New Perspectives for Self-Research

Beth Ann Walker, Arizona State University

The concept of self has fascinated social scientists for centuries. Some of social sciences most important philosophers, psychologists and social psychologists, clinicians, anthropologists, sociologists and symbolic interactionists have placed self squarely in the center of their theories of human behavior. Although self-research in marketing is more recent, interest in self has been equally pervasive, beginning with "motivation research" in the 1950's, followed by self-concept research in the 1960's and 1970's (cf. Sirgy 1982), and continuing today with a more anthropological and sociological perspective emphasizing the role of symbolic consumer behavior in the maintenance and construction of the self (Belk 1988; Mehta and Belk 1991; Schouten 1991). This perspective has been most useful, revealing a complex and powerful self that is implicated in all aspects of consumer's lives. However, given the richness and complexity of the self-construct, multiple perspectives and visions of self are needed to address the multitude of research issues that have intrigued self-researchers for decades. Only by combining and integrating frameworks and perspectives can one more fully understand self as it relates to consumer behavior.

The purpose of this special session is to bring together a group of researchers with distinct and unique "visions" of self that may serve as a catalyst for future self-research. The session will familiarize the audience with alternative theoretical perspectives that can be used to investigate the self. New research issues and questions not previously addressed in the consumer behavior literature are identified and include understanding the core or authentic self, the relationship between self, affect and emotions, motivation, and decision-making, the representation of self in memory, and finally how self is constructed and measured. Most importantly, however, is the session's objective is to stimulate creative thinking and research on self from these alternative points of view.

Conceptualizing the Self from a Cognitive Structure Perspective

The session begins with Beth Walker's presentation of her theoretical conceptualization of self from a cognitive structure perspective.

Much of the recent work on self describes how symbolic consumer behaviors are used to maintain and construct the self, without clearly conceptualizing or defining the concept. In this presentation, the author addresses the issue "what is self?" by discussing how self may be represented in memory. The proposed framework, which integrates the self, motivation, and situation literatures, details how self and self/product relationships may be stored or represented in memory.

Specifically, self is conceptualized as a multifaceted cognitive-affective structure which contains, among other beliefs, consumer's representations of motives, goals, hopes and desires

which are hierarchically organized at different levels of abstraction. Products and services may be linked to important self-goals through means-end structures. Once activated, self and self/product structures have motivational properties that direct affective and cognitive processes and overt behavior. In contrast to the early self-concept research (Sirgy 1982), this framework emphasizes the dynamic, flexible and goal-directed aspects of the self. Implications for understanding consumer's affect and emotion, information processing, and felt involvement and ideas for future research are then discussed.

This is Really Me! The Consumer's Search for the Authentic Self

Linda Price presents her work with Walker which focuses on consumer's sense of their core or authentic self.

The assumption that there is a "real self" that is more than a composite product of our performances, is among our most cherished beliefs. As participants in a culture that privileges the authentic self, but demands rehearsed and planned role performances, we value experiences, interactions, and possessions that lead us to exclaim "this is really me!" While answering the philosophical question of whether there is a "real" self is difficult, the more tractable goal is understanding the authentic self as conceived by the person, and the relationship between this self, experience and possessions in a social world.

In this presentation, Price presents the results of a phenomenologically based investigation of the meaning of "really me" to consumers from their own, everyday lived experiences. While one group of subjects provided descriptions of their most recent "really me" purchases and possessions, a second group provided descriptions of a "really me", "impulse" and "high involvement" purchases. For both groups, minimally structured interviews combined with more structured scales of affect, experience characteristics, and memory of experience were used to collect the data.

The results illustrate that the interrelationships between these different "really me" experiences and purchase experiences form an important nexus of meanings through which a personal sense of self emerges. The results also identify structural relations between meanings of authenticity and between types of purchase, possession, and consumption experiences. Interesting relationship between the incidence of affective content of "really me" experiences and measures of self-complexity are also discussed. Finally, suggestions are made for future investigations of the authentic self.

Narrative Constructions of the Self

Using narrative theory as their theoretical foundation, John Howard and Jerry Olson present their view of how self is represented and actively

constructed as consumers relate continually evolving stores that represent their life experiences.

Narrative is the basic mode of representing experience that people use to construct meaningful interpretations of the events in their lives (Bruner 1986). The authors conceptualize self as a complex narrative, composed of many interrelated stories which evolves as the narratives change over time. Narrative, then, is used to create and represent self-meaning. Howard and Olson elaborate and establish this position by drawing on several relevant literatures concerning narrative theory and its many applications.

First, they describe the narrative mode of thought and distinguish it from other forms of representation and communication such as logical argument and description, and illustrate how self is constructed by creating narrative representations of events in one's life. People who possess a well-developed self narrative can easily travel backward and forward in time, telling stories about who and what they are, were, and hope to become. Next, the advantages of a narrative perspective for understanding self are discussed, and implications of a narrative construction of self for consumer research illuminated. Since everyone continually constructs self narratives that reflect the self, narratives can also be used to measure aspects of self. The authors propose that such self-stories could be more revealing of self than more common methods such as self-ratings of traits in structured questionnaires.

The Self, the Whole Self, and Nothing but the Self: Toward New Theory in Consumer Behavior

John Schouten concludes the session by presenting his vision of self as the unifying construct which may serve as the foundation for integrating theory and research on emotion and cognition.

One of the earliest conceptualizations of the self comes from Plato who defined it as the experiential center of all human thought, feeling and action (Bostock 1986). In other words, the individual self not only performs the functions of cognition, affect, and conation, it also interprets the results of those activities in a holistic fashion, thus giving meaning to the world and to its own place therein (Allport 1943). Furthermore, the self employs the same functions reflexively to understand the inner world. The resulting self-concept has a strong cognitive component consisting of multiple schemas, as well as an affective one which arises from evaluation of self-schemas to the expectations of self and others.

After presenting his vision of self as an integrating framework, Schouten concludes his presentation by highlighting areas for future research, and stressing the need for an integrative approach to further research and theory development.

In sum, this special session introduces several alternative visions of self to the consumer behavior discipline, with concrete suggestions for future research with the hope of stimulating creative thinking and research on the emerging topic of self.

Consumer and Employee Roles in Service Encounters

Michael Guiry, University of Florida

ABSTRACT

The consumption of services often involves the personal interaction of consumers and service employees. Past services research has focused almost exclusively on the behavior of service employees and excluded the consumer's role in this dual social process. Qualitative in-depth interviews were used to conduct an experiential investigation of how consumers want to participate in their service experiences and how satisfaction develops as a function of their participation expectations. Emergent consumer role themes of "autonomy - mutuality - dependence" and employee role themes of "indifference - cooperation - dominance" that shape the consumption experience are identified and discussed in relation to consumer satisfaction in service encounters.

The personal interaction between consumers and service providers is the heart of most service experiences. Whether the interaction consists of a flight attendant's brief standardized greeting to boarding passengers or entails the personalized attention of a physician during a medical exam, the moment the exchange commences the consumer is simultaneously involved in the production and consumption of the service and becomes an integral part of the service process. The consumer's experience within the service process is an important determinant of his/her satisfaction with the service and facilitates his/her assessment of service quality (Bitner 1990; Bitner, Booms, and Tetreault 1990; Parasuraman, Zeithaml, and Berry 1985, 1988; Surprenant and Solomon 1987). In "pure" services, such as health care, financial planning, and auto repair, where a physical product is not exchanged and the service experience is difficult to evaluate, the interaction epitomizes the service from the consumer's perspective. But even when the focus of the exchange is a tangible object such as clothing purchased in a department store, the interaction can leave an indelible impression on the consumer.

The personal interaction between consumers and service providers has been termed the "service encounter" in the services marketing literature (Czepiel et al. 1985; Shostack 1985; Solomon et al. 1985; Surprenant and Solomon 1987) and has become the focus of attention in recent service quality research (Bitner 1990; Bitner et al. 1990; Surprenant and Solomon 1987). The research on service encounters and the service quality research of Parasuraman et al. (1985, 1988) suggests a number of factors that may influence consumers' satisfaction with services. These factors pertain to both the service outcome and the manner in which employees deliver service to consumers. The factors relating to the interaction between consumers and employees address how consumers expect employees to behave while providing service. However, prior research has not considered *how consumers expect to participate in the*

service process and define their service experience.

For example, when some consumers shop for clothing they may want to move freely through the store on their own and avoid interacting with salespeople, while other consumers may welcome a salesperson's advance and want him/her to take an active part in helping them select the right merchandise. Service quality research has focused almost exclusively on the employee's part in the service setting. Thus, the consumer's service experience, including the service encounter, has not truly been viewed as an interactive and dynamic social process. The purpose of this article is to understand how consumers want to participate in their service experiences and how service satisfaction develops through the service encounter as a function of consumer participation expectations.

BACKGROUND

The services marketing literature has identified three significant characteristics of services - intangibility, inseparability, and heterogeneity - that reveal the human dimension of service delivery and consumption (e.g., Parasuraman et al. 1985; Zeithaml, Parasuraman, and Berry 1985). These characteristics may make it difficult for consumers to evaluate the service offering in the absence of more concrete product attributes (Zeithaml 1981). As evaluation becomes more subjective, consumers are likely to draw more heavily on the total consumption experience, i.e., not only what service is delivered, but also how it is delivered, when assessing satisfaction and service quality. The service employee's perceived performance, including his/her projected attitude and behavior while interacting with consumers, may affect their evaluation process.

Service Quality

Parasuraman et al. (1985, 1988) propose that consumers evaluate a firm's overall service quality on five underlying dimensions: tangibles, reliability, responsiveness, assurance, and empathy. They developed a multiple-item scale called SERVQUAL that measures perceived service quality by comparing consumers' perceptions of a service firm's performance with their expectations of how firms in that industry should perform along the five service dimensions. This research affirms the importance of the personal interaction between consumers and service providers in realizing service satisfaction. Three of the five dimensions of service quality - responsiveness, assurance, and empathy - relate directly to the interactive nature of services. Furthermore, the reliability of a service frequently depends on employee performance. Service employee performance that falls short of consumer expectations leads to consumer dissatisfaction and poor service quality.

Parasuraman et al. (1988, p. 23) define the three interpersonal service quality dimensions as follows:

Responsiveness - willingness to help customers and provide prompt service

Assurance - knowledge and courtesy of employees and their ability to inspire trust and confidence

Empathy - caring, individualized attention the firm provides its customers.

Taken together they suggest that service providers must be active participants in the consumer's service experience. However, consumers' expectations about the amount and type of interaction they will have with employees may differ depending on how they want to act in the service. While some service settings may require that employees stay in close contact with consumers throughout the delivery process, at other times consumers may only need to know that an employee is available if needed, i.e., good service can be provided from a distance. Although responsiveness, assurance, and empathy are important factors when consumers assess service quality, the meanings of these dimensions may differ among consumers depending on the way in which they want to participate in the service process.

The Service Encounter

In recent research that focuses on the role of the service encounter in service satisfaction, Bitner et al. (1990) asked respondents to describe specific events and employee behaviors that led them to distinguish between satisfactory and unsatisfactory experiences. The study uncovered three major categories of employee behaviors: employee response to service delivery failures; employee response to customer needs and requests; and unprompted and unsolicited employee actions. Although this study is useful in identifying employee behaviors, it does not address how consumers participate in the service setting, thus leaving an incomplete picture of the consumer's service experience. The interpersonal nature of services suggests that the way in which consumers themselves take part in a service may also influence their satisfaction.

Role Theory

The meaning of service satisfaction can be developed further by understanding the way in which consumers want to present themselves in service encounters. Solomon et al.'s (1985) work on the service encounter proposes a role-theoretic framework for understanding consumer participation in the service environment. They argue that the service encounter can be understood by considering the specific roles consumers and service employees play during their interaction. In addition, they suggest that the roles that are enacted will affect consumers' service satisfaction. However, Solomon et al. stop short of identifying the different roles that consumers and employees may play in the service environment.

Role theory is based on a theatrical metaphor. Consumers and service employees participate within the service encounter like actors on stage reading from

a common "service script" that represents each party's expectations of their own behavior as well as the anticipated complementary behavior of each other (Smith and Houston 1983). Their roles encompass a set of learned behaviors appropriate to the particular service setting and depend on situational cues such as each other's attitudes and behaviors. Consumers and service providers must understand each other's position to engage in a satisfactory and stable relationship. Employees must recognize and respond to the different needs of consumers and the way consumers expect to participate in the service. The failure of either consumers and/or employees to adhere to their prescribed roles and scripts may hinder service delivery and result in dissatisfaction with the service encounter. At present the application of role theory to the service encounter remains at a conceptual level, leaving a void in understanding how consumers participate in their service experiences.

In sum, Parasuraman et al.'s SERVQUAL model highlights the interpersonal nature of services in three of its five dimensions. Past service encounter research explicitly recognizes that the interaction between consumers and service employees is an important determinant of consumer satisfaction, but extant research focuses exclusively on employee actions and behaviors, excluding the consumer's role in the interaction. Solomon et al. have recognized the duality of the service encounter by suggesting a role theory perspective, but their work remains at a conceptual level since they have not cashed it out. So, the purpose of this research is to explore the roles consumers enact in service encounters and how their desired actions and behaviors influence service satisfaction.

METHOD

Qualitative in-depth interviews were used to study consumer roles in different service settings. The in-depth interview method used in this study combined the critical incident technique (Flanagan 1954; Bitner et al. 1990) with an existential-phenomenological interview approach (Thompson, Locander, and Pollio 1989, 1990). The motivation for this approach was to go beyond the straightforward critical incidents and gain a more thorough understanding of the consumer service experiences. The critical incident technique reveals what events occurred, while existential-phenomenology provides a means of interpreting and understanding the experience.

The present research was based on the verbatim transcripts of twenty-eight qualitative in-depth interviews conducted with undergraduate students at the University of Florida who were enrolled in an introductory marketing course. Each interview was conducted by the principal researcher and lasted between thirty and forty-five minutes. The interviews were tape recorded and later transcribed verbatim by the researcher.

Each interview began with the question, "Can you think of a time when you had a particularly satisfying or dissatisfying experience with a service business?" The purpose of the initial question was to focus the interview on descriptions of specific

consumer service experiences from which critical incidents could be discerned and thematic descriptions of consumption experiences would emerge. Additional questions arose from the ensuing dialogue and were largely driven by the informant's responses to ensure a first-person description (see Thompson et al. 1989).

During the interview, informants were free to describe satisfying and/or dissatisfying service experiences with any service business. Informants often talked about more than one experience. The majority of their consumption experiences occurred in restaurants and retail stores. Consistent with the principles of emergent design, the research evolved into a study largely confined to these two settings. The focus on these two service environments is not surprising given the informants' demographics and the university town setting where the interviews were conducted. However, restaurants and retail stores form a substantial portion of the American service economy. The format of the interview was designed to be very flexible to allow the informants to fully discuss their personal service experiences, including their own attitudes and behaviors.

The verbatim interview transcripts were the data from which thematic descriptions of consumer service experiences unfolded through an interpretive process (Denzin 1989; Thompson et al. 1989, 1990). Thematic description required careful readings of each transcript to understand individual informant's service experiences from a first-person perspective. The individual transcript analysis revealed that informants view their service experiences as a dynamic interactive process comprised of their own participatory views and behaviors as well as the service employees' attitudes and behaviors. After the transcripts were analyzed individually, the separate interviews were related to each other and common patterns or themes were identified emerging from informants' discussions of their service experiences. The interpretation sought the discovery of convergent themes across divergent consumption experiences. An emic approach to interpretation was followed that attempted to describe the recorded experiences from within the informant by using his/her own terms rather than the researcher's (Denzin 1989; Thompson et al. 1989, 1990).

An Experiential Portrayal of Service Encounters

The Figure presents the consumer's view of the service encounter as a lived meaningful experience that encompasses much more than a discrete monetary transaction. The service encounter is symbolized by the major interpretive themes that emerged from the interviews: 1) "autonomy - mutuality - dependence" portraying the roles consumers play while receiving service and 2) "indifference - cooperation - dominance" describing the roles that consumers see employees enacting while giving service. These themes are interrelated and emanate from consumers' descriptions of the meaning of satisfaction in service encounters. The emergent themes will be described individually and then synthesized in relation to consumer satisfaction. To provide a clearer

understanding of the consumer's own consumption experience, illustrative excerpts from the interviews will be offered within the thematic descriptions.

The Figure depicts the service encounter as a social process that encompasses the exchange between consumers and employees in the service environment. At the core of the service encounter resides consumer satisfaction arising from the fusion of giving and receiving service during the personal interaction between consumers and service employees. The emergent roles identified in the transcripts give credence to Solomon et al.'s use of role theory to understand the service encounter and consumer satisfaction. Informants often discussed the roles they expected service employees to play while giving service in relation to their own roles while receiving service. Their first person description of themselves in their service encounters gives a more thorough understanding of consumers' service experiences. The service encounter is a dual undertaking, not just driven by consumers' expectations about employee behaviors. Consumers are active service participants, with their own expectations about how they want to experience a service.

The congruence between the service employee's role and the consumer's serves as a "measure" of good service and a source of consumer satisfaction; as such this congruence notion is quite compatible with Parasuraman et al.'s service quality model, which measures the gap between consumers' expectations and perceptions of service performance. This research extends Parasuraman et al.'s model by identifying consumers' expectations about their own roles and their accompanying expectations about employees. The interpersonal dimensions of service quality are not products of the service firm, but rather are dynamic processes that occur within the service encounter. Consumers' expectations about employee behaviors are framed by how they want to participate in the service.

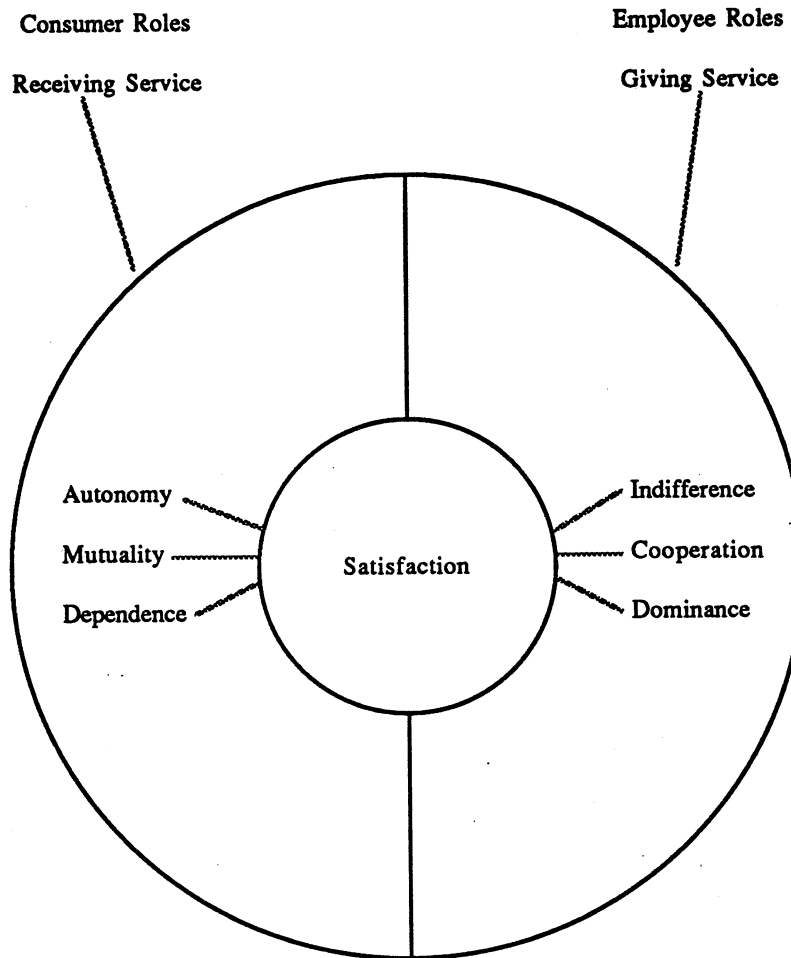

The Consumer Role of Dependence

One experiential role for some consumers is being dependent while receiving service. The theme of dependence arose during informants' discussions of consuming a service in which they have limited knowledge or expertise. The dependent consumer feels vulnerable and uncomfortable in the service setting and needs the service employee to provide guidance and assistance during consumption as illustrated in the following interview excerpts:

"I felt more secure because I'm getting a service done that I have no idea about. He made me feel at ease like he was in control, like he knew what was going on. When you don't know anything about something you want to feel that way. You know like a doctor should make you feel that way. It's the same kind of thing." (wf, early 20s)

"When you buy a tennis racket there's a lot of stuff you want to know. At first I was nervous to ask this guy. He's a pro. What if I ask him a

FIGURE
An Experiential Portrayal of Service Encounters

stupid question. Will he think I'm an idiot or something. I didn't want to ask him any questions. Then he started talking to me, explaining about the tension of the racket, stuff like that. He made me feel more comfortable right away. It makes you feel more comfortable to ask questions." (wm, early 20s)

The dependent consumer wants the employee to take an active role and participate in his/her service experience. The dependent consumer particularly values the three dimensions of service quality - responsiveness, assurance, and empathy - that are strongly affiliated with the service employee's role in the service delivery process. In the preceding passages, service satisfaction is judged by the service employee's ability to respond to the needs of the consumer and facilitate the consumption experience. The employee is expected to not only help the consumer by providing knowledge about the service, but also must be reassuring and empathetic to make him/her more comfortable and at ease in the setting.

The Consumer Role of Autonomy

In contrast to the dependent consumer stands the autonomous consumer. The theme of autonomy was revealed most frequently in informants' descriptions of shopping in retail stores, where they indicated a desire to be on their own while shopping for clothing. Self service is an essential and desired part of their consumption experience.

The following interview excerpts illustrate autonomy:

"When I'm shopping I like to look on my own and not feel like there's someone looking over my shoulder. Some people like attention and help, but I personally don't. I like to look on my own. I like to look for bargains or sale items. I can't go in there and buy whatever they show me." (wf, early 20s)

"I don't like to be crowded. If I'm going to a clothing store where I know what kind of clothes I like, I don't like someone around me who's like, oh this will look good on you,

because I know what's going to look good on me and what I like." (wf, early 20s)

The autonomous consumer wants independence—to be free to make decisions and choices on his/her own. The consumer knows what he/she likes to buy and shopping becomes a personalized experience where the consumer is in control, freely moving throughout the store, devoid of any outside interference. An autonomous consumer expects employees to be responsive to his/her desire for independence by backing off and giving the consumer space to shop, although the employee should stay on the periphery and be ready to serve if needed. The autonomous consumer may need employees to perform procedural tasks, such as opening a fitting room or ringing up a sale.

This view of responsiveness differs sharply from Parasuraman et al. (1988), who describe responsiveness as the employee's willingness to help consumers and provide prompt service, suggesting a proactive and highly visible position in the service setting.

The Consumer Role of Mutuality - The Employee Role of Cooperation

The emergent themes of mutuality and cooperation are discussed together to emphasize their close interrelationship. It is difficult to tease apart differences in the meaning of mutuality and cooperation since the two themes flow together within the interview dialogue. Mutuality represents the consumer's role in the service encounter, while cooperation describes the service employee's role. The themes of mutuality and cooperation emerged for the most part while informants were describing satisfying service experiences. Consumers received their desired service with the mutual cooperation of the service employee. The service encounter takes on an air of synergy and coordination as exhibited in the following two passages:

"It's satisfying because of the interaction by the waiters. They make the fondue at the table. They explain all the different ingredients that they are putting in there. It makes you feel important since they're taking the time to talk to you. It's the interaction rather than at a place where they just come and take your order and then come back with your food." (wf, mid 20s)

"I went to a car stereo place. The person there like totally helped me. I could tell he wasn't just trying to get me to buy the most expensive one. He was looking for what I wanted. He didn't immediately start showing me top of the line things. He said, what was it about your old car stereo that you liked? What features were the most important to you? That made me feel comfortable that he was not just trying to make a buck. He was really looking to get what I wanted and needed." (wf, early 20s)

These passages reveal a sense of care and concern for the consumer by the service employee. The consumer is given a sense of status and importance that results from the service employee's treatment. The relationship moves beyond the mere interaction of consumer and service employee to a mutual process of human cooperation and coordination. The roles of mutuality and cooperation may come closest to representing the ideal of service quality. Consumers and service employees understand their roles and work together in giving and receiving service. Informants' satisfying experience arose from interacting with employees who were responsive, assuring, and empathetic while providing service (Parasuraman et al. 1985, 1988).

The Employee Role of Indifference

The theme of indifference describes service employees who are disinterested in giving service. The term service employee is a misnomer since the person is on the job, but is barely doing his/her job of serving consumers. Consumers often need these employees to provide assistance, information, or solutions to problems as illustrated by the following interview excerpt in which the informant had received an incorrect airline ticket through the mail and was attempting to resolve the problem over the telephone:

"When I spoke with the travel agent she wasn't nice at first. At first she seemed kind of mad and she was kind of silent on the phone. She was doing something with her computer and she didn't really say anything. I didn't think the problem would be resolved. She never said anything until I asked her. She wasn't very accommodating since it was more like I was asking the questions. I was trying to figure things out more than she was. She just said, oh and then she just got silent. I didn't know what she was doing or anything like that. If she had just been a little bit more reassuring. If she had talked a little bit more." (wf, early 20s)

Instead of facilitating the service delivery process, indifferent employees complicate the situation. The employee is insensitive to the needs of the consumer and conducts his/her business in a very impersonal manner, disregarding the human element of the service encounter.

The following passages further illustrate employee indifference:

"I know I'm pretty much dissatisfied with a lot of places because a lot of the people are just standing around talking and they're not doing their job. When I walk into a store I expect to be acknowledged. I expect them to at least say hi, how are you doing? Do you need any help or anything? Then I can let them know if I need any help or not. If I'm not acknowledged that's a turnoff. Most of the time I'll just walk out because they should be there to help me. They should be happy that I'm there." (wf, early 20s)

In this situation indifference is evidenced by a lack of attention and courtesy to the consumer before she has experienced the tangible aspects of the environment. The indifferent employee can affect a consumer's service experience regardless of the consumer role assumed. A dependent consumer will expect help throughout his/her service experience, while an autonomous consumer who prefers to look for clothing on his/her own will be dissatisfied if he/she can not make a purchase because the cash register has been left unattended.

The Employee Role of Dominance

The emergent theme of dominance is used to describe the over zealous service employee who gives "too much" service, to the point of creating a dissatisfying service experience. The service employee has crossed the consumer's perceived threshold of service attention and responsiveness as expressed by two informants:

"Always going by, but not necessarily asking you if you need anything, but going by so if you need to ask them for something, you can get it. It's also overkill if they're asking you too often. There's a fine line there when they are helping too much or not helping enough. Somewhere between those two they need to be." (wm, early 20s)

"I don't like it when people are over polite to me, but at the same time I want them to respect me for going to their service. Just be conscientious, that customers are people and that they're serving people and that's their job. They should be respectful and nice, but they don't have to be overly going out of their way. Because that can also make me feel uncomfortable." (wf, early 20s)

Both of these experiences occurred in restaurants, the predominant settings for the emergence of employee dominance. The waiter/waitress can be termed the "pesty" employee who will not go away and would like to take a seat and join the consumer for dinner rather than giving service. The service employee no longer gives good service, but hinders service delivery through inappropriate behaviors that may not be apparent to him/her. The actions of the service employee could be characterized as "consuming the consumer" in his/her endeavor to provide what is thought to be good service and dominate the service setting.

"I think when they check back with you too often and they have to be all flowery about everything, I think that's a turnoff. We're there to eat and I'm not there to socialize with my waiter. I really felt like he was interrupting us all the time. We'd be in a conversation and he'd come up or we'd be taking a bite out of our sandwich and he'd come on up. He was always there, running back, checking on us. Kind of

like he was hovering, watching us." (wf, mid 20s)

This last passage reveals that the service employee may believe that consumers will equate increased attention with good service and make additional purchases in a store or leave a larger tip. Employee dominance may result from pressure from management to increase sales, especially in a commission based sales job, and it also raises the question of how adequately the employee has been trained in providing service quality. Perhaps the employee was told no more than to be friendly or check often on your customers' tables, leaving it to the employee's discretion to determine the meaning of "friendly" and "often".

DISCUSSION

The emergent themes of autonomy - mutuality - dependence and indifference - cooperation - dominance provide an interpretive first-person understanding and description of the roles assumed by consumers and employees in the service encounter. The service encounter is a dynamic process that for the consumer is much more than a static exchange of money for a particular service. Interpersonal roles are at play that influence consumer satisfaction. The compatibility between consumers and service employees' interactive modes is a strong precursor to judgments of satisfaction. None of the twenty-eight informants described their service experiences without at least some mention of the service employee, reaffirming the notion that the service employee is an integral part of the service delivery process (e.g., Bitner et al. 1990; Parasuraman et al. 1985, 1988).

Limitations and Future Research Needs

The main limitation of the study is that most of the informants' service experiences occurred in restaurants and retail stores. Although these two settings are prominent service industries, further research is needed to determine if the emergent role themes identified in this research are found across different service settings. The amount of employee involvement required to provide the service may affect the roles consumers' assume and their accompanying expectations of employees' roles. The restaurants and retail stores discussed by informants are settings where a tangible product is exchanged and interaction with employees occurs on an intermittent basis. Future research should examine service settings where the focus of the service is more intangible and employee interaction is a more significant part of the service experience.

While this research identifies the roles consumers and employees assume in restaurants and retail stores, further research is needed to develop a model of how roles develop contingent on situational and individual factors. Consumer knowledge is one factor that emerged from informants' descriptions of their service experiences that influences consumer roles and their expectations of employees' roles. Research currently being conducted by the author indicates that store loyalty and goals while shopping

(i.e., looking for a specific item, browsing, shopping for fun) may also affect consumers and employees' roles.

CONCLUSION

This research offers a finer grained understanding of the interactive roles that consumers and employees perform while in the service environment and reveals that consumer satisfaction develops not only through the expectations consumers have about employees, but also through the expectations that they have for themselves. Past research on the service encounter has focused almost exclusively on employee behaviors during the service delivery process. The emergent role themes identified in this research give insight into an overlooked aspect of service quality research, *the way consumers want to participate in their service experiences*. In addition, the emergent roles form a basis for building role theory into the understanding of consumer service satisfaction. Consumers see themselves as active participants in their service experiences and view the service encounter as a dual process. Consumer roles are lived out during the service encounter and service satisfaction develops during the interaction between consumers and employees.

This research extends the service quality research of Parasuraman et al. by indicating that the interpersonal dimensions of service quality are not outcomes of the service firm, but instead arise during the interaction between consumers and service employees. Consumers have expectations about their own roles, and thus service firms can not just tell employees to be responsive, assuring, and empathetic. Employees must live out these dimensions during the service encounter, in conjunction with the roles consumers expect to play.

Organizational Characteristics and Employee Excuse Making: Passing the Buck for Failed Service Encounters

Donna J. Hill, Bradley University

Robert Baer, Bradley University

Rustan Kosenko, Bradley University

ABSTRACT

When a service failure occurs customers will frequently look to front-line employees to seek redress or explanations. The manner in which these employees respond could have a significant impact on the customer's satisfaction and future patronage behavior. This paper looks at the response of employees to customer's expressions of dissatisfaction in the context of excuse theory. Then, organizational characteristics are relied upon to suggest when conditions for one particular type of excuse behavior, deflection, is most likely to occur.

INTRODUCTION

Managing employees' reactions to customer's complaints is especially important in the services context where there may be not only a large number of product failures but where it becomes increasingly difficult to arrive at attributions for these failures (Adam, Hershauer and Ruch 1981). Since the production of most services entails some interaction between the service provider and the customer, there is increased difficulty in managing the quality of the outcome (Ziethaml, Parasurman and Berry 1985). Furthermore, people engaged in many services work in environments where many factors contribute to the service outcome. Since there are many ways to generate the service output, and there is a propensity for people to make mistakes, it is not unreasonable to expect a large number of errors in the production of services. When a service fails or an unsatisfying experience occurs, customers frequently complain to frontline employees. The manner in which the employee handles resulting customer's concerns could have a significant impact on customer impressions of the service and concomitantly, the firm itself (Booms and Nyquist 1981; Gronroos 1982; Schneider and Bowen 1985).

The employee may react by "passing the buck" back to the customer, other members of the firm, or even to outside forces. In this paper we (1) introduce excuse theory, (2) analyze organizational characteristics which are conducive to employee excuse making, and (3) volunteer propositions regarding organizational variables that are likely to forewarn the occurrence of employee excuse making.

CUSTOMER COMPLAINTS AND EXCUSE MAKING

When a customer voices a complaint to an employee, the employee can respond in at least one of three ways. First, the employee may volunteer to make restitution or correct the error. This is more likely to occur if a correctable error can be identified, such as undercooked meat in a restaurant. Second, the employee may ignore the complaint, by either

refusing to obtain complete information, denying that any problem exists or by negating the customer's right to restitution (e.g., an auto mechanic who tells a customer that nothing is wrong with the squeaky car). Third, the employee may provide an excuse in an attempt to explain or justify their behavior. Although marketers have extensively studied the first two options (e.g., Singh 1988; 1990), they have devoted much less attention to employee excuse-making.

Recently, however, the psychology literature has shown an interest in the topic of excuse making (Kernis and Grannemann 1990; Shaver 1975; Shaver and Drown 1986; Snyder 1985; Snyder, Higgins and Stucky 1983; Snyder and Higgins 1988; Higgins and Snyder 1991; Teneen and Affleck 1990). The most comprehensive excuse theory has been presented by Snyder et al. (1983). Revised recently (Higgins and Snyder 1991), they define excuse making as "the motivated process of (a) diminishing the perceived negativity of esteem threatening outcomes and (b) shifting the causal attribution for negative outcomes from sources more central to the person's sense of self to sources that are relatively less central" (p. 85). Their writings show that people have an entire repertoire of excuse-making strategies that they may invoke when acts or outcomes reflect poorly on them. In this paper we examine one prevalent type of excuse--the tendency to avoid blame by denying one's own responsibility. In its simplest form, this type of excuse may merely entail a "I did not do it". However, this excuse strategy can be greatly enhanced by pointing the finger at another possible culprit as the cause of the problem, that is, by shifting responsibility toward some other potential cause. We have termed this phenomenon "deflection," more commonly known as "passing the buck". We define deflection as the motivated process of shifting responsibility for a bad act or outcome away from oneself toward another source. This is a major theme of excuse theory and is also predominant in Snyder, Stephan's, Rosenfeld's (1978) theory of attributional egotism as well as Shaver's (1975) theory of defensive attribution. These works indicate that when people are faced with what others would consider a negative appraisal of their character or abilities, they will attribute the failure not to their own shortcomings--as would objective observers--but to factors beyond themselves. In this paper, we examine deflection in the service encounter.

The basic motivational process in excuse making is one of seeking distance from negative acts or outcomes. Higgins and Snyder (1991) describe two appraisals which are made whenever one is confronted with negative information that is discrepant from their current view of themselves: (1) a linkage-to-act appraisal representing the degree to which the individual perceives him or herself to be linked (from

no linkage to total linkage) to a particular act or outcome and (2) a valence-of-act appraisal representing the individual's qualitative assessment of the positiveness of the act or outcome (from positive to negative). Excuse making motives are stimulated whenever an individual perceives him or herself to be linked to an act or outcome that is perceived negatively. Of the multitude of excuses possible, all of them serve the function of either reducing the perceived negativity of the event or reducing the individual's perceived linkage to the act. Deflection serves this latter function. Individuals who attempt to "pass the buck" are seeking to minimize the extent to which they are perceived as linked to the negative event. Employees can seek to divert responsibility to a number of possible sources including the customer, one's supervisor, company policies or even unavoidable external circumstances.

Excuses provide a useful role in our society (Higgins and Snyder 1991). If honored (accepted) by the customer, they have the ability to shore up a fractured situation. Excuses can prevent conflicts from arising by verbally bridging the gap between promise and performance, between action and expectation (Scott and Lyman 1968) and thus, they can mitigate consumer displeasure over a service encounter that does not meet expectations. If the excuse is honored, we may say that it was efficacious and that equilibrium was restored: An honored excuse will restore the status quo ante. To the extent that an excuse is honored, ramifications exist for post-purchase attitudes, future complaining behavior and repatronage activities. For example, Bitner (1990) has shown that when an employee places the blame on something or someone other than him or herself or the firm, that excuse is likely to lead the customer to believe that the firm had less control over the failure than when the employee either implicates himself or the firm. Other investigators (Folkes 1984a, 1984b; Folkes, Koletsky and Graham 1988; Krishnan and Valle 1979) confirm that the type of excuse or explanation offered will affect customer perceptions of and reactions to the situation.

Although sometimes useful, deflection can also be harmful to the organization. What sometimes arises is a massive game of finger pointing in which no one takes responsibility for a poor service outcome. "Passing the buck" may be detrimental to the organization for at least three reasons: (1) customers may become irritated by a system that does not take responsibility for itself, (2) although individual employees may succeed in deflecting responsibility from themselves, responsibility may simply be diverted to another part of the organization, resulting in no mitigation of organizational responsibility in the eyes of the consumer, and (3) organizations or individual employees who are involved in buck passing may fail to capitalize on a valuable source of consumer information. Systematic problems may go unnoticed, problems go unsolved, and customers go unserved. Customers should be encouraged to complain so that problems can be addressed and corrective action taken (Sellers 1989).

It is the major contention of our paper that rather than allowing employees to haphazardly (inconsistently) handle complaints in their own manner, they should be trained to handle complaints in a systematic manner; one detailed, disseminated and controlled by the firm. As a result, management should be cognizant of the excuse making activities of their employees and of the organizational variables which are most conducive to such behavior. By effectively managing their employee's excuse behavior, firms are more likely to influence the outcome of the complaint process. The ultimate objective of managing employee excuse making activity is not for the firm to deny responsibility for the service failure or for the firm to avoid correcting the mistake but, rather to handle the customer's complaint in such a manner as to reduce customers' initial dissatisfaction and reestablish confidence in their perceptions of quality. These, in turn, should have positive word-of-mouth communications and repatronage behavior ramifications.

ORGANIZATIONAL FACTORS SHAPING EMPLOYEE DEFLECTION BEHAVIOR

Excuses are not necessarily false. They do, however, involve an interpretation of the events that led to a specific outcome. When there are few objective yardsticks regarding the "truth" of varying explanations of events and several alternative explanations may equally fit, then it is in this gray area that excuses flourish (Mehlman and Snyder 1985). Service organizations, to a varying degree, present conditions that are in this gray area. That is, some service firms have characteristics which provide ample opportunities for employee deflection.

Front line employees should be able to deflect to the extent that their own contribution to the service failure is obscure. Obscurity can occur when there is more than one possible cause for a bad outcome and to the extent to which the cause of the bad outcome stemmed from ambiguous criteria or standards. The discounting principle (Kelley 1971) states that when there is more than one plausible cause for an outcome, the attribution to any one of those causes will be weaker than if one of those causes stands alone. Organizations are often structured such that there are potentially more than one cause for service failures. This makes organizations structurally evasive when it comes to responsibility taking (Snyder et al. 1983; Ogilvey 1977). Responsibility in organizations becomes elusive to the degree which (1) more than one factor (people or variables) was involved in causing the act or outcome, (2) any factor could have plausibly contributed to causing the negative event, and (3) the task and roles to be performed or the performance standards were structurally ambiguous to begin with. Structural evasiveness, in turn, should provide grounds that encourage deflection activity. In the next section we relate specific service and organizational characteristics to deflection behavior. Although it is recognized that many of these variables are inter-related, they will each be discussed separately.

Degree of Intangibility

The intangibility of services refers to both the absence of a physical referent as well as to the difficulty of mentally grasping the qualities or characteristics of the service. This results in what Bowen and Jones (1986) refer to as performance ambiguity (i.e., the difficulty in judging how well the service was performed as well as to the subjectivity of many of the performance standards). Performance ambiguity makes it difficult to measure the performance of different parties in the exchange and to determine the role that various factors played in contributing to the final outcome. Thus, performance ambiguity makes it difficult to establish the cause-effect relationship that produced the service. Consequently, to the degree that a service is dominated by abstract, intangible attributes, or to the degree that the tangible attributes are not easily evaluated, the employee may experience difficulty in assessing attributions for the failure or may hold an attribution only tentatively. Intangibility causes doubt regarding the number of plausible explanations towards which blame may be attributed by the employee and provides greater opportunity for employees to shift blame.

P1: Employee deflection activity will vary positively with the intangibility of the service attributes.

Degree of Inseparability

Inseparability refers to the simultaneous production and consumption of services. While the degree of inseparability may be determined by the type of service, it can also be controlled by management (Chase 1978; Lovelock 1983). In services characterized by a high degree of inseparability, there is considerable overlap between the core service operations and customer contact. Unlike with goods where the customer's main form of participation is the purchase act itself, with services the customer may also play a role in the service production. This role may be minute such as in situations in which the contact personnel simply acts as an intermediary between the customer and the core service provider, or it can be quite extensive such as when the contact personnel is actually the core service provider and when consumption and production of the service occur simultaneously, e.g., health and beauty care. In many services characterized by a high degree of inseparability, feedback from the customer determines the selection, combination and order of service delivery, thus furthering the customer's involvement in the service production. To the degree that the customer participates in the service process (inseparability), then he or she becomes a plausible source of blame should the service performance fall short of expectations. A high degree of inseparability provides opportunities for the employee to shift blame toward the customer.

P2: Employee deflection should be positively related to the degree of service inseparability.

Degree of Complexity

The complexity of a service is defined by the number and the intricacy of the steps required to perform it (Shostack 1987). According to Thompson (1967), the most long-linked services are those that are designed such that the customer contact personnel and the core service operations are totally separate from one another. This type of service usually involves a series of independent and discrete steps that can be performed by different intermediaries. For example, a customer's purchase of customized home decorating products is likely to entail a long delivery system that may include a salesperson, contractor, decorator and installer. The dissatisfied customer is likely to complain first to the last link in the chain. However, in a series of deflection strategies by the various workers involved, blame can be shifted from one source in the link to another, i.e., the installer blames the decorator who, in turn, blames someone else. In complex services such as this, many different people and factors contribute to the service outcome. Thus, service failure can be caused by a number of different variables, providing a large number of plausible explanations upon which the employee can rely.

P3: Employee deflection activity will vary positively with the complexity of the service.

Duration of The Service Delivery Process

The longer it takes for service delivery to be completed, the more likely it is that customers will require information on work in progress-- such as estimated completion dates, quality of on-going tasks, projected costs, and so forth. This increases the number of contacts as well as enhances the likelihood of an employee to engage in deflection activity. Moreover, the longer the duration of the service delivery then the more opportunities for mistakes or poor service to occur with a subsequent increase in plausible sources for the mistakes.

P4: Employee deflection activity will vary positively with the length of the service delivery process.

Role Conflict

The role attached to any position in an organization represents the set of behaviors and activities to be performed by the person occupying that position (Katz and Kahn 1978). The role is defined through the expectations, demands, and pressures communicated to employees by individuals (e.g., top managers, immediate supervisors, customers) who have a vested interest in the manner in which employees perform their job (Katz and Kahn 1978). One particularly relevant type of role conflict is the perceived clash between expectations of customers and expectations of the organization as understood by employees (Kahn, Wolfe, Quinn, Snoek, and Rosenthal 1964; Rizzo, House, and Lirzman 1970). Because contact employees are the links between the company and the customer, they

must satisfy the needs of both. Conflict can even occur over how problems are to be resolved. For example, several writers (Blau and Scott 1963; Bar-Yosef and Schild 1966; Katz and Danet 1973) have pointed out that organizations normally require universal and specific treatment of clients while the client expects the service-giver to consider their special case and to treat them as a whole person. Shamir (1980) has referred to this as "The Two Bosses Dilemma."

Role conflict may occur when employees are expected by customers to perform a service for a customer on time (deliver the pizza to the table within 15 minutes of ordering) and are also expected by management to collect money, clear tables, keep orders straight, etc. When a customer expresses dissatisfaction the employee may respond by shifting blame to other customers ("We are extremely busy tonight") or to "back-room" personnel ("The kitchen mixed up your order").

Role conflict can also be generated for employees through excessive paperwork or unnecessary internal roadblocks. For example, retail clerks who must complete numerous and time-consuming forms for each return or exchange no matter what the price or reason, may experience role conflict if other customers are waiting to be served. Complicating the issue is that the other customers in line may become irate and complain (which leads to a potential to engage in deflection behavior) and or leave the store. Additional conflict may also be generated by the reality that the clerk may be measured -- and rewarded--on the basis of selling achievements without regard to how well they handle a customer returning merchandise. Such situations are more likely to lead to increased usage of deflection strategies because the unclarity regarding the appropriate tasks to be performed permits the employee to divert responsibility by drawing attention to the fact that they were effectively fulfilling their other role. This shifts blame toward the sources of role conflict.

P5: Employee deflection activity will vary positively with the amount of role conflict.

Role Ambiguity

When employees do not have the information necessary to perform their jobs adequately, they experience role ambiguity (Katz and Kahn 1978; Walker, Churchill, and Ford 1977). Role ambiguity may increase deflection activity because the employee does not have a clear understanding of their own (or other parties to the service process) responsibility in affecting the service delivery. Thus, when service failure occurs, it is unclear with whom responsibility for the failure should be most directly linked. This may be especially true if other policies and procedures are in place which dictate or constrain behavior in such a way as to prevent causal resolution.

P6: Employee deflection activity will vary positively with the amount of role ambiguity experienced.

Span of Control

Span of control refers to the number of employees reporting to a single manager (Ouchi and Dowling 1974). The wider the span of control, the less potential there is for control over the employee and the greater the individual responsibility and initiative among employees' (Child 1984; Worthy 1950). Employees are more likely to use their own discretion in influencing blame with wide spans of control. Moreover, employees can evade responsibility to the extent that they are managed by a supervisor who must also direct many other employees.

P7: Employee deflection activity will vary positively with the size of the span of control in the organization.

In summary, it is hypothesized that organizational variables that encourage employees to evade responsibility exert a powerful force on employee excuse-making behavior. An organizational characteristic such as span of control can lead the employee to engage in excuse behavior that is detrimental to the firm and customer satisfaction. Organizational variables such as role conflict and role ambiguity can lead the employee to make excuses that lessen the blame on themselves but shift it to other sources in the firm. Several organizational variables that we have discussed are interrelated. Intangibility, duration of the service delivery process, and complexity of the service are all likely to influence role ambiguity. Likewise, wide spans of control can lead to more role ambiguity as well as role conflict (Chonko 1982). The interdependence of these variables will complicate this process by either magnifying or diluting the effects of these variables.

CONCLUSIONS

Excuses are a common part of our everyday lives. They appear in a wide variety of situations including the work environment and they can have a major impact on customer perceptions of service quality and satisfaction. If the customer honors the excuse, it is much more likely that the gap between what happened and what should have happened will be bridged. The excuse provides a causal explanation that if plausible, restores customer faith in the service. However, if the excuse is not honored, and then the employee and customer disagree about who or what is to blame, customer perceptions of service quality and customer dissatisfaction are likely to be impaired. Deflection behavior may be unethical if the excuse is false or misleading. Additionally, deflection behavior may result in the the loss of valuable information if the customer is dissuaded from pursuing their complaint. Thus, deflection behavior and its consequences should be of concern to marketers. We have argued that certain organizational characteristics

should act like warning signs for potentially unmanaged deflection activity and should signal to the manager that steps should be taken to ensure that employee excuse-making is effectively managed. If the complaint process is to be strategically managed, then it becomes essential to know when excuse making is most likely to occur.

The theoretical framework advanced in this paper provides a rich environment for research. Obviously, empirical investigations of the propositions presented need to be conducted. Such investigations would necessarily involve a classification scheme of service industries that explicitly considered intangibility, inseparability, complexity, and duration of service delivery. Because inseparability is frequently a strategic variable, a central issue for managers centers around understanding the customer-employee interface and its management. The questions of how employees handle the service failure process and how the service firm can optimize the outcome should assume importance in the marketing process and represent important concerns for consumer behaviorists.

A second area to investigate is the impact of deflection activity on both the customer and the employee as it pertains to different deflection targets. Although this issue has been addressed previously (Bitner 1990), a full classification scheme of deflection targets has not been addressed. For example, what are the ramifications of deflecting vertically within the organization or externally to another agent? To what extent does the customer differentiate between the contact person and the other members of the firm and what are the ramifications of distinguishing between them? Clearly, employees frequently offer such excuses ("I'm sorry for the error. We're training a new clerk and it's his first day on the job," or "We subcontract that part of the job out and I have no control over what they do"). But should employees "pass the buck" and to what extent does such deflection activity moderate the resolution outcome for both the employee and the customer?

Other areas could be addressed as well. For instance, research in deflection activity could help managers determine the type of personnel selection and training programs which can lead to successful deflection outcomes, as well as the impact of successful/unsuccessful deflection activity on customer and employee retention. Other variables not directly discussed in this paper could also be investigated. For example, how does deflection activity differ between experienced and inexperienced employees or between part-time and full-time employees? What role does advertising play in this process? Finally, how does deflection activity impact the customer's and the employee's perception of service quality? In an increasingly complex and competitive environment further elaboration of the process occurring among the employee, the customer, and perceived service failure needs to be developed and their implications clearly outlined.

Health Promotion Services Consumption: Involvement and Program Choice

Nora J. Rifon, Michigan State University

Brian E. Mavis, Michigan State University

Elizabeth Tucker, Michigan State University

Bertram E. Stöffelmayr, Michigan State University

ABSTRACT

This study examines consumer involvement as a predictor of employee decisions to enroll in worksite health promotion programs. The research extends the application of the involvement construct to the area of the consumption of services, and contributes to the validation of Zaichkowsky's (1985) Personal Involvement Inventory. A short form of the PII is developed specifically for use in adult, non-student populations, and is used to effectively differentiate among employee health promotion program choices.

INTRODUCTION

The conceptualization and scaling of involvement has been of interest to consumer researchers since the concept's introduction to consumer behavior almost three decades ago (Krugman 1965). As the concept and its measurement have evolved, issues related to the dimensionality of the construct and appropriate strategies for the measurement of involvement have been debated in the literature (Higie & Feick, 1989; Jain & Srinivasan, 1990; Laurent & Kapferer, 1985). Nevertheless, there is a consensus among many researchers that the essence of involvement is perceived personal relevance (Celsi & Olson, 1988; Higie & Feick, 1989; Krugman, 1967; Petty & Cacioppo, 1979; Zaichkowsky, 1985).

Zaichkowsky (1985) has developed a measure of involvement based on its definition as perceived personal relevance. The Personal Involvement Inventory (PII) was designed to be generalizable across people, objects and situations. The research reported here illustrates and further validates the use of Zaichkowsky's (1985) PII for the measurement of an individual's involvement with a service category in a non-traditional consumer situation. In addition, this paper describes the development of a shortened version of the PII for use in adult, non-student samples. Further, as researchers and providers in the area of worksite health promotion, we examined involvement's capacity to predict an individual's participation behavior in one of four worksite health promotion programs (smoking cessation, weight/nutrition management, stress management and exercise/fitness).

BACKGROUND

Zaichkowsky (1985) addressed the conceptualization and measurement of involvement, independent of its behavioral consequences. She defined involvement as "a person's perceived relevance of the object based on inherent needs, values and interests" (p. 342). Celsi and Olson (1988) further explicate involvement as essentially perceived personal relevance. Perceived relevance is a function

of a consumer's perceptions of his/her needs, goals and values and their congruence with the consumer's knowledge of the product category. "More specifically, the personal relevance of a product is represented by the perceived linkage between an individual's needs, goals and values (self-knowledge) and their product knowledge (attributes and benefits)" (p. 211). The greater the perceived linkage, the stronger the feelings of personal relevance of the product category.

It has been suggested that an individual's level of involvement affects product-related information searching and decision-making (Engel, Kollat & Blackwell, 1978; Bettman, 1979), as well as his/her processing of persuasive communications and resultant attitude change (Petty & Cacioppo, 1986).

Using involvement to explore employee relationships with worksite health promotion programs will advance the study of employee participation in several ways. It will provide practical information for program providers as well as basic information for theory development. A primary goal of health promoters is to increase participation in worksite health promotion programs. Studying involvement will increase the health promoter's understanding of the factors influencing the decision-making process of those individuals choosing to participate or not participate in the programs. Ultimately, involvement could be used as a segmentation variable, particularly for the development of appropriate promotional messages for the varied target audiences.

In addition, using involvement to profile the target audience's perceived relevance of health promotion programs would add a valuable consumer dimension to the study of participation in health promotion activities. Research on participation in worksite health promotion programs has provided little insight regarding an individual's decision to participate in programs, and has been dominated by a medical perspective for profiling and targeting audiences.

In a review of the literature on worksite health promotion programs, Conrad (1987) concluded that "participants seem to be a self-selected, somewhat healthier group of employees" (p.318). A more recent, but unpublished review of the participation literature suggests that there are few variables consistently found to be related to participation. From among 40 variables reported in 21 studies, only self-efficacy, smoking status and education level consistently distinguished between participants and non-participants (Mavis, Stachnik, Gibson & Stöffelmayr, unpublished manuscript). The self-selection process has been troublesome to health promoters, since individuals who participate are not

the individuals who exhibit the most health-related need.

This research investigates an individual's perceived relationship with worksite health promotion services by measuring the individual's involvement with the specific programs offered. In contrast to the traditional approach of health risk profiling, we hypothesize that involvement levels with the health promotion programs will differentiate audiences for a variety of programs.

Measuring Involvement

Involvement was defined as an individual's "perceived relevance of the object based on inherent needs, values, and interests" (Zaichkowsky 1985, p. 342). The scale used to measure involvement was Zaichkowsky's (1985) 20-item semantic differential Personal Involvement Inventory (PII), which has been shown to have reliability and validity.

Unlike previous studies which have used the PII to study involvement using primarily student-based samples (Celsi & Olson, 1988; Jensen, Carlson & Tripp, 1989; McQuarrie & Munson, 1987; Zaichkowsky, 1985; 1987), this research examined involvement levels in one adult sample of employees, and one adult sample with some graduate students. Since we were primarily interested in the adult sample, we were concerned about the appropriateness of the PII when used with groups other than students. We decided to systematically modify the scale for future use in an adult, non-student population.

These concerns appeared to be well-founded. McQuarrie and Munson (1987) commented on the syllable count of some of the words used in the scale, noting "in general, the syllable count for the PII seems uncomfortably high" (p. 37). In addition, when the present researchers pretested the scale, feedback from participants indicated that the length of the scale would prohibit its usage more than once in a sitting. In fact, some respondents reported that one presentation of the scale was "annoying". We thought it necessary to shorten the PII by eliminating problematic items, while maintaining the scale's integrity.

Research Objectives and Contributions

The initial objective of this research was to examine the utility of involvement for the study of employee participation in worksite health promotion programs. However, given the previously mentioned considerations, the development of a short version of the PII for use in non-student samples became another objective of the research.

The results reported in this paper focus on the measurement of involvement. The study tests the factor structure of Zaichkowsky's (1985) 20-item scale with an adult, non-student sample, in response to a service rather than a product. In addition, the short version of the scale was developed based on the data from one sample of subjects and then cross-validated in another sample to assess its criterion-related validity against a behavioral outcome measure obtained two months after the scale was administered.

PII MODIFICATION

The rationale for the modification of the PII was based on meeting the following objectives:

1. the development of a 10-item version of the PII to minimize respondent annoyance and fatigue when the scale is used in a repeated measure situation;
2. the identification and elimination of scale items which may prove problematic to some subjects as a function of their level of education;
3. the minimization of redundant items (McQuarrie & Munson, 1987); and
4. the maintenance of the factor structure established by Zaichkowsky (1985).

Problematic items were identified using missing value data and reading levels associated with the words used in the scale. One sample of subjects was used to generate missing value data and the factor structure of the full PII scale. A second sample was used to evaluate the shortened version.

The Health Promotion Services Package

The services subjects rated were a package of health promotion programs available through the university. Four behavioral modification programs, stress management, exercise/fitness, weight control and smoking cessation were available to units requesting the service. Employees could participate in programs free of charge, however, the unit administrators incurred fees to cover the costs of programs. The programs consisted of supervised, group, weekly meetings and continued over the course of fifteen weeks.

Missing Value Data: Sample I

All of the employees with offices located in the administration building of a major midwestern university were used as subjects in this part of the study. Since the health promotion programs were offered to the employees of an entire building or "worksite" at one time, the design required that all employees within the building be eligible for participation in the research. At the time of this study, the administration building had been targeted for the next series of health promotion activities.

As a part of a larger research project, the 20-item involvement scale was included in a survey distributed to the sample via intracampus mail. The survey was a pre-intervention measure, used to obtain baseline measures of health-related psychographic variables, as well as demographic profiles. A total of 287 useable surveys were returned; this represents a 57.3% response rate. The characteristics of the respondents are listed in Table 1.

Each participant was asked to rate one of four health promotion programs using the 20-item involvement scale. The four programs were weight management, exercise, smoking cessation, and stress management. Pre-testing the survey led us to believe that asking subjects to rate more than one program

TABLE 1
Demographic Characteristics of Sample I Survey Respondents

<u>Characteristic</u>	<u>Males</u>	<u>Females</u>
Sample Size	77 (26.9%)	209 (73.1%)
Age (Mean Years)	43.3	39.5
Median Years	42	40

MEAN	28.8	2.8	13.3	12.7

would severely reduce our response rate, and possibly create respondent fatigue, boredom and response bias.

Respondents were categorized into three employee groups: faculty, supervisors, and clerical-technical support staff. The frequency of missing values for each of the 20 items were tabulated separately for each employee group. Table 2 lists the items in ranked order based on the total missing values across all three employee groups. The number next to each word pair indicates the order of presentation of

the word pair within the scale. Figure 1 graphically depicts the pattern of missing values for each employee group and for the total sample.

Certain word pairs were unanswered more often than others; faculty had the lowest rate of missing data across all items compared to the two other employee groups. The pattern of missing data suggests that the education level of the respondent was related to successful completion of the Personal Involvement Inventory.

FIGURE 1
Frequency of Missing Responses for Each Word Pair

Another possible contributing factor is subject fatigue. The data in Figure 1 do not suggest any overall fatigue in the response pattern, although a possible interaction with level of education is evident. Little or no evidence of a fatigue effect, as indicated by an increased frequency of missing items tended to be found for faculty. The frequency of missed items tended to increase among the responses for supervisory staff, whereas the clerical-technical staff patterns show the clearest evidence of possible fatigue.

Grade Level for Personal Involvement Items

The *American Heritage Word Frequency Book* reports the results of a survey of over 2,000 public, private and parochial schools, 10,000 texts and 5 million words, for the frequency of word usage by grade level. The information provided in the report indicates the modal grade level at which the words are presented to students. In order to assess the reading level of the involvement scale, the grade assignments provided by the word frequency book were determined for the word pairs comprising the scale.

Table 3 displays the grade levels associated with the words in each word pair for the 20-item involvement scale. The word pairs are listed in the same order as in Table 2, representing their ranking based on missing values. The average grade level associated with the scale is 6.13, the median grade level is 7, and the grade level ranges from second to twelfth grade.

Factor Analysis

The data used in the factor analysis included all 287 subjects' responding to the four different health

promotion programs. The results of the factor analysis for the 20 items comprising the scale, using varimax rotation, are reported in Table 4.

The first factor explained 63.6% of the total variance; the amount of variance explained by the second factor was 7.0%. All of the items loaded positively on the first factor. The residual factor consisted of four items with higher loadings on the second than the first factor. The word pairs comprising the residual factor were boring/interesting, unexciting/exciting, mundane/fascinating, and appealing/unappealing. The two-factor solution was comparable to that reported by Zaichkowsky (1987), with the same items loading on the residual factor. The data validate the scale's factor structure, even when used to measure involvement with a service category not traditionally considered in consumer behavior.

THE SHORT FORM OF THE PII

A rational-empirical approach to scaling (Jackson 1970) was used to combine the information on the average reading levels of the word pairs, their missing value frequencies, and the factor analysis to select 10 items for deletion from the scale. Of the ten items with the highest missing value frequencies, eight were dropped. This effectively reduced most of the redundancy in the scale, and eliminated items with high grade levels such as vital/superfluous and mundane/fascinating. Of the items with the lowest missing value frequencies, two were dropped. The six items with highest missing values were eliminated. Of those six, three belonged to the second factor; consequently, appealing/unappealing (the remaining item on the second factor) was retained.

TABLE 3
Grade Reading Level for Personal Involvement Items

16. mundane	9	fascinating	7
14. unexciting	3	exciting	3
20. not needed	2	needed	2
12. vital	7	superfluous	12
13. boring	8	interesting	4
18. undesirable	7	desirable	9
10. uninterested	7	interested	4
17. essential	7	nonessential	9
11. significant	7	insignificant	8
19. wanted	2	unwanted	7
15. appealing	8	unappealing	8
9. matters	7	doesn't matter	7
7. trivial	7	fundamental	7
3. irrelevant	7	relevant	9
2. no concern	5	of concern	5
5. useless	3	useful	3
4. means a lot	3	means nothing	3
8. beneficial	9	not beneficial	9
1. important	3	unimportant	7
6. valuable	6	worthless	5

With six items eliminated, four items from the first factor were then identified for elimination. Congruent with McQuarrie and Munson's (1987) concerns that four of the items "seemed inappropriate for use with a non-college educated population", trivial/fundamental and significant/ insignificant were eliminated. Mundane/fascinating and vital/ superfluous had been already eliminated based on their overall missing values and reading levels. Significant/insignificant exhibited relatively high missing values and reading levels. Despite the fact that the overall missing value for trivial/fundamental was not in the top ten rank, it was more highly ranked for the occupational group of staff people, who were likely to have lower levels of education than the other two occupational groups.

Using both the missing values and reading levels, wanted/unwanted and beneficial/not beneficial were the last two items eliminated. Wanted/unwanted had the highest missing values of the items remaining (not including essential/nonessential) and beneficial/not beneficial had the highest reading levels. (Essential/nonessential had been retained since other items with similar meanings, such as not needed/needed, and trivial/fundamental, had already been eliminated.)

The final shortened version retains one item from the residual factor (appealing/unappealing) and nine items from the main factor. The items in the shortened version of the PII are uninterested/ interested, essential/nonessential, appealing/ unappealing, matters/doesn't matter, irrelevant/ relevant, no concern/of concern, useless/useful, means a lot/means nothing, important/unimportant, and valuable/invaluable.

The reading level information on the original and short forms of the scale are presented in Table 5. The average reading level of the shorter version is less

than that of the original; this change is not statistically significant ($t(58) = .502$). However, the highest grade level associated with the scale has been reduced from twelfth grade to ninth grade.

The data from the original sample were rescored based on the new 10-item short form of the scale. The correlation between the original and short forms of the scale was .98. The internal consistency estimates for each version of the scale, using Cronbach's alpha, were comparable. Alpha was .968 for the full scale and .946 for the short scale. A comparison of the distribution of the scale scores for the administration building sample are provided in Table 6.

Sample II

The short version of the PII was administered to a second sample of subjects. The 268 subjects were faculty, staff and graduate students in two academic campus buildings where health promotion programs were being offered. Subjects were asked to provide ratings of personal involvement for each of three programs: weight management, stress management and exercise programs. The demographic profile of the this second sample is displayed in Table 7. In contrast to the characteristics of Sample I, Sample II consisted of more males than females, was somewhat younger, and contained graduate students.

Internal Consistency

Since subjects' responded on the short form of the PII for all three health promotion programs, Cronbach's alpha was calculated across subjects' responding for each program. The scale exhibited high internal consistency for all three programs; the short form PII alphas were .946 for the weight management program, .945 for the exercise program and .952 for the stress management program.

Criterion-Related Validity

Six weeks after the short form PII scores were collected, program enrollment began. One might hypothesize that individuals who viewed health promotion programs as more personally relevant would be more likely to use the programs than individuals who viewed the programs as less personally relevant. In fact, individuals viewing a specific program, such as weight management, as more personally relevant than the other programs, would be more likely to use the weight management program rather than the stress or exercise programs.

Based on these speculations the following hypotheses were developed:

1. Program participants will have scored higher on the short PII in response to all programs as compared to non-participants.
2. Participants in the weight management program will have scored highest on the short PII in response to the weight management program as compared to their scores in response to the exercise and the stress programs.
3. Participants in the stress management program will have scored highest on the short PII in response to the stress management program as compared to the exercise and weight programs.
4. Participants in the exercise program will have scored highest on the short PII in response to the exercise program as compared to the weight and stress programs.

To test these hypotheses, the short form PII scores of program participants and non-participants were compared using a four group ANOVA with a repeated measure. A significant main effect of program enrollment (see Tables 8 and 9) confirms the first hypothesis; program participants exhibited higher short form PII scores than non-participants. Hypotheses 2, 3 and 4 were confirmed by the pattern

of short form PII scores and the significant interaction (see Tables 7 and 8).

Involvement and Program Choice

Other research on worksite health promotion program participation has indicated that self-efficacy, smoking status and education are related to participation. The findings on the relationship between smoking status and participation are somewhat tautological: smokers join programs on smoking cessation and non-smokers do not. Additional analyses were performed to determine the potentially confounding effect of education on program choice (self-efficacy was not measured in this study).

Education was not directly measured in this study so job level was used as a surrogate measure for education. A three group ANOVA (Faculty, Staff, Graduate Student) with a repeated measure (PII scores for the weight, stress, and exercise programs) produced no significant main effect of job level ($F(2,237)=1.17, p=.311$).

DISCUSSION

The data presented in this paper support the generalizability of Zaichkowsky's PII across situations and objects. The full form PII exhibited the same factor structure as reported by Zaichkowsky in 1985. However, the data also suggest that the PII may not be as generalizable across people. The education level of the subjects appears to be an important factor in assessing the applicability of the PII for measuring involvement in adult, non-student populations. The subjects in our study represented a broader range of adults than usually seen as respondents in studies on involvement; the supervisory and the clerical-technical staff exhibited a greater number of item omissions on the full form PII than the faculty in our sample. Indeed, the supervisory and clerical-technical staff exhibited a tendency towards response fatigue which may have indicated a greater degree of difficulty with the PII than experienced by faculty.

The short form PII provides an alternative measurement tool when education levels are an issue in the sample being studied. In addition, when more than one administration of the PII is desirable, the short form PII would lessen the likelihood of respondent fatigue. When involvement is measured in applied settings, rather than the laboratory, scale length is crucial particularly when it is included as one of a series of measures. In contrast to Zaichowsky's claim that a reduction in scale length would not affect ease of administration (1985, note 1), the results of this research suggest that scale length is important.

The results of this study provide a new direction for the study of health promotion. The relationship between the short form PII scores and enrollment behavior was especially encouraging, and the six week time delay between the collection of the PII scores and subjects' enrollment choices strongly supports the observed relationship. This finding may be useful to worksite health promoters for the planning and implementation of communication strategies. Individuals in this study enrolled in programs which appeared personally relevant to them. The traditional medical model approach to health promotion program enrollment ignores the perceived needs and desires of the employees and uses risk factors to assess the individual's need for a particular program.

Additional issues of scale validation arise regarding the generalizability of the finding that involvement is related to program choices. The results may be generalizable to other worksite health promotion situations, however, how do they relate to other types of brand choices? The specific worksite health promotion program offerings studied in this research have been viewed by the researchers as varieties of a brand. For some time the researchers have become acutely aware of the need to establish "corporate" image, brand name recognition and brand identity on campus. Marketing and communication

efforts have been incorporated into the structure of the overall health promotion plan; even a logo has been developed to enhance image and recognition. Nonetheless, worksite health promotion services constitute a wide product category and the domains of brands versus product categories remains unclear.

For instance, an alternative perspective is to view different programs as representative of different product categories. A weight management program can be viewed as a product category within which several brands are offered, including private labels such as Weight Watchers, and public sector brands, such as the one in this study.

The three programs offered in this study are all based on the same behavior modification theory and are structured in similar ways. In fact, one person with a need to lose weight could satisfy that need in an exercise program and one person with a need to reduce stress could do so in the exercise programs, as well. The different programs may satisfy the same need, but cater to different tastes for behavioral change. It is difficult to know how to classify the programs from a brand or category perspective, however, consumer perceptions may provide the necessary information for clarifying this point. Clearly, additional research is needed to further validate the use of the shortened version of the PII.

The area of worksite health promotion is increasing in its importance and individuals are coming in contact with such services on a more regular basis. Indeed, the commercialization of health promotion has dramatically grown in the past decade as evidenced by the increased number of advertisements promoting home exercise equipment, weight control programs, and diet/nutritional supplements. As the focus of health shifts from an illness perspective to a preventative and health maintenance perspective, these issues will become a more important part of the consumer's daily living and health services decision-making activities.

A Factor Analytic Investigation of Belk's Structure of the Materialism Construct

Seth R. Ellis, University of San Diego

ABSTRACT

Materialism has been identified as a potentially important dimension to further the understanding of consumer behavior. A series of articles, principally by Belk, has traced the development of a scale to measure aspects of materialism: possessiveness, nongenerosity, and envy. Belk implies that materialism may be a second-order factor composed of these traits, and possibly other unspecified traits. This research extends the study of the reliability and validity of the materialism construct through the use of confirmatory factor analysis on both the implied first-order and second-order congeneric factor models as well as on a congeneric composite model. All of the models tested did not meet the criteria for most generally accepted goodness of fit indicators. It is suggested that continued work is necessary to develop a set of unidimensional measures for the subscales.

Belk (1984) believes materialism to be a critical but neglected issue in consumer behavior. The materialism construct may be an important segmentation criteria during the 1990's, especially if there is a shift away from a monetary orientation and self-centeredness (Van Gorder 1990). Advertising has been condemned as a force promoting materialism as the means to happiness, status seeking, social stereotypes, shortsightedness, selfishness, and preoccupation with sexuality and conformity. But measures for materialism have not been available to assess empirically any of these charges (Belk & Pollay 1985; Pollay 1986; Lantos 1987).

In addition to the assessment of a possible causal link with a variety of social ills facing the modern world, measures for materialism may also be useful marketing tools in the quest for profitable segmentation strategies. Response functions for segments based on ranges within the materialism dimension may differ for various product types, product quality, and service quality.

Belk hypothesizes that materialism is composed of several traits including, but not necessarily limited to, possessiveness, nongenerosity, and envy. Possessiveness is defined as "the inclination and tendency to retain control or ownership of one's possessions (Belk 1983, p. 267)." However, anecdotal evidence suggests that the role of objects as cultural icons to emphasize social ties or accomplishments may not be related to the possessiveness component of materialism (Wallendorf and Arnold 1988). Nongenerosity is defined "an unwillingness to give possessions to or share possessions with others (Belk 1984)." Belk (1985, p. 268) reports Schoeck's definition of envy as "displeasure and ill will at the superiority of another person in happiness, success, reputation, or the possession of anything desirable."

After traditional scale development for the three measures of materialism traits, Belk found

moderate reliabilities for the scales based on the inter-item and item-to-total correlations. His findings showed coefficient alphas of .68, .72, and .80 for the scales measuring possessiveness, nongenerosity, and envy, respectively.

Belk (1985) also offers evidence that the three subscales are oblique factors of the materialism construct by finding non-zero correlations between the sums of the items for each subscale. This furthers speculation that materialism may be a second-order factor responsible for the correlation among these first-order factors. However, based on this correlation matrix and other evidence Belk (1985) proposes the use of the aggregation of all three scales as a measure of materialism, and believes it to be adequate for the exploration of some of the macro issues facing consumer behavior with respect to materialism.

The nature of the materialism construct, with respect to these subscales and their measures, can be further tested with hypotheses by applying the confirmatory factor analytic techniques of Joreskog (1969). Recent developments have emphasized the theory-testing abilities of this technique (Bentler & Bonett 1980; James, Mulaik and Brett 1982). Competing hypotheses regarding the factor structure can be tested with various chi square statistics. When an a priori model has been specified, the goodness of fit of the model to a set of data can be determined (Joreskog & Sorbom 1986).

Purpose

The purpose of this study was to use the confirmatory factor-analytic methodology to provide a further test of Belk's scale items for the first-order constructs of possessiveness, nongenerosity, and envy. If these scales are satisfactory measures of the first-order constructs, then this methodology also can be used to test a hypothesis that materialism is a second-order factor composed, in part, of some combination of these constructs.

The Measurement Model

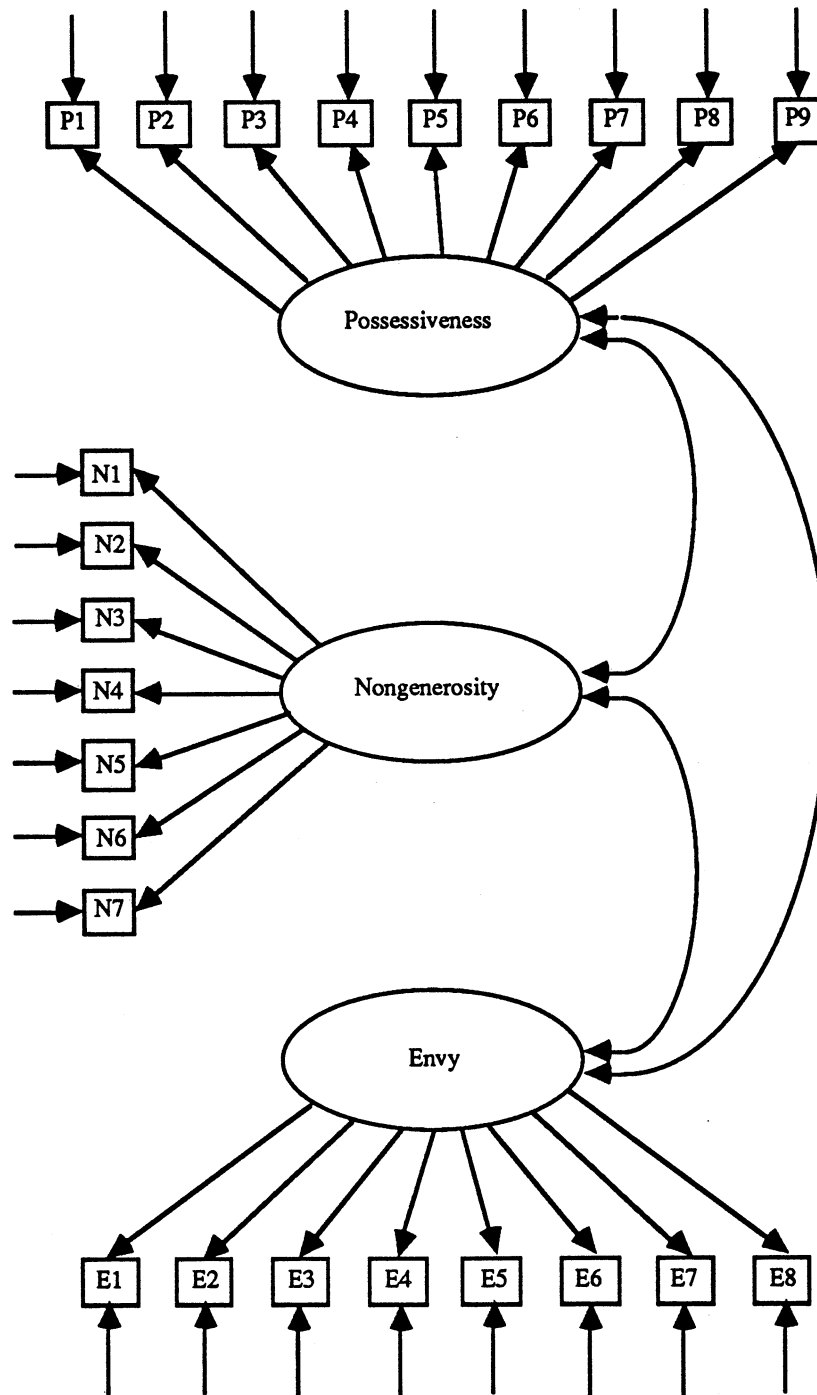

The three dimensions of materialism are identified in Figure 1. Items P1 through P9 are Belk's measures for the possessiveness construct, items N1 through N7 are measures of nongenerosity, and items E1 through E8 measure envy. The arrows from each construct to the items are factor loadings and the lone arrows represent measurement error. Uncorrelated measurement errors are assumed. The curved lines linking the factors represent correlations among the factors. The specific statements for the scale items are found in Table 1.

METHOD

The Sample

The data for the tests were gathered as part of a larger survey conducted in a large, southwestern

FIGURE 1
The First Order Factor Model of Belk's Materialism Construct

Note: Latent variables are circled and measures are within rectangles.

metropolitan area. Personal interviews were conducted and the interviewers read the statements to the respondents. Each respondent was given a coding card with a seven-point scale from one equals strongly agree to seven equals strongly disagree and asked to

rate each statement. There were 148 usable responses gathered. Two-thirds of the respondents were female.

The construct validity of the factors was evaluated by Joreskog's confirmatory factor analysis procedure using LISREL VII (Joreskog and Sorbom 1989). A one-factor and an oblique, three-factor model

TABLE 1
Belk's Materialism Subscale Items

Possessiveness

- P1 Renting or leasing a car is more appealing to me than owning one.*
 P2 I would rather buy something I need than borrow it from someone else.
 P3 I worry about people taking my possessions.
 P4 When I travel I like to take a lot of photographs.
 P5 I never discard old pictures or snapshots.
 P6 I tend to hang on to things I should probably throw out.
 P7 I get very upset if something is stolen from me, even if it has little monetary value.
 P8 I don't get particularly upset when I lose things.*
 P9 I am less likely than most people to lock things up.*

Nongenerosity

- N1 I enjoy having guests stay in my home.*
 N2 I enjoy sharing what I have.*
 N3 I don't like to lend things, even to good friends.
 N4 It makes sense to buy a lawnmower with a neighbor and share it.*
 N5 I don't mind giving rides to those who don't have a car.
 N6 I don't like to have anyone in my home when I'm not there.
 N7 I enjoy donating things to charities.*

Envy

- E1 There are certain people I would like to trade places with.
 E2 When friends have things I cannot afford it bothers me.
 E3 I am bothered when I see people who buy anything they want.
 E4 I don't know anyone whose spouse or steady date I would like to have as my own.*
 E5 When friends do better than me in competition it usually makes me happy for them.*
 E6 People who are very wealthy often feel they are too good to talk to average people.
 E7 I don't seem to get what is coming to me.
 E8 When Hollywood stars or prominent politicians have things stolen I really feel sorry for them.*
-

Note: * indicates reverse scored items.

were specified and compared to a null model. A reference metric was provided in each model by setting all of the diagonals in the factor correlation matrix (PHI) to one.

RESULTS

Confirmatory factor analytic techniques set a priori definitions of the theoretical factor structure. Factor loadings can be constrained to zero thus allowing the estimation of pure factors in the sense that the test will load only on the targeted factors. In all of the models tested here, the diagonal elements of the factor correlation matrices (PHI) were set at one to fix the scales of measurement so that the common factors would have unit variance. This puts all of the parameter estimates in a standardized metric. Each model was estimated with the correlation matrix in order to find appropriately comparable values of the root mean square residual (RMSR).

The confirmatory factor analysis literature has yet to settle on one particular criterion for model acceptability. Commonly used criteria are included in

Table 3 for each model tested. LISREL 7 output provides the chi square statistic (CHISQ), the degrees of freedom (df), a goodness of fit index (GFI), an adjusted goodness of fit index (AGFI), and the root mean square residual (RMSR). Smaller values for the chi square statistic, the chi square statistic divided by the degrees of freedom (CHISQ/df), and the root mean square residual indicate better fitting models. Better model fits are indicated as the goodness of fit indicator and the adjusted goodness of fit indicator approach 1.0.

Another useful index reflects the improvement in fit of one model with respect to another model, typically the null model. The normed fit index (Bentler and Bonett 1980) reflects the proportion of chi square eliminated by the competing model. This index ranges from zero to one; Bentler and Bonett suggest a minimum value of .90 when the competing model is compared to a fully-restricted null model. For confirmatory factor analysis the fully-restricted null model specifies an individual factor for each measurement item with factor variances set equal to

one and no covariance is allowed among the factors. Also, all of the factor loadings are set equal to one and there is no correlation specified among the errors in the measurement variables. Such a model should result in a large chi square value that many theoretically grounded alternative models will surpass with respect to various goodness of fit indices based on estimations from a reasonable data set.

The literature suggests several potential models. In one study, Belk (1985) aggregated the items in the three subscales to form a one-factor solution. In fact, he advocates its use as an overall factor for materialism (see Model 1 in Table 2). In discussing the subscales, Belk alludes to an alternative possibility that materialism is a second-order factor composed, in part, of the three first-order subscales of possessiveness, nongenerosity, and envy. If this is true, substantial positive correlation should be evident between the first-order constructs. Another interpretation of the situation is that materialism is a composite construct composed, in part, of the three subscales. Such an interpretation does not require positive correlations among the component constructs.

Belk's research suggests that an appropriate first-order model may be the oblique, three-factor, congeneric model (shown as Model 2 in Table 2). This model permits correlations among the three factors but maintains unidimensional measures. Indeed, a successful second-order model would be expected to have positive and significant correlations among the first-order factors. Perusal of the correlation matrix for the three factors and their respective standard errors indicates that only the correlation between possessiveness and envy is not significant. Model 3 in Table 2 is structured in a similar fashion but reflects the results of discarding those items with large modification indices (>5) on factors for which they are not theoretically prescribed. These large indices suggest that the items are not congeneric and, therefore, they were discarded in the interest of maintaining unidimensional measures. Scale items that are not unidimensional in nature are usually considered unacceptable because they violate an assumption of test theory (see Lord and Novick 1968). However, from a substantive stance, discarding those items to produce a more parsimonious model may change the nature of what the scales purportedly measure.

Table 3 summarizes the fit indices for the theoretical models and the empirically derived reduced models as well as two null models. The first null model (MA) was developed for the 24 item models and the second null model (MB) was developed for the 16 item, reduced models. As expected neither provides a particularly good fit on any of the indices.

Although Belk argues for the aggregation of the three factors into one general factor called materialism, this model (M1) is not particularly successful. Although there is some improvement over the null model, the normed fit index of .29 is not near the recommended value of .90 for a good fitting model. The other indicators also suggest a poor fit with the data.

Models 2 and 3 (M2, M3) are both oblique, congeneric three-factor models with the reduced version (M3) showing the results of the removal of those items that may not be unidimensional. This reduced version compares very favorably with the full 24 item model. Nonetheless, the fit indices are not conclusive: the adjusted goodness of fit indicator almost reached .90, the root mean square residual did slip below .10, but the normed fit index of .67 did not approach the suggested minimum for the fully restricted null model of .90. Also, this model, and all of the empirically derived reduced models, may capitalize on the individual nature of this particular data set.

The literature suggests that materialism may be a higher-order construct composed, in part, of the scales just investigated. The implied second-order factor model is shown in Figure 2. Although not all three subscales are positively and significantly correlated with each other, it might be argued there are enough positively correlated factors that might be capturing some aspects of this higher-order materialism construct.

The goodness of fit indicators associated with the second-order factor model (M4 in Table 2) suggest this model is essentially equivalent in quality to the three-factor first-order models (M2) but not to the reduced version of the three-factor first-order model (M3). In other words, none of the indicators suggest the second-order model is a good representation of the data, but it fares no worse than the relevant competing models tested here.

Although a second-order factor structure is theoretically defensible from the previous research that has been done, the structure of materialism could be specified as a composite construct, that is, as an aggregation of constructs, much like socioeconomic status in that it is considered a composite of social class, education and occupation and not a causal factor. This view of materialism does not require positively correlated constructs, but simply defines the materialism construct as an aggregate of subscales. Also, as Belk points out, there may be other, as yet unidentified, constructs that are additional constituents of materialism. This composite view of the materialism construct is shown in Figure 3 and for this particular model equal weights are specified for the three subscales by fixing ones in the diagonal of the gamma matrix. Additionally, the possibility of other constructs influencing the composite materialism construct is modeled by freely estimating the size of the uniqueness associated with the composite. The goodness of fit indices resulting from testing this model are listed as models 5 and 6 (M5, M6) in Tables 2 and 3. The full composite model appears to be essentially equivalent to both the full, second-order model and the full, three-factor, first-order model. Analogous results are apparent for the reduced version of the composite model, thus the models fare no better and no worse than their respective first and second-order counterparts.

FIGURE 2
Materialism As A Second Order Factor

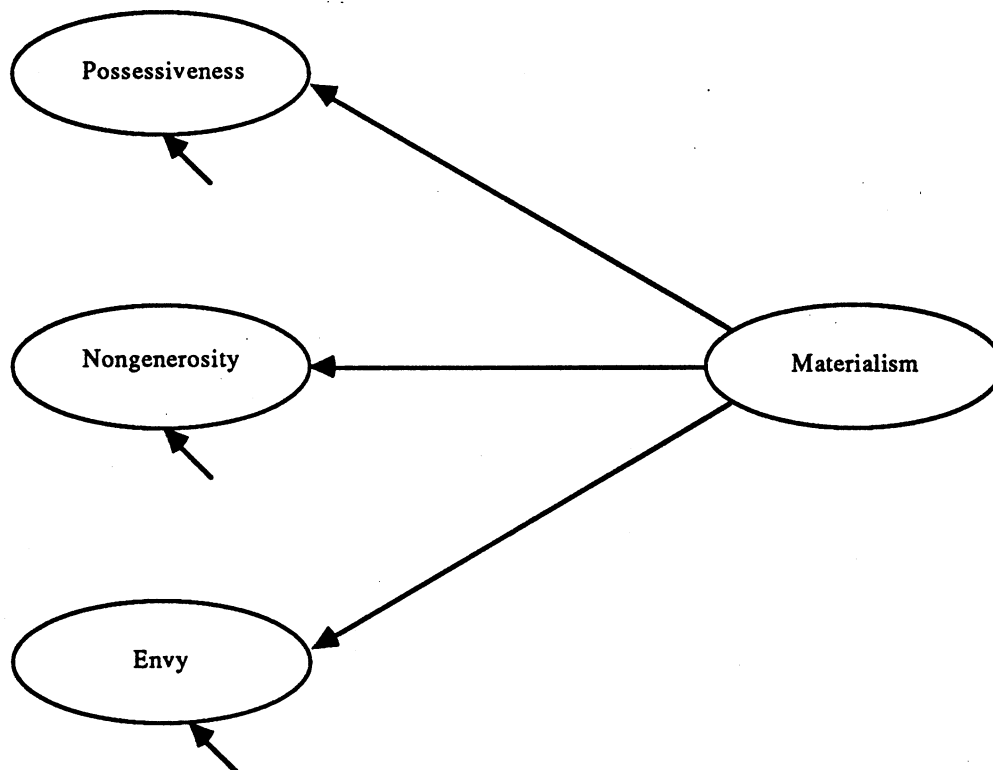

FIGURE 3
Materialism As A Composite Construct

SUMMARY AND CONCLUSION

Materialism has been identified as a potentially important dimension to further the understanding of consumer behavior. A series of articles, principally by Belk, has traced the development of a scale to measure aspects of materialism: possessiveness, nongenerosity, and envy (Belk 1982, 1983, 1984a, 1984b; Belk and Pollay 1985). Belk implies that materialism may be a second-order factor composed of these traits, and possibly other unspecified traits. This research extends the study of the reliability and validity of the materialism construct through the use of confirmatory factor analysis on the implied first-order and second-order factor models as well as a composite model alternative. None of the tested models were acceptable from the point of view of generally accepted goodness of fit indicators, however, the versions using a reduced set of scale items performed markedly better than the full set of scale items. The reduced set was empirically derived from the data and the models tested were not specified as a priori tests so their validity is questionable.

It appears that a three-factor model is a better specification than an aggregated one-factor model, however, continued work is necessary on the scale development. One of the problems suggested by the tests is that a substantial number of the items are not congeneric. Indeed, the removal of a group of items with large modification indices immediately improved the fits of all the models tested. If unidimensional measures are sought, the overall suggestion from these

tests is to continue modification of the subscales possessiveness, nongenerosity and envy so that each of the items constitutes a unidimensional measure of the respective constructs. The various goodness of fit indices suggest that any complex theories based in part on the present operationalization of these materialism subscales will be problematic, at least if they are specified as congeneric structures. As Belk has cautioned, the use of these particular scales continues to be recommended for exploratory research only.

Applying Conjoint Analysis to Social Advertisements

Moshe Engelberg, Stanford University
Rosalind M. Pierson, Stanford University
Hiroshi Kashio, Stanford University¹

ABSTRACT

A pilot field study (N=30) explored the feasibility of using conjoint analysis to examine important attributes of mass-mediated messages. Conjoint analysis is a technique typically used for measuring consumer trade-offs among multi-attributed products or services; however, little research has been conducted as to whether this type of analysis is appropriate for the study of more complex stimuli, like social advertisements. Using a fractional factorial design, 16 advertisements (copy only) promoting recycling were developed, each comprised of three factors: spokesperson, message/setting, and sponsor/format. Results revealed that the message/setting factor was most important to respondents, with a relative importance of 65.4%. Congruency between setting and message was highly valued. Spokesperson was the second most important factor at 31%; however, the most motivating spokesperson varied depending on the audience segmentation strategy used. Sponsor and format was the least important message attribute, with a relative importance of only 4.1%. Overall, conjoint analysis did an adequate job of depicting both individual and group preferences for particular message attributes. These results lead us to conclude that conjoint methodology is an interesting, creative and effective way to gather information not only about traditional products and services, but for designing advertisements as well. Research and managerial implications of extending conjoint analysis to the domain of advertisements are discussed.

BACKGROUND

The purpose of this pilot study was to determine whether conjoint analysis methodology would be useful in the development of television advertisements, an area in which it has received minimal application. Conjoint analysis is a set of techniques typically used for measuring consumer trade-offs among multi-attributed products or services (Green & Srinivasan, 1990). It decomposes overall judgements about a set of complex alternatives such as brand name, price and various product features into utility scales which reflect the relative importance of various attributes (Green & Wind, 1975). This study used social advertisements as stimulus material to provide new ground for the application of conjoint analysis techniques, while investigating conditions under which message elements common to most television advertising influenced motivation to comply with the behavioral request in the advertisement.

THEORY

Social Advertisements

Advertisements for consumer goods and social concerns each constitute a class of messages which compete within and across classes for public attention and support. Social advertisements include those that deal with issues like pollution, population growth, homelessness, AIDS, unemployment, and recycling (Flora & Maibach, 1990). The use of social advertisements in this study heeds the call for attention to what has been called "the dark side of consumer behavior" (Hirschman, 1991), and more generically reflects an aspect of social marketing (Kotler & Roberto, 1989).

In terms of message design considerations, these two classes of messages are similar on some dimensions and different on others (Slater & Flora, in press). The similarities apply to most television advertising; e.g. a short, unsolicited message imbedded in selected programming, choices around what is said, who says it, and the context and manner in which it is said. Ads for social issues and consumer goods often differ in terms of objectives, style of appeal, portrayed benefits, motives of message source, and production value. Some distinctions between these two classes of ads can blur, as in a campaign for beverages built around the product's environmentally sound packaging. In this study, we investigated message elements that can be found in many classes of ads, though the relative utilities of these elements may be a function of the class of ad.

Elements of Advertisements

A first step towards building research-based design strategies for advertisements is to assess the relative influences of various message attributes. The tradition of involvement research in consumer behavior and communication suggests that salient features of advertisements can be conceptualized in terms of central or peripheral cues, which in turn affect the way information is processed and used (e.g. Petty & Cacioppo, 1986).

Research concerned with effects of persuasive messages often divides message attributes into source factors, message factors, and context factors (O'Keefe, 1991). Source factors may include the presenting source (spokesperson), and the sponsoring source. Message factors encompass a multitude of both content and structural characteristics. Context factors can include the viewing situation, type of programming surrounding the ad, and the packaging of the ad. Typically, attention to message content reflects a central route to persuasion, while attention to source and context cues lead to a peripheral route to persuasion (Petty & Cacioppo, 1986).

¹The authors gratefully acknowledge the comments of V. Srinivasan.

Application of Conjoint Analysis to Advertisements

This study conceptualizes the advertisement as the product, and uses conjoint analysis to determine consumers' utilities for various message components. By doing so, we are assuming both theoretically and methodologically that ads consist of reasonably independent and additive components, and that an ad's overall utility can be decomposed and represented by the sum of the utilities for its separate components. We do not claim that the ad elements investigated in this study represent the gestalt of the ad, any more than the factors in any conjoint study represent everything about the product or service under examination. Rather, our intent is to decompose ads by looking at reasonably independent and additive elements which have received previous empirical attention, albeit with different methods, and are critical in terms of message design considerations.

The well-documented role of involvement in message effects (Petty, Cacioppo, & Schumann, 1983; Salmon, 1986) led us to focus on motivation, an involvement construct, as the criterion variable. This reflects our belief that for campaign managers and ad agencies to make maximum use of research concerned with effects of involvement, some research needs to focus on when and how various message elements generate involvement. Thus, we asked respondents to rank the advertisement scenarios in terms of how motivating they were, realizing that ad liking may figure into their judgement processes.

METHODS

Overview

Respondents were told that the Stanford Recycling Project (hypothetical) needed their input to design a motivating television spot aimed at increasing recycling among young adults in the Bay Area. They then rated and ranked sixteen profiles of such spots, which had different combinations of spokesperson, message and setting, sponsor and format. Concepts, procedures, and stimulus materials were thoroughly pretested, and results were cross-validated with self-explicated rankings.

Sample

A total of thirty Stanford graduate and undergraduate students participated in this study. Demographically, our sample was 57% male, 63% graduate students, and 87% single. Additionally, our sample represented 14 majors, which we collapsed into two categories known at Stanford University as "fuzzies" and "techies". "Fuzzies" (53%) are students who are primarily liberal arts majors, whereas "techies" (40%) are students who are classified as science or engineering majors (7% were undecided).

Experimental Design

We utilized a three factor fractional factorial design (Addelman, 1962) with four levels of each factor. Source, message, and context factors were represented.

Two source factors were manipulated; the spokesperson and the ad sponsor. Spokespersons were chosen to be highly credible or not, and highly likable or not. Ad sponsor was intended to represent for-profit motives or public service motives. Ad sponsor was used in combination with the format of the message, a context factor, that is whether it was described as an advertisement or public service announcement. Selection of message factors drew on framing principles (Tversky & Kahneman, 1986) by using a positive message (gain), or mathematically equivalent negative message (loss), in combination with a positive or negative setting. The positive and negative settings were intended to qualitatively represent a gain and loss respectively. This led to the construction of 16 advertisement profiles, as follows:

FACTOR	LEVELS
Spokesperson	Bill Cosby, actor and philanthropist William K. Reilly, head of EPA Bo Jackson, professional athlete Ron Smith, Bay Area graduate student
Message and setting	Positive message, pristine lake Positive message, dirty landfill Negative message, pristine lake Negative message, dirty landfill
Sponsor and format	Danville Corporation, PSA Danville Corporation, advertisement Recycling Cooperative, PSA Recycling Cooperative, advertisement

A complete description of the messages and settings can be found in Table 1.

The message/setting factor and the sponsor/format factor are both combinations of two two-level factors. Making each into a four level factor allowed us to examine interactions visually, and with minimum constraints in our model, as well as avoiding the inflation of relative factor importance due to unequal number of levels. A sample profile is illustrated below.

Spokesperson: Bill Cosby, Entertainer & Philanthropist

Setting: Beautiful, pristine mountain lake with gentle breeze blowing.

Message: (with disdain) This year alone, two-thirds of our glass, aluminum, and newspapers were dumped in landfills. We are destroying our planet now and it may not survive past this generation. Save our planet... recycle!

This advertisement is sponsored by the Danville Corporation

Respondents first read a cover sheet which briefly described the scenario of our recycling message

TABLE 1
Setting and Message Descriptions

Positive Setting/Positive Message

Beautiful, pristine mountain lake with gentle breeze blowing.

(with enthusiasm) This year alone, one-third of our glass, aluminum, and newspapers were successfully recycled. We are celebrating our planet now so that future generations may thrive on it. Celebrate our planet...recycle!

Positive Setting/Negative Message

Beautiful, pristine mountain lake with gentle breeze blowing.

(with disdain) This year alone, two-thirds of our glass, aluminum, and newspapers were dumped in landfills. We are destroying our planet now and it may not survive past the next generation. Save our planet...recycle!

Negative Setting/Positive Message

Dirty, overflowing city landfill with trash blowing everywhere.

(with enthusiasm) This year alone, one-third of our glass, aluminum, and newspapers were successfully recycled. We are celebrating our planet now so that future generations may thrive on it. Celebrate our planet...recycle!

Negative Setting/Negative Message

Dirty, overflowing city landfill with trash blowing everywhere.

(with disdain) This year alone, two-thirds of our glass, aluminum, and newspapers were dumped in landfills. We are destroying our planet now and it may not survive past the next generation. Save our planet...recycle!

design project, and their task. Because the profiles included a substantial amount of information, direct rankings of sixteen profiles would have been too difficult. Therefore, respondents first rated the cards on a seven point Likert scale (1=not at all motivating to 7=extremely motivating), and then ranked each stack of cards.

Respondents were given four practice cards to rate and rank, before working with the actual profiles. After completing the primary task, respondents completed a questionnaire with items on demographics, recycling involvement and behavior, and television use. Lastly, respondents provided self-explicated ratings of factor importance (1=not at all important to 7=extremely important) for use as cross-validation data.

Pretesting

Because application of conjoint analysis to messages is relatively unexplored, we conducted three levels of pretesting:

- 1) During the concept development phase of this project, we ran a focus group whose feedback led us to include both positive and negative messages and settings, and suggested certain levels for our other factors.
- 2) 21 students rated 20 potential spokespersons on the dimensions of credibility and likability, which led us to select one spokesperson for each possible combination of high or low credibility crossed with high or low likability.

- 3) Six pretest subjects went through our whole experiment, which allowed us to identify procedural and methodological problems.

RESULTS

Validity and Reliability of Data

Rank order results were analyzed using the LINMAP program (Srinivasan & Shocker, 1973). Overall, validity of results across respondents was fairly consistent, with all respondents having less than 10% of pairs violated. Multiple regression analysis was used to validate the LINMAP analysis of the ranked data, and to compare results obtained from the rankings data and ratings data. In both cases, regression analysis and LINMAP results were consistent. Self-explicated ratings of factor importance corroborated the relative importance percentages obtained through LINMAP.

Aggregate Results

Results for the average part worth utilities for the entire sample are shown in Figure 1. The combination setting/message factor was clearly the most important factor across respondents with a relative importance of 65%. Messages that had congruent setting and message were the most motivating. Respondents most preferred the negative setting/negative message combination, followed by the positive setting/positive message combination. Respondents least preferred the negative setting/positive message combination.

Spokesperson was the next most important attribute with a relative importance of 31%. Bill

FIGURE 1
Average Part Worths by Factor

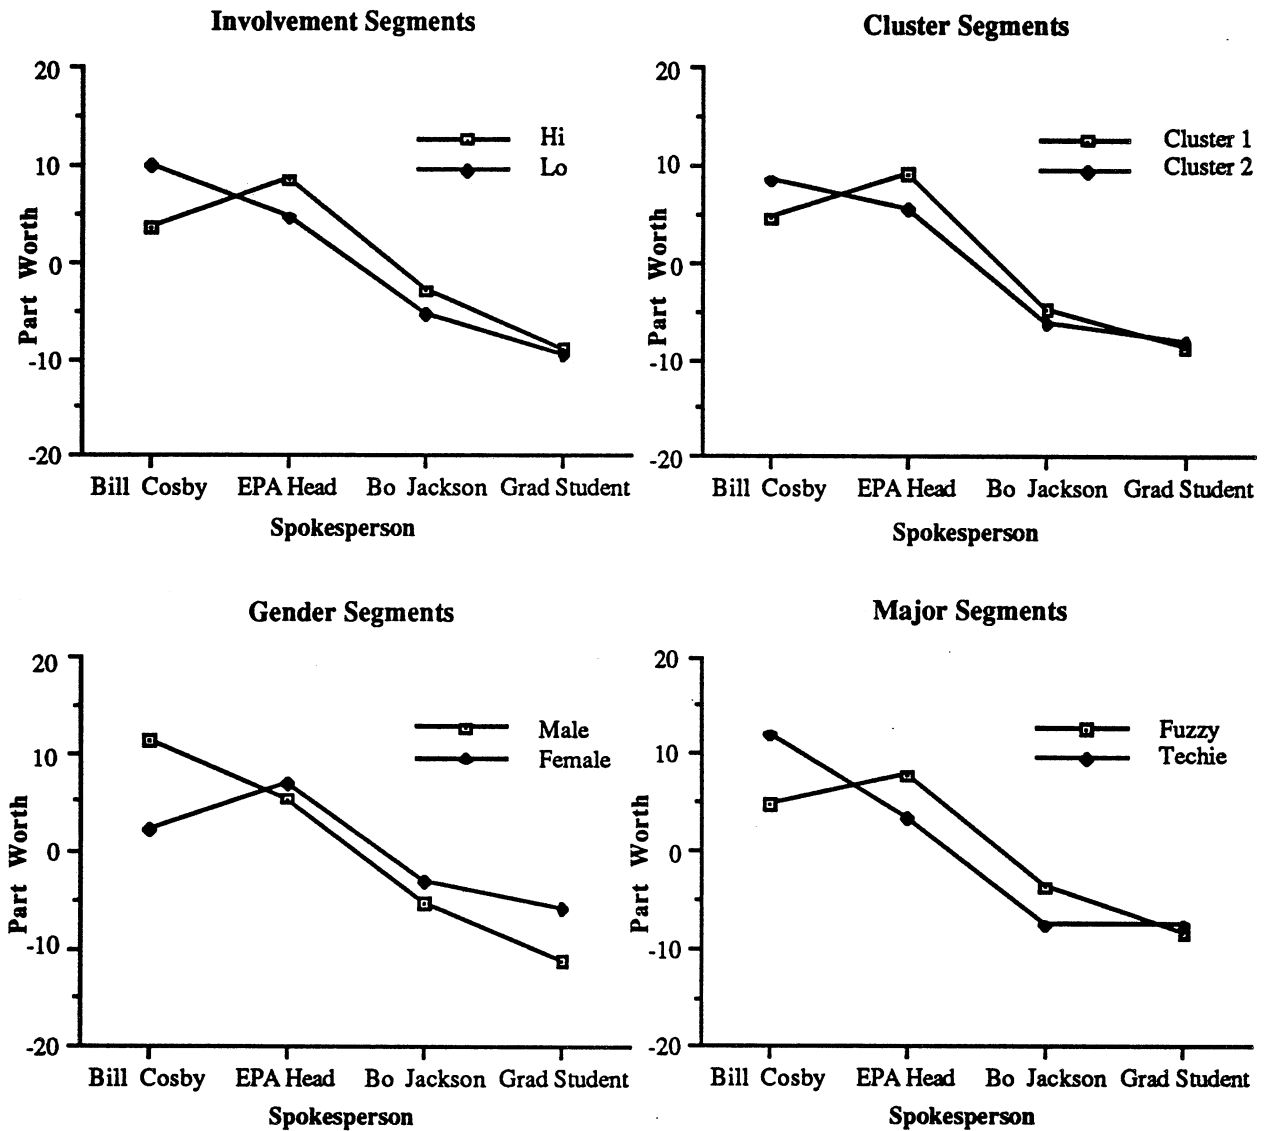

Cosby was the most preferred spokesperson, followed by William K. Reilly, head of the Environmental Protection Agency (EPA). Bo Jackson came in third; thus Bo may be more adept at promoting "sneakers", than motivating people to recycle. Ron Smith, a hypothetical Bay Area graduate student, was the least motivating spokesperson.

Not surprisingly, sponsor/format came in as least important, with a relative importance of 4.1%. During the debriefing phase of our study, many respondents stated that they either failed to really notice the sponsor/format, or that it only played a role when they went back and ranked profiles within a

stack. The first attribution suggests the need for counterbalancing order of factors. However, we purposely put sponsor/format at the bottom of the profile, as these features are typically not explicitly germane to most social advertisements.

The following analyses illustrate that the patterns described above generally held up for the message/setting factor and the spokesperson factor, across segments for all four segmentation strategies. The lack of consistent patterns on the sponsor/ format factor is interesting in its own right. These results are organized by factor in Figures 2 - 4. Figure 5 displays

FIGURE 2
Segmentation Analyses by Part Worths: Spokesperson Factor

relative factor importance across segmentation strategies.

Demographic and Psychographic Segmentation Analyses

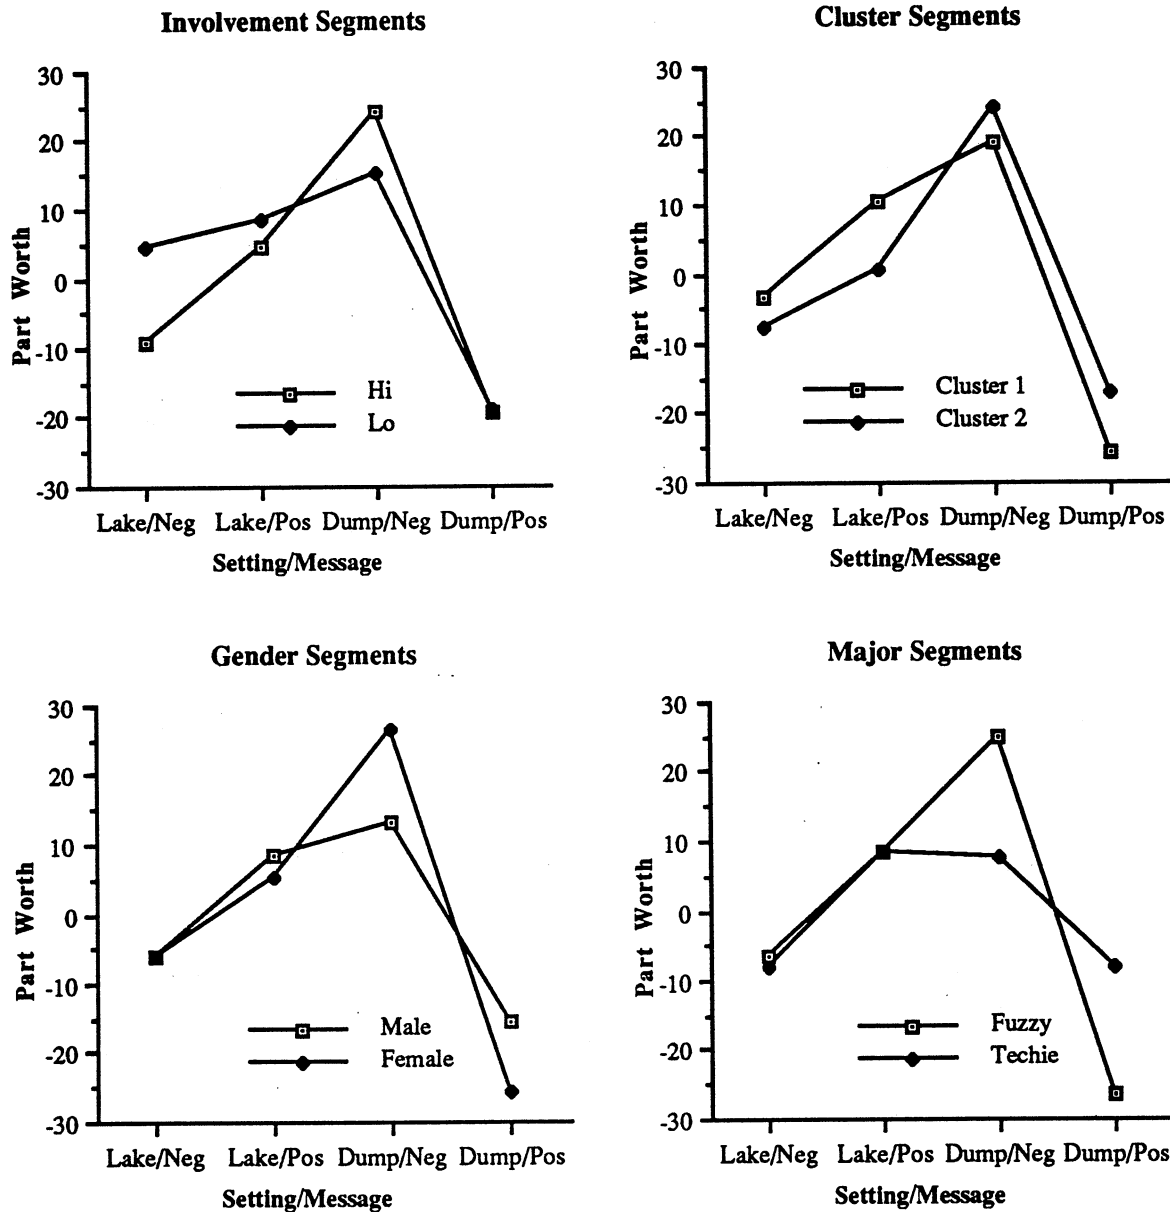

Segmentation analysis was performed to examine whether meaningful differences between groups existed for each factor and level. Our findings revealed the following pertinent information.

- 1) **Males versus Females:** Results from the gender segments indicated that males found the spokesperson to be more important than did females (42% vs 19%). Also, males chose Bill Cosby as their preferred

spokesperson, whereas females selected William K. Reilly.

- 2) **"Fuzzies" versus "Techies":** Techies were more sensitive to spokesperson than were fuzzies (48% vs 22%). Fuzzies preferred William K. Reilly and techies preferred Bill Cosby. Fuzzies were more sensitive to the setting/message factor than techies (71% vs 40%). Also, fuzzies most preferred the negative setting/message combination, whereas techies equally preferred the two congruent setting/message duos.
- 3) **High versus Low Involvement:** Highly involved respondents were those who

FIGURE 3
Segmentation Analyses by Part Worths: Setting/Message Factor

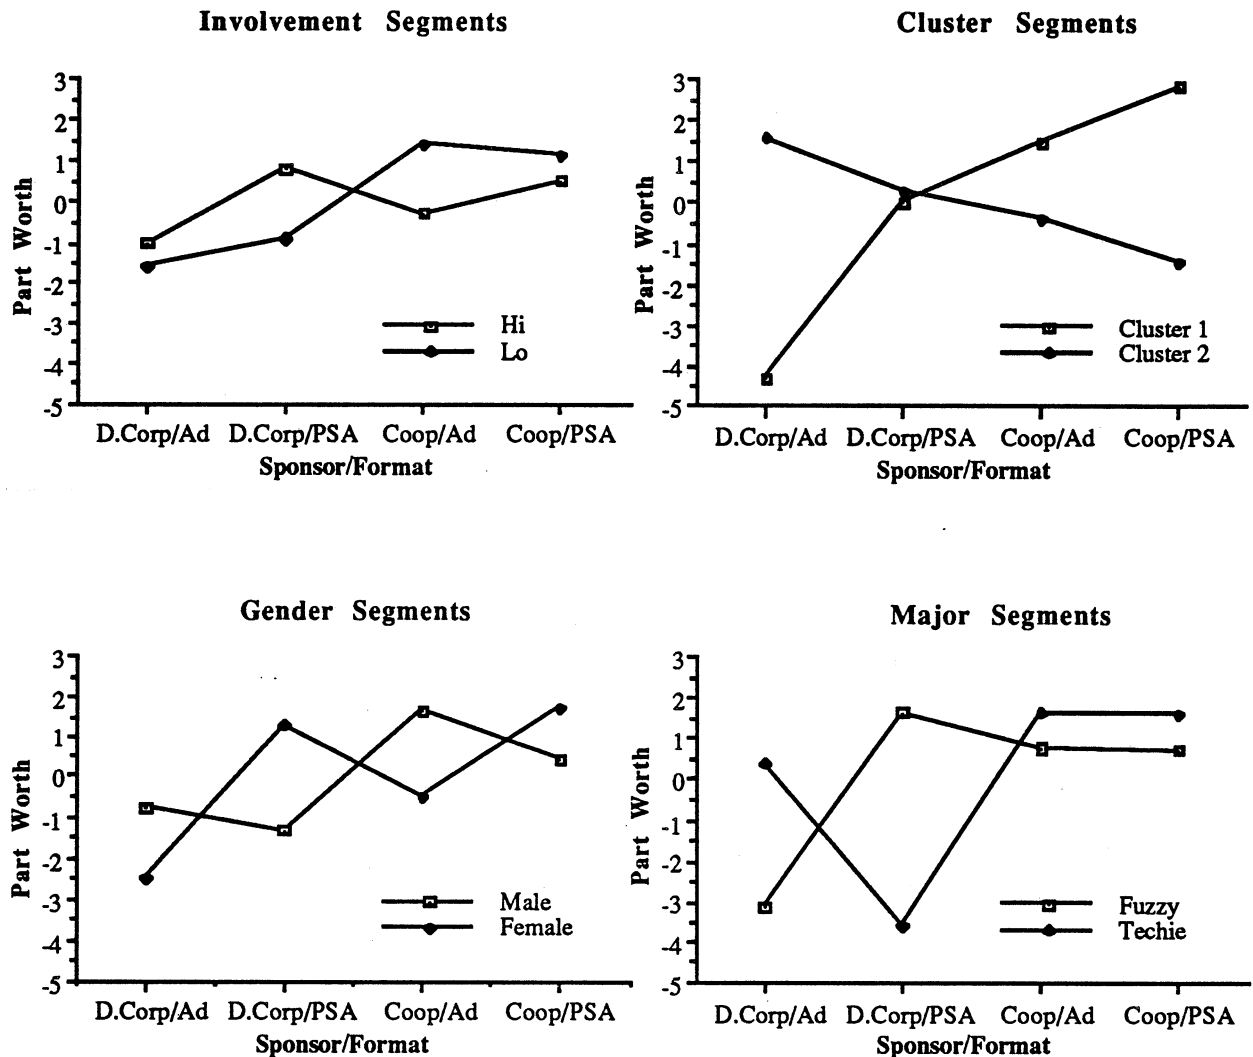

reported extreme concern about recycling efforts. Their most preferred factor was setting/message (69%) with less involved respondents finding this factor a bit less motivating (60%). Less involved respondents were more sensitive to the spokesperson (35% vs. 28%), with the spokesperson of choice being Bill Cosby. William K. Reilly was most preferred by the high involvement group.

Segmentation Based on Cluster Analysis
Respondents were also segmented empirically, based on results from cluster analysis. Two, three, and

four cluster solutions were examined. We selected the three cluster solution because its distinctions were richer and more interpretable. However, upon further review, we discarded the third of the three segments because of the lack of cohesion among the three cases which comprised the cluster, and retained the two larger segments for final analysis.

Key differences between the segments were: The sponsor/format factor was approximately twice as important to Segment 1 as to Segment 2, with Segment 1 preferring the Recycling Cooperative as sponsor, and Segment 2 preferring the Danville Corporation. Preference for the negative

FIGURE 4
Segmentation Analyses by Part Worths: Sponsor/Format Factor

setting/message combination was much stronger for Segment 2 versus Segment 1. Segment 1 found Bill Cosby most preferable, while Segment 2 selected William K. Reilly.

To help us better understand the two segments derived from cluster analysis, regression analysis was used, with demographics, involvement and television use as predictors of group membership. (This technique is mathematically equivalent to discriminant analysis, when the criterion variable is two-category nominal). Segment 1 was characterized by respondents who were undergraduates ($p > .01$), fuzzies ($p = .02$), and less involved ($p = .11$), while Segment 2 tended to be more involved, graduate students, and techies.

DISCUSSION

Summary

This study was an attempt to assess the feasibility of using conjoint analysis to examine complex stimuli such as social advertisements. Overall, subjects reacted positively to the conjoint task and had little trouble understanding or completing the task. Our results revealed that both individual and group part-worth functions adequately depicted individual and group preferences. For example, although both males and females believed the setting/message combination was the most important factor, a high percentage of males reported that the spokesperson was also fairly important.

These results have important implications for message design issues, like spokesperson importance and selection, in relation to audience segmentation strategies. Individuals who reported being highly

FIGURE 5
% Importance by Segments

involved in the recycling issue, were less likely to care about the spokesperson than individuals who reported low involvement in the issue, as is consistent with the elaboration likelihood model (Petty & Cacioppo, 1986). Furthermore, the spokesperson of choice for highly involved individuals was the little known expert William K. Reilly, compared to the popular Bill Cosby for the low involvement group.

Finally, although it is clear that the setting and tone of a message plays an important role in how motivating it is perceived to be, it seems that other factors, like spokesperson, and to a smaller extent sponsor and format, can either contribute to or detract from the message, depending on the audience being targeted.

Both the results gathered in this study and our own intuitive insights indicate that conjoint analysis is an interesting, creative, and effective way to gather information which can aid the development of advertised messages. If the technique is applicable in the more abstract domain of social issues, it seems likely that it will be at least as useful for advertisements for consumer products.

In the future, we hope to develop actual messages based on results of conjoint analysis and test them with audiences similar to the research participants. This will allow us to determine the conditions under which consumers can essentially design their own messages, which we believe to be an important extension of the fundamental marketing concept of consumer sovereignty (Blaug, 1990).

Limitations

Our extension of conjoint to a new domain of inquiry, mass media messages, is limited by a number of methodological considerations. The validity of this study rests on our presumption that advertisements can be decomposed into reasonably independent constituent parts in order to justify use of an additive main effects model, as well as the notion that individuals can predict their response to those constituent parts (see Kahneman & Snell, 1990 for a discussion of predicting utility). However, we do not presume that these processes would remain valid under all conditions, e.g. investigating preferences for structural features like cuts and zooms through stimulus material consisting of written copy only.

The use of written copy only here accurately reflects our preference for experimental control over true message complexity at this stage in the game. We would expect this preference to gradually shift if the marriage of conjoint to messages garners further attention.

Finally, the lack of a holdout sample, lack of covariates in group level analyses, and only one order of factor presentation limit validity and generalizability, and should be addressed in subsequent work.

Recommendations

Recommendations for future research applying conjoint analysis techniques to the study of messages in general, are as follows:

- 1) Larger scale studies should be implemented in order to gather more reliable and statistically significant data.
- 2) Conjoint techniques should be applied to other advertising design issues, both in the domains of social issues and consumer goods, in order to more fully test the applicability of this research methodology to mass media messages.
- 3) In further testing of this technique on advertisements, it may be worthwhile to actually develop storyboards or audio-visual profiles that consumers could actually view. This way, consumer preferences would not need to be inferred from evaluations of written descriptions of messages, thus leading to more accurate and meaningful results.
- 4) Before any commercial study of this type is undertaken, the actual cost/benefit of the study should be accurately assessed to determine if the initial outlay of resources is worth the time, energy and money. Agreeing on what constitutes "benefit" should be an early consideration.

Confirmatory Factor Analysis of a Country-Of-Origin Scale: Initial Results

R. Mohan Pisharodi, Oakland University
Ravi Parameswaran, Oakland University

ABSTRACT

The globalization of markets since the 80's has enhanced the urgency of research on the impact of country-of-origin image (CO) in cross-national consumer behavior. A rich harvest of such studies has consequently been generated. Prior weaknesses in such studies, such as poor handling of a complex construct, single cue studies and lack of methodological rigor, are being addressed. This study is in the genre of such research where the nature and dimensionality of the CO construct is examined using confirmatory factor analysis. Findings suggest that the theorized structure needs modification.

INTRODUCTION

Critical reviews on country-of-origin (CO) studies have identified several major inadequacies which have thus far prevented a definitive identification of the precise nature of the impact of CO in influencing purchase behavior. Among the factors which have been suggested as contributing to this slow progress are included complexity of the construct, the presence of other cues, and methodological issues (Bilkey and Nes 1982; Hong and Wyer 1989; Baughn and Yaprak 1991). Baughn and Yaprak (1991), for example, called for the increased use of multiple cues (such as CO, brand name and price instead of just CO); use of both intrinsic (taste, design, and performance) and extrinsic (price, brand name, warranties, CO) cues; use of "real" products, "typical" users, and "true" characteristic content; in addition to the strengthening of methodological rigor. Hong and Wyer (1989) exhorted their colleagues to include cognitive mechanisms which mediate CO effects on product evaluations, both at the theoretical and empirical levels. Ozsomer and Cavusgil (1991), after a thoroughly exhaustive review of CO effects on product evaluations called for more research in the area. They concluded "although much has been said and done on the relationship between CO and product familiarity, conflicting results call for more research." A basic question that still needs focusing on is conceptual and methodological. How should the CO construct be operationalized into a methodologically rigorous CO scale? How complex is the construct? In other words, what is its dimensionality?

The focus of this study is a rigorous examination of the nature of the country-of-origin construct and a confirmation of the scales that have been developed to measure it. We do this by subjecting a scale developed to measure country image (Parameswaran and Yaprak 1987) to the confirmatory factor model whose "ability to test specific structures suggested by substantive theory gives it a major advantage over the exploratory factor model (Long 1983)." Thus, it is hoped that we may begin to unravel the complexity of the construct through methodological rigor.

THE COUNTRY-OF-ORIGIN CONSTRUCT

The country-of-origin construct has been a gradually evolving construct which was conceived from the idea that people attached stereotypical "made-in" perceptions to products from specific countries and which influenced purchase and consumption behaviors in multinational markets (Rierson 1967; Nagashima 1970, 1977; Schooler 1971; Anderson and Cunningham 1972; Lillis and Narayana 1974). A single "made-in" indicant of country-of-origin, serving as an extrinsic cue (Thorelli, Lin, and Ye 1989), led to the hypothesis that all factors impinging on the marketing environment had a potential of impacting consumption behavior (Nagashima 1970). A plethora of empirical studies determined that several environmental factors had negligible to minimal effect on product perceptions leading to the current theory on the determinants of country image. The gradual evolution of the country-of-origin image construct and its attendant scales is unlike scale development in marketing and consumer research in the 1980's in that psychometric rigor was not a prime consideration in its evolution (for an example of a recent scale development, see: Shimp and Sharma 1987). Subjecting the CO construct to a rigorous evaluation, the purpose of this paper, is therefore a valuable exercise.

Contemporary Theory Underlying the Country-Of-Origin Construct

As mentioned above, the impact of CO information on consumer purchase behavior has inspired a large body of literature (for excellent reviews, see Cavusgil and Nevin 1981; Bilkey and Nes 1982; and Baughn and Yaprak 1991). Nagashima (1970) has been credited with first defining country image as "the picture, the representation, the stereotype that businessmen and consumers attach to products of a specific country. This image is created by such variables as representative products, national characteristics, economic and political background, history and tradition." Subsequent empirical researches (refer to summaries in Ozsomer and Cavusgil 1991; and Baughn and Yaprak 1991) have led to our contemporary understanding of the phenomenon. The impact of the CO cue on consumption behavior has been related to producing country characteristics. For example, it has been demonstrated that consumers' willingness to purchase products is related to the economic, political, and cultural characteristics of the product's country-of-origin. Papadopoulos, Heslop and Bamossy (1989) summarized this notion by stating that the perceptions of sourcing countries are impacted by cognition about, and affect and conative orientation toward, that country's peoples. CO effects have also been related to perceptions about the overall product

offerings of a particular sourcing country. Papadopoulos, et. al. (1989) noted that a consumer's image of a people with whom he/she is not familiar may well be formed upon the basis of knowledge about that people's capacity for producing quality products in general -- and that perception impacted his/her evaluation of specific products from that country. As an example, they showed a high level of affect toward the Japanese people and specific Japanese products even when few non-Japanese consumers were familiar with Japan and its peoples. Yaprak and Parameswaran (1986) called the former component the general country attribute (GCA) and the latter the general product attribute (GPA). Bearing Bilkey and Nes's (1982) criticism of single cue studies and their drawbacks, Yaprak and Parameswaran (1986) hypothesized that purchase intentions and behavior are impacted by CO effects (GCA and GPA) as well as by specific product attributes (including product-, marketing-, and firm-goodwill related attributes [SPA]).

The relative importance of country and general product image (GCA, GPA) cues in shaping purchase behavior is not entirely clear based on past research. Johansson, Douglas, and Nonaka (1985) claimed that the CO effect, as a result of single cue studies, may be overstated and that its effects may be contaminated by the effect of other cues. Heslop, Liefeld and Wall (1987) stated that the CO effect gained in strength with product complexity, increased risk, and decreased purchase frequency. Bilkey and Nes (1982) reported that a negative CO image was not overcome by a well known brand name.

MEASUREMENT METHODOLOGY

The Measuring Instrument

An extensive literature search was conducted in the design of the questionnaire that was used in this study. The scales which comprise this questionnaire are modifications of the scales used by Yaprak and collaborators (Yaprak 1978; Yaprak and Parameswaran 1986; Parameswaran and Yaprak 1987). Parts of that scale have been used in a recent psychometric evaluation of the CETSCALE (Netemeyer, Durvasula, and Lichtenstein 1991). A market country's consumers' attitudes towards a source country (in this case, Germany) were measured using twelve statements that are commonly found in the country-of-origin literature. Their attitudes toward the general nature of products from that country were measured using eighteen statements -- these statements again being those that are commonly cited in the CO literature. Their perceptions in regard to specific product related cues were measured using 10 relevant automobile attributes. The specific make of automobile that the survey respondents were evaluating was the German car, the Volkswagen Jetta. The above predictor variables -- GCAs, GPAs, and SPAs -- were measured on a 10-point scale where '1' represented that the statement was 'not at all appropriate' while '10' represented that it was 'most appropriate.' The dependent variable, their likelihood of purchasing a Volkswagen Jetta, was operationalized as a 10 point

likelihood scale where '1' represented 'not at all likely' and 10 represented 'extremely likely' to purchase that make of car. A list of indicators is presented in Table 1.

Sampling and Data Collection Procedures

Data were gathered from the adult population of a large midwestern metropolitan area which is highly heterogeneous in terms of ethnic composition. These people represented the then current and potential users of automobiles -- both domestic and foreign. In order to adequately capture the ethnic flavor of the metropolitan area, relevant ethnic associations were contacted, membership lists acquired and representative samples selected therefrom. Blank questionnaires were hand delivered to the selected respondents and completed questionnaires were collected within the next two weeks. In order to achieve a high response rate, the president/committee members of these associations were approached and requested to encourage their members to participate. A total of 678 completed and useable questionnaires were returned from the 1025 that were originally placed, a 66% response rate.

ANALYTICAL METHODOLOGY

A covariance matrix based on the data collected from the 678 respondents was analyzed in order to find out whether the scale developed for the measurement of the CO (GCA, GPA, and SPA) consisted of three sets of unidimensional and reliable measures of these three constructs. In order to assess the unidimensionality of the CO scale used in this research, confirmatory factor analysis (CFA) was employed. CFA has been recognized to be a superior approach for the analysis of unidimensionality vis-a-vis other often-used approaches such as item-total correlations, exploratory factor analysis (EFA), and coefficient alpha (Gerbing and Anderson 1988; Anderson, Gerbing, and Hunter 1987). Unlike EFA, CFA is a hypothesis testing procedure in which an *a priori* model is tested for goodness-of-fit against a data set (Bagozzi 1983). Thus, it can be used to determine whether the collected data supports the *a priori* categorization of the indicators into (unidimensional) measures of the three CO constructs.

A second objective of the statistical analysis presented in this paper was to respecify the measurement model (if necessary) through an understanding of the dimensionality of the three concepts of interest. CFA also possesses diagnostic capabilities which assist in the identification of model misspecification (Bagozzi 1983). It can be used in a more exploratory sense by progressively respecifying and relaxing constraints (as dictated by theory) beginning with a more restricted initial model.

The process of analysis was based on the updated paradigm for scale development proposed by Gerbing and Anderson (1988). The analysis consisted of four steps: (1) the specification of the *a priori* model, (2) the examination of model misspecification, (3) the theory-guided respecification of the *a priori* model resulting in the adjusted model, and (4) comparison of the *a priori* model with the adjusted

TABLE 1
List of Indicators

Indicator	Label
<i>GCA (General Country Attributes)</i>	
1. Friendly & likeable	C1
2. Artistic & creative	C2
3. Well educated	C3
4. Hard working	C4
5. Technical education	C5
6. Achieving high standards	C6
7. Raised standard of living	C7
8. Technical skills	C8
9. Similar political views	C9
10. Economically similar	C10
11. Culturally similar	C11
12. Participates in international affairs	C12
<i>GPA (General Product Attributes)</i>	
13. Unreasonably expensive	P1
14. Luxury products	P2
15. Meticulous workmanship	P3
16. Imitations	P4
17. Known mainly for industrial products	P5
18. Sold in many countries	P6
19. Not attractive	P7
20. Intensely advertised	P8
21. Frequent repairs	P9
22. Wide range of models	P10
23. Long lasting	P11
24. Advertising informative	P12
25. Difficult to service	P13
26. Cheaply put together	P14
27. High technology	P15
28. Good value	P16
29. Easily available	P17
30. Prestigious products	P18
<i>SPA (Specific Product Attributes): Car</i>	
31. Good fuel economy	S1
32. Exterior styling attractive	S2
33. Workmanship good	S3
34. Handles well	S4
35. Little maintenance	S5
36. Very comfortable	S6
37. Difficult to get parts	S7
38. Quality service	S8
39. Made to last	S9
40. Overall excellent	S10

model. The refined measurement model resulting from the analysis is expected to be more useful than current measurement models used for the study of county-of-origin effects.

CFA was applied to the collected data using two complementary approaches: (a) the full information method wherein all the parameters of the measurement model are estimated simultaneously, and (b) a limited information method which uses only the covariances of the variables in any one equation of the model to estimate the parameters in the equation (Anderson and Gerbing 1982). The former approach is more

attractive from a theoretical perspective since it explicitly recognizes all the relationships in a measurement model in a single analysis. It also generates more efficient statistics in large samples and provides more indicators of fit. The latter approach estimates the parameters of each factor separately and independently. In the presence of model misspecification this is a strength since poor specification of one factor does not affect the estimation of parameters in another (Anderson and Gerbing 1982).

Maximum likelihood estimation procedures available in the statistical package LISREL 7 (Joreskog and Sorbom 1989) were used for the application of the full information method. The covariances in the input data set were tested against the covariances expected as the result of the *a priori* specified model. When the parameters of the model are estimated through the method of maximum likelihood (an option in LISREL), the differences between the relationships reflected in the data and those specified by theory are tested using a chi-square statistic. The chi-square statistic tests the overall fit of the model to data, smaller values of the statistic typically representing better fit. The measurement model was also evaluated using other indicators of global goodness-of-fit such as the Adjusted Goodness of Fit Index (AGFI) and Root Mean Square Residual (RMSR) and measures of fit of the internal structure of the model (such as squared multiple correlations, modification indices, and standardized residuals).

Oblique centroid multiple groups factor analysis (MGRP) available in the statistical package ITAN (Gerbing and Hunter 1988) was used for the application of the limited information method. The unidimensionality of the measurement model was assessed through the evaluation of internal and external consistencies (two statistical criteria for unidimensionality) using the procedure recommended by Hunter and Gerbing (1982) and Anderson and Gerbing (1982). The output of MGRP analysis of a correlation matrix was evaluated (a) for internal consistency through the examination of item-factor loadings and the pattern of inter-item correlations, and (b) for external consistency by examining similarity coefficients. Further, measure reliability was assessed by evaluating the values of standard score coefficient alpha computed by ITAN.

The process of model respecification described in this paper was strongly driven by theory. In other words, model respecification based purely on data (and possessing no theoretical rationale) was avoided. Thus, while improvement in fit was sought through respecification, the objective of this process was to develop an improved measurement model which was theoretically defensible and which could be useful for the measurement of CO effects and not to just to develop a perfect-fitting model.

According to Anderson and Gerbing (1988) there are four basic ways to respecify indicators: by relating the indicator to a different factor, by deleting the indicator from the model, by relating the indicator to multiple factors, or by using correlated measurement errors. They recommend the use of the first two ways since "these approaches preserve the potential to have unidimensional measurement, without obscuring the meaning of the estimated underlying constructs." Keeping the objectives of this research in sight, improvement of fit through the linking of indicators to multiple factors or the correlation of error terms was consciously avoided. Although the correlation of error terms would certainly have improved fit, such a procedure would have made the resulting model less elegant from a theoretical perspective without any significant gain in its

substantive interpretability (Bagozzi 1983, Gerbing and Anderson 1984). Improvement in fit was achieved in this research through the respecification of factors and through the deletion of poor indicators.

Model 1: The Initial Model

The initial model (Figure 1) consisted of three constructs (unobservable variables): GCA, GPA, and SPA, and 40 indicators (observable variables). GCA was measured using 12 indicators, GPA by 18 indicators, and SPA through 10 indicators. The indicators of goodness-of-fit obtained through the analysis of the model using LISREL 7 indicated a very poor fit (Table 2). The poor fit was also reflected in large standardized residuals and modification indices. Among the within-factor residuals the largest had the value of 17.78, and 44.9 percent exceeded 2.58, the cut-off point for good fit (Bagozzi and Yi 1988). Among the within factor modification indices, the largest had a value of 229.26 and 52.08 percent exceeded the value of 3.84, a cut-off point recommended by Bagozzi and Yi (1988). While the composite reliability indicated by the total coefficient of determination was found to be high (0.999), 22 out of the 40 items possessed squared multiple correlations below 0.5, indicating low individual item reliabilities.

Similarly, the inter-item correlations generated by ITAN indicated the three constructs were being measured using indicators which lacked internal consistency. The indicator sets measuring GCA and GPA seemed to include correlated sub-clusters of indicators. The average correlation of an item with its prespecified underlying factor (item-factor correlation) was 0.555. Many items possessed very low correlations with the factors they were supposed to measure. In fact, two of the indicators loaded more highly on factors which they were not selected to measure, than on those they were selected for.

The values of the standard score coefficient alpha for the sets of measures of GCA, GPA, and SPA were quite high (GCA: 0.829, GPA: 0.847, SPA: 0.763) given the observed degree of misspecification. However, this may partly be the result of the large number of indicators in each set since the formula used for the computation of coefficient alpha is influenced by the number of indicators that are included. It is also important to recognize that a high value of coefficient alpha does not reflect unidimensionality (Gerbing and Anderson 1988). In fact, a high alpha in the relative absence of unidimensionality is not an indication of measure reliability since unidimensionality is a prerequisite for reliability.

Model 2: The Intermediate Model

Through a close examination of indicators of poor fit and through an iterative process of progressive respecification and reexamination of results (but without deleting any indicator), the intermediate model (Model 2) was developed. The indicators of GCA were reclustered into two groups, one consisting of indicators (C1 to C8) which measured general attributes of the country and its people (GCA1) and the other consisting of indicators

FIGURE 1
The Initial Measurement Model (Model 1)

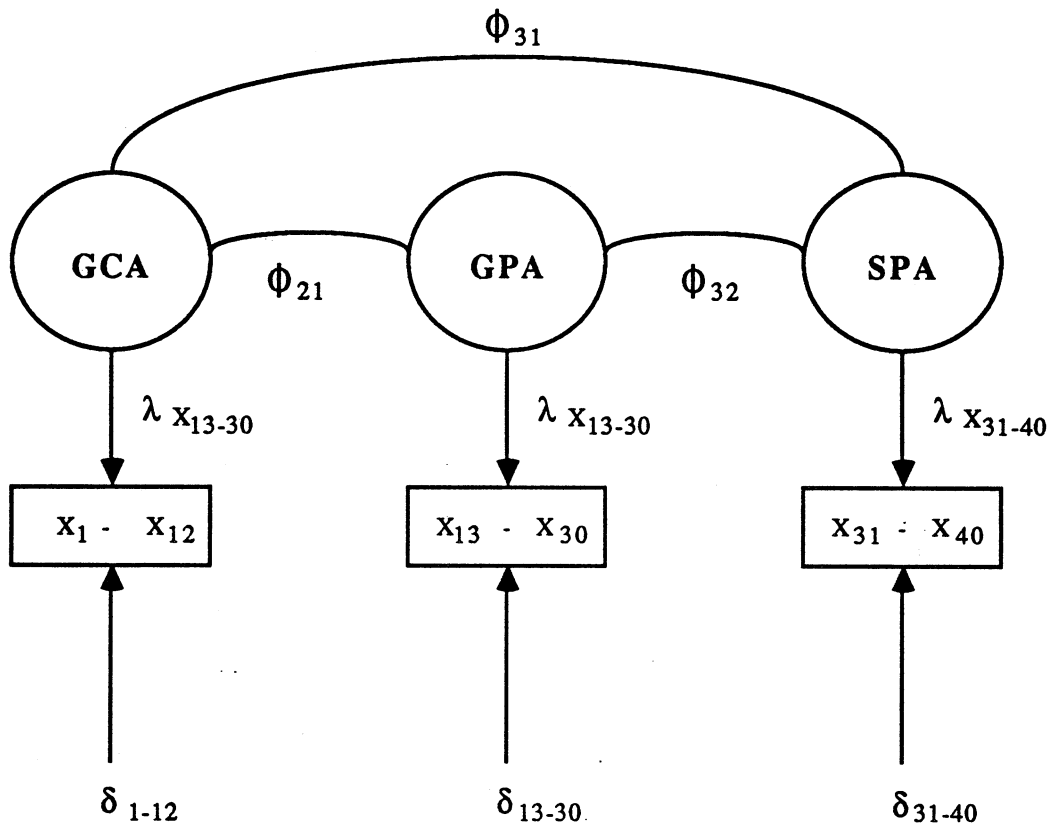

TABLE 2
Goodness-of-fit Measures (LISREL)

	Model 0	Model 1	Model 2	Model 3
Chi-square	8704.8	5769.56	2669.86	646.71
Degrees of freedom	740	736	730	237
p	0.000	0.000	0.000	0.000
GFI	0.491	0.582	0.832	0.928
AGFI	0.436	0.534	0.811	0.909
RMSR	30.657	2.414	2.256	1.615

(C9 to C12) which measured interaction of the country being evaluated with the respondent's country or other countries (GCA2).

Similarly, GPA was reclustered into two groups, one of which (GPA1) included all the indicators (P1, P2, P4, P5, P7, P9, P13, P14) which measured negative product attributes (poor service, poor quality, etc.), and the other (GPA2) included all the indicators (P3, P6, P8, P10, P11, P12, P15, P16, P17, P18) which measured positive attributes. The presence of two such dimensions was very clear from the results of the analysis of Model 1, although the polarity of the responses to negative attributes had been reversed prior to statistical analysis through appropriate data transformation so that higher values reflected superior evaluation. No change was made to the specification of SPA.

The respecification of GCA and GPA in Model 2 resulted in a considerable drop in chi-square and the other indicators of goodness-of-fit (Table 2) vis-a-vis Model 1 indicating a much improved fit of the model to the data, although the chi-square by itself indicated a lack of fit. This finding was also reflected in the standardized residuals and modification indices generated by LISREL and the inter-item correlations and the item-factor loadings computed by ITAN. The average item-factor loading increased to 0.696. The improvement in the measurement model was also reflected in the values of standard score coefficient alpha (GCA1: 0.853, GCA2: 0.803, GPA1:0.934, GPA2: 0.871).

Model 3: The Adjusted Model

An examination of the results of LISREL and ITAN analysis of the intermediate model indicated that many of the indicators of the intermediate model still possessed correlated errors and contributed to the relative lack of unidimensionality of the measures of the five unobservable variables in the intermediate model. Hence, through an iterative process, 16 indicators were dropped from the measurement model. During the iterative process, it was also found that GPA2 needed further subdivision into two dimensions: GPA2 and GPA3, the former consisting of indicators (P6, P8, P12, P17) which reflected distributional and promotional aspects of the marketing mix and the latter consisting of indicators (P11, P16, P18) which reflected product image. The list of indicators selected after assessment of unidimensionality and model respecification are presented with the adjusted measurement model in Figure 2.

The results of analysis using ITAN indicated a measurement model which satisfied the criteria for unidimensionality quite well. The item-factor correlations generated by ITAN indicated that every item in the measurement model loaded much more highly on its own factor than on any other factor. The average correlation of an item with its underlying factor is 0.824. Within-construct similarity coefficients were found to be much higher than between-construct coefficients. The values of coefficient alpha of the factors in the adjusted model were 0.872, 0.849, 0.918, 0.735, 0.796, and 0.819

respectively for GCA1, GCA2, GPA1, GPA2, GPA3, and SPA.

The goodness-of-fit indices generated by LISREL are presented in Table 2. The indices presented in Table 2 point to a much improved fit, although the chi-square statistic still indicated a lack of fit. The total coefficient of determination is 1.000 and all but four of the squared multiple correlations exceed the value of 0.5. Among the within-factor residuals the largest had a value of 6.57 (absolute), and 31.58 percent exceeded a cut off point of 2.58 and among the within factor modification indices, the largest had a value of 30.16 and 34.21 percent exceeded the cut-off point of 3.84. Although a major proportion of the standardized residuals and modification indices possessed values larger than their recommended cut-off points, they were much smaller in magnitude than those generated during the analysis of Model 1.

While it would have been possible to obtain a better fit of the model through the correlation of error terms, due to theoretical and substantive reasons, such a step was avoided.

INCREMENTAL FIT ANALYSIS

One of the problems of the chi-square statistic, which is used to test the overall goodness-of-fit of structural equation models, is that it is influenced by sample size. When the sample size is large (as in this research $n=678$), due to a bias in the statistic, it is particularly difficult for a model to be accepted. To overcome this bias, Bentler and Bonett (1980) have proposed an alternative method involving the analysis of "incremental fit." This method is based on the study of improved fit (represented by lower chi-square values) as a model is respecified.

The results of incremental fit analysis are presented in Table 3. The first model (Model 0) is the most restricted model in which all the 40 indicators are specified as observable variables of one unobservable construct. The drop in chi-square values with each model modification is noticeable and statistically significant ($p=0.05$) indicating that model respecification significantly improves the fit between the specified model and the data. The values of the Non-normed Fit Index and the Normed Fit Index indicates that the final model explains a large portion of the variance unexplained by the first model.

CONCLUSIONS AND LIMITATIONS

Over three decades of pre-occupation with the CO construct and its impact on consumer perceptions have led to a reasonably widely held belief that CO effects are created by a market country's people's cognition (level of economic development, nature of political climate, etc.), affect (toward a country's people) and conation (desired level of interaction with a country's people) regarding the source country. CO effects are also related to perceptions about the overall product offerings of the particular source country. In addition, CO effects are affected by the perceptions of the specific product being evaluated. Scales, such as the one used in this paper, are developed which

FIGURE 2
The Adjusted Measurement Model

incorporate three constructs that include the above generalizations. The results of our confirmatory factor analysis indicated that such a structure may need modification. A five factor model produced a significantly better fit which was still substantively

in line with the theory of the CO construct. The general country attributes, including cognition, affect and conation are in effect two dimensions -- conation impacting perceptions significantly different from cognition and affect. Similarly, the GPA construct

M3 - M0	8058.12	503	0.839	0.926

* M0 to M3 are abbreviations representing Models 0 to 3

** All the chi-square differences listed in this table were found to be significant at $p = .05$

splits into three components--negative attributes behaving differently than positive ones. Positive attributes relating to promotional/distributional image constituted the second GPA dimension and product image the third. This six construct model improved fit substantially more than the original three factor model.

This study has to be viewed as an initial attempt at identifying the proper structure for the CO construct. Our results may be product category specific in that the only product category tested in this study was automobiles. Further replications using other product categories and different source and consuming countries should provide definitive evidence regarding country and product images.

Listen to the Music: Its Impact on Affect, Perceived Time Passage, and Applause

Brian Wansink, Dartmouth College

ABSTRACT

This paper integrates a series of interesting findings related to how one responds to a musical stimulus. In particular, this paper focuses on one's affect toward a musical stimulus ($Affect_{ms}$) and uses information theory to examine the complexity of a music stimulus. Two models are then developed which provide a general framework for understanding applause duration and for understanding the perceived time duration of a musical stimulus.

Few topics in marketing are of wider appeal than those which examine the impact of music on processing, preference, and behavior. Though much of the work done in this area is either inconclusive or methodologically flawed, the three papers described below provide solid methodological advances toward better understanding of music on culture (Blair and Hatala 1992), on time perception (Kellaris and Altsech 1992), and on affect (Kellaris 1992). In further examining the contributions of the issues raised by these papers, this paper will raise additional insights related to the results of the studies in the latter two papers.

ESTIMATING THE TIME DURATION OF MUSIC

Music Volume and Gender Effects

The research of Kellaris and Altsech (1992) suggest that the estimated duration of a song is systematically underestimated by females if the song is played at a soft volume (60 dB). The differential impact of music on gender is well documented. Not only are females more sensitive to higher frequencies, and to increases in musical amplitude, but it also appears that they may generate less processing of auditory information in the left hemisphere of their brain. Though Kellaris and Altsech hypothesized that increases in the volume of music would cause females to *overestimate* the length of the music, in this study it resulted in them accurately estimating the time along with both the males who listened to loud music and those who listened to soft music.

The most interesting result of this research is the degree to which females *underestimated* the time duration of soft music. The critical issue that this result raises, however, may have less to do with gender differences and volume than it does with one's affect toward the musical stimulus ($Affect_{ms}$) and volume. The music used by Kellaris and Altsech (1992) was an instrumental piece described as "light pop-rock" or what might be considered "easy listening." In general, let us assume that females are more attracted to this type of music than males (who tend to instead "prefer loud 'Heavy Metal' music"). This is a reasonable assumption, given that informal interviews confirm that this gender bias is reflected

both in radio listenership and in the music purchases of "light pop-rock."

The Interaction of $Affect_{ms}$ and Comfort

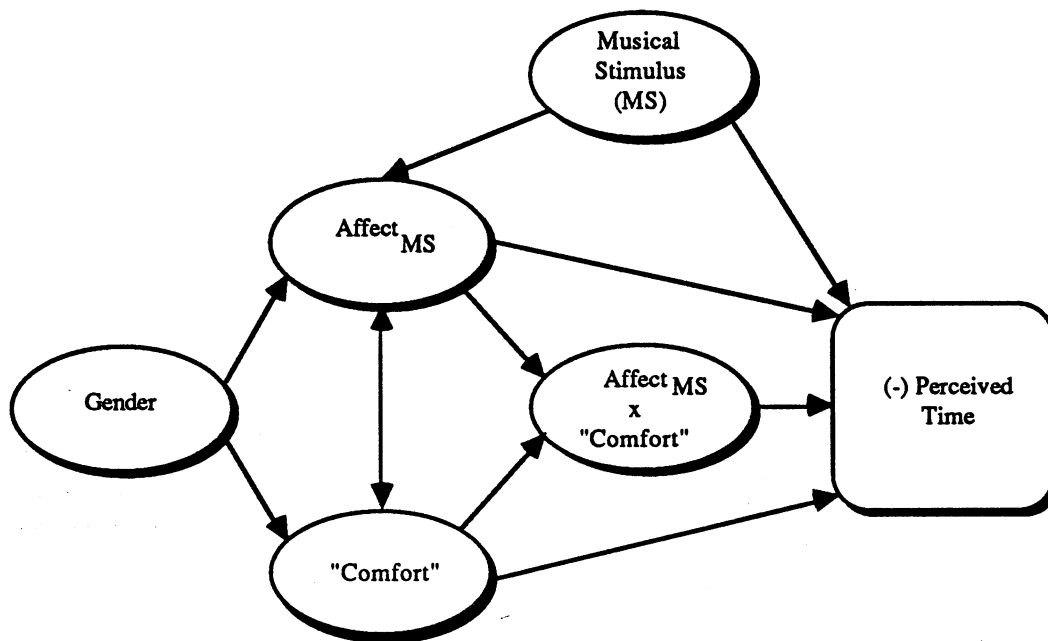

It is worth positing that the critical mediating variable when assessing time duration estimates would be $Affect_{ms}$: The more favorable one is toward the music, the shorter its perceived duration will be. In effect, the time spent listening to the music is more enjoyable, it does not seem to "drag," and it is accompanied by anticipation, not unlike what occurs when one views a favorite advertisement (Rossiter and Percy 1987). Therefore, given that females might favor "light pop-rock" more than males, we might expect a much different pattern of results if all the subjects were instead exposed to heavy metal music. In this case, *males* would tend to underestimate the duration of the music.

Though such a rationale would predict a main effect in the difference of the estimates between males and females, it does not explain the results of why we find that soft music is perceived by females as having less duration than loud music.

Rather than focusing on loudness as a variable, it may be that loudness should be viewed more in terms of the specific impact it has on an individual. Since females are more sensitive to loud music than males, at some decibel level loud music will result in greater annoyance or even discomfort. Under these conditions, one's general comfort-level might suggest an even more robust model. If "comfort" is used as a moderating variable, it would result in gender interacting with volume to impact on "comfort," which in turn influences one's perception of time duration. Figure 1 provides a model of these variables. This interpretation of the interaction of gender and volume on time duration is consistent with the results reported by Kellaris and Altsech (1992).

Given this interpretation of time duration, the type of music listened to can either increase or decrease one's $Affect_{ms}$ and in turn affect perceptions of time duration. $Affect_{ms}$ would have an impact on one's perception of a musical stimulus's duration both directly and indirectly through its interaction with one's comfort level. (In general, one's "comfort" is thought to be influenced by such factors as physical comfort and psychological comfort -- Thompson 1975. As antecedents to comfort, these two variables encompass such disparate factors such as music loudness and physical crowding). To the degree that loudness can affect one's comfort, it can affect one's perceived duration of music. In addition, as the results of the study suggest, if a high level of comfort (e.g., the music is soft) is coupled with high $Affect_{ms}$, we would expect one to underestimate the duration of the music stimulus. In summary, when one is experiencing a low level of comfort, or has low

FIGURE 1
Basic Determinants of Perceived Music Duration

Affect_{ms}, we would expect a higher estimate of the musical stimuli's duration than if one is "comfortable" and "likes the music." Such a model makes the results much more general and less driven by gender issues.

Insofar as gender can impact both Affect_{ms} and one's comfort level (through greater sensitivity to loud noises, etc.), we would expect the results found in the study.

The primary contribution of Kellaris and Altsech (1992) is that its findings suggest a new paradigm (Figure 1) that is rich for consideration. Fruitful future research in this area would test the validity of the model proposed in Figure 1 and would further investigate this issue of an audience member's "comfort."

THE IMPACT OF STIMULUS COMPLEXITY ON AFFECT_{MS} AND APPLAUSE

Kellaris (1992) presents a clever and rigorous field-study which uses a balanced experimental design that carefully accounts for confounds, and unobtrusively obtains a behavioral measure of Affect_{ms} by observing the duration of audience applause. The results indicated that the impact of a song's tempo on a crowd's applause follows a Wendt curve. Though this hypothesis is consistent with past research, the results indicated that the downward-sloping effect past the asymptote was highly significant for songs in minor chords but not those played in major chords.

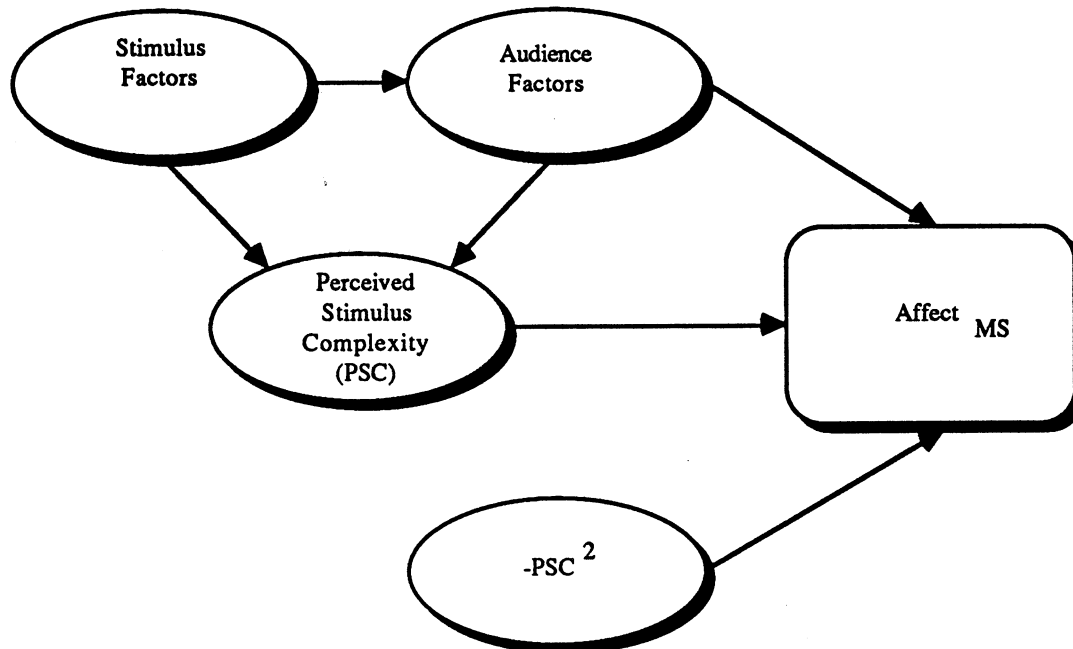

Information Theory and Stimulus Complexity

To make the basic Wendt model more generalizable to account for these results, it is useful to relate it with information theory (Shannon and Weaver 1949). In doing so, let us view a musical stimulus as providing a certain amount of information (Wansink 1984). For instance, a musical stimulus that is highly organized or structured (e.g., it has a melody that is repeated, is constructed with familiar musical elements, etc.) contains less information because it is more predictable than a less organized musical stimulus, the extreme case would be represented by random sounds at random volumes).

Given this orientation of information theory, it is reasonable to look at this distinction between major and minor chords in terms of their complexity as stimuli. In general, one can say these two differ on a dimension we could label as objective stimulus complexity. Because major chords are more commonly encountered and are more familiar (or predictable) to us, they can be seen as containing less information and as being less complex than minor chords. This variable of objective stimulus complexity could be measured using an information theory approach (Wansink 1984).

To restate a preceding point, since minor chords are less common and therefore less predictable, they contain more information than major chords and can therefore be viewed as objectively more complex than major chords. The results of Kellaris (1992) support this. If we assume that the songs played in major chords are at the top of an Affect_{ms} asymptote (as represented by a Wendt curve with objective

FIGURE 2
Proposed Determinants of Affect Toward a Musical Stimulus

stimulus complexity on the x-axis and $Affect_{ms}$ on the y-axis), those songs played in minor chords would be on the downside of this curve because they are objectively more complex. This is consistent with Kellaris' quadratic results: Songs in minor chords exhibited this nonmonotonic relationship with applause duration while major chords did not.

Stimulus Factors and Audience Factors Affecting Complexity

Because of the limitations of even such well-executed field studies as Kellaris', the data are not available to examine what audience-related factors might affect this measure of applause. Familiarity, fatigue, involvement, and arousal would all have effects not only on $Affect_{ms}$ but also on Perceived Stimulus Complexity (see Figure 2.). From an information theory perspective, PSC can also be increased by any stimulus factors that increase the amount of uncertainty associated with a stimulus, such as unfamiliar tempos or chords, or irregular tempos and chord changes. Up to a point (see Figure 3 -- point x'), increases in objective stimulus complexity (such as those that are associated with chord changes and tempo changes) have a positive impact on $Affect_{ms}$. After this point, however, additional changes will have a negative impact, unless accompanied by increases in a relevant audience state variable (such as arousal, familiarity, etc.) which would represent a shift in Figure 3 from State A to State B.

Given the detailed coding of Kellaris' (1982) study, a number of general conclusions could be reached by analyzing the indirect impact of these

different stimulus-related variables (tempo, duration, meter, modality, presence of lyrics, instrumentation, type, etc.). In addition, this data could be further analyzed by examining the presentation order of songs and by running a regression which includes a lagged-term of applause (e.g., applause length on the previous song) to assess the impact of arousal and also of fatigue. In effect, the more aroused a crowd (see Figure 3), the more they are likely to respond toward a song that is more complex than a song at point x (but less complex than one at point x").

The impact of these factors will undoubtedly vary across people. As suggested by Anand and Holbrook (1986), the more aroused an individual is, the more likely it is that he or she will desire a stimulus that is objectively more complex (to point x" in Figure 3). This shift from State A to State B has different implications for how favorably one will be toward a complex stimulus ($Affect_{ms}$). It is not unreasonable that such shifts would also occur as a person's familiarity with the music changes or as his or her comfort level changes (Kellaris and Altsech 1992).

SUMMARY

Though music represents a complex gestalt that one "pulls apart . . . only at one's peril" (Anand and Holbrook 1986), a number of fascinating findings exist that can be best understood by broadening and generalizing the context in which they are observed. This paper integrates a series of interesting findings by providing an information theory approach to

FIGURE 3
Audience Factors and Their Relationship Between Objective Stimulus Complexity & Affect Toward a Musical Stimulus

Affect_{ms} and by suggesting how this interpretation can influence Affect_{ms}, which in turn affects other variables such as perceived time duration.

The Use Of Rap Music In Children's Advertising

M. Elizabeth Blair, Ohio University

Mark N. Hatala, Ohio University

Rap music, with its boastful rhymes and synthesizer-created claps and pops, has moved out of the ghetto and into the mainstream of popular culture. In rap music, African-Americans have found a powerful expression of their culture. Rap's rhythmic chants and hip style fit the image of products like sneakers and soft drinks. Since children and teens are the major consumers of rap music, it is only logical that rap should be used to promote products to these age groups. The purpose of this paper is to investigate and observe how a social statement about life of oppressed youth in the ghettos becomes so acceptable to the mass culture that it is used by many white advertisers to sell products.

INTRODUCTION

Music in advertising is being studied by marketing scholars in an increasingly diverse number of ways. Initially, there was an emphasis on the measurement of aesthetic qualities of the music (Holbrook and Huber 1979; Holbrook and Bertges 1981). In these studies a number of semantic differential items were factor analyzed and the factors were given names that corresponded with certain qualities of the piece of music (e.g. activity, coolness, heaviness, and sadness). Several years later, Gorn (1982) stimulated interest in the use of music in the background of advertisements. This study provided evidence that preferences for products could be classically conditioned through the use of music. Bruner (1990) recently reviewed the diversity of ways in which music has been studied by marketing scholars and, like the Holbrook studies cited above, emphasizes the decomposition of the music into components such as time (includes rhythm and tempo), pitch and texture. A new rhetorical approach to the study of music in advertising was introduced by Scott (1990). This article criticizes previous music-in-advertising research for ignoring the cognitive involvement of the listener. It is emphasized that music can be informative or affective, and should not be separated from its social context and meanings that are culturally shared. Culturally-shared meanings in music have been largely ignored in previous studies and the current research is one of the first to examine advertising music from an anthropological/sociological perspective.

Rap music, with its boastful rhymes and synthesizer-created claps and pops, has moved out of the ghetto and into the mainstream of popular culture. In rap music, African-Americans have found a powerful expression of their culture. Some rap artists have attempted to use this force to bring about social change, for example, by speaking out about black-on-black violence. Pepsi-Cola, Coca-Cola and the British Knights athletic footwear company have all signed popular rap artists to promote their products. Rap's rhythmic chants and hip style fit the image of products like sneakers and soft drinks, especially with

young consumers. Because children and teens are the major consumers of rap music, it is only logical that rap should be used to promote products to these age groups. Advertisers believe that rap music facilitates memorization of the product information and creates excitement (Barber 1987). Rap music also allows more lyrics per 30 seconds than any other form of music (Winters 1990).

Many black rappers are concerned that as rap music moves into the mainstream, they will not be given the appropriate credit and compensation. In his introduction to *The Rap Attack* (Toop, 1984), Tony Van Der Meer states the problem with the commercialization of rap music:

There is nothing wrong with one community learning from the cultural forms produced by another, if it respects their specific shapes and meanings. There is something horribly wrong with a dominant community repeatedly co-opting the cultural forms of oppressed communities, stripping them of vitality and form—the heritage of their creators— and then popularizing them. The result is bleached pepsi culture masquerading as the real thing. This is what threatens to dilute the real feeling and attitude of hip hop, preventing its genuine forms the freedom to fully develop. The expression of Black people is transformed when it is re-packaged without any evidence remaining of the Black historical experience.

In the 1950's and early 1960's producers were interested in promoting white artists, such as Elvis Presley, to perform rock and roll music which had been previously recorded by black artists. The white performer was instrumental in promoting acceptance of a musical style among mainstream audiences. According to Peterson and Berger (1975) black rhythm and blues performers were most often the victims of the "cover tactic", where major companies would quickly record and market a version of a fast-selling song recorded by a smaller independent company. The development and acceptance of rock-and-roll was in many ways similar to the development of rap in the late 1980's and the development of jazz in the 1920's. All of these movements began in the black community. Both rap and rock-and-roll used the language of that era's youth to express the conflicts in their lives. Some of the first rap concerts, like some of the first rock-and-roll concerts, were plagued by riots, leading people to believe that this new music was corrupting today's youth. These public reactions parallel the moralistic reaction against jazz in the 1920's. According to Peterson and Berger (1975), this controversy indicates that the music was viewed as important and radically different from the music that preceded it.

How does a subcultural phenomenon such as rap become integrated into the mainstream of mass culture? The purpose of this paper is to investigate and observe how a social statement about life of oppressed youth in the ghettos becomes so acceptable to the mass culture that it is used by many white advertisers to sell products. Children's advertising is examined as a vehicle of mass culture, in order to observe how intensively rap music has penetrated the mainstream of society and how blacks are represented in ads using rap.

A MODEL OF MASS CULTURE

Gottdiener (1985) proposed a model of mass culture which is inspired by Marxian hegemony theory, but is at the same time critical of that theory. He suggests a semiotic approach for explaining the influence of various subcultures, particularly youth subcultures associated with certain musical styles, on the mass culture. The concept of hegemony means the way in which an entire ideological complex of beliefs, values and attitudes that function for the sustenance of the ruling class comes to dominate every aspect of society. This model assumes that social groups of all kinds, including powerful, as well as less-powerful groups, are understood to be the bearers of meaning. "Mass" culture is made up of various individual subcultures, which vary in the extent to which they interact with the dominant ideology in society. Before there is a "mass" culture there must be "culture", meaning the conceptual forms and accumulated knowledge by which social groups organize everyday experience. The "mass" culture develops as a result of dynamic meaning creation from groups which may or may not be closely allied with the dominant ideology (Gottdiener, 1985).

Gottdiener visualized the production and control of ideological meanings as operating in three separate stages. In the first stage, producers produce objects for their exchange value, whereas purchasers of those objects desire them for their use value. The link between the producers and users occurs when producers communicate an image for the product, usually through advertising. Even though advertisers have been accused of controlling the consciousness of the purchaser, most advertisers would testify that their efforts to control consumers are often unsuccessful. Successful transfunctionalization of goods from exchange value to desirable use value status has been achieved by several large sporting goods companies. The manufacturers of Reebok, Puma, Nike and Adidas sneakers are making huge profits because their shoes have become accepted not only as the most technologically advanced, but as stylish and prestigious. These manufacturers did not intentionally market these products to appeal the hip hop (rap) subculture, but their products were subsequently adopted by this group, becoming part of its identifiable look.

In the second stage, users modify objects of mass consumption in order to express certain cultural symbols, or in connection with specific group practices or for use in subcultural activities. This is when culture is actually *created* by the users of the

object. The primary use value of the object is transformed, so that the object becomes a sign of belonging to a subculture. In some cases, the commodity may become so personalized that it is no longer effective in its primary function. An example is when a vehicle is modified by a subculture to achieve a particular look, resulting in the vehicle becoming impractical as a daily means of transportation. In rap music, this process occurred when D.J.'s took old recordings from a number of artists ranging from James Brown to The Rolling Stones and repeated the same few bars during the drum break of the song, extending the break into a new instrumental composition. D.J.'s teamed up with MCs (rappers) who provided the show, creating spoken rhymes over the beats. A style of dress developed in which sneakers became high fashion (Toop 1984).

During the third stage, the producers of mass culture decide to capitalize on these subcultural trends. The transfunctionalized objects produced by the subculture become the raw material for cultural production by the mass culture industries. During this process, subcultural meanings are changed by mass producers (such as advertisers) into more marketable, less radical meanings. This third stage is extremely important to the process of ideological control. The first and third stages of this semiotic model together constitute a powerful social practice by which the user/object relation is controlled in order to reproduce the social relations necessary for capitalist production. It is evident that big business is making big money from the impact and influence of the rap culture. Major publishers are publishing books illustrating the techniques of "popping", "moonwalking", "spinning" and other breakdancing moves. Sections of these books also inform the reader how to "dress like a breakdancer" and how to "talk like a breaker" (Toop 1984). Gottdiener concludes that theorists advocating ideological domination fail to appreciate the importance of the relative autonomy of subcultural life. It is true that the consumption habits of individuals are so manipulated by the mass culture industries as to transform the production of meaning by subcultures into a managed market purchase. But this does not always happen because consciousness *itself* cannot be controlled. Fortunately, there will always be groups who desire to distinguish themselves from the mainstream and produce meanings for cultural objects that are independent of the logic of exchange value and dominant cultural sensibilities. Interestingly, these two sources of cultural production are dependent on each other.

The Development Of Rap

Rap music originated in the Southeast Bronx of New York City, when some street gangs decided to put their energies into more creative pursuits. Rap started as a verbal competition and was related to the Afro-American tradition of word battles such as "the dozens." Rap developed in the Bronx as part of the hip hop subculture, along with breakdancing and graffiti art. Hip hop parties (known as "house parties") usually included a show put on by a D.J., rappers, dancers, and graffiti artists who provided the

decor. The first rap music was happy, party music and often involved nonsensical bragging between males. During this time, there was also competition among D.J.'s to develop the most creative sampling of records. Old "Monkees" tunes, T.V. themes (such as Gilligan's Island) as well as Funk and Rhythm-and-Blues classics were all borrowed and sampled in unusual ways. Often the original tune was unidentifiable because D.J.s would alternate between two different turntables, repeating the drum sequence from each record a number of times. As predicted by the model of mass culture, described above, the hip hop subculture borrowed some musical products from the popular culture, and "personalized" them to be distinctive to their own group's activities.

Although they were not prominent in the initial development of rap, the introduction of rap into a national audience was accomplished by a three-man group known as Run-DMC. Their remake of the song "Walk This Way", originally a hit for the white rock group Aerosmith, sold 3.3 million copies, and demonstrated to artists and producers that rap was not just a passing phase (McKinney 1989). Rap has moved off the East coast and prominent rappers are popping up all over the country. Though originally a male phenomenon, many prominent female rappers are now expressing their unique points of view (DiPrima 1990). Vanilla Ice is the name of a white man who has become a hit rap artist. Rap has diversified considerably and much of the recent rap music could be described as a crossover between rap and some other style, such as pop, funk or R&B. The most important development in recent rap music is that it has become more political, and serious intelligent messages about life in urban black neighborhoods have replaced the emphasis on nonsensical, party-type lyrics (Adler, Foote, and Sawhill 1990).

THE REPRESENTATION OF BLACKS IN ADVERTISING AND MASS MEDIA

A recent article in *Marketing News* (Schlossberg 1991) stated that advertisers often miss the mark with black consumers and are sometimes insulting. In this article, a black ad agency owner, a black human resources consultant and a black marketing professor expressed their views on the representation of blacks in advertising. They said that "many corporate management organizations, especially those that are predominantly white males, hold stereotypes which prevent them from seeing the market as it truly is and communicating to it properly." Contributing to this problem is the fact that marketers must try to appeal "to the growing black market without alienating the dominant white market" (Bush, Hair, & Solomon 1979). Historically, some researchers feared that using African-Americans in advertising, whether exclusively or in "integrated" commercials with whites, would create a "white backlash" among extremely prejudiced whites resulting in a negative sales response (Cagely & Cardozo 1970). Subsequent research has dispelled this fear, with research showing that white and black consumers do not differ in attitude or purchase

behavior when exposed to black, white or integrated promotional stimuli (Solomon, Bush, & Hair 1979).

In the past, evidence did indicate that blacks were underrepresented in the media, and when presented, were often shown in stereotypical roles such as "Uncle Tom and Aunt Jemima" (Colfax and Steinberg 1972; Kassarian, 1969). Blacks were infrequently seen on television throughout the 1950's, except in the sort of negative stereotypes portrayed on the Amos 'n' Andy show, which was eventually cancelled in 1964 due to pressure from the Civil Rights movement (Northcott, Seggar, & Hinton, 1975; Dominick & Greenberg, 1970). In 1965, Bill Cosby was the first black actor to really break into prime time television with his co-starring role in "I Spy", for which he eventually received three Emmy awards (Dominick & Greenberg, 1970). By the mid-1970's, blacks were more prevalent on television and there were even a few all-Black or "segregated" shows such as *Good Times*, *That's My Momma*, and *Sanford and Son* (Banks, 1977). Although blacks also appeared in "integrated" television shows such as *The Rookies* and *Mannix*, they didn't usually play the part of a major character. Black characters tended to be clustered in only a few television programs (Gerbner, Gross, Morgan, & Signorielli, 1982), and appeared in programming and commercials only about 9% of the time (Weigel, Loomis, & Soja, 1980). It was found that, even though 67% of the American work-force was employed in blue-collar or service industry jobs, only 10% of all television characters were, and these characters were likely to be black (Gerbner, Gross, Morgan, & Signorielli, 1982; Pearl, Lazar & Bouthilet, 1982). This was especially true of black characters on "segregated" television programs; blacks on "integrated" television programs tended to be better assimilated into white society and held higher status jobs than their less assimilated brethren (Banks, 1977). Content analysis studies have shown that since the mid-1980's, blacks have been increasingly shown in culturally assimilated television shows, indicating a change from "low-income all-black settings to more upscale middle-class ones" (Matabane, 1988, p.30). With the success of shows such as *The Cosby Show*, *Amen*, and *A Different World*, this trend is likely to continue.

If blacks have been underrepresented on television shows, they have been seen even less frequently in television advertising. For example, in 1964, African-Americans were given .65% of the speaking roles in commercials and 1.39% of the nonspeaking roles (Kassarian, 1969). By 1967, only 2.3% of all television commercials used any Blacks, Orientals, Puerto Ricans, or Native Americans (Dominick & Greenberg, 1970). When actually used in a commercial, African-Americans were typically shown in a background role with a large number of other people. For example, in 1967 the median number of people in an advertisement in which a black appeared was 10; for advertisements without blacks, the average was 1.6 (Dominick & Greenberg, 1970). O'Kelly and Bloomquist (1976) counted the frequency of blacks and females in children's programming, adult programming and news programming. The frequencies

of blacks and females in the advertisements were compared with frequencies during the programming that contained them. It was found that non-whites represented 1.6% of the characters in children's programming and only 3.8% of the characters in the commercials. This significantly under-represents the percentage of blacks in the population of the U.S. (about 12%). More recently, however, this is changing and many companies have recognized the importance of the ethnic market. The black professionals mentioned above stated that Coca-cola and McDonald's are particularly sensitive to the heterogeneity that exists within the black subculture (Schlosberg 1991). Advertisers must recognize that using rap music may not be appropriate for appealing to all blacks, and may be especially inappropriate for upscale blacks who associate rap music with "hanging out" on the street corners.

RESEARCH METHODOLOGY

The objective of the methodology is to examine the pervasiveness of rap music in children's advertising and to observe the hegemonic process. Because the methodology is largely exploratory, it is difficult to predict in what ways the hegemonic process will manifest itself, if at all. This study is preliminary, in that it does not look at evidence over time, only advertisements appearing within one month's time are examined. Content analysis (Kassarjian 1977) is used to examine how frequently rap occurs and to record the types of products and types of characters by race and sex. It is expected that blacks will appear more frequently in ads that use rap than in other types of ads. It is also possible that blacks will appear in stereotypical ways, because their subculture is not likely to be understood by advertisers. Advertisers are expected to present rap in ways that they believe to be highly acceptable to the mainstream audience.

The sample of ads came from Saturday morning programming (8 am to 11 am) on each of the three major networks. The programming and ads were videotaped on three consecutive Saturdays in October 1990. All advertising that occurred during these programming hours were included in the content analysis, except for one half-hour show on NBC. The NBC videotape contained one show called "Inside the NBA", which was a preview of Saturday afternoon basketball games. Since it was not targeted toward children, and the advertising differed dramatically from the typical children's ads, the advertising from this show was eliminated from analysis and the advertising from 11am to 11:30am was substituted.

Each commercial was identified by the product name, network and number in commercial sequence. People or characters in the ads were coded as white only; black only; black and white; white and other; white, black, and other; or doesn't apply. Characters were counted as black if they appeared to the judges to be at least partly of African-American heritage. Asian and oriental characters were the most commonly occurring characters to be identified as "other". The sex of the people or characters was identified as males only, females only, both or doesn't apply. Products

were classified by gender orientation (boy, girl or both) and type of product. If rap music was used, the rapper was identified by sex, race and type of character (e.g. real human vs. cartoon). Two judges were used to code the advertisements. One of the judges is the first author and the second judge is a friend and business person who was paid, and was not involved in the writing of the paper or development of the coding scheme.

RESULTS

There were a total of 224 advertisements in the sample, including commercials that were repeated. Commercials appearing only once made up 58% of the sample, while repeated commercials made up the remaining 42%. The subsequent analysis is based only on ads that are unique to the sample. In other words, an ad that appeared more than once, whether between networks or within the same network, was counted only one time. There were 130 advertisements which fit this description.

The interjudge reliability was 88% and, in the case of a discrepancy, the judgement made by the first author is reported here. Eleven commercials were judged by the first author to contain rap music. The second judge was not as strict in his definition of rap music, but was in agreement with the first author that these particular eleven commercials contained rap. To be considered rap music the words had to be spoken in rhythm and not sung to a melody. Rap music was usually accompanied by typical rap behavior such as; wearing sneakers, baseball caps and work-out suits, speaking into microphones and break-dancing.

Upon examining the race of the characters in the ads, it was found that a majority of the advertisements showed white people only (55%), and an additional three percent of the ads were classified as having characters that were white and other (not black). Three advertisements (3%) showed black people only. Twenty-nine percent of the ads showed whites, blacks and at least one person classified as "other". The remaining eight percent of the ads contained characters that were not human and could not be characterized by race (e.g. a rapping Teddy Bear).

Females were represented almost equally with males within the set of advertisements. Twenty-five percent of the ads contained males only, eighteen percent contained females only and all except three of the remaining ads contained people of both sexes. Once again, these three ads did not contain any characters which could be classified by sex (e.g. cartoon honey bee). Most of the products in the ads were directed toward children of both genders (69%), while twenty-three of the ads (18%) were aimed at females and seventeen ads (13%) were aimed at males.

In the original sample of 224 ads (including repeats), rap music was used in twenty-four of the ads, which is ten percent of the sample. In the subset containing only unique ads, eleven ads used rap music, which is nine percent of the subset. Interestingly, the rappers used by the advertisers were equally divided between blacks and whites. Five ads used a white rapper, five used a black rapper and one used animated characters that could not be classified by race. The

rappers were male in nine ads, female in two ads. Both ads using female rappers were promoting toys in the "Barbie doll" line (Barbie Trading Cards and Cool tops Skipper doll). These rappers were considered to be white because all of the girls appearing in the ads were white, even though the little girls who were actually singing did not appear. Four different ads for Lego products were included in the sample of unique rap ads because they were advertising different toys. All of the Lego ads showed the same black boy who mouthed the words to a rap song, while two white boys danced on either side of him and appeared to be "backup singers." The Hot Wheels Racer ad also showed one black boy as the rapper, while the other white boys were shown in the background. The three white male rappers were all cartoon characters. "Barney Rubble" was a rappin' detective talking about Pebbles Cereals. A "Campbell Kid" and a rapping Teddy Bear take turns rapping in an advertisement for Campbell's Teddy Bear soup. "Punchy", who looks like a little Hawaiian tourist, does the rap for Hawaiian Punch. Finally, the most unusual rappers in the sample were the "Chicken McNuggets" from McDonald's, which looked like little brown puppets and were counted as being male because of their voices and baseball caps.

An important observation is that white rappers always appeared in ads with only white people, while the black rappers always appeared with white people, never other blacks. The rule which seems to apply here is to never isolate the "majority". This is consistent with the finding by Dominick and Greenberg (1970) that blacks are typically shown in the larger context with other characters. This rule also seemed to apply to gender representations in children's advertising, assuming that males are a "psychological" majority. In the twenty-one ads that were obviously aimed at boys, males only (usually adult) provided the voiceover. The voiceover was defined as a person who does not appear in the advertisement but does have the last word. In the ads directed toward girls, a female (usually adult) always provided the voiceover. For products aimed at both boys and girls, males usually had the last word. In seventy of these ads, a male provided the voiceover, while females provided the voiceover in only eight advertisements.

DISCUSSION AND IMPLICATIONS

The results provide some preliminary evidence that rap music may be undergoing a hegemonic process because of its interpretation by advertisers. They seem to believe that because rap is popular, kids will like any message that is presented in a rhyming way, which is probably true. The advertisements for boys' toys were most true to the original rap style. The Hot Wheels and Legos ads each used a black boy as the rapper and included a little bit of dancing with their singing. Perhaps these advertisers felt that rap music could appear in a more true form with these toys because rap has been traditionally macho. It appeared that the Barbie ads were the least rap-like, with the little girls speaking in unison in a rhythmic way, but certainly avoiding any male symbolism. The fact that the other rappers were white cartoon characters is

further indication that rap music is being trivialized in some ways.

There is also evidence which indicates that both blacks and females are more frequently represented in this study than in previous studies. For example, O'Kelly and Bloomquist (1976) examined the frequency of both blacks and females in children's advertising. In their content analysis, every single character was coded according to race and sex. They found that 302 characters were white and 12 characters were nonwhite (only about 4% of the sample). In the present study, both white and black characters are represented in more than 25% of the advertisements. This difference in results is possibly due to a couple of different things. First, in our study we did not count individual characters. It was only noted whether or not at least one black or female person appeared in the commercial. It is likely that these "minorities" were outnumbered by "majority" children. The difference between our results and those of O'Kelly and Bloomquist (1976) may also indicate a greater consciousness on the part of advertisers to represent blacks and females more frequently. It is our opinion that blacks were not shown in particularly insulting or stereotypical roles. Usually, their roles were no different from the white children in the commercials. On one hand it might be argued that the Lego commercials used a "token" black. On the other hand, this boy was in an enviable position as the leader and rapper of the group. It was a role that boys of all races could admire. In conclusion, rap music appears to be moving into the third stage of Gottdiener's (1985) mass culture model, in which a social trend is sanitized by the producers of mass culture. It is in some ways unfortunate that the mass culture industries have the ability to dominate and manipulate the development and diffusion of rap music, because most of these producers have little understanding about the subculture from which it originated. For most Americans, exposure to the group life of others takes place through the agency of mass culture (Gottdiener 1985). This is the most unfortunate outcome for a subculture in which many young people hoped that rap could be a "way out" for disadvantaged youth and a chance that others might listen to what they have to say.

The Experience of Time as a Function of Musical Loudness and Gender of Listener

James J. Kellaris, University of Cincinnati
Moses B. Altsech, Pennsylvania State University

ABSTRACT

This study examines the influence of music and gender on the experience of time. Consumers experience waits and delays in many contexts. Environmental factors such as music may diminish (or augment) perceived time during these periods. An experiment found musical loudness to increase perceived duration of time passage among female listeners. A second dimension of temporal experience, perceived pace, was positively influenced by loudness irrespective of listener gender. Practical implications and directions for future research are discussed.

INTRODUCTION

Consumers frequently experience waits and delays in checkout lines, bank teller lines, registration and voting lines, airports, restaurants, medical offices, and many other consumptive contexts. A recent advertisement for long distance telephone services illustrates the adverse effects of excessive "hold time" on customers placing orders by telephone. Since many consumers consider time a valuable personal resource (Jacoby, Szybillo, and Berning 1976; Hornik 1984; Bergadaa 1990), longer waits may lead to greater inconvenience, annoyance, and dissatisfaction. In extreme cases, sales may be lost when customers are kept waiting too long.

As a practical matter, marketers cannot always control actual waiting time. They can, however, manipulate factors in the stimulus environment which can influence consumers' perceptions of time passage during these periods. Environmental music is one such factor.

As the popular utterance suggests, time seems to fly when one is having fun. Thus, the presence of enjoyable music might be expected to diminish listeners' perceptions of time passage. The process by which music influences listeners' perceptions, however, may not be that simple. Music is not a "generic sonic mass" that operates through its mere presence or absence (Bruner 1990). It is composed of numerous variables, each of which, along with their interactions (Kellaris and Kent 1991), can influence cognitive outcomes (Dowling and Harwood 1986).

The perceived duration of a time interval "filled" with music should depend on the specific character of that music. The character of a piece of music is determined by the interplay of its stimulus properties with listener characteristics (Bruner 1990). Loudness is an important musical stimulus property. It is a basic characteristic of all forms of music, and it can be easily controlled by marketers. Gender is an important listener characteristic that may moderate the effects of musical properties on cognitive outcomes such as time perception. Previous research has found the sexes to differ in terms of hearing sensitivity (Corso 1963), cognitive processing of auditory

stimuli (Kimura 1985), and preferences for stimulation levels (Kellaris and Rice, forthcoming). Although gender differences in music perception remain largely unexplored, we expect differences to emerge based on theory and research findings in audiology, brain physiology, cognitive psychology, and psychomusicology.

This study examines the effect of music on consumers' experience of time. Two aspects of temporal experience -- perceived duration of a time interval and perceived pace -- are examined. Based on theory drawn from diverse disciplines, gender is hypothesized to moderate the influence of music's loudness on perceived time passage such that louder music augments subjective time experience to a greater extent for female listeners. Perceived pace, the subjective speed with which a succession of events takes place, is also expected to be a function of music's loudness, with a similar moderating effect of gender.

REVIEW & HYPOTHESES

Perceived Time

Time flies when you're having fun. On the other hand, a watched pot never boils. These expressions refer to the relationship between the events filling a time interval and its subjective duration. As William James (1890/1952) noted over a hundred years ago, "In general a time filled with varied and interesting experiences seems ... long as we look back ... empty time seems ... in retrospect short" (p. 408).

There are several models of psychological time that relate stimulus properties of events filling a time interval to the experience of duration (Levin and Zakay 1989; Block 1990). Although alternative models provide different explanations, they tend to make similar predictions concerning basic stimulus-response relationships. For example, when a time interval is filled with more events, more information, more complex, intense, or salient stimuli, the perceived duration of that interval is generally greater. Ornstein (1969) would explain this in terms of the amount of memory or "storage size" associated with the judged interval. Zakay (1989) might explain this in terms of attentional resources required to process the stimulus information. Greater allocation of attentional resources to processing nontemporal aspects of the stimulus reduces attentional allocation to the internal clock ("cognitive timer") assumed by his model. Fraisse (1984) emphasizes the role of change as a determinant of perceived duration. The greater the change (i.e., number of successive events that take place during a time interval), the greater the perceived duration of the interval. This type of inference is based on the simple heuristic "it must take longer for more things to happen."

In addition to perceived duration, consumers experience time in terms of subjective pace. A succession of events within a time interval, irrespective of the duration of that interval, can take place slowly or rapidly. Children learn to associate time, velocity of motion, and distance at a fairly early age (Piaget 1927/1969). It takes a certain amount of time for an object traveling at a given speed to move a fixed distance. Because a faster moving object travels a greater distance than a slower moving object during a fixed time interval, the faster moving object is perceived as moving for a longer time -- even when the faster and slower moving objects start and stop at the same time (Levin and Zakay 1989). By analogy, the velocity or pace of sounds may be perceived in the same way as visual objects. Auditory stimuli which "move" at higher levels of perceived activity should be perceived as longer in duration.

Based on these models, we can predict effects of musical stimulus properties on the experience of time. For example, music which is louder, more salient, or more complex should be perceived as longer in duration and faster in pace. Among musical stimulus factors that affect the experience of time, loudness is probably the simplest to manipulate. Marketers can easily control the volume of atmospheric music in retail environments, or the level of "hold music" on telephone answering systems.

Moderating Effect of Gender

As previously noted, reactions to music are not determined solely by the objective properties of sound. Listener characteristics influence the subjective perception of music. For example, one study found musical preferences to vary by age of listener (Holbrook and Schindler 1989). Many studies have found extent of musical training to influence reactions to music (Dowling and Harwood 1986). We believe that gender may also moderate the impact of music on listeners. There are several reasons for anticipating this.

First, men and women differ in terms of hearing sensitivity. College-aged females generally have more acute hearing, particularly in the higher frequency range (i.e., 4000 Hz and above), than do college-aged males (Corso 1963). This not only means that a given sound may seem louder to females, but, because high frequency overtones determine the timbre or "tone color" of a pitch (Dowling and Harwood 1986), musical sounds may be perceived more vividly by females. As a result females may be more sensitive to music in general, and particularly to effects stemming from sound intensity.

Second, brain physiology research has documented sex differences in auditory information processing (Kimura 1985). Musical information tends to be processed predominantly in the right hemisphere of the human brain. For many processing tasks, including the processing of nonverbal information, females exhibit less lateralized encephalographic activity. If one assumes this to indicate the involvement of more cognitive resources in nonverbal auditory processing among females, females may be more prone to cognitive effects of musical stimuli.

Third, there is limited anecdotal and empirical evidence that suggests college-aged males and females may prefer different levels of auditory stimulation. Anecdotally, it appears that the majority of listeners who prefer loud "Heavy Metal" music tend to be young males. An empirical study by Kellaris and Rice (forthcoming) found a negative effect of musical amplitude on the affective evaluations of women. Males' affective evaluations were statistically invariant across loudness conditions, but showed a slight positive increase as loudness increased. Given this finding, we might expect loudness to augment duration perceptions among females. Time should seem to "drag" when the level of stimulation induces a decrement in positive affect. (See Loftus et al. (1987) for further discussion of differential effects of stimulation level on time estimates of males and females.)

Fourth, Block (1990) proposed that "characteristics of the time experiencer" interact with the "contents of a time period" to influence time-related judgments. Gender is among the important characteristics of the time experiencer in Block's conceptual model. Although Block's model does not explicitly state how gender is expected to interact with contents of a time interval, theory and findings from audiology, brain physiology, and psychomusicology provide a sufficient basis for prediction.

Hypotheses

Based on our review, we anticipate the following effects of music on temporal experience. First, since louder music confronts listeners with more sensory information and evokes greater involuntary attention which distracts from time processing, we expect the loudness of music to augment the perception of time passage for most listeners. Specifically:

H₁: Louder music will be perceived as longer in duration.

Second, we expect gender to moderate the effect of loudness on time perception. Given differences in hearing sensitivities, cognitive processing, and stimulation level preferences, females should be more prone to the influence of loudness on perceived time passage. Stated formally:

H₂: The effect of music's loudness on perceived duration will be significantly more positive for female listeners.

Third, we expect loudness to affect perceived pace of the stimuli filling a time interval. Loudness, like the brightness of a light, is a physical property of sound closely associated with stimulus intensity. Based on the relationship between stimulus intensity and perceived activity (Anand and Holbrook 1986), one might anticipate louder, more intense stimuli to produce the illusion of faster pace. Furthermore, the internal arousal state induced by higher levels of stimulation should reinforce this effect (Smith and Curnow 1966). Thus:

H₃: The loudness of music will have a positive effect on perceived pace.

Finally, as with perceived duration, the effect of loudness on perceived pace may also be moderated by gender for similar reasons.

H₄: The effect of music's loudness on perceived pace will be significantly more positive for female listeners.

EXPERIMENT

Overview

We tested our hypotheses in a 2 X 2 factorial experiment using a between-Ss design. Treatments included two levels of musical loudness (soft = 60 dB, loud = 90 dB) and gender of listener. The dependent variables were retrospective duration estimates and perceived pace. Ss were randomly assigned to treatment conditions and processed in small groups. They listened to the stimulus music over a loudspeaker, then filled out a brief questionnaire.

Subjects

One hundred eight ($n = 108$) undergraduate students (54 males, 54 females) participated in the study. Course credit was offered as an incentive. Ss were naive to the study's purpose. Ages ranged from 20 to 27 years, with a median age of 21.

Stimuli

The stimulus music was an original light pop-rock style composition produced in a digital sound studio at the University of Cincinnati's College-Conservatory of Music. The instrumental piece was 180 seconds in duration. It was scored for soprano sax, trumpets, strings, electric bass, and drums, and recorded at the moderately fast tempo of 120 BPM. The composition was produced using sequencer software and digitally sampled sounds as per Kellaris and Kent (1991). Bruner (1990) provides a brief, nontechnical explanation of this technology.

To manipulate loudness, volume levels were preset on the amplifiers that powered speakers in the listening rooms. Using a decibel meter (placed at room center), volume levels were preset to 60 and 90 dB to represent soft and loud conditions respectively. The 60 dB level is slightly softer than normal conversation, and typical of "background" music heard in retail environments. The 90 dB level is typical of "foreground" music. A post-test manipulation check verified the subjective difference between these volume levels on a seven-point loudness scale (1 = soft, 7 = loud). The 60 dB treatment produced a mean rating of 3.68 and the 90 dB treatment a mean rating of 5.60 ($t = 9.73$; $p < .001$).

Procedure

Ss were randomly assigned to treatment groups upon arrival at a behavioral lab. An equal number of males and females was assigned to each loudness condition. Groups were directed to separate sound-

proof listening rooms for concurrent processing. There were no more than eight Ss in any given room during each session. They were instructed not to talk, and told to leave the questionnaire face down until the music stopped playing. Unobtrusive observation of the Ss during the procedure found no violations of these instructions. After the music stopped, Ss completed the questionnaire. Ss anticipated "opinion questions" about the music they heard, but did not anticipate duration estimate or perceived pace items.

Measures

The dependent measures included a duration estimate item and a perceived pace scale. The duration item asked respondents to "please estimate how long the music lasted." Blank spaces labeled "___ minutes and ___ seconds" were preceded by the prompt "I estimate the music I heard lasted for about:" This standard measure has been used by many psychological time researchers (Fraisie 1984; Hornik 1984; Zakay 1990). The pace measure was a single-item seven-point semantic differential scale with end points labeled "slow" (1) and "fast" (7), preceded by the prompt "The music I heard was:" This item was taken from Kellaris and Kent (1991).

Both dependent measures were embedded among dummy items relating to the music. The duration measure preceded the pace scale. The filler items used the same response formats as the dependent variables, including sentence completion (e.g. "A good name for this piece of music might be ___"), and seven-point semantic differential scales (e.g. "Harmonious/Dissonant").

The questionnaire also included the previously described manipulation check item, and items relating to gender, age, musical preferences, and training.

RESULTS

Perceived Duration

Retrospective duration estimates of the three minute musical piece ranged widely, from thirty-five seconds to over seven minutes. The median estimate was exactly three minutes (180.00 seconds). This is consistent with previous research which found duration estimates to vary widely about an accurate central tendency (Fraisie 1984). Whereas females tended to underestimate actual time by about fifteen seconds ($X = 165.41$), males overestimated actual time by the same margin ($X = 195.61$).

ANOVA results support Hypothesis 1. There is a significant main effect of loudness on perceived duration ($F = 3.90$, $d.f. = 107$, $p = .05$), although the magnitude of the effect is fairly small (omega squared = .02). The effect is in the expected direction. Louder music was generally perceived as longer in duration ($X = 193.17$) relative to softer music ($X = 167.85$).

Hypothesis 2 was also supported. There is a significant two-way interaction of loudness with gender on perceived duration ($F = 8.26$, $p < .005$). The magnitude of this effect is .06 (omega squared). See Figure for illustration.

FIGURE
Interactive Effect of Music's Loudness and Gender of Listener on Duration Estimates

$F = 8.26, p < .005$
 $\omega^2 = .06$

The loudness of the music has a positive effect on the duration estimates of females ($t = 3.23, p < .002$). Loudness has a slight decremental effect on males' time perceptions, although this is not statistically significant ($t = -.67, n.s.$). While the time estimates of males and females differ significantly under the soft music condition ($t = 3.97, p < .001$), they converge under the loud music condition ($t = -.26, n.s.$).

Perceived Pace

Pace ratings ranged from three to seven on the seven-point scale, with a mean rating of 5.41. Females tended to perceive the pace as slightly faster ($X = 5.52$) relative to male listeners ($X = 5.30$), although this was not a statistically significant difference.

Hypothesis 3 was supported. There is a significant main effect of loudness on perceived pace ($F = 6.19, p < .014$), with louder music perceived as faster ($X = 5.61$) than softer music ($X = 5.20$). The magnitude of this effect is .045 (omega squared).

Hypothesis 4 was not supported. Although there is a slightly sharper increase in perceived pace across loudness conditions among females ($X_{\text{soft}} = 5.22; X_{\text{loud}} = 5.81$) than among males ($X_{\text{soft}} = 5.19; X_{\text{loud}} = 5.41$), this effect is not statistically significant ($F = 1.28, n.s.$).

DISCUSSION & CONCLUSION

This study examined the influence of music's loudness and gender of listener on two aspects of temporal experience. Experimental findings generally supported our hypotheses. Louder music augmented both perceived duration of a time interval and

perceived pace of the stimulus event. Gender had a moderating influence in that the effect of loudness on perceived duration was significantly more positive among females.

These findings suggest that consumers' time perceptions may be influenced by manipulating atmospheric features such as music. This has several practical implications. For example, marketers may be able to diminish the perception of time passage while customers are in checkout lines or waiting areas by making appropriate adjustments in the volume of environmental music. Given the main effect of loudness on perceived pace, it may be possible to use music to mitigate consumers' feelings of being "rushed" in certain situations, such as dining at restaurants.

Contrary to our expectations, gender did not moderate the influence of loudness on perceived pace. The expected effect might emerge over a wider range of loudness than that used in the present experiment; however, we believe our loudness levels represent what consumers typically encounter in the world outside the behavioral lab. If music needs to be louder than 90 dB for loudness to interact with gender, this interaction would have little practical relevance for marketing applications.

It should be recognized that the generality of these findings is constrained by several limitations. Each of these limitations suggests a possible direction for future research. First, our study examined listeners' experience of duration in retrospect. Several authors have mentioned possible differences between the experience of duration in passing versus the remembrance of a time interval (e.g. Block 1990). Our retrospective measure of perceived time captures the remembrance of a time interval, not the

"psychological present" as it occurred. While both aspects of temporal experience may influence consumptive outcomes (e.g. satisfaction with a store), we expect consumers' retrospective judgments to have a greater influence in the long run.

Second, the forced exposure condition may have resulted in more attentive listening than would be typical in retail environments. It is not certain how (if at all) the exposure condition might have influenced the results; however, to test the generality of our findings, the study should be replicated using a more passive exposure to the stimulus music.

Third, an additional limitation may stem from the procedure. The ambiguous instructions may have encouraged subjects to evaluate the music during its presentation. (Recall that Ss were told to listen to the music without being told the specific purpose.) Since "bad" music may seem to play forever and "good" music may seem to end too soon, an "evaluative mind set" could have contributed to temporal effects of the music.

Fourth, this study assumes a link between temporal experience and consumptive outcomes (e.g. satisfaction) but does not establish such a link empirically. This task must also be commended to future research.

In conclusion, evidence from this study suggests that consumers' perceptions of time can be influenced by music. Both the retrospective duration and perceived pace dimensions of temporal experience were augmented by increasing the loudness of music. Females were more sensitive to the effects of music's loudness on perceptions of time passage. Given the present findings, the effects of other musical properties, other listener characteristics, and other types of atmospheric variables should be explored in future research.

Consumer Esthetics Outside the Lab: Preliminary Report on a Musical Field Study

James J. Kellaris, University of Cincinnati

ABSTRACT

This paper reports preliminary analyses on a field study designed to explore responses to music as a function of its objective properties. Musical stimulus properties were manipulated in a quasi-experimental design using live music. Behavioral responses of audiences were unobtrusively observed. Hedonic response, operationalized as applause duration, was found to be a nonmonotonic function of musical tempo; however, the specific nature of this relationship varied across modes.

INTRODUCTION

Aesthetic objects can evoke numerous affective, cognitive, and behavioral responses in consumers of the "aesthetic experience." While some forms of aesthetic communication stimulate changes primarily in internal states (e.g. visual arts), other forms are strongly associated with overt behavioral responses. For example, musical performances often encourage audience participation in the forms of rhythmic hand-clapping, body swaying, dancing, singing along, shouting, and applauding. These common forms of participation in the music-consumptive experience are shared across many cultures.

Most previous studies in consumer esthetics have focused on affective and cognitive responses to aesthetic stimuli (e.g. Anand and Holbrook 1986; Kellaris and Kent 1991). The majority of these studies were conducted as controlled experiments involving forced exposure to aesthetic stimuli in laboratory settings. In many cases, artificial stimuli such as "tone sequences" (Crozier 1974) or digitally synthesized music was used.

While lab studies can offer valuable insight into the influence of music on consumers, it would seem desirable to study music where it actually touches the hearts and lives of listeners. As Pavelchak et al. (1988) stated, a real world setting is important because "context is an integral part of emotional experience and because results obtained in laboratory settings need to be externally validated" (p. 360).

The present study examines behavioral responses to an aesthetic object -- Greek music in this case -- in natural settings. This preliminary report focuses on the influence of two structural properties of music (tempo and modality) on hedonic response as measured by applause duration. Tempo and mode were selected for study because of their theoretic and practical importance as "design features" of musical "products." This study combines elements of previous consumer research to produce a unique contribution. Whereas previous field studies have examined influences of music as an environmental background feature (e.g. Milliman 1982, 1986; Yalch and Spangenberg 1990), and controlled lab experiments have examined self-reported responses to music as a focal stimulus object (e.g. Anand and Holbrook 1986;

Kellaris and Kent 1991), the present study examines a behavioral response to music in natural settings where music is the focal stimulus object.

BACKGROUND & HYPOTHESES

As Bruner (1990) states, "music is not simply a generic sonic mass, but rather a complex chemistry of ... elements" (p. 94). Music is composed of multiple time-, pitch-, and texture-related variables (Dowling and Harwood 1986). Bruner proposes that musical variables are capable of producing main and interactive effects on consumers' thoughts, feelings, and behaviors. There is scattered evidence that supports this proposition, but Bruner concludes that "at this time the relevant body of literature is still meager" (p. 102). More research relating musical variables to listeners' responses is needed.

Among musical variables, tempo (the speed or pace of music) is believed to make a particularly important contribution to music's aesthetic character (Hevner 1937; Rigg 1940). While some studies report a positive linear relationship between tempo and affect (e.g. LeBlanc and McCrary 1983), there is ample reason to expect a nonmonotonic relationship (Anand and Holbrook 1986). Theory suggests that positive affect should be greatest at a moderate level of arousal (Wundt 1874; Berlyne 1974). Since arousal is closely linked with stimulus intensity, variation in affect can be anticipated across stimulus patterns (Vitz 1966).

This principle can be applied to musical stimuli. Specifically, very slow or very fast musical tempi should produce less positive affect than a moderate pace. Thus, across a wide range of musical examples, one might anticipate a nonmonotonic relationship between tempo and hedonic response. Although this study is exploratory in nature, there is sufficient basis to hypothesize the following general relationship:

H₁: There will be a significant nonmonotonic relationship between musical tempo and hedonic response of listeners.

Furthermore, tempo may interact with other musical variables (Bruner 1990). A recent lab study by Kellaris and Kent (1991) found that the effects of tempo depend on the "modality" (key) of the music. Modality refers to the configuration of intervals between pitches that comprise a musical scale (Apel 1973). The influence of tempo on music's perceived appealingness differed across major, minor, and atonal modes in the Kellaris-Kent experiments. Given the expectation of a positive correlation between perceived appealingness and behavioral manifestations of hedonic pleasure, the moderating effect of modality should generalize to the tempo-applause relationship in a natural setting. Thus:

H₂: Musical modality will moderate the influence of tempo on hedonic response.

The present study examines the influence of tempo and modality in the real world beyond the behavioral lab, using unobtrusively observed behavioral measures of hedonic response to live Greek music. Greek music was chosen because it employs a wide range of tempos and modes, and because it customarily involves active audience participation representing a broad range of overt behaviors (Holst 1975). The focus of this preliminary report, however, is solely on applause. Applause is a simple indicant of hedonic response which is nearly universal across musical audiences.

METHOD

Overview

The purpose of this study is to examine the influence of objective stimulus properties of music on audience responses in natural settings. Songs were selected from the standard Greek repertoire to manipulate musical variables in a quasi-experimental design. These songs were performed live at six different social events in hellenic communities in the United States. Behavioral responses of audiences were unobtrusively observed and recorded by the author, who participated as a musician in an orchestra. Musical properties and outcome variables were coded by experts and data were analyzed using the individual song performance as the unit of analysis.

Subjects

Audience members at six events served as subjects. The events included an AHEPA conference ball, two Greek Orthodox wedding receptions, and outdoor Greek Festivals in three southeastern cities. Audience sizes ranged from 200 guests at one wedding reception to over 1000 at the outdoor festivals. Subjects were not told that their behavior was being observed.

Stimulus Materials

Forty songs from the standard Greek dance music repertoire were used to manipulate musical properties. The songs, performed at each of six events, included traditional and modern pieces, both *laiki* (urban) and *demotiki* (rural mainland and island) genres, representing multiple dance rhythms (e.g. *calamatiano*, *syrto*, *tsamiko*, *syrtaki*, etc.). About a third of the songs were sung and the remainder performed as instrumentals. Most of the songs were familiar to Greek audience members, as supported by the observation that many "sang along" with the tunes, including those performed instrumentally.

At each performance the songs were presented in one hour "sets," with a brief pause between selections and a break of ten to fifteen minutes between sets. Each set consisted of about ten songs. Song durations ranged from just over one minute to almost seven minutes, with a median time of about 3.5 minutes. The order in which the songs were played varied across performances.

The individual song performance was the unit of analysis. Some cases were lost due to technical problems with recording equipment, and some could not be used due to missing data. The usable sample included 192 complete observations.

Procedure

The stimulus songs were performed by Nick Demos and the Greek Islanders, a Greek-American musical group that performs predominantly in the southeastern United States. The instrumentation of the orchestra included an eight-stringed electric *bouzouki* (played by the author), clarinet, electronic keyboard, bass, and kit of drums, including middle-eastern percussion instruments (e.g. *doumbek*).

The music was preselected and the sequence of performance determined in cooperation with the orchestra leader. Each performance was unobtrusively tape-recorded using a Toshiba RT-7016 to facilitate coding at a later time.

Measures and Coding

Independent variables included the following objective measures of musical stimulus properties: (X1) tempo, coded in beats per minute (BPM), (X2) duration of song, coded in seconds, (X3) meter, coded categorically as "even" (duple meter), "triple," or "odd/mixed," (X4) modality, coded categorically as "major," "minor," or "other" keys, (X5) presence of lyrics, coded as "1" for vocals and "0" for instruments, (X6) instrumentation, coded categorically according to which instrument was the principal melodic or solo instrument for a given song, and (X7) dance type (i.e., *calamatiano*, *syrto*, *tsamiko*, etc.), also coded categorically. These variables are a representative subset of the cantometrics taxonomy (Lomax 1976) used in empirical ethnomusicological research, and are similar to the set used by Stout and Leckenby (1988) in their ad music study, with obvious ethnic adaptations.

Both the researcher and a doctoral candidate in Musical Arts coded the independent variables for each song by listening to audio recordings of the performances. A Seiko digital metronome (SQM-342) was used to measure tempo in BPM. Disparities in coding judgments were reconciled by discussion.

To allow assessment of possible confounding effects, the following variables were also included in the data set: (X8) "gig," which specified the performance at which a given song was performed, (X9) "set," which specified the grouping in which a given song was performed, and (X10) order of presentation.

The dependent variable was hedonic response, measured as duration of applause in seconds. There is ample precedent in the social sciences for using applause as an indicant of audience pleasure or approval (e.g. Heritage and Greatbatch 1986). Applause duration was coded by the author by listening to tapes of each performance. As a check on the coding, a Musical Arts student coded a subset of the stimulus songs. There were no coding disagreements. The coding procedure was pretested using a video tape

recording of a live performance. Pretest data were *not* included in the data set analyzed in this study.

ANALYSES

Confounding Checks

Lack of experimental control is the bane of quasi-experimental field studies such as the present one (Campbell and Stanley 1963). Because of this inherent lack of control, data analysis began by performing statistical confounding checks. A variety of metric and nonparametric tests were used since the independent set includes categorical, ordinal, and metric variables.

Based on conventional wisdom, one might anticipate a natural rise ("warm-up" effect) and fall ("fatigue" effect) in hedonic response over the course of a performance. This effect should be independent of the influence of musical variables; however, serial order of presentation may be correlated with musical variables in the data set. Thus, the first confounding check explored the relationship of serial order to tempo and mode. No statistical associations were found.

Other confounding checks explored relationships between tempo, mode, and other musical characteristic. Not surprisingly, tempo was confounded with two other time-related variables: meter (the division of musical pulse into strong and weak beats) and song duration; however, neither meter nor duration was statistically related to applause duration after controlling for tempo. Since these variables have no effect on applause independent of their association with tempo, this confounding is not problematic. Tempo was statistically unrelated to the other musical variables.

A final confounding check explored performance context effects. Since audience sizes and composition varied across performances, performance context may have influenced responses to the music. Although the distribution of tempi and modalities varied slightly across performances, this variation was not statistically significant. This suggests that data can be meaningfully aggregated across performances.

H1: Tempo Effects

Based on earlier work in empirical esthetics (e.g. Fetchner 1876) and more recent work in consumer esthetics (e.g. Anand and Holbrook 1986), a nonmonotonic tempo-response relationship was anticipated. But, whereas previous studies have reported several different types of nonmonotonic relationships, the present analysis explored applause duration as a logarithmic, power, and quadratic function of tempo using OLS regression.

A significant nonmonotonic (quadratic) tempo-applause relationship was found. This finding supports Hypothesis 1. Applause duration peaked around 147 BPM, then diminished with further increases in tempo. The fit of this curve was modest but statistically significant ($R^2 = .06$; $F = 6.15$, d.f. = 192, $p < .003$), with significant contributions from both tempo ($t = 2.41$, $p < .02$) and tempo-squared ($t =$

2.21 , $p < .03$). Although the R-squared is low relative to those found in lab studies, this is what one might expect to find outside the controlled environment of the behavioral lab due to extraneous "noise" (McGrath 1981).

H2: Moderating Effect of Mode

Given Kellaris and Kent's (1991) finding that modality moderates the influence of tempo, separate analyses were conducted for major, minor, and "other" (neither major nor minor) modes. Findings support Hypothesis 2.

A significant quadratic tempo-applause relationship was found for the 51 songs pitched in minor keys ($R^2 = .22$; $F = 6.85$, $p < .002$), with significant contributions from tempo ($t = 3.48$, $p < .001$), tempo-squared ($t = -3.38$, $p < .002$), and a constant term ($t = -2.55$, $p < .02$).

For the 106 songs pitched in major keys, a different type of nonmonotonic tempo-applause relationship emerged. A logarithmic function produced the best fit ($R^2 = .07$; $F = 7.64$, $p < .01$). Only the log of tempo contributed significantly ($t = 2.76$, $p < .01$) to the prediction of applause duration.

Among the 33 songs in non-major or minor modes, no statistically significant linear, logarithmic, exponential, or quadratic relationship was found between tempo and applause duration.

To summarize, the data provide support for both hypotheses. There is a nonmonotonic relationship between musical tempo and hedonic response. The specific nature of this relationship varies by mode.

DISCUSSION & CONCLUSION

This study examined a behavioral response to an aesthetic object as a function of its objective properties in natural settings. It found significant nonmonotonic relationships between the tempo of live Greek music and hedonic response of audiences as measured by applause duration. The strength and nature of the relationship varied across different modes. Consistent with Kellaris and Kent's (1991) recent lab findings, tempo and modality were found to exert an interactive influence on hedonic response. Specifically, applause duration was a quadratic function of tempo for songs pitched in minor keys, and a linear function of the logarithm of tempo for songs pitched in major keys. There was no statistical relationship between tempo and applause for songs pitched in non-major or minor keys.

Over a fairly wide range of tempi (68 to 178 BPM), and across all modes, applause duration followed an inverted U-shaped curve as tempo increased. This is the "Wundt-curve" pattern predicted by psychobiological theory (Berlyne 1974; Anand and Holbrook 1986). The finding indicates that listeners prefer a moderate level of stimulation. This quadratic response pattern held for songs pitched in minor keys, but changed for major and other modes.

The loglinear response pattern for songs in major keys may be explained in terms of the relative informational complexity of major vs. minor modes. Minor modes contain altered pitches -- notes that

depart from the natural overtone series on which major scales are based (Apel 1973). In information theoretic terms, minor modes have higher "uncertainty levels" than major keys (Crozier 1974). Major keys, in contrast, may be characterized as less complex, or lower in uncertainty. For any mode, increases in speed create greater "informational density," i.e., more notes per minute. Affective arousal is, in part, a function of the amount of information contained in a musical stimulus (Berlyne 1974). Since major keys contain less varied information than minor keys, one might expect an eventual decrease in hedonic response to occur at a higher tempo. In other words, the observations in the present study may simply be on the "uphill" side of an inverted U-shaped "Wundt curve" for major keys. This explanation could be tested using a more extreme range of tempi; however, the songs in the present study represent a realistic range. Listeners are unlikely to encounter dance music performed at speeds greater than the max of 178 BPM in this study.

There was no statistical tempo-applause relationship among the non-major or minor songs. The relative novelty of these modes which used atypical combinations of pitches may have called more attention to the pitch dimension of the music, thereby mitigating effects stemming from the temporal dimension (i.e., from tempo). Alternatively, there may have been too few observations in this category to allow the presence of tempo effects to be detected.

The generality of these findings are limited by the design and setting. Since the data were collected in natural settings, rigorous experimental control was not possible. As a result, the design was nonorthogonal, cell sizes were uneven, and there was some confounding of independent variables with exogenous influences. The audiences were self-selected. But, whereas the present findings are consistent with theory and previous findings in consumer esthetics, the tempo-hedonic response relationship is apparently robust to the methodological perils of field settings.

Although a number of statistical checks were performed to assess potential confounding, these tests did not examine the relationship of objective musical attributes to qualitative variables such as subjective meaning. For example, faster and slower songs may have differed not only in tempo, but in meanings, associations, and imagery evoked.

Generality of findings is also limited by the type of music used in this study. Greek music tends to be highly rhythmic, and perhaps emphasizes the temporal dimension of music to a greater extent than do some other types of music. This may make temporal effects more likely to emerge. The effects reported here may generalize to other highly rhythmic forms of music, such as rock, hip-hop, or reggae, but may not generalize to all styles of music.

Having recognized these limitations, some preliminary implications can be drawn. The first implication concerns external validity. This study demonstrates the external validity of laboratory experiments that found objective properties of sound

to influence consumers' responses to music. It is important to verify that such relationships exist outside the artificial world of the behavioral lab.

Second, the substantive findings on tempo's influence hold practical implications for parties who use music to influence consumers. There may be an optimal tempo at which hedonic response is maximized for different types of music. Perhaps the design features of music in ads or in retail environments can be "aesthetically engineered" to optimize music's positive influences on listeners.

Third, the finding on the moderating role of modality suggests that time- and pitch-related musical properties should be considered jointly. Several studies in marketing (e.g. Milliman 1982, 1986) have varied a single property of music without considering possible interactive influences. As Anand and Holbrook (1986) suggested, "The term 'music' denotes a wide range of stimuli ... that hang together in an extremely complex gestalt. One pulls apart this gestalt only at one's peril" (p. 655).

This study suggests several possible directions for future research. Certainly other types of music and other audiences must be studied to test the generality of the psychobiological principles underlying the music-aesthetic experience. While applause is probably an important indicant of an audience's pleasure, many other behavioral responses could be studied. It would be interesting to observe audience behaviors such as facial expressions, finger tapping, or even yawning. Other dimensions of applause could also be investigated, including loudness, reaction time or response latency, and applause "density," i.e., portion of audience applauding.

As consumer research efforts often do, the present study seems to raise more issues than it can address conclusively. It offers only one small tile to the Byzantine mosaic of consumer esthetics. Future research must contribute more "tiles" before a clearer picture of the influences shaping the music-hedonic consumptive experience can emerge.

To Choose or Not to Choose: This Is The Question

Ravi Dhar, University of California, Berkeley

ABSTRACT

The question of how people choose from a set of alternatives has been extensively examined at the expense of addressing another interesting and related issue: *whether* or not to choose from a given set of alternatives. The theme underlying normative theory of consumer choice emphasizes that consumers maximize outcome utility. The assumption is that people arrive at an overall value (utility) by combining a vector of attributes or outcome sequences for each option. For example, when selecting from multiattribute alternatives, the vector of product attributes is reduced to a scalar called utility that is maximized. Similarly, consumers selecting between extended sequences choose the plan that maximizes the discounted value of the component outcomes. The findings presented here argue against the adequacy of the classical utilitarian view that decisions are evaluated solely on the basis of their ends rather than their means. We test this general premise for two consumer decision making scenarios: preference for not choosing and choice between extended sequences. This session shows that the process of deciding influences choices in a manner such that normatively equivalent outcomes result in different preference orders. This paper summarizes the session by providing a brief overview, and by describing representative ideas from the four papers comprising the session.

OVERVIEW

Marketers have extensively examined the decision rules that consumers use to choose from a given set of alternatives (Bettman 1979). One aspect of consumer choice that has received little attention pertains to the question of how consumers decide whether they are ready to choose or even more fundamentally, if they want to make a choice. As we know from our everyday experience, a question that consumers often face is not which alternative to choose but whether or not to make a choice. For example, a potential vacationer may choose between vacation spots, collect more information, or simply decide to postpone the holiday (Corbin 1980). It is somewhat surprising how little empirical attention has been devoted to this issue.

Consumers may sometimes choose to delay choice if the alternatives are unfamiliar or undesirable. Greenleaf and Lehmann (1991) identified five general factors that causes delay in consumer decision making. Delay arising from many of these factors, such as uncertainty, task avoidance, and risk of product performance can be justified on normative grounds. In such cases, the option of not choosing can be rationalized by a more complete inventory of individual preferences, one that captures the utility of not choosing. Such a specification of not choosing can be incorporated into the general framework of multiattribute utility theory (MAUT).

One case of preference for not choosing that is problematic for normative theory to handle arises when consumers are less likely to choose when a choice situation involves more than one attractive alternative. The cornerstone of economic viewpoint is that providing consumers with additional attractive alternatives can not decrease utility, and therefore, can not decrease the preference for choosing. In other words, the choice utility cannot be less than the utility of the most attractive option in that set (Meyer 1981). This leads to the obvious conclusion that having fewer options should never be more attractive than having more options. The first two papers question this premise and empirically show that people may prefer a restricted choice set to a larger one. The papers show that adding alternatives to increase choice may affect the willingness as well as the ability to choose. The resulting violation of the normative theory can not be accommodated within the classical framework.

One reason why consumers prefer to not choose when the choice set is expanded to include more attractive options is conflict. The increase in the number of available alternatives increases conflict (Berlyne 1957). Conflict arises because choices typically involve tradeoffs between attributes that appeal to different values. The increased conflict due to more number of attractive alternatives induces greater indecision, lowering the likelihood of choosing (Tversky and Shafir 1991). The difficulty of deciding between alternatives is not captured by the classical framework (e.g., the weighted additive utility model) which assumes that people have well defined attribute weights or preferences that are mapped onto the particular choice situation (see Shugan 1980 for a modified framework).

A second reason why people do not prefer to have a choice is when both alternatives are valued and there appears to be no clear reason to prefer one over the other. The rejection of the non chosen alternatives potentially induce feelings of responsibility, not considered in the classical framework. The feelings of regret are further moderated by the ease of imagining that the foregone alternative could have been selected (Kahneman and Miller 1986). When these emotions influence decisions before any consequences actually materialize, they are referred to as anticipatory regret. Thaler (1980) cites an instance of restricting choice even when restricting choice clearly has economic costs attached to it. For instance, members of the Israeli Army display a resistance to trading patrol assignments, even when it would be convenient for both individuals to do so, presumably due to anticipatory regret. The present view contends that a choice criteria in addition to the choice rule needs to be developed to determine if a choice is made. Furthermore, since consumers may not choose given attractive alternatives, cut off based strategies (e.g., conjunctive rules) allow us to infer when people will not choose, rather than when they will choose.

Since in usual choice situations consumers always have the options to search for more alternatives, an interesting issue that arises is whether consumers may sometimes voluntarily restrict the set of available options. Some evidence is found in the observation made by Thompson et al (1990) that participants in their study sometimes experienced a greater sense of freedom when placed in a restricted situation and gained a feeling of control by giving up control.

The second issue addressed in this session concerns the decision involving choosing between extended outcomes. Most economic analyses of preference between outcome sequences relies on the discounted utility model with a positive discounting function. According to this perspective, people should prefer desirable outcomes that occur as soon as possible and delay undesirable outcomes whenever feasible. However, Loewenstein (1985) showed that preferences for outcomes can also be affected by the utility from their anticipation. The utility of anticipation, positive for gains (savoring) and negative (dread) for losses, has been shown to result in preferences for delaying desirable outcomes and accelerating undesirable outcomes.

An interesting extension addressed in this session is its application to the domain of risky choice. One could argue that for anticipation to kick in requires that the outcome occur with a high degree of certainty. Furthermore, since probabilities of outcomes can be described for the occurrence or non occurrence of an outcome, it is possible that savoring and dread are susceptible to framing effects. For example, a probabilistic desirable outcome could be described in terms of its probability of success or failure. The frame describing the probability of success would generate positive utility of anticipation whereas the frame describing the probability of failure will generate negative utility of anticipation. Some preliminary evidence for this phenomena in the domain of risky choice.

The utility of an extended sequence is not only evaluated by its discounted worth but is also influenced by the sequence frame. The discounted utility model computes the value of outcomes extended over time to arrive at a single value. An independent factor that may distort the discounted utility in reality is the degree of saliency. The outcomes that are concentrated would be more salient, and as a result, have a greater impact on computed value of a sequence, than outcomes that are diffused over a longer period. This allows us to understand why certain borrowing and saving plans are preferred over others even though their discounted utility as predicted by the normative model may be equal or even lower.

SUMMARY OF ABSTRACTS

The first paper "Choosing Not To Choose: Context and Task Effects on Indecision," by Ravi Dhar argues that an interesting phenomena that has been largely ignored in empirical studies of consumer choice is the topic of undecidability. The author explicitly incorporates the option of not choosing in the decision problems executed in an experimental

setting, just as consumers often do. The author argues that consumers often delay choices even when the available alternatives are desirable. The factors that influence the level of indecision, such as the degree of anticipated regret and conflict, are shown to moderate the willingness to choose. The degree of conflict and regret is manipulated by expanding the choice context. The choice context imparts utility to choosing, either positive or negative, thereby influencing the preference for choosing. These results violate normative theory which states that consumer preference should not be context dependent. The results also support the premise that the process of choosing influences the utility experienced from the outcomes.

An instance of indecisiveness occurs when consumers are unable to discriminate sufficiently between options. The author manipulates the degree of indecision by changing the choice context and the nature of the task. This is consistent with the viewpoint that choice is often based on reasons that are generated in support of one option over another (Slovic 1975). Normatively, this should not influence consumer willingness to choose as relative advantage has little implication for instrumental effect on the attractiveness of the alternative. The context effect on indecision is however consistent with the notion that consumer preferences are constructed in the process of choice (Payne, Bettman and Johnson in press).

The choice context is manipulated by increasing the number of attractive alternatives or by varying the difficulty of making attribute tradeoffs among available alternatives. The experiments show that willingness to choose differs across contexts. Furthermore, the effect of indecision is reduced if the task is changed to allow subjects to choose more than one option. The observed violations in axiomatic choice theory are explained in terms of the assumption that the two psychologically different states of indifference and undecidability map onto the same behavioral response. We discuss the implication of these results for marketers and outline other factors that may moderate indecision, and are to be investigated in future research, such as accountability and positive affect.

The second paper "Decision Seeking and Decision Aversion," by Jane Beattie, Jonathan Baron, John Hershey, and Mark Spranca questions the normative models of economic choice that assumes that people would always rather have more choices than fewer choices. They forward two constructs: decision seeking and decision aversion and identify the major determinants of the two constructs.

Decision aversion occurs when an individual prefers to give up the more preferred items to avoid making a choice. An example of decision aversion would be to prefer either of your children alone to be educated at a good private school, but to send both to the worse public school because you could only afford the tuition for one child and were unwilling to choose which child would be sent to the good school. The causes for decision aversion are examined and a strong argument is obtained based on subjects' fear of blame for poor outcomes as the major determinant.

Decision seeking involves a preference for the choice between two items that are not individually preferred to the single item. The main causes of decision seeking appears to be love of self-determination and desire to appear to cause good outcomes. The hypothetical role of the subject in the decision situation (e.g., doctor or a lay person) also affect the level of decision aversion and decision seeking, as do stable individual differences. These findings, the authors contend, argues against the descriptive adequacy of the classical utilitarian view that decisions should be evaluated solely on the basis of their ends rather than their means.

The third paper "Impact of sequence frames on borrowing and saving programs," by Drazen Prelec and George Loewenstein builds on the premise that intertemporal choice is strongly affected by the sequence frame, i.e., whether the relevant items are considered in isolation or whether they are perceived as part of a larger sequence. A central finding of this research is that when events are placed into a sequence, then the preferences of the representative individual become strongly oriented towards the future.

The present paper explores two hypotheses the sequence frame on consumer preference over borrowing and saving schedules. Decisions concerning purchase timing reveal consumer's utility for money which can then be used to predict choices in other settings. Whether this utility is experienced in a concentrated fashion or is diffuse over the lifetime of a durable is not considered fundamental to the analysis. Normative theory assumes that the pleasure or pain can be reduced the single dimension of utility.

The present research presents descriptive evidence that argues against the above premise. The first hypothesis states that the preference for different types of borrowing and saving programs depend on the degree to which the cash flows are psychologically coupled to the specific products. For savings programs, they predict a preference for a highly coupled arrangement, such as savings for a college tuition, rather than more loosely coupled ones, such as saving for some general category of expenditure. However, with borrowing programs, the loans that weaken the sequence frame and hence a preference for loose coupling would be more attractive. A loan taken out specifically to finance a recent vacation, for instance, should be unattractive whereas loans taken on credit card would be more attractive.

A number of explanations are explored for the observed patterns of preferences. For instance, the role of the sequence frame is affected by the temporal concentration (diffuseness) of the relevant costs and benefits (e.g., a vacation as opposed to consumer durable). The authors expect to show that concentration of benefits will increase the attractiveness of saving up for an item, and decrease the attractiveness of paying back for it. The reverse would be expected for consumer durables only if the loan program starts at the end of the life of the product, an unusual case.

The fourth paper "The Consumption of Uncertainty," by Dan Lovallo and Daniel Kahneman investigates the preference for the resolution of

uncertainty surrounding uncertain outcomes, that are not immediately resolved. The delayed resolution of uncertainty is the norm in decisions ranging from new product introductions to marriage. The authors draw together research from both risky choice and intertemporal choice, and describe how the experience of unresolved uncertainty systematically affects the attractiveness of a prospect.

The authors build on the concept of savoring and dread (Loewenstein 1985) that have been empirically demonstrated to accompany future riskless prospects into the domain of risky choices. The anticipations has been shown to affect the utility for the outcome in a consistent manner: dread for losses and savoring for gains. The authors argue that both disappointment and elation are influenced by prior expectations and only become relevant for sufficiently high probability events.

Drawing from the principle of loss aversion, the authors argue that disappointment and dread dominate savoring and elation. The anticipated utility from a positive but uncertain event depends on the outcome valence as well as the probability of occurrence. For example, dreaming about a 10% chance to win a tour of Europe may be fun (savoring), whereas a 90% chance of winning the same trip is reframed as a 10% chance of missing out (dread). These phenomena have implications for the timing of resolution for the uncertainty. The results show that people prefer immediate resolution of the uncertainty for the vacation when the probability of winning the vacation is high. However, when the probability of winning is small, people prefer to defer the timing of resolution. These results are replicated in the domain of losses. Furthermore, consistent with loss aversion, resolution timing for good outcomes are driven by disappointment whereas the timing of bad outcomes are largely determined by feelings of dread.

CONCLUSION

The research issues discussed here are consistent within the constructivist framework that argues that preferences or attitudes are not revealed but elicited in the process of making a judgment or choice. In the same way that preferences are ambiguous, consumer goals may also be imprecise and constructed in a given situation. Thus, the assumption made in hierarchical models of consumer choice, that the decision to choose is independent of which alternative to choose, may not always be valid. On the contrary, consumers may often decide whether or not to choose depending on the context. Furthermore, consumers may shift their preferences in the direction of alternatives that minimize conflict. This would provide a competitive advantage for the niche brand simply from the consumers manner of processing information (Carpenter, Glazer, and Nakamoto 1991).

Good Guys Don't Wear Polyester: Consumption Ideology in a Detective Series

Cathy Goodwin, University of Manitoba

ABSTRACT

Consumer researchers have studied consumption ideology in movies and television series. Best-selling novels have been recognized as mirrors of contemporary consumption values. This analysis focuses on another well-recognized medium of popular culture--the hard-boiled detective story. While previous research identified a secular/sacred dichotomy, this analysis identifies a bipolar opposition based on elements of taste and style. Analysis of three novels reveals themes which have been identified in social analyses of contemporary American culture. These themes of cognitive acquisition and lifestyle therapy suggest directions for further consumer research.

INTRODUCTION

Recent consumer researchers have analyzed popular media vehicles, such as films and television series, as myths which communicate and represent consumer social values and ideologies. This paper examines consumer ideologies in the contemporary detective story, focusing on texts from Robert B. Parker's popular novels featuring Spenser. Analysis is based solely on the novels; the television series, "Spenser for Hire," bore little resemblance to the original.

While a sacred/spiritual -- secular/profane opposition emerged from several film analyses (Hirschman 1987, 1988), a structural analysis of specific Spenser novels suggests a binary opposition relating to what Lears (1983) and Agnew (1983) call acquisitive cognition. Inept, tasteless consumption is associated with inappropriate social and family behaviors, while people who "know how to act" also consume appropriately. Mediating between these oppositions of appropriateness and inappropriateness are characters, actions and consumption which will be called incongruous: they know society's rules but break them deliberately.

THE DETECTIVE STORY AS POPULAR CULTURE

Friedman (1985) observes that best-selling novels can be useful vehicles to study consumer norms and values. Detective fiction "has long displaced the cowboy novel as the staple of American popular writing" (Winks 1980). An English professor writes:

"As the most popular of popular forms of fiction, and as a central mythology for the age of the individual lost in the crowd, the detective story serves as a barometer for our changing conceptions of ourselves, and as an important, perhaps even central, model for the more 'serious' fiction produced in our age." (McConnell 1988).

The genre mirrors American myths and aspirations (Winks 1980) and influences American values, such as values associated with alcohol consumption (Filloo 1986). The private detective is a contemporary hero figure (Rickman 1983), "a person of special powers, a shaman or even a savior" (Nelson and Avery 193, p. 465). In general, mythical heroes "tend to represent goals to be approached rather than definable human figures" (Norman 1969, p. 3). Similarly, detective heroes emerge *ex nihilo*, with minimal references to their past lives. Their characters contain elements of implausibility, such as Spenser's single name and his invincibility in slaying modern-day dragons.

Scholars of the genre tend to distinguish the hard-boiled detective, who gets involved in situations that end up in murder, from the cerebral detective uses clues to uncover the identity of a murderer. Examples of the latter include Sherlock Holmes and Nero Wolfe; examples of the hard-boiled school include Marlowe, the Continental Op, Lew Archer, Travis McGee, and Spenser. Spenser is immensely popular. According to one critic, he is also a "state of the art" example of the tough detective's evolution "from cynical, professionally efficient operator to observer and personification of the noblest popular insights of his day" (Gray 1984).

A STRUCTURAL APPROACH TO THE SPENSER NOVELS

Hirschman (1988, 1989) has identified structures in film and television vehicles based on a binary opposition between sacred/spiritual and secular/profane elements. In her analyses, sacred consumption is associated with attributes such as home-made, inexpensive, or close to nature. Sacred characters value loyalty, friendship and family.

When this approach (Levi-Strauss 1965, 1973) is applied to the Spenser novels, a bipolar opposition emerges based on elements of taste and style. The poles can be labelled "appropriateness" and "inappropriateness." Appropriateness is associated with suitability, goodness of fit, congruence, lack of artifice and wise choice. Well-fitting clothes, sophisticated food, and in general "knowing how to act" are appropriate. Inappropriateness is associated with a lack of taste or fit due to ignorance or ineptitude: overweight, sloppiness, clothing or furnishings in poor taste, and food that Levy (1981) would categorize as lower class. White bread and polyester are symbols of not knowing any better; in one scene, Spenser teases the police, "Don't get marshmallow fluff on those photos."

Mediating between the poles of inappropriateness and appropriateness are situations and people who can be labelled incongruous. Incongruity is associated with a lack of harmony which is deliberate, conscious, unexpected, even playful. A well-tailored suit is appropriate; a hard-boiled detective who knows how to cook is

incongruous. A corrupt police chief is inappropriate; a tough policeman who looks like a shoe salesman is incongruous.

Incongruities often derive from the juxtaposition of Spenser's consumption style with the qualities he shares with traditional genre hard-boiled dicks. For example, in *Ceremony*, he accepts teenaged April's determination to be a prostitute: "Her morals are her business." However, he wants April to be the "right kind" of prostitute--i.e., a knowledgeable consumer who knows how to eat in restaurants, order wine and dress appropriately. On a stake-out, Spenser stocks up for a long night--with feta cheese and Syrian bread, or with Hebrew national salami and pumpnickel.

In *Early Autumn*, where his philosophy is most explicitly stated, he says:

"Lots of people need certainty. They look around for the way it's supposed to be. They get a television-commercial view of the world. Businessmen learn the way businessmen are supposed to be. Professors learn the way professors are supposed to be. Construction workers learn how construction workers are supposed to be. They spend their lives trying to be what they're supposed to be and being scared they aren't." (pp 139-140)

Spenser, of course, is different. He seems to agree with his girlfriend's verdict: "I work too hard to thwart people's expectations" (p 140). To thwart expectations, one has to know what those expectations are.

Thus, the appropriate person knows the rules and follows them; the inappropriate person doesn't know s/he's violating the rules; and the incongruous person knows the rules and chooses to break them--even makes up new rules. These positions can also be defined in relation to abductive logic (Eco and Sebeok 1983; Holbrook 1987). Abductive logic involves reasoning from rule to case to result; to take Holbrook's example:

Rule: All people who drive Cadillacs are elite.
Case: Jane drives a Cadillac.
Result: Jane is elite.

Abductive logic will probably lead to accurate results when applied to instances of appropriate and inappropriate consumption, but will be less useful when applied to incongruities. The incongruous person deliberately creates misleading clues--thwarts expectations, as Spenser would say. It is hard to imagine a rule about men who wear pastel colors, soft fabrics and lavender silk shorts that would encourage one to infer that the wearer is Spenser's associate--the dangerous leg-breaker Hawk.

HEROIC CHARACTERS

Three figures recur in the series: Spenser himself, his ally Hawk and his girlfriend Susan Silverman. Like the stereotyped hard-boiled dick, Spenser has a remote past which features the standard

firing from the police force for insubordination. He wise-cracks, philosophizes and imposes his own order on situations. However, while the classic private eyes were satisfied with coffee, hamburgers or steaks, Spenser's meals are described in loving detail; in some novels, food descriptions appear every ten pages, with leisurely digressions for menus and recipes (Saylor 1984). While the personal pleasures of classic private eyes were limited to drinking, women and "self-destructive" activities (Porter 1981), Spenser reads good books, follows sports teams, creates gourmet meals even when alone, and has a steady girlfriend.

The stereotyped tough private eye doesn't color-coordinate his wardrobe, or wear Brooks Brothers shirts, but Spenser does. Spenser's clothes fit because he knows where and how to shop ("You don't have much choice for a 48 long") and because he is in shape. He doesn't need expensive tailoring to cover flaws in his physique, like the Father in *Ceremony*. However, Spenser emphasizes functionality: a linen jacket is appropriate for the suburbs, blue jeans for working. He jokes about covering up his gun because it doesn't match.

Spenser's ally Hawk, the hit man and leg breaker, also has heroic properties. His appearance is striking, his powers seem limitless ("Could Hawk guard you alone? Hawk could guard Yugoslavia alone," Spenser says in *Early Autumn*) and his background is even vaguer than Spenser's. He needs his mystery: "We could not invite Hawk for Thanksgiving," Spenser says in *Ceremony*; he'd be "compromised." Hawk values friendship and loyalty: he will risk his life to help Spenser without asking why; when an out-of-town hood offers Hawk money to kill Spenser, Hawk not only refuses but offers to stick around for awhile. However, he has no qualms about cold-blooded killing for hire.

Hawk drinks Taittinger champagne and drives a Jaguar. He dresses impeccably with full awareness that he violates role expectations. His taste features pastel colors and soft fabrics, such as a powder blue suit and pink silk shirt (*Promised Land*); a white cashmere sweater with white denim jeans (*Ceremony*); a dark gray three-piece pinstripe suit, with diamond accessories (*Ceremony*). He takes exquisite care of his clothes and he wears lavender silk shorts (*Judas Goat*). When Hawk wears a pink suit, Spenser drily notes that nobody comes up to call him a sissy (*Early Autumn*).

Susan Silverman, Spenser's girlfriend, is presented as a heroine. Susan is good-looking, sexy and intelligent: her clothes, always well-suited to the occasion, show evidence of fashion in good taste and her make-up is described as "flawless." She eats "with style" and her personal interaction skills are phenomenal. Even Hawk likes Susan: she is the only person he shows any feeling for (*Early Autumn*).

While Susan's consumption is thoroughly appropriate, she does show elements of lifestyle incongruity. She lives in a conservative neighborhood in a conservative suburb, where she works as a high school guidance counselor, yet she dates a hard-boiled private detective. Although she gets exasperated when Spenser brings his cases home (sometimes literally), she is cool under fire. After a

ANALYSIS OF THREE NOVELS

This paper will focus on the consumption ideology articulated through these dimensions in three Spenser novels: *God Save the Child*, *Early Autumn* and *Ceremony*. The plot similarities of these novels suggest that they may be analyzed together, analogous to three versions of a single myth. The Exhibit demonstrates their common structure. Each novel opens with a scene of inappropriateness. Inappropriate actions are paralleled by inappropriate consumption behaviors. The victim moves from inappropriateness to appropriateness with the help of Spenser and Hawk, the incongruous heroes, and sometimes with incongruous actions.

In each novel, the young victim's transformation from an inappropriate state is developed (*Early Autumn*) or suggested as a future development (*God Save the Child* and *Ceremony*). When read in order of publication, the three novels show a progression away from traditional family values toward Spenser's own code. In *God Save the Child*, a family is reunited; in *Early Autumn* a son is

separated from his family, but financially supported in an endeavor that is antithetical to parental values; in *Ceremony*, a fifteen-year-old girl is permanently estranged from her family, engaging in an occupation antithetical to societal values but which Spenser finds suitable to her own. The next section of the paper will provide plot summaries, highlighting examples of appropriateness, inappropriateness and incongruity.

PLOT SUMMARIES

God Save the Child

Distressed parents Marge and Roger Bartlett ask Spenser to find their missing teenage son, Kevin. Their concern accelerates after they receive ransom notes from an alleged kidnapper. They are presented as inappropriate parents. Marge's acting, art, and sculpture lessons have enhanced her self-centeredness rather than evoked creativity; to pay for her activities, Roger works so hard he has little time for family (Geherin 1980).

The Bartletts' parental ineptness is paralleled by their inappropriate consumption behaviors:

Residence: "You don't often see a red refrigerator."

Entertainment: While Kevin is still missing, the family lawyer is murdered in the Bartletts' living room. Marge decides not to cancel a dressy, catered cocktail party, which is held only a few hours after the murder, on the very spot where the body was found.

Clothing: As narrated by Spenser: "Just below [Marge's] rib cage I could see the little bulge where her girdle stopped and the compressed flesh spilled over the top."

Dressing for the inappropriate party, reference is made to her "uninterrupted gleam of make-up," and "Everything fitted very snugly, and one got a sense of Latex stretched, of pressures tightly contained. Her bright blond hair was...doubtless sprayed in place."

Roger, the father, wears blunt-toed stacked-heel shoes "that made him walk a little awkwardly. His tailor looked to be Robert of Hall."

While investigating Kevin's high school, Spenser meets the attractive guidance counselor, Susan Silverman, who remains his girlfriend throughout the series. Spenser soon learns that Kevin has disappeared voluntarily and has staged the kidnapping. Marge Bartlett displays more inappropriate consumption behavior:

Clothing/Grooming: Spenser arrives to take Marge to pick up her son from the alleged kidnapper. The mother's first reaction is, "But my hair's a mess." Spenser underlines the inappropriateness of Marge's attitude: "We're not going dancing." Undeterred, Marge changes to a double-breasted blue pin-striped pants suit with a blue and white polka-dot shirt and 3-inch platform shoes, appearing fully made up and "hair stiff with spray" (*God Save the Child*, p. 307).

Situation: Spenser shows the Bartletts the apartment where the kidnapper, Vic Harroway, has been staying with their son; Marge comments approvingly on Vic's attractiveness and the neatness of the apartment.

At the novel's end, Marge and Roger Bartlett tearfully reach out to their son. Transformation is suggested when Susan says that this family relationship may be transformed through therapy, although there are no guarantees. The ending of this early novel suggests that appropriateness will be achieved through the traditional family structure. The inappropriateness of the family is contrasted with appropriateness of an ideal family.

Early Autumn

Early Autumn appeared about eight years after *God Save the Child*. Spenser is hired by Patty Giacomini to get her son, Paul, back from her divorced husband Mel. The father's parental inappropriateness is suggested by the presence of his attractive young mistress as well as his use of hired thugs to gain

illegal custody of his son. His ill-fitting polyester clothing is also inappropriate; Spenser teases, "You can't look tough when you're wearing Ban-Lon."

Spenser finds Paul easily by following the father's mistress. Paul is brought back to a scene as inappropriate as the Bartletts' cocktail party in *God Save the Child*. The mother's young, self-consciously-dressed boyfriend (whom Spenser labels "Disco Steve") expresses inappropriateness not only by his presence but by his genial, country club greeting to Spenser ("Good to see you"). Patty hands Spenser \$20 to take Paul to dinner as she is "too busy." Her clothing is loud, featuring pink and lavender colors in carefully selected outfits.

A few months later, Spenser is hired to guard mother and son from thugs who have been hired by the father. Spenser's incongruity contrasts directly with Patty's inappropriateness during his sojourn as household bodyguard: the hard-boiled detective is a better parent than the real mother. Patty doesn't bother to make breakfast for her son and leaves him alone on weekends while she goes to New York; Spenser tries to help the boy. Patty awkwardly tries to seduce Spenser, who dismisses her effort as "contrived;" Spenser remains faithful to Susan. Patty serves Boursin cheese and shredded wheat squares to her boyfriend, while Spenser shows Paul how to order and eat Szechuan food. Patty's "idea of fancy cooking was cheez-whiz on broccoli," but Spenser prepares innovative gourmet meal from odds and ends he finds in the cupboard.

After husband Mel hires thugs to invade Patty's home, Spenser agrees to hide out with the boy on Susan's country property in Maine. The staging of the scene reinforces Patty's inappropriateness as a mother: Patty can't take Paul because she's hiding out with boyfriend Steve, who doesn't like Paul. ("Is he afraid his cashmere sweaters will wrinkle?" Spenser wonders.)

Spenser expresses his concerns. The kid doesn't know how to do anything. He's not especially bright or good-looking. His clothes don't fit. He can't order in restaurants. Susan, his guidance counselor girlfriend, asks, "Why is it so important to know how to order in a restaurant?" Spenser's answer holds the key to his philosophy: knowing how to order in a restaurant is a sign that one has been taught how to act in life.

Up in Maine, Spenser teaches Paul how to cook, work out, perform carpentry tasks, listen to music and appreciate good books. He takes him to Louis of Boston to buy clothes, to North Conway to buy running shoes. This section of the novel further clarifies the way Spenser's consumption values clearly differ from sacredness in a television series (Hirschman 1988). While *Dynasty/Dallas* suggests that sacredness is identified with the outdoors, Spenser admits he'd rather be in the city. While *Dynasty/Dallas* characters fill traditional gender roles as they approach sacred consumption, Spenser thoughtfully encourages Paul to value androgyny. As Paul quotes his traditional father ("Men don't cook" and, "Only fags do ballet") Spenser corrects him ("He was only half right" and, "I don't know about their sex

lives, but they're magnificent athletes)." By the end of the summer, Paul has acquired muscles, carpentry skills, and a sense of direction--and he knows how to order in a restaurant.

While some reviewers dismissed Spenser's role as a "baby-sitter," Spenser appears to have practiced what Cushman (1990) calls life-style therapy. Cushman suggests that contemporary psychotherapists often serve as models for their clients, filling the clients' empty selves with values and activities. Advertising, he notes, serves a similar purpose by holding out consumption ideals for the uncertain. Both the lifestyle therapies described (though not necessarily advocated) by Cushman (1990) and Spenser's theories suggest that knowing how to consume can lead to a better life: salvation can be found in consumer socialization.

While Spenser is hiding out with Paul, Patty runs out of money and Spenser realizes that neither parent wants the boy. The novel's resolution is filled with incongruities. Spenser plans to blackmail both parents to help Paul. In return for silence about some arson insurance scams, the father agrees to support Paul's education. Paul chooses a dance-oriented school--a choice that must have appalled the father who dismissed male dancers as "fags." Spenser uses the mother's parental inappropriateness to help Paul: the weekend "shopping" trips alone in New York turn out to be occasions of sexual indiscretions which must be kept secret from Mel, the husband, and especially from Steve, the boyfriend.

Thus, using the parents' own ineptness as leverage, Spenser replaces the traditional family structure with a distant, financially-based relationship. He is an incongruous social worker. Spenser allows Mel Giacomini to continue his mob-related business: "I don't want him in jail. I want him earning money to support his son."

Ceremony

Ceremony appeared two years after *Early Autumn*. Once again, inept, uncaring parents call Spenser, this time because they believe their daughter, April Kyle, has run away to "turn tricks" in the Combat Zone. The father, Harry, claims April is no longer his daughter. Guidance counselor Susan encourage the parents to hire Spenser to find April, saying, "You can't reject a child simply because she doesn't please you." Susan's words convey an image of returning unwanted items to a store, suggesting that April has become a piece of merchandise to her father as well as her clients. The mother, Bunni, is presented as tearful and ineffectual. In the language of twelve-step programs, she enables April's drinking. A cop tells Spenser he's brought April home drunk several times; the mother will "take her in and clean her up...so the old man won't know."

Once again, inappropriate consumption parallels inappropriate parenting:

Residence: The Kyle house ("a perfect house in a perfect development") features furniture in "massive Mediterranean oak," and "you could

tell they'd bought it all at once." Spenser speculates:

"I was willing to bet my new blackjack that there was a dining room set in the living room and at least four bedroom sets upstairs. The cellar probably had a cellar set, all coordinated with the furnace." (p 10)

Spenser sees the whole neighborhood this way:

"new colonial houses....expensive variations of the same architectural plan like the Kyles' furniture on a larger scale, a neighborhood set: functional, costly, neatly organized, and as charming as a set of dentures." (p 25)

Clothing: The mother, Bunni, wears pink pants, shirt and shoes. The father's expensive clothes do not compensate for his overweight appearance. Spenser shows his own awareness of the father's expensive suit: "Fat as he was, there was no gap between the vest and the pants."

Spenser learns that April's entry into prostitution was facilitated by a corrupt educational administrator, Poitras, whose appearance also parallels his professional inappropriateness: "an ugly fat guy...dresses like Woolworth's;" his home features mass-produced paintings of mountains.

Both Paul in *Early Autumn* and April in *Ceremony* are shown initially as lost teenagers, shabbily dressed, neglected by their families. While Paul is transformed by the end of *Early Autumn*, April remains unchanged. She resists both Spenser's offer of release from her "employers" and his offer of high-quality food: she is dismayed to learn that there is no white bread in Spenser's apartment, where she is taken after Poitras is arrested. Spenser realizes that April lacks motivation to leave prostitution, but he does not want her back on the streets with a pimp. Therefore, he calls an old friend, Patricia Utley, a high class madam in New York. Utley was introduced in the third Spenser novel, *Mortal Stakes*, where she reported helping another young woman:

"She was eighteen when I took her. She didn't know anything. She didn't know how to dress, how to do her hair, how to wear makeup. She hadn't read anything, been anyplace, talked to anyone...I gave her books to read, showed her how to make up, how to dress." (p. 402).

Echoing Utley's words as well as his own goals for Paul in *Early Autumn*, Spenser says to April:

"If you're going to be a whore, at least we can upgrade your level of whoring...You'd be dealing with a relatively civilized clientele.

You'd learn how to dress and talk and order wine in a restaurant."

Spenser convinces Susan Silverman, the guidance counselor, that this incongruous solution is tolerable, though not ideal. The solution also represents an evolution within the three novels. In *God Save the Child*, both Spenser and Susan hoped that a particularly inept set of parents would benefit from psychotherapy. In *Early Autumn*, Spenser did his own therapy. Here, Spenser suggests that a high-class madam may serve as April's agent of transformation, explicitly dismissing the therapy option Susan suggests. Susan's own role has shifted from conventional guidance counselor, to reluctant advisor in *Early Autumn*, to a skeptic willing to risk her job by helping Spenser take April to the call girl operation in New York in *Ceremony*.

DISCUSSION

The analysis of these Spenser novels offers some interesting contrasts to analyses of other vehicles of popular culture. Most obviously, the contrast between sacred and secular has been replaced by a contrast based on sophistication of consumption. A number of themes can be identified.

First, the ideology presented here is distinguished by emphasizing not *what* is consumed, but *how*. It echoes the role that has been ascribed to advertising vehicles. Lears (1983, p. 23) argues that advertisers began to "promise the maintenance of domestic harmony through intelligent consumption." In the same volume, Agnew (1983, p. 73) suggests that

"Each advertisement promises a fix on the complexities of the market by appealing to the power of purchase as a mental power, a matter of possession and leverage in an indeterminate situation. For every actual purchase, countless contemplated purchases prepare the way...What modern consumer culture produces, then, is not so much a way of being (profligate, miserly, reserved, exhibitionist) as a way of seeing--a way best characterized as visually acquisitive."

Belk (1983) identifies possessiveness with "control or ownership of one's possessions." The Spenser novels emphasize control over not only what is consumed, but an understanding of how consumption objects will be interpreted by others. Appropriate and inappropriate consumption is undertaken with conscious awareness of the audience. Inappropriate consumption leads to unintended impressionable consequences, just as inappropriate actions lead to actors' downfalls.

However, Spenser distinguishes between behavior arising from genuine knowledge and "other-directed anxieties" vividly described by Lears (1983). Exaggerated attention to impression, which is inappropriate, will create an unintended impression of artificiality; this style is exemplified by the seamless make-up and sprayed hair of Marge, the mother in *God Save the Child*, and Patty's boyfriend Steve in *Early*

Autumn, who sits carefully to preserve the crease in his pants and whose shoes are "artfully broken in."

Similarly, unthinking adherence to stereotypical categories is rejected. Throughout the series, criminals are not necessarily distinguished by appropriateness of consumption, let alone specific objects of consumption. Red, a notorious pimp in *Ceremony*, drives a Jaguar; so does Hawk. Indeed, criminals aren't clearly labelled: Spenser tells Paul in *Early Autumn*, "Hawk's not good, but he's a good man." He later tells Paul that his father's sexual stereotypes ("Men don't cook") emerge because people aren't willing to think about who they are: if the father acknowledged that men cook, he'd have to think about what's involved in being a man.

In summary, the theme of this Spenser trio is that knowing how and what to consume is evidence of goodness. Knowing how and what to consume, but sometimes consciously choosing to be inappropriate, is evidence of superiority, strength or originality. The person who is merely appropriate cannot aspire to heroic status (Anonymous 1991). At the other extreme, people who don't know the rules are destined to be unhappy.

CONCLUSION

As Hirschman (1989) observed, culture vehicles can be interpreted in a number of ways. For instance, in this series, one could focus on class distinctions and the role of detective as service provider: Spenser uses his consumption style to attain equal status with his clients. The sacred-secular dichotomy seems less applicable because these novels are very middle-class. Fathers are a contractor, a casualty insurance broker, and a life insurance agent. They are very comfortable but not wildly rich. The sacred-secular distinction might apply to other Spenser novels; for instance, in *Judas Goat*, Spenser is hired by a very wealthy man to avenge a terrorist bombing which killed innocent victims.

The themes identified in this analysis suggest new avenues for consumer researchers. These themes unconsciously echo trends identified in social research studies of contemporary American culture: the "therapeutic ethos," or emphasis on process and self-development (Agnew 1983); "acquisitive cognition," or salvation through consumption knowledge (Lears 1983); and "lifestyle therapy" (Cushman 1990). Research of these trends may be useful to supplement current research on possessiveness, materialism and symbolism associated with possessions.

Finally, consumer values are generated and represented by a variety of vehicles: advertising, television, film, and popular literature. Because these vehicles attract different audiences, they may express and represent differing consumer values and ideologies. An understanding of these values and ideologies will deepen our understanding of consumer behavior.

The Marlboro Man as a Twentieth Century David: A Philosophical Inquiry into the Aristotelian Aesthetic of Advertising

Barry Vacker, University of Texas

ABSTRACT

The David represents the climax of the influence of Aristotle's philosophy of aesthetic on Michelangelo. Thus the David is an aesthetic abstraction of the Aristotelian ideal in the form of High Renaissance sculpture. Some advertising, by its very essence, contains fundamental Aristotelian ideas in its formal aesthetic. Thus the Marlboro Man is an aesthetic abstraction of the Aristotelian ideal in the form of 20th century advertising. This paper posits that because of the Aristotelian ideas manifest in the David, advertising aesthetic, and the Marlboro Man, both the David and the Marlboro Man have come to symbolize similar meta-ethical, aesthetic and political ideas.

"A convincing impossibility is preferable to an unconvincing possibility."--Aristotle

INTRODUCTION

Recent years have seen scholars apply the ideas of semiotics (Pierce, 1931-1958) and symbolism (Langer 1942, 1953) to better comprehend the advertising and consumption processes. In applying semiotic and symbolism theory, scholars have found that the advertising and consumption process involves signification at many levels (Holbrook 1987; Kloepfer 1987; McQuarrie 1989; Mick 1986, 1987, 1988), the creation of symbolic meaning (Levy 1959, Solomon 1983), the creation and transfer of cultural meaning and values (McCracken 1986, 1987; Sherry 1987), the creation and representation of ideals (Schudson 1984, Belk and Pollay 1985), and the acceptance of a wide range of ideas and philosophies (Belk 1988). Some scholars have begun to apply literary theory to consumer research (Durand 1987; Stern 1988) while others have realized the impact aesthetic plays in the advertising process (Feasley 1984, Kloepfer 1987, Holbrook 1987, Noth 1987, Schudson 1984). In a more specific context, Kloepfer (1987, p. 136) observed that advertising draws from all of the arts to make use of the aesthetic potential and Holbrook (1987, p. 88) noted the close alliance of semiotic theory and aesthetic philosophy. In light of such research, inquiry based on aesthetic philosophy could be fruitful.

The purpose of this paper will be to show that an Aristotelian aesthetic philosophy is manifest in both Michelangelo's The David and the Marlboro Man. Aristotelian aesthetics has many ramifications and implications, but for the purposes of this paper, the emphasis will be on the Aristotelian priority of representing or portraying the ideal individual (or the ideal in nature) as attainable in "this world." As aesthetic abstractions, both The David and the Marlboro Man are "this worldly" ideals. Since The David and the Marlboro Man are both derived from Aristotelian aesthetic philosophy, they have both come to symbolize the same metaphysical, ethical and

political ideas or values. By investigating the fundamentals of Aristotelian aesthetic and its processes, this paper posits the potentially controversial idea that the Marlboro Man is a twentieth century David.

Since its creation, the David has been considered a masterpiece of aesthetic expression. However, on a more philosophical level, the David is seen as an aesthetic abstraction in form representing an Aristotelian metaphysical view of man. (While Michelangelo is often considered a Neoplatonist, which may be true later in his life, the David, carved when he was but 29, represents a much stronger Aristotelian influence). Art scholars have observed that the David is an ideal representing man as a noble, conscious being, at home in the universe, and master of his own destiny (Symonds 1901, Rolland 1915, Bargellini 1971). This egoistic ideal thus became the political symbol for independence, liberty, and justice (Vasari 1550, Bargellini 1971). The Marlboro Man too is an egoistic ideal; a noble and conscious being, at home in his universe, master of his destiny. Thus the Marlboro Man has come to symbolize individualism, independence and capitalism. To understand how these aesthetic processes operate we must first turn to the aesthetics of Aristotle.

ARISTOTELIAN AESTHETICS

The origins of Greek aesthetic thought first appeared in criticisms and reflections upon poetical works, painting, and sculpture. During this period, the word "mimesis"--meaning "imitation" or "representation"--came to indicate the relationships of the various arts to the objects in reality or nature (Croce 1909). Although Aristotle never, to our knowledge, formulated a complete theory of aesthetics, he did form coherent ideas about the position art held, for the Greeks, in relation to nature, science and morality (Butcher 1896, p. 116). As in Western philosophy and science, Aristotle has had a most influential impact on Western aesthetic (Butcher 1896, Clark 1953, Cook 1913).

For Aristotle, art is meant as a state of capacity to make or create, wherein art involves a true course of reasoning and a lack of art involves a false course of reasoning (*Ethica Nicomachea* VI 4, 1140a20-23). "Art imitates nature," said Aristotle (*Physics* II 2, 194a21). However, this does not mean that art provides an "exact" imitation of the object in nature. Art imitates nature in that art (like nature) has certain ends requiring means which are found in nature; but, since nature can sometimes fail in its effort to complete, perfect, or bring in to being, art imitates the essence of the object in nature by eliminating the accidentals and improving the object in nature (*Physics* II 8). Thus, art emphasizes that which is essential to the nature of the object and completes or

perfects what nature alone could not complete or perfect.¹ Thus, art must conceptualize the result to be produced before its realization in the material. This is consistent with Aristotelian teleology in which the ends must be known before the means can be chosen. Thus, in this sense, art is a potency, an originitive source of change, accompanied by a rational formula (Metaphysics IX 1, 1046a10-1046b1). As such, art is concerned with coming into being and perfecting matter through matter's union with (the art) form (Metaphysics VII 7). Thus, the artist should "imitate" things as they ought to be (Poetics IX, XXV). Aristotle held that art arises because this type of imitation is natural and delightful to man, the most imitative creature in the world (Ethica Nicomachea VI 4, 1148b3-10).

For Aristotle, art as a capacity to make involves imitation of the essence or universals of nature and change (or coming-to-be) in matter. The form of art is found in the artist's soul which possesses reason. Since reason is concerned with discovering the truths of nature, art should concern itself with universals.

"Hence poetry (art) is something more philosophic and of graver import than history, since its (art) statements are of the nature of universals, whereas those of history are of singulars" (Poe. 9, 1451b5-7).

Therefore, the artist's function is to present, not what has happened, but in accord with the universal nature of man, what *might* happen or what is possible, as being probable or necessary (Poetics 9). Aristotle held that art should portray man/characters not necessarily as he is but as he *should* be. Aristotle cites the example of portrait painters who "reproduce the distinctive features of man, and at the same time, without losing the likeness, make him handsomer than he is" (Poetics 15, 1454b10-12). Aristotle concluded, that for the purposes of art, "a convincing impossibility is preferable to an unconvincing possibility" (Poetics 25, 1461b11). Since art was an imitation as a perfection of nature, including human nature, the forms of art would thus present the universals or essence of man in an ideal state. In presenting this ideal, art imitates the ideal character, emotion, and action of man if he or she followed the principle of reason in their own nature. The action imitated was primarily an inner action, the activity of reason, which manifested itself as the outer action of character and/or emotion. Thus, art does imitate and complete the moral ideal via an aesthetic ideal. While a harmony of soul and body indicated a moral ideal, the ideal beauty contained order, symmetry, and definiteness (Metaphysics XIII 3, 1078b1). Thus, for

the Greeks, a beautiful face with no sign of inner conflict was the ideal (Sures 1969, pp. 605-606).

Aristotle was the first to distinguish between "fine" art and "useful" art. However, this distinction is made only in the context of the exact teleological purposes of each. Fine art is a free and independent activity with its own end. Useful art (such as advertising) has another end in conjunction with its own artistic end. However, both fine and useful art follow the same principles in that they both imitate and complete nature. For useful art follows the guidance of nature and simultaneously supplies any deficiencies (Politics I 2, 1253a2). Key to Aristotle's theory of art is understanding its teleological purpose. The general movement of organic nature, including the life of man, is movement toward the "better" or the "best." For man and art, it is the "purpose" or "design" which is identified with the best. Thus, art imitates the movement to a more perfect completion and, as a consequence, strives for an ideal "better" than the real (Poetics XXV). For Aristotle, unlike say Plato or Kant, the ideal is real and natural, not unreal and supernatural.

This brief discussion of some of Aristotle's fundamental aesthetic ideas is in no way complete, but it does explain some of the fundamental Aristotelian concepts of the ideal at work in some art and some advertising. However, it would be fruitful to turn to some modern Aristotelian aesthetic philosophers in order to better comprehend how the Aristotelian process works in art, particularly with the David, and in advertising, particularly with the Marlboro Man.

Butcher (1896, p. 156), in discussing Aristotle's ideas, states that nature's (including man) "true beauty and significance are visible to the eye of reason." For Aristotle, a work of art is an image of the sense impressions made by an independent reality upon the mind (reason) of the artist with reality reflecting the facts of human life and human nature. Art discovers the *form* towards which an object tends. From the particulars or individuals art presents the universal, the ideal. "The ideal is the real, but rid of contradictions, unfolding itself according to the laws (reason) of its own being apart from all influences and the disturbances of change" (Butcher 1896, pp. 150-151). The ideal is represented through the *abstractions* of universal concepts. Aesthetic presents moral and spiritual ideals via signs or symbols. Inner qualities are manifested in outward forms in which symbols and signs are visible tokens of the unity of body and soul (Butcher 1896, pp. 126-134). Universals and ideals are *objectified* through form. Whether sculptor, poet, or painter, the true artist should portray the ideal form by abstracting the universals or essentials and eliminating the particulars or accidentals. Thus, the artist should portray man or life as he or it "might" be, based on a rational formula. Realism and symbolism must work together to make fiction symbolize truth (Butcher 1896, pp. 391-392). In the Aristotelian sense, the purpose of art was to objectify the real, the essential, the universal, the complete (Fleming, 1955, pp. 49-53).

It is the objectification of universals through abstractions in form that can give Aristotelian

¹The author wishes to thank the Aristotelian scholar Professor Jacques Brunshwig of the University of Paris for helping me clarify my thoughts on Aristotle's concept of imitation in art. However, the responsibility for the interpretation here lies solely with the author.

aesthetic a potential for fulfilling a fundamental psychological/epistemological/emotional need in man and thus having potentially powerful mental/emotional effects. In building on Aristotle, Rand (1971) holds that man needs art precisely because his cognitive faculty is conceptual. This means that man acquires his rationality and knowledge by the process of forming abstractions and thus has an epistemological need to bring his widest metaphysical abstractions into his immediate, perceptual awareness (p. 45). "Art fulfills this need: by a means of a selective re-creation, it concretizes man's fundamental view of himself and of existence. It tells man, in effect, which aspects of his experience are to be regarded as essential, significant, important. In this sense, art teaches man how to use his consciousness. It conditions or stylizes man's consciousness by conveying to him a certain way of looking at existence" (p. 45). Thus, with regard to symbolism in art, the artist does not *fake* reality, he *stylizes* reality. The artist selects the essentials, and omits the accidentals, of life or objects in existence which he or she regards as metaphysically important and by emphasizing, isolating, and stylizing them, the artist objectifies, in an aesthetic form, his or her view of life or existence (or nature). Thus, the aesthetic concepts or forms are "not divorced from the facts of reality--they are concepts which integrate the facts and his metaphysical evaluation of the facts" (p. 36).

Thus, in a most fundamental sense, aesthetics serve as an objectification of metaphysics and the means for the communication of moral ideals. The aesthetic process, via aesthetic forms or concepts, enables man to bring "concepts to the perceptual level of his consciousness and allows him to grasp them directly, as if they were percepts" (p. 20). This is what gives aesthetics the potential for conveying or invoking such powerful emotions. Metaphysical and/or ethical concepts are, via aesthetic abstractions in form, brought to one's perceptual level to "see." In broad fundamentals, this helps explain the complex psychological/epistemological process of aesthetic communication between an artist and a viewer. This process may be summarized, in essence, as follows: "the artist starts with a broad abstraction which he has to concretize, to bring into reality by means of the appropriate particulars; the viewer perceives the particulars, integrates them and grasps the abstractions from which they came, thus completing the circle" (p. 35).

Hopefully, this section has briefly shown the fundamentals of Aristotelian aesthetics and its complex processes. We can now see a little clearer how Aristotle's "convincing impossibility," Butcher's fiction symbolizing truth, and Rand's abstractions as stylized reality can be utilized to great aesthetic effect, both in the David and in the Marlboro Man.

The David

Michelangelo's David is, by most accounts, one of the greatest artistic achievements in history (and this brief discussion can only touch upon a few ideas about the David). Michelangelo, in a sense, was a product of his century. The 16th century is

characterized by the spirited rebirth of Aristotelian thought, which challenged the authority of the church and state and which fueled the incredible artistic achievements of the High Renaissance. Man as having reason, virtue, independence, and happiness in this world were ideas that were manifest in the meta-ethical, political, and aesthetic thought of the time and in the Renaissance idea of the "perfect" man, both in thought and action. Aristotle's *Poetics* were first translated to Latin in 1498 in Venice (Butcher 1896); the David was begun in 1501 and completed in 1504.

The David (Exhibit 1) represents the climax of an Aristotelian influence in Michelangelo (for his later work was more Platonist, tragic, and religious). Michelangelo believed that his "intelletto," the reason in the eye of the artist, was capable of discovering the form or "potentia" (Clements, pp. 14-21) that existed in the huge block of marble with no value, marred by the work of a previous and lesser sculptor (Vasari, pp. 15-16). Michelangelo returned from Rome and Venice to Florence and accepted the commission to salvage the marble block from the Board of Works of S. Maria del Fiore (Symonds, pp. 86-90). Working from a small 18" wax model, Michelangelo abstracted the ideal form of face (Exhibit 2) from several individual faces to help convey the "terribilitá," an "awe-inspiring" conception (Symonds pp. 99-101). The David, with its intense purposeful stare, its furrowed brow, its both slightly oversized head and masculine hands (Exhibit 3), and its height (nine cubits: approx. 17 feet), conveys the essence of self-efficaciousness and masculinity in the Aristotelian sense. The David is a complete ideal abstraction in form, Aristotelian in spirit but definitely a creation of and for the Renaissance. Conceived in Michelangelo's soul, the completion of what nature could not finish, an imitation and perfection of nature, a universal man, handsomer than any one particular man, a face with no inner conflict, a man of action as a man could and should be, according to the principles of nature and reason, the David stood tall in the civic area of the Palazzo Vecchio and conveyed great symbolism for the Florentines. Conveyed via the particulars of the sculpture, the nude figure embodied the ideal of perfection in man ("man" meaning woman and man). Fiction symbolizing beauty and truth.

"Self assured, his gaze fixed on a goal already attained, Michelangelo's David truly represented the consciousness of a man, master of his own destiny, who victoriously opposed brute force with the invincible power of the spirit...(and) became the silent assessor of the republican independence that was soon to be suppressed but not vanquished forever (Bargellini, p. 2)."

The Aristotelian aesthetic ideas manifest in the David naturally led to the David symbolizing the meta-ethical concepts of reason, independence, egoism and efficacy and the political concepts of republican liberty. Thus, the David is the objectification of an

EXHIBIT 1

EXHIBIT 2

EXHIBIT 3

Aristotelian ideal conveying profound meta-ethical, political, and aesthetic meaning.

ARISTOTELIANISM IN ADVERTISING AESTHETIC

The idea that Aristotelianism (as opposed to Platonism or Kantianism) is manifest in some advertising may seem quite unusual. However, upon philosophical investigation, we can see that it is quite natural. Some scholars have observed that Aristotle is the primary philosophical source for Western classical liberalism and constitutionalism (Hayek 1960), and by implication, capitalism. However, on a more fundamental ethical level, Aristotle's concept of "eudaimonia" (the self-sufficient full life of thought and action) and happiness in "this world" remain influential in the Western world. This has important implications for advertising.

The view that man can better himself in "this world" with ideas and goods is predominantly a Western concept. Production is the creation of ideas, goods, and services to better satisfy individual wants and needs (Mises 1949). On another level, production is the application of reason (ideas) to reality (matter). Thus, production completes what nature cannot bring to a finish. Ideas, goods, and services are produced to improve man's life on earth, both intellectually and materially. Therefore, advertising necessarily presents the idea that goods and services can improve life on earth. Advertising presents (or implies) that a particular good can contribute to some potential form of happiness for an individual. Though a produced good or service exists as an actual object in reality, it exists only as a potential with regard to consumption and happiness. Only after the product is consumed or in the process (whatever it may be) of being consumed can the advertised potential form of "happiness" actualize for the individual. Advertising presents the product or service as a potential originative source of change for man from a given state to a desired state of "happiness," as could or should actualize. Thus, the teleology of advertising is to necessarily present potentials as they could or should actualize. A product or service could or should bring some form of "happiness" (to whatever extent) to an individual consumer. Advertising aesthetic necessarily represents life as it could be or should be or ought to be. While both production and advertising also have a catallactic end, the primary end for each, respectively, is to cause and portray movement toward the better.

Advertising aesthetics consist of a conception of a potential result before it is realized or actualized in the material. Advertising aesthetics presents a potency of change via a rational formula which should necessarily be intelligible through reason. Advertising presents products and services that do exist as objects in reality and for their function or meaning to be understood by a particular potential individual, advertising must impart its meaning through some form of reason and values. This meaning is communicated/symbolized through abstractions of universals (the concern of reason) via aesthetic forms. The meaning of objects, which exist

independently in reality, is communicated through intelligible aesthetic representations. Thus advertising aesthetics imply an independent reality, epistemological realism (Kelley 1986), and a rational faculty in man (in this context).

Advertising aesthetics are mimetic of the universals of the potencies of man and existence in a Western capitalistic, political/economic system. Advertising aesthetic is not fine art (though it may serve this function), which exists solely for its own end. Advertising aesthetics, like architecture, is a form of Aristotle's useful arts. Advertising is an aesthetic activity in which an idea, good, or service and its potential value is re-created as an abstraction of reality according to the advertiser's metaphysical values. The form of the abstraction may be any combination of literary/aural/visual/sensory forms. The form of the presentation and the style in which the product and reality is abstracted is determined by the advertiser and its agency. Advertising re-creates and stylizes aspects of reality through abstraction as form.

Thus in advertising art, abstractions in form represent the product in reality, with reality including the product and its potential, and the background, setting, people, characters, etc. By stressing that which is fundamental and universal and omitting the particular, thus abstracted is not any particular one of the products advertised, but rather the universal form of the product and reality. For example, the casting process is a form of abstraction and omission, in that a model is selected to be the form of the universal abstraction of the chosen character, spokesperson (excluding celebrities) or individual symbol of a demographic category. The casting process, wardrobe, set selection and design, lighting effects, photographic techniques and make-up processes all represent the process of abstraction for a particular advertisement. This process of abstraction necessarily leads to a presentation of a universal form, i.e. an ideal. The ideal is thus better and more important than the real. For example, through the process of abstraction via special effects, lighting, photography, etc., a soft drink bottle or a lipstick tube or a person/character become more "real" in their stylized form in advertising than any particular form in reality. Thus, a soft drink bottle may look more frosty or a lipstick tube may look more "wet" or "red" or a person/character may look more beautiful than any particular soft drink or lipstick or person in reality, although a bottle or lipstick tube or person *could* look that frosty or red or beautiful. Thus, in advertising aesthetic, the ideal is more "real" than the real.

Advertisers attempt to objectify in form the universal or essential. For advertisers, it is the universal in product, service, man and reality. Advertisers also objectify the complete, the unified whole. All parts contribute to the whole; the non-essential is omitted and nature is completed. An abstract hero may overcome a conflict or obstacle. A hero, either product or person and product, faces a seemingly impossible or significant conflict, which is ultimately resolved through change caused by the

EXHIBIT 4

EXHIBIT 5

EXHIBIT 6

EXHIBIT 7

product. The aesthetic process of abstraction thus changes this change by representing the change in its universal, potential form. The ad presents the changes in the form of obstacles being overcome, values being won, happiness being achieved, nature being completed. Advertising is necessarily Aristotelian in that it is always portraying the coming-to-be.

Advertising, in pure form, is individual-centered. It does assume and state that individuals can be happy and experience eudaimonia in "this world." Advertising is necessarily egoistic. Advertising presents a form of the moral individual. Moral and spiritual inner qualities are manifested in the outward forms in advertising. The universals in form thus symbolize or signify this harmony of mind and matter, soul and body, spirit and material. Advertising necessarily presents the egoistic ideal; how life could and should be when guided by nature and reason's formula. The state of affairs is potential happiness, a full life of thought and action. In presenting how life could be, advertising often presents the ideal man or woman as a symbol of the way he or she could be. The moral man or woman is a universal abstraction in form. Many times national advertising presents the universal abstraction in form, while complementary local advertising provides specific information on how, where, and for what price the product is available so the consumer can begin the process of change (coming-to-be) to a more universal or pure moral form. Thus the outer forms pictured in advertising symbolize the tendencies of the universal inner qualities. The aesthetic outer symbolizes the moral inner. A beautiful face symbolizing no inner conflict.

Advertising utilizes aesthetics in re-creating reality through abstractions as forms. Herein lies where advertising reaches its greatest potential as an art form. Man's need for art lies in his need to have his widest metaphysical abstractions brought to the perceptual level. Advertising aesthetics do bring to the perceptual level various metaphysical abstractions about man. Advertising presents reality, objects, ideas and concepts via a perceptual form (pictures, sounds, words, etc.). The criterion for an aesthetic abstraction is: "What is important?" In creating an advertisement, the advertiser selects the aspects of the product and existence which the advertiser regards as important. These aspects of the product and existence become the elements or content of the ad. The objects/elements in the advertisement signify metaphysical importance and the style/technique signifies epistemological importance. By selecting, isolating, and stressing the aspects deemed as important and by omitting the insignificant and accidental, the advertiser presents his view of his product and its potential in existence. These aesthetic abstractions are not divorced from the facts of reality; they should, in a proper form, be abstractions which integrate the facts and the advertiser's evaluation of the facts. Advertising, like art, is egoistic in that it appeals to the psycho-epistemological needs of man by re-creating reality through various abstractions that give form to important values about man and woman and life on earth. It is in the objectification, through universal abstractions in outward form, of

metaphysical, epistemological, and moral evaluations of man and woman that advertising aesthetics (the useful) most approaches Aristotelian aesthetics (the fine).

The Marlboro Man

Perhaps the most famous and successful advertising campaign in history is the Marlboro Man campaign for Philip Morris. As others have noted, the Marlboro Man is more than just a cowboy selling cigarettes (Camargo 1987, Lohof 1971). The Marlboro Man is the objectification, in advertising form, of universals concerning the meta-ethical nature of man. Like the David, the Marlboro Man is too a product of his century. The Aristotelianism manifest in the nature of some 20th century advertising created the philosophical framework for the creation of a Marlboro Man. This Aristotelianism has led to the Marlboro Man coming to symbolize the same meta-ethical, political and aesthetic ideas as the David.

First commissioned in 1954 by Philip Morris, 450 years after the David, the Marlboro Man was created to give value to an object, a failing cigarette brand, where little value had existed before. In repositioning the Marlboro cigarette for men, the Leo Burnett agency explicitly chose to convey the abstraction of masculinity via the American cowboy (Burnett 1966). In creating the abstraction of masculinity via the cowboy, the creators of the Marlboro Man have utilized many men to represent the universal of man, but not of any particular man. Interestingly, but naturally, the Marlboro Man also is similar to the David in many actual aesthetic executions (Exhibit 4). Often the Marlboro Man is shown "in action" with his hand reaching into his pocket for a cigarette or a lighter much like David with his hand grasping his slingshot. The Marlboro Man is often depicted in profile, emphasizing the straight nose, square jaw, and furrowed brow (Exhibits 5 & 6) over an intense, purposeful look in the eyes. Additionally, like Michelangelo with the David, there is an emphasis on oversized masculine hands grasping the fundamental object, the cigarette and/or lighter (Exhibit 7). In sum, there are striking executional emphases and similarities in both the David and the Marlboro Man: the emphasis on the strong square-jawed "Western" profile, the oversized masculine hands grasping a sling or a cigarette, the Aristotelian man of action (the exhibits are just a few among many that could have been chosen).

However, the greatest similarity between the David and the Marlboro Man is the philosophical ideas they symbolize. Via the chosen particulars, strong profile, the masculine hands, the man of action (as both inner thought and outer action), the Marlboro Man symbolizes the universal in man: reason, independence, efficacy, and egoism. Like the David, the Marlboro Man controls and is at home in an intelligible universe, comprehending reality and acting in accordance with it. Fronting the essential facts of life, the Marlboro Man purposely exists as his own end, doing what must be done. An imitation and perfection of nature, the completion of the nature of man, the potential as abstraction in form, man as he

EXHIBIT 8

could be, more handsome than any particular man, more real than the real, the Marlboro Man symbolizes the same meta-ethical, aesthetic and political ideas as the David. The Marlboro Man stands tall on the billboards of the world as the Aristotelian aesthetic ideal, symbolizing reason, independence, efficacy, egoism and explicitly or implicitly, republican liberty (Exhibit 8). In Aristotelian fundamentals, the Marlboro Man is a 20th century David.

Consumers and Movies: Information Sources for Experiential Products

Elizabeth Cooper-Martin, Georgetown University

ABSTRACT

Experiential products are defined as ones which consumers choose, buy and use solely to experience and enjoy; movies are studied as an example. This paper identifies two types of information sources for such products: experiential, which convey a sense of the consumption experience, and non-experiential, which do not describe consumption. Results of a survey indicate that subjects find experiential sources more useful and credible than non-experiential for choosing movies. More specifically, for subjective features, subjects report that experiential sources are more useful and credible than non-experiential sources but report no differences for objective features.

All goods and services are consumed, but for some products, like the performing arts, wine, and vacations, the consumption experience is an end in itself and serves as the primary benefit in use. This paper focuses on this type of product and labels them *experiential* products. Consumers choose, acquire and use experiential products solely to experience them and enjoy them. Experiential products include both physical goods, such as wine and recreational drugs, and services, such as sporting events and restaurant meals. The dominant benefit of these products is hedonic consumption, that is the feelings, emotions and sensations experienced during product usage (Hirschman and Holbrook 1982).

Given the special nature of experiential products, consumer behavior for them is likely to differ from that for other types of products. Building on an earlier study (Cooper-Martin 1991), the purpose and contribution of this study is to further understand the unique aspects of consumer behavior for these special products by studying the information sources consumers use to choose them. This paper builds on the experiential or hedonic perspective (Hirschman and Holbrook 1982; Holbrook and Hirschman 1982) by using the consumption experience, which differentiates experiential products from others, to identify two types of information sources. They are experiential, which convey a sense of the consumption experience, and non-experiential, which do not describe consumption. Specifically, this paper uses movies as an example of the class of experiential products.

The next section discusses experiential products in more detail and develops the hypotheses on the types of information sources that consumers use for movies. The following two sections describe the methodology and results. The discussion section includes suggestions for additional research on experiential products and potential implications for managers interested in marketing movies.

EXPERIENTIAL PRODUCTS

Experiential products are defined by their dominant emphasis on the consumption experience. The main benefit from these products is the pleasure or

hedonic value in consumption. Experiential products contrast with goods and services that primarily fulfill utilitarian functions. For example, the major benefit of shampoo is to leave hair clean and shiny, blankets keep one warm, a visit to the dentist protects one's teeth. Clearly, there may be hedonic aspects of consuming non-experiential products; for example, the lovely fragrance of a peach-scented shampoo or the fondness for a blanket received from a dear relative. But the primary reason for consuming these products is not to experience them.

Just as utilitarian products may have some hedonic value, experiential products may have some utilitarian functions. For instance, food clearly has the utilitarian benefit of keeping one alive. Thus under certain circumstances, for example grabbing a quick snack to stave off hunger pangs, food is more of a utilitarian product. But under certain circumstances, food can be an experiential product; for example, in a first-class restaurant. The emphasis then is clearly hedonic; to enjoy the sight, aroma, texture and taste of the food. A restaurant meal can be hedonic in other ways: savoring a fine wine, soaking in the elegant surroundings, enjoying the luxury of excellent service.

This paper uses movies as an example of experiential products because they appeal to a wide range of consumers, compared to the arts (see summary in Capon and Cooper-Martin 1990) or wine (Jobson 1989). Further, movies are purely experiential, as compared to television and radio which may accompany other activities. For example, broadcast music can serve as a background for shopping (Milliman 1982) or a restaurant meal (Milliman 1986). Further, it appears that consumers do consider movies to be experiential; an earlier study found that involvement for movies (as well as for another experiential product, wine) is dominantly hedonic (Cooper-Martin 1991).

For experiential products, such as movies, consumers search two types of information sources: experiential and non-experiential. To learn about experiential products, consumer should turn to experiential sources which are distinguished by their ability to convey a sense of the consumption experience, that is, of what it is like to see, hear, taste, touch or smell the product. In a survey of information sources for movies, subjects rated previews and friends' comments as more useful and more credible for evaluating movies than magazine advertisements, radio advertisements or critics' reviews (Faber and O'Guinn 1984). Compared to the latter three sources, television advertisements were rated more useful, but not more credible. Previews and television advertisements are experiential sources; they provide a chance to try the movie. Friends who have seen the movie can describe it and so are another experiential source. Non-experiential sources, such as print or radio advertisements, are less useful because they do not illustrate or mimic the consumption

experience. Although reviews should be an experiential source, the subjects found them less useful. But, in general, the following hypothesis seems justified.

- H1.* For experiential products, experiential information sources are more useful and credible to consumers than non-experiential information sources.

In selecting a hedonic or experiential product, such as movies, consumers rely more on subjective than objective features (Cooper-Martin 1991). ("Feature" is used here to refer to a product characteristic defined by consumers. It is not used in the sense that such characteristics are dichotomous.) Subjective features describe the consumption experience, for example, what it is like to see and hear the movie. Objective features can be externally verified; examples for a movie are the director, starring actor, admission price or schedule convenience.

In choosing experiential products, subjective features are more useful than objective features for two reasons: their abstractness and their reflection of the hedonic experience. Features that are more abstract describe a greater number of alternatives than concrete features (Johnson and Kisielius 1985). Hence, they facilitate comparisons with different product classes; for experiential products, such as movies, consumers consider other product classes as alternatives (Cooper-Martin 1991). Because the benefit from experiential products is pleasure in consumption, consumers should choose movies and similar products based on what they like and enjoy, on what pleases them, in other words, based on intrinsic preference (O'Shaughnessy 1987). Subjective features reflect this viewpoint, that is, the personal nature of the experience. Such product features are important from an experiential perspective (Holbrook and Hirschman 1982) and by extension are important for experiential products. In fact, these subjective features can be described as aspects of consumption (Holbrook and Hirschman 1982).

Consumers also consider objective features of experiential products; they are often tangible and utilitarian (Holbrook and Hirschman 1982). They should be less important for experiential products than subjective features because such products, by definition, do not fulfill utilitarian functions.

The different types of information sources, experiential versus non-experiential, relate to subjective and objective features as follows. The usefulness and credibility of an information source may depend on what information it provides. Specifically, a non-experiential source (e.g., a magazine ad) may be just as credible and useful as an experiential source (e.g., a friend) to determine objective features (e.g., the movie's director). However, for subjective features (e.g., how funny the movie is), experiential sources (e.g., a friend) should be more credible and useful than non-experiential sources. This reasoning leads to the following hypotheses:

- H2.* For subjective features of experiential products, experiential information sources are more credible and useful than non-experiential sources.
- H3.* For objective features of experiential products, experiential and non-experiential information sources are equally credible and useful to consumers.

METHODOLOGY

Subjects

The subjects were 98 undergraduate students enrolled in a business course; they received course credit for their participation. The sample was 31% women and 69% men; ages ranged from 18 to 30 years and the mean age was 20.4 years. This age group is very appropriate for a study about movies, because 15-24 years old account for nearly half of movie admissions (Newspaper Advertising Bureau 1984).

Procedure

Subjects responded to a written survey; they were tested in two groups but each subject filled out the survey individually. Subjects rated each of seven information sources on four questions: credibility for learning about an objective feature, usefulness for learning about an objective feature, credibility for learning about a subjective feature, and usefulness for learning about a subjective feature. Examples of a question on usefulness and on credibility are in the Exhibit. Note that questions on usefulness defined it as capable of providing the information and that questions on credibility defined it as believable. Subjects answered each question for all information sources before proceeding to the next question. The order of the questions was systematically rotated across all subjects and the order of the information sources for each question was randomized.

The seven information sources were chosen from a set identified as those involved in the initial decision of whether to see a particular film (Faber and O'Guinn 1984). This set excluded newspaper advertisements, which are used more for the decision on when and where to see the film, but included radio advertisements. The latter were eliminated because in an earlier survey, the same population as the current study almost never mentioned radio advertisements as an information source for movies. This deletion also had the advantage of shortening the questionnaire.

Because of the emphasis on experiential sources, Faber and O'Guinn's (1984) source, comments from friends, was expanded to two sources: comments from friends who have seen the movie (an experiential source) and comments from friends who have not seen the movie (a non-experiential source). Thus, the survey used five experiential sources: comments from friends who have seen the movie, critics' reviews, television ads, previews, and comments from someone you know and who you consider to be a film expert, and two non-experiential sources: comments from

EXHIBIT

Examples of Questions on Usefulness and Credibility

When you want to learn who the producer is for a particular movie, how *USEFUL* (i.e., capable of providing the information) is each of the following sources? For each question, please circle the number that indicates how useful that source is. For example if it is *very useful*, circle 7.

Television ads

1	2	3	4	5	6	7
Not at all useful						Very useful

When you want to learn whether a particular movie is good, how *CREDIBLE* (i.e., believable) is each of the following sources? For each question, please circle the number that indicates how credible that source is. For example if it is *very credible*, circle 7.

Comments from friends who have seen the movie

1	2	3	4	5	6	7
Not at all credible						Very credible

friends who have not seen the movie and magazine ads.

To insure generalizability, this study included three subjective features used to choose a movie: serious, good, and funny, and three objective features used to choose a movie: the producer, the setting, and the leading actor or actress. An earlier survey of the same population produced lists of subjective and of objective features (Cooper-Martin 1991); the features in this study were taken from these lists. From the list of objective features, those related to movie-going (e.g., location or price) were eliminated. Of the remainder, all of which were related to the movie itself, the three most frequently mentioned ones were used in this study. From the list of subjective features, those which could not be used with every information source in this questionnaire (e.g., others wanted to see it) were eliminated. Of the remainder, the three most frequently mentioned ones were used in this study.

Each subject answered questions on only one subjective feature and on one objective feature. All possible pairs of the three objective and three subjective features were used and rotated across all subjects.

RESULTS

The results for credibility and usefulness were analyzed separately with a 2 (information source) X 2 (feature) repeated measures ANOVA. The two levels of information source were experiential (consisting of the sum of comments from friends who have seen the movie, critics' reviews, television ads, previews, and comments from someone you know and who you consider to be a film expert) and non-experiential (consisting of the sum of magazine ads plus comments from friends who have not seen the movie); the two levels of feature were subjective and objective. Due to missing data from one subject, the analysis incorporated only 97 subjects.

The main effect for source in the ANOVA tested Hypothesis 1. As predicted, subjects rate experiential sources (5.33) as more credible than non-experiential sources (3.46, $F(1,96) = 483.0, p < .0001$). Also, as predicted, subjects rate experiential sources (5.38) as more useful than non-experiential sources (3.45, $F(1,96) = 439.5, p < .0001$).

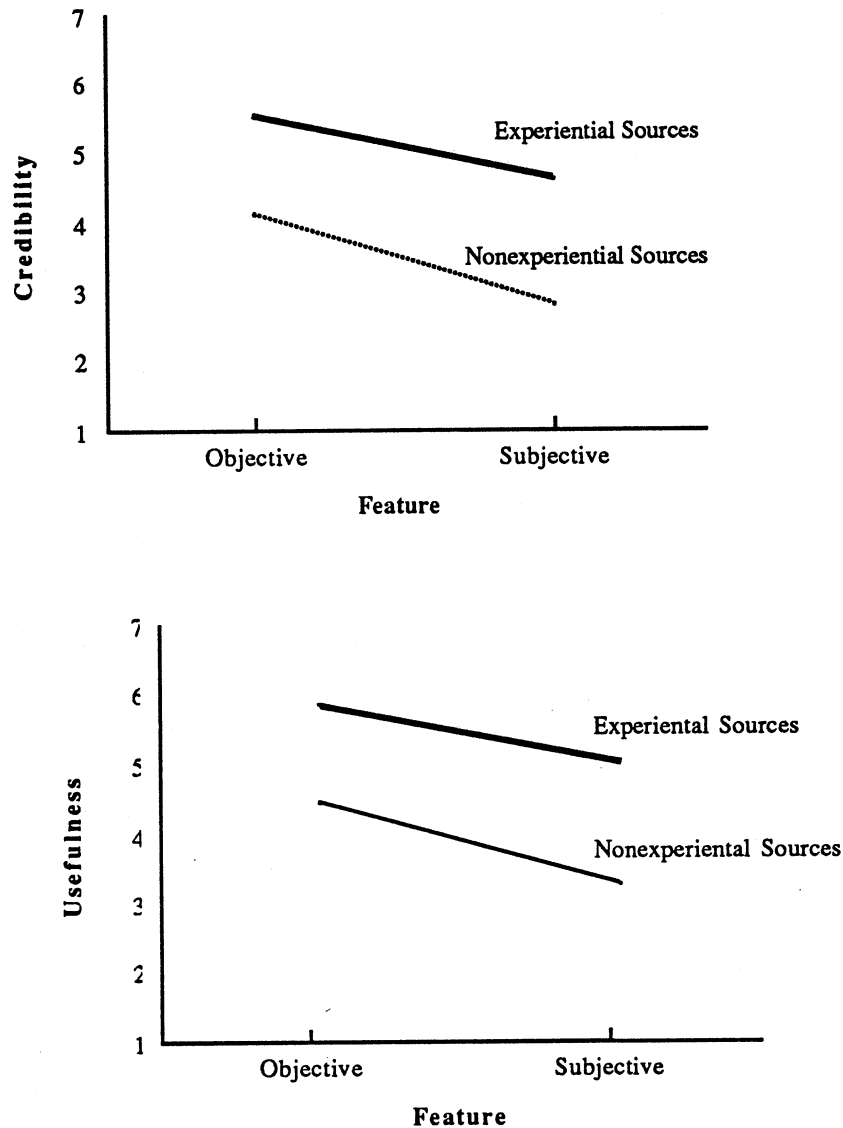

To test H2, planned contrasts between experiential sources and non-experiential sources for subjective features were used. As predicted, for subjective features, experiential sources (4.96) are more credible than non-experiential sources (2.84, $F(1,96) = 4.18, p < .05$). Also, as predicted, for subjective features, experiential sources (5.17) are more useful than non-experiential sources (2.87, $F(1,96) = 5.21, p < .05$).

To test H3, planned contrasts between experiential sources and non-experiential sources for objective features were used. As expected, for objective features, experiential sources (5.71) are not more credible than non-experiential sources (4.09, $F(1,96) = 3.13, p > .05$). Further, as predicted, experiential sources (5.58) do not differ in usefulness from non-experiential sources for objective features (4.04, $F(1,96) = 1.95, p > .10$). These results for H2 and H3 are consistent with significant interactions between source and feature in the ANOVAs for both credibility ($F(1,96) = 22.8, p < .0001$) and usefulness ($F(1,96) = 43.9, p < .0001$) (see Figure).

DISCUSSION

As expected, this study confirms the greater credibility and usefulness of experiential over non-experiential information sources for movies, as an example of experiential products. Such sources provide a sense of the consumption experience which is an end in itself for experiential products. Thus experiential sources are particularly valuable to consumers for information on subjective features,

FIGURE

those characteristics which reflect the personal nature of the consumption experience. For objective features (those which can be externally verified), at least of movies, the two types of information sources do not differ on credibility and usefulness.

It appears that experiential sources, by illustrating or describing consumption, provide a trial of the product. Faber and O'Guinn (1984) argued that previews serve this role. Such trial seems particularly useful for experiential products like movies or the performing arts which are typically new or unfamiliar to the consumer; consumers usually go to a movie that they have not seen before. For new products, trial is a useful step in the decision process, before final adoption (Wilkie 1990, p. 360).

The relative usefulness and credibility of six of the information sources tested converge well with the findings of Faber and O'Guinn (1984), who also used a seven-point semantic differential scale. To make this comparison, the results from this study were averaged across both subjective and objective features. Rankings on credibility from Faber and O'Guinn follow (with the most credible first and the least credible last): experts' comments, friends' comments, previews, critics' reviews, television ads and magazine ads. (In tests of differences between the sources, Faber and O'Guinn (1984) found no differences between the first three sources and the last three sources in this list.) The ranking from this study was almost identical; the only difference was that the rankings of

previews and critics' reviews were reversed. The rankings on usefulness differed more. However, previews, friends' comments and expert's comments were in the top three in both studies; likewise, critics' reviews, television ads and magazine ads were in the bottom three sources in both studies.

Another useful distinction among information sources used by consumers is personal versus impersonal sources (e.g., Engel, Blackwell and Miniard 1990). The experiential sources used in this study included both personal sources (i.e., critics' reviews, comments from film expert, and comments from friends who have seen the movie) and impersonal ones (i.e., previews and television ads). Likewise, one non-experiential source was personal (i.e., comments from friends who have not seen the movie) and one was impersonal (i.e., magazine ads). Because both experiential and non-experiential sources include both personal and impersonal sources, this difference does not support an alternate hypothesis for the results. Further, all the analyses reported above were repeated for personal versus impersonal sources. Neither the main effect for source nor the contrasts on credibility and usefulness for subjective versus objective features were significant. Thus, the distinction between experiential and non-experiential sources seems more useful in understanding consumer behavior for movies, and likely for experiential products, than the difference between personal and impersonal sources.

The current findings are limited by a non-random, relatively small sample that focuses on the most important age group for movie-goers but neglects other important age group targets, such as teenagers. If a study with a bigger, projectable sample confirms the current findings, then certain managerial implications would result. For example, communication efforts for movies and other types of experiential products should focus on experiential sources. Although some of these sources (e.g., word-of-mouth by friends and experts) are difficult for marketers to control, they can put more emphasis on vehicles such as television advertisements and previews rather than on magazine advertisements. The former two sources should be particularly effective in communicating the subjective nature of the product; for example, whether a movie is funny, suspenseful, scary, or romantic. If the marketer prefers to emphasize objective features, then television advertisements and previews should be more effective than magazine advertisements, but the difference in effectiveness is somewhat less.

Beyond replicating this study with a larger and broader sample, future research using the same dependent variables should consider the use of MANOVA for the analysis, as usefulness and credibility may be related. Further it would be helpful to test the credibility and usefulness of experiential versus non-experiential sources with utilitarian or non-experiential products, as well as other examples of experiential products. Another study on movies might use the director as an objective feature, as directors (e.g., Spike Lee, David Lynch) typically have more impact on the film's quality than the producer (a feature used in this study).

In trying to understand the role of experiential versus non-experiential sources, this study incorporated the differences between subjective and objective features of a product. In keeping with the experiential perspective, it would be worthwhile to explore the relation of these two types of sources to the differences between verbal and nonverbal (i.e., sensory) product cues (Holbrook and Hirschman 1982), as well.

The results of this study are encouraging and support the idea that experiential products have specific patterns of consumer behavior. It appears that hedonic consumption can define a category of products and, further, that such consumption is key for understanding them. This emphasis thus contributed towards the need in the field of consumer behavior to address the experiential aspects of consumption (Hirschman and Holbrook 1982; Holbrook and Hirschman 1982).

Involvement and Advertisement Size Effects on Information Processing

Jin K. Han, Columbia University¹

ABSTRACT

This study examines the moderating role of involvement on advertisement-size effects to predict the extent of information processed. The results indicate that, in the moderate product involvement situation, larger ads are given greater attention and thus are better recalled than smaller ads, whereas, no such difference is observed in the low involvement situation. These findings are explained in the context of previous findings on: 1) advertisement size 2) involvement, 3) distraction and attention capacity, and 4) hierarchical information processing.

INTRODUCTION

Ever since the advent of print advertising, the size of ads has been a key component of interest to both managers and scholars (i.e., Copland 1958; Finn 1988; Holbrook and Lehmann 1980; Hendon 1973; Rossiter 1981; Strong and Adams 1912; Yamanaka 1962). Apparently, there is a positive relationship between the ad size and the attentional value of the ad itself, which has direct implications to a firm's budgetary and media scheduling decisions.

The size of an ad contributes to the ad's attentional value in two ways simultaneously. One is enhancing the probability of the ad being viewed due to its sheer size, while the other is reducing the number and/or the size of other surrounding materials (i.e., other advertisements, editorials) which may detract from the ad's attentional value (Sandage, Fryburger, and Rotzoll 1979). Despite the strong focus on the advertisement size's ability to attract attention, the size literature appears to have overlooked the effect of involvement, which is an integral component in attention allocation decisions (Kahneman 1973; Norman 1976). The extent to which the size effect may be influenced by the advertisement's surrounding may be governed by the audience's involvement with the product in the ad (Finn 1988). There are a number of studies which suggest that involvement, in conjunction with executional factors (i.e., ad size), may affect the processing of the advertised information (Batra and Ray 1983; Cohen 1983; Muncy and Hunt 1984). For example, Muncy and Hunt (1984) posit that "factors such as the media in which the communication is present, the editorial content surrounding the communication,... have all been related to involvement" and are very likely to affect the processing of the advertisement message. Although these studies suggest the presence of potential interaction effects between involvement and external factor(s) on the extent of the message processed, no directional effects have been proposed.

Hence, the objective of this study is to explore whether the involvement factors moderate the effects of ad size in the processing of the information presented in the advertisement. Since the premise of this study is to examine how various levels of involvement affect the ad size's contribution to the ad's attentional value, we are particularly interested in observing consumer responses to ads under conditions of freely allocated attention. The conjectures presented in this study are based on the previous findings of: 1) advertisement size, 2) involvement, 3) distraction and attention capacity, and 4) hierarchical information processing.

The paper is organized in the following manner. The first section enumerates the general findings of ad size which relate increased processing (attention and comprehension) with an increase in ad size. The second section depicts the distinction between the high and the low levels of involvement. The following section integrates the findings from ad size studies and from involvement studies with the distraction/attention capacity theories in the context of hierarchical processing framework. The conceptual framework is followed by a description of an experiment that investigates whether, 1) in a low involvement condition, there is any difference between a large ad and a small ad on attention and comprehension; 2) in a moderate involvement condition, attention and comprehension are greater for a large ad compared to a small ad.

THE EFFECT OF SIZE OF A PRINT ADVERTISEMENT

The importance of print advertisement's attention value have long been acknowledged, and a number of studies have focused on the ad characteristics' ability to enhance the attentional value of print advertisements (i.e., Diamond 1968; Finn 1988; Hanssens and Weitz 1980; Hendon 1973; Holbrook and Lehmann 1980; Sparkman 1985; Strong and Adams 1912-1920; Twedt 1952; Yamanaka 1962). For example, ad characteristics have been found to account for more than 45% variance in print ads' effectiveness measures (i.e., recall, read most score), and among ad characteristics, ad size was shown to be strongly correlated (.78) with the effectiveness measures (Hanssens and Weitz 1980).

Hence, ad size, being an influential ad characteristic and also a significant cost factor, has been examined from various perspectives. Some research used experiments (i.e., Strong and Adams 1912-1920), whereas others relied on readership scores (i.e., Diamond 1968; Finn 1988; Holbrook and Lehmann 1980; Troidahl and Jones 1965) to explore the relationship between size and attention and/or comprehension. Both methods reveal that as the advertisement size increases, so does the ad's effectiveness. In fact, Hendon (1973) reports that Strong and Adams (1912-1920) and Copland (1958) found that the permanency of an advertisement

¹The author is grateful to Donald R. Lehmann and the two anonymous ACR reviewers for their helpful comments and suggestions.

impression varied directly with the square root of the increase in ad area. The positive effects of ad size is also corroborated by the findings from readership studies. In Finn (1988)'s meta-analysis of readership studies, there is an overwhelming evidence for ad size's positive effect on cognitive activity: 14 findings on attention, 2 on comprehension, and 6 on elaboration. Additionally, Troidahl and Jones (1965) found that ad size alone explained over 40% of the variability in readership, and that the correlation between ad size and ad readership were .64 among men and .73 among women. There, however, appears to be one exception: Ferguson (1935) found that there was no relationship between the size of an ad and the ad's attentional value.

With the exception of Ferguson (1935)'s null effect, there seems to be a relatively strong consensus on the positive relationship between ad size and the attentional value of an ad. The effect of ad size on behavior, though significant, is not as strong as the effect on the attentional aspects: ad size accounted for 19 to 36% of the variance in *inquiry generation* prompted by advertisements (Hanssens and Weitz 1980). They explain this phenomenon with a hierarchy of effects model, which states that "the communication variables typically have a greater effect on lower order responses (awareness) than higher order responses (behavior)." In any case, it is evident that ad size has considerable impact on both awareness and behavior.

Despite the tremendous focus on the attentional aspects of advertisement sizes, however, past research on ad size has overlooked the role of involvement, which is an integral element determining the allocation of attention. The size studies have yet to account for the effects of involvement in the context of ad size effects. This concern is expressed by Finn (1988):

... A study of the relationship between level of involvement, type of processing, recall, and recognition responses to print ads is needed to resolve the validity issue (of ad characteristics)

The consideration of involvement factors is critical when examining the effects of ad size, because the size of an ad indirectly affects the composition of the advertisement's environment. Muncy and Hunt (1984) report that a stimulus' environmental factors (i.e., media, editorials) have been found to be related to involvement and also to affect the processing. For example, Mitchell (1981) illustrates a scenario in which a consumer in a market for a new automobile devotes disproportionately more attention to the advertisement's background rather than to the information of the car, which results in the inferior encoding of the latter. Hence, there are some initial indications that involvement and ad size may jointly affect the attentional value of a print advertisement.

One theory that provides initial insight into how size effects might operate under different levels of involvement is the Elaboration Likelihood Model (ELM). According to the ELM, peripheral cues (i.e., simple acceptance/rejection cues) have a greater effect

on persuasion under low involvement conditions, whereas, the quality of message (via central route) has a greater impact under high involvement conditions (Petty and Cacioppo 1979; Petty, Cacioppo, and Schumann 1983). Hence, the ELM would predict that ad size, as a peripheral cue, would likely to be more effective in low involvement conditions than in high involvement conditions. The ELM, however, considers the involvement continuum as being either *high or low*; therefore, a further investigation of the size effects in the context of a wider range of the involvement continuum is warranted.

INVOLVEMENT

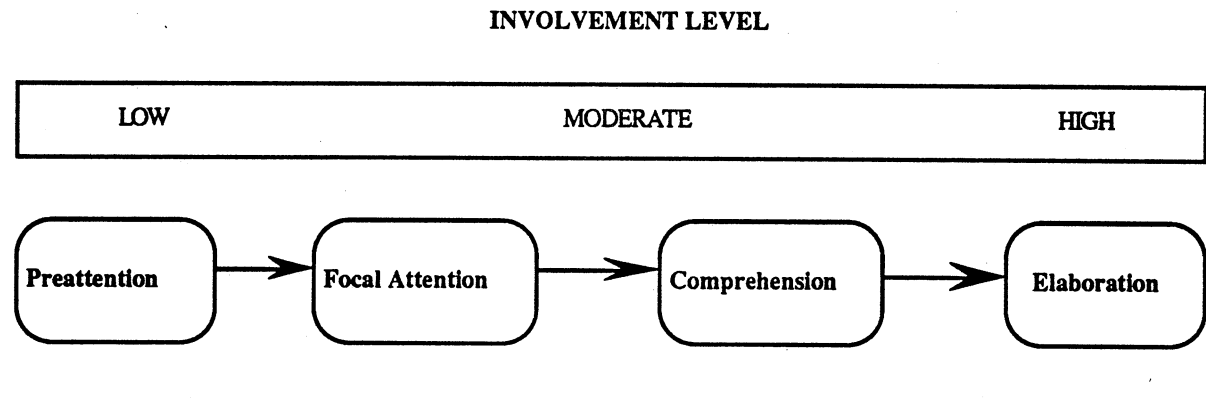

The importance of acknowledging the differences between high and low levels of involvement is evident in many advertising studies. Kassarian (1981) points out that:

Research on the hierarchy of effects in marketing communications is an excellent example of the fact that cognitive activity for low involvement and high involvement are simply different and that one cannot generalize research results from one situation to the other.

Hence, the underlying cognitive processes for the high and the low levels of involvement appear to be the key explanatory factor for the involvement-level specific responses. Specifically, the substantial support for this notion comes from the studies focusing on the attentional and processing aspects of involvement (i.e., Batra and Ray 1983; Celsi and Olson 1988; Cohen 1983; Greenwald and Leavitt 1984; Harris 1987; Mitchell 1981). The consensus of the findings is that involvement mediates the intensity of attentional effort devoted to a stimulus: low levels of involvement elicit minimal or negligible attentional effort - as the involvement level heightens, the attentional level follows suit. The reason for the frugal rationing of attentional effort at low involvement levels has been attributed to *non-arousal* (Mitchell 1979; Woodside 1983), *lack of motivation* (Burnkrant and Sawyer 1983), and *mental laziness* (Harris 1987). In any case, it is evident that relatively little (substantial) cognitive activity takes place under low (high) involvement conditions. This contention is believed to be observable not only in attentional efforts but also in the comprehension measures as well (Cohen 1983; Greenwald and Leavitt 1984; Mitchell 1981), which is consistent with the hierarchical information processing framework.

Hence, at very low levels of involvement (preattentive level), we would expect no significant effects of ad size since the viewers will not even put in the effort to process the advertisement. According to the ELM, however, ad size, as a peripheral cue, should be most effective at low levels of involvement. The conflicting predictions can be resolved by considering what the ELM means by "low" levels of involvement. The central premise of our study is to observe how consumers behave under *natural* newspaper viewing settings without specifically being instructed to evaluate a particular ad in the newspaper.

FIGURE A
Hierarchical Advertising Processing Model

Consequently, in our framework, the subjects who do put in the effort to process the target ad will be considered as at least being *moderately* involved, whereas, the ELM studies specifically instruct all the subjects to evaluate the target stimulus, consequently making the subjects at least *moderately* involved. Hence, the ELM's "low" level of involvement is not equivalent to our definition of *low* (which is *preattentive*); rather, the ELM's "low" is closer to our definition of *moderate*. Henceforth, the study will refer to *low* as *preattentive*.

Unlike the cognitive processes at low levels of involvement, the processing at *moderate* levels of involvement may encounter the constraints of *attention capacity*. Attention capacity is analogous to the related concept of STM (short-term memory) store - once a stimulus occupies part of the attention-capacity space, the availability of "free" attention-capacity space necessarily decreases for another stimulus, which results in reduced cognitive processing for the latter stimulus (Kahneman 1973; Norman 1976). Greenwald and Leavitt (1984) relate this phenomenon to high involvement: "Because high levels of involvement are demanding of a limited resource (attention capacity), involvement in one message is necessarily limited when capacity is allocated to some other message." This notion is also in line with distraction effects (i.e., Batra and Ray 1983; Cohen 1983; Osterhouse and Brock 1970).

The key implication is that attention capacity limitation may operate in different directions for the target ad at *moderate* levels of involvement. Specifically, when categorically considering the higher levels of involvement continuum as *moderate* and *high*, attention capacity limitation may work *against* or *in favor* of the target ad, respectfully. Under *moderate* involvement conditions, the primary attention may be devoted to the target ad's environmental materials rather than to the ad itself (Mitchell 1981; Muncy and Hunt 1984), thereby potentially being subjected to attention capacity limitation (Norman 1976). Consequently, the size effects should be apparent at *moderate* levels of

involvement. Using our definition of *moderate*, this conjecture is also in line with the ELM.

HYPOTHESES

- H1: At a low (*preattentive*) involvement level, there will be no significant difference in attentional effort and comprehension measures between a larger ad and a smaller ad.
- H2: At a moderate involvement level, there will be a significant difference in attentional effort and comprehension measures between a larger ad and a smaller ad.

In sum, we hypothesize an interaction effect between ad size and involvement for both attentional effort and comprehension measures.

METHOD

Research Design

A 2x2 factorial design (involvement: moderate, low x ad size: larger or smaller) was employed. The sample consists of 60 undergraduates of a large Eastern university. We differentiated the involvement levels among the subjects by choosing the ad message as an announcement for a meeting concerning an increase in the graduations requirement effective with the sophomore class. This method of involvement manipulation has been shown to differentiate involvement successfully in past studies (i.e., Apsler and Sears 1968). Furthermore, Rossiter (1981) posits that "personal reference may stimulate reader involvement with the headline," therefore, the headline in the announcement explicitly contained the words "Class of '92 and '93" to ensure the proper manipulation of involvement.

An equal number of moderate involvement subjects (30 underclassmen) and low involvement subjects (30 upperclassmen) were randomly selected. The sample was selected by making room-to-room visits in the undergraduate dormitories (underclassmen

dormitory for moderate involvement group and upperclassmen dormitory for the low involvement group). Since all of the moderate involvement subjects were selected from a freshman dormitory, there were no sophomores in the moderate involvement group. Similarly, since all of the low involvement subjects were selected from a senior dormitory, there were no juniors in the low involvement group.

VARIABLES

Ad Size. There are two ad sizes (larger and smaller) in this experiment which varies the amount of distraction salient for the target ad. The larger ad is a full-page ad, and the smaller ad is a quarter-page ad with editorials around it on the same page. (See experimental procedure for more details.)

Involvement. Two levels of involvement (moderate and low) are used in this study. Moderate (Low) involvement is defined by the information in the ad that is personally (ir)relevant to the viewer. As previously mentioned, we implemented Apsler and Sears (1968)'s method to manipulate involvement. The ad contains information about a new graduation requirement effective with the freshmen and the sophomore class. Therefore, the underclassmen are in the high involvement group, whereas the upperclassmen are in the low involvement group.

Dependent Measures. Two measures are used to measure the subjects' responses. One is the amount of time the subject spends when viewing the ad. This measure acts as a proxy for attentional effort (Celsi and Olson 1988). The other measure is the number of items correctly recalled from the information presented in the ad. The ad contains eight key information (i.e., time and place for the meeting, speaker, language requirement). Hence, recall serves as a measure for the level of comprehension (i.e., the extent of the information processed) (Celsi and Olson 1988; Petty et al. 1983).

EXPERIMENTAL PROCEDURE

A mock school newspaper was prepared for the experiment. The newspaper consists of eight pages: pages one through eight contain all text (i.e., articles and editorials) and no advertisements other than the target ad. The target advertisement was placed after the fourth page. The mock newspaper was varied across treatments as follows: one version contains a full-page size of the target advertisement, and the other version contains a quarter-page size of the advertisement with several current-affair articles filling up the rest of the page as the attention-competing materials. The advertisement was an announcement for a forum for discussing an increase in graduation requirement. The advertisement states that the new policy will go into effect starting with Class of '92. The choice of Class of '92 differentiates the involvement level of the ad: underclassmen are in the moderate involvement group, and upperclassmen are in the low involvement group. During each room visit, the subjects were asked to view the mock newspaper as a prototype of a new school newspaper. The subjects were instructed to view the paper and give

an evaluation of the newspaper. The purpose of this instruction was to prevent the subjects from guessing the research objective. While the subject was viewing the newspaper, s/he was timed for the viewing of the advertisement. The time measure provides a measure for the subject's attentional effort (Celsi and Olson 1988). A stopwatch, which measures the attentional effort, was kept from the subject's view (i.e., in a pocket). After the viewing of the paper was over, the subject was asked to fill out an evaluation form. One part of the evaluation form was a recall test concerning the information in the advertisement. The recall test serves as a measure for the amount of advertisement information processed (Celsi and Olson 1988; Petty et al. 1983). When this procedure was done, the subject was given a debriefing and thanked for the cooperation.

RESULTS

Manipulation Check

Due to the design of the study, a successful manipulation of the involvement levels is inherent in achieving the research objective. We used the subject matter of the announcement to vary the involvement. In order to check the extent of the involvement manipulation, a manipulation check question was included in the questionnaire. The question asked the subjects to rate their interest in the announcement on a 5-point scale (1=low, 5=high). The t-test result ($t=1.99$; $df=39$; $p=0.05$) shows that the mean interest of the moderate involvement group (2.80) was significantly greater than that of the low involvement group (1.86).

Hypothesis Testing

The hypotheses predicted that there will be no significant difference in attentional effort between a larger ad and a smaller ad under *low* involvement. On the other hand, if the involvement level is in the *moderate* range, we expect the attentional effort to be greater for a larger ad than a smaller ad. The average results are given in the *Table*. ANOVA indicates that the interaction effect between ad size and involvement is not fully significant [$F=2.67$; $df(1,56)$; $p=0.10$]. Further analysis of contrast effects, however, show that the findings are directionally in line with the hypotheses for *low* and *moderate* involvement conditions, respectively: no difference was observed in the *low* involvement condition in attention effort between a larger ad and a smaller ad ($t=0.17$; $df=28$; $p>0.05$), whereas the larger ad received more attention than the smaller ad in the *moderate* involvement condition ($t=2.22$; $df=28$; $p<0.05$). See Figure B.

Similarly, the hypotheses predicted that there will be no significant difference in recall between a larger ad and a smaller ad under *low* involvement. If the involvement level is in the *moderate* range, we expect the recall to be greater for a larger ad than a smaller ad. ANOVA indicates that the interaction effect between ad size and involvement is indeed significant [$F=4.30$; $df(1,56)$; $p=0.05$], hence supporting the hypotheses for *low* and *moderate* involvement conditions. Further analysis of contrast

TABLE
The Effects of Size and Involvement on Effort and Recall

Involvement		Advertisement Size	
		Full-Page Ad	Quarter-Page Ad
Moderate	Effort ^a	2.34 (2.00) ^b	1.02 (1.12)
	Recall	1.87 (1.40)	0.67 (1.20)
Low	Effort	1.32 (0.86)	1.24 (1.60)
	Recall	0.53 (0.91)	0.60 (1.12)

^aEffort expressed in seconds.
^bStandard deviations in parenthesis.

effects show additional support the hypotheses for *low* and *moderate* involvement conditions, respectively: no difference was observed in the *low* involvement condition in recall between a larger ad and a smaller ad ($t=0.17$; $df=28$; $p>0.05$), whereas the larger ad was recalled better than the smaller ad in the *moderate* involvement condition ($t=2.48$; $df=28$; $p<0.05$). See Figure C.

DISCUSSION

The main objective of this study was to observe consumer responses to a target advertisement under a freely-attention-allocating, *casually*-newspaper-viewing setting, with *ad size* and *involvement* as the variables of interest. Despite the ad size studies' preoccupation with print ads' attentional value, strangely enough, most size studies have neglected to explicitly consider involvement factors, which play a critical role in the allocation of attention. Hence, this study set out to answer such questions as: "Do size effects exist at all levels of involvement? If not, how do involvement effects mediate the effects of advertisement size? The findings of this study provide some preliminary answers to these questions.

At the *lower* end of the involvement spectrum, we expected to see no significant difference in the amount of attention given, consequently in the number of items recalled between a full-page ad and a quarter-page ad. The rationale for this conjecture is that there is well documented evidence of consumers choosing not to expend any attentional effort on materials personally irrelevant to them. Therefore, an ad, large or small, will have a very small probability of being processed at very low levels of involvement. This seems to be the case with the seniors in the sample. Since the ad message is intended for undergrads, the seniors appear to pay hardly any attention to the message. The seniors' lack of interest is evident in their indications of their interest in the

message (i.e., 1.86 where 1=low, 5=high). Further evidence of low involvement comes from the response measures. In terms of the time spent viewing the ad, the seniors spent on average a little over one second (1.32 seconds for the full-page ad, 1.24 seconds for the quarter-page ad). Consequently they recalled negligible amount of information (0.53 item for the full-page ad, 0.60 item for the quarter-page ad).

At moderate levels of involvement, consumers are believed to somewhat actively process information due to personal interest, relevance, etc. Hence, we hypothesized that, at moderate levels of involvement, there would enough difference in the intensity of processing from low levels of involvement such that the effect of ad size will be apparent. The premise for this conjecture is that, although it is likely that there is active processing of information, there is a fairly good chance that the primary attention may allocated to some other material (i.e., other ads, editorials) in the vicinity. Therefore, the processing of the target ad may be subjected to distractions and/or attention capacity limitation. Thus, we expect the size of an ad to reduce the presence and/or the number of potentially distracting materials, thereby, enhancing the attentional value of the target ad.

For the freshmen in the sample, their involvement seems to be in the *moderate* range. Their interest level indication, significantly greater that of the seniors, is at the 2.80 mark (1= low, 5= high). The means for the attentional effort and the recall measures seem to further support the *moderate* involvement position for the freshmen. The attentional effort for the full-page ad (2.34 seconds) was significantly greater than that for the quarter-page ad (1.02 seconds) ($t=2.22$; $df=28$; $p<0.05$). Similarly, the recall for the full-page ad (1.87 items) was significantly greater than that for the quarter-page ad (0.67 item). Additionally, the amount of time spent and the number of items recalled seem to further

FIGURE B
Interaction Effects of Ad Size and Involvement on Effort

FIGURE C
Interaction Effects of Ad Size and Involvement on Recall

suggest that the freshmen's involvement was moderate.

The contrast analyses at the low and the moderate levels of involvement suggest an interaction between involvement and ad size, which is consistent with our hypothesis. ANOVA confirms the contrast analysis for the recall measure [$F=4.30$; $df(1,56)$; $p=0.05$] but not for the attentional effort [$F=2.67$; $df(1,56)$; $p=0.10$]. The lack of interaction in the

attentional effort may perhaps be attributed to fact that there was more room for measurement error in timing the viewing of the ad in comparison to counting the number of correctly recalled information.

In sum, this study was an exploratory look at how ad size effects might operate at two levels of involvement: low and moderate. The conjectures derived from past involvement and ad size studies suggest an interaction effect, where size effect is not

apparent at low levels but present at moderate levels of involvement. At these levels of the involvement continuum, a significant interaction between ad size and involvement was found for recall but not for attentional effort (however, there is directional support for attentional effort). Thus, although we do not have a direct support, the results lend some support for the distraction/attention capacity limitation explanation at the moderate involvement level.

Hence, one implication of this study is as follows. Given a budget for an ad campaign, one needs to decide on the involvement level of the target audience first. For a low involvement audience, an advertiser should perhaps spend more for frequency rather than for the size of the ad. For moderate involvement audiences, however, size should be a key consideration in addition to the frequency aspect.

LIMITATIONS AND FUTURE RESEARCH

The premise of this study was examining how involvement and ad sizes influence the processing of advertisements. As dependent measures, attentional effort and correct number of recalls were used to determine an ad's effectiveness. Other measures of effectiveness, especially the evaluation of the ad, warrant further research. The advertisement used in this study contains no pictorial materials, therefore, the findings cannot be generalized to all advertisements. Further, the mock newspaper did not carry other advertisements besides the target one. Future studies could incorporate how such factors affect the processing of the target ad. Additionally, other significant advertisement components (i.e., color, bleed, location) need further looking into.

Most importantly, the biggest limitation of this study is that the data does not cover the whole range of the involvement spectrum (i.e., extremely high levels of involvement). The ELM and other studies from distraction/attention capacity area suggest that the effects of ad size may not be apparent at extremely high levels of involvement. Hence, there might be a curvilinear relationship: no effects of ad size at extremely low and high levels but present at moderate levels. Hence, future studies should gather data to cover the whole range of involvement.

Lastly, the findings should be viewed in the light that the results may be study specific. We cannot discount the possibility that the results may have been due to a confound of category involvement.

Clarifying the Simple Assumption of the Information Load Paradigm

Robert S. Owen, Ohio State University

ABSTRACT

Debate over the "information overload" phenomenon has continued for almost two decades. This paper argues that further theoretical and managerial interest in the subject of consumer mental workload should be directed less toward issues of information quantity and more toward changes in processing quality as consumer mental workload is increased. Recent advances in our understanding of issues relevant to consumer mental workload are reviewed.

INTRODUCTION

To err is human. In September 1989, USAir Flight 5050 dropped into the East River at Laguardia Airport one minute after takeoff. The experienced pilot had attempted the takeoff with the rudder in full left trim. In March 1979, a reactor core at the Three Mile Island nuclear power plant overheated. Supervisors manually overrode an automatically activated coolant pump after misinterpreting control panel indicators, resulting in catastrophe. A month later, a marketer reported the observation that consumers were choosing the wrong product when asked to compare too many features or too many product alternatives (Malhotra 1979, 1982).

Given that human and environmental safety is involved, incidents such as the first two are clearly deserving of a quest to understand what went wrong to cause the human error. As a sort of "information processing system", human ability is subject to the same constraints as any sort of machine system; the human system is certainly limited in its capacity to do work, and, like any machine, exhibits problems of reliability as that capacity limitation is approached. The study of human reliability is based substantially on an attempt to understand causes of error in an entire system which includes both a machine component and a human component (cf., Park 1987; Wickens 1984). Few would argue the importance of understanding the reliability and causes of error that occur in a system composed of pilots, flight controllers, and a myriad of lights, switches, and circuit boards.

Our understanding of human error is equally important, however, with regard to more typical everyday situations. Pressing the wrong elevator button after an intense business meeting or turning on the windshield wiper instead of the headlights while in heavy traffic are individually not serious enough incidents to seem worthy of study. Nevertheless, the occurrence of such everyday incidents does suggest that human processing mistakes are not a rarity, but are, rather, quite normal. The pioneering studies of "information overload" in the marketing discipline were concerned with the everyday mistakes that shoppers might make in the purchase of such mundane products as instant rice (Jacoby, Speller, and Berning 1975), prepared dinners (Jacoby et al.), laundry detergents (Jacoby, Speller, and Kohn 1974), or peanut butter (Scammon 1977). The mistaken

purchase of the "wrong" brand of peanut butter is certainly not, as an isolated incident, a catastrophe of the magnitude of a downed airliner. On the other hand, if enough consumers in aggregate make the same mistake, the result can cost consumers millions of dollars and can result in large profits for the seller of an inferior product. In the case of a product like a house (Malhotra 1982) or even an apartment (Payne 1976a), a decisional mistake could lead to the purchase of an inferior choice alternative with which the buyer and his/her family will have to live for a substantial portion of their lives.

Debate over the existence of empirical proof of such a marketing phenomenon as "information overload" which could lead to purchase mistakes by consumers ensued soon after publication of the pioneering studies (Jacoby 1977, 1984; Jacoby, Speller, and Berning 1975; Malhotra 1982, 1984; Malhotra, Jain, and Lagakos 1982; Russo 1974; Scammon 1977; Summers 1974; Wilkie 1974). More recently, Meyer and Johnson (1989) have voiced additional concerns (see also Keller and Staelin 1987, 1989). As Jacoby (1984) notes, however, even a breakfast cereal package might have over 100 separate items of information, exclusive of additional graphic information, and a single store may carry as many as 90 different brands: that people can and would make mistakes under mentally taxing conditions would seem to be intuitively obvious, whether as pilots of jet aircraft or as everyday consumers.

Science does bear the obligation to provide empirical evidence even for that which appears to be intuitively obvious, and the pioneering studies appear to have provided reasonable evidence in support of intuition. There has been, however, a curious lack of work toward extending the pioneering notion of "information overload" with respect to the broader subject of consumer mental workload; this is only the preface of many more theoretically interesting and managerially rich chapters that still could and should be written on the subject. The notion that there exists some sort of "red line" in peoples' abilities, beyond which there is some kind of breakdown in the reliability of the processing machinery, is conceptually appealing. However, such a "red line", if one exists, is likely to be so smeared and fuzzy in real-world application that it could not alone be especially useful in application by a manager. Moreover, even if a specific "red line" point could be identified, what is a manager supposed to do with this interesting bit of knowledge?

This paper argues that theoretical and managerial interest should not be directed so much toward issues of information *quantity*, but more toward changes in processing *quality* as consumer mental workload is increased. The general purpose of a marketing communication is to inform and persuade, and we should therefore be interested in the kind of information retained and in the changes in attitudes toward a product when a communication is processed

under conditions of low, moderate, and high levels of consumer mental workload. Additionally, this paper argues that we should focus more interest on the quality of particular (non-chance) product choice decisions under conditions of increasing mental workload, rather than the more simple issue of whether or not some "correct" choice, however defined, was made. Although many of the points made in this paper have previously been noted by others (e.g., Jacoby 1975, 1984; Malhotra 1984), this paper attempts to provide a review of recent advances in our understanding of issues relevant to consumer mental workload since the conduct of the pioneering marketing studies. It is hoped that this will help to clarify what it is that "information overload" may or may not mean in the broader context of mental workload and, further, that this will help to stimulate research beyond the simple issue of whether or not consumers can or will be "overloaded".

THE INFORMATION LOAD PARADIGM

The notion of "information load" in marketing has primarily been concerned with product choice "errors" made by prospective consumers under conditions of high informational loads. Information "overload" is assumed to have occurred when the prospective buyer is unable to complete the buying task successfully, as might be evidenced, for example, when an objectively inferior product choice is made by a high proportion of consumers under high load conditions. The underlying cause of this phenomenon is assumed to be due to a "limited capacity" processing system, and that approaching this limit results in decisional errors (cf., Malhotra 1982).

These assumptions necessarily parallel those of the notion of "mental workload". The concept of mental workload, from engineering psychology, is concerned with errors made by human operators of machine systems under conditions of high mental loads. "Overload" is assumed to have occurred when the operator is unable to complete the task successfully (cf., Albanese 1977, cited in Willeges and Wierwille 1979). The underlying cause of this phenomenon is assumed to be due to a "limited capacity" processing system, and that approaching this limit results in operator error (e.g., Wickens and Kramer 1985; Willeges and Wierwille 1979). The notion of information overload, then, appears to be entirely consistent with the notion of mental workload; "information load" is apparently a limited subset of the broader concept of "mental workload". As such, these should, as concepts and as constructs, share certain similarities and limitations.

THE MAGICAL BUT FUZZY RED LINE

The "information overload" studies in marketing appear to have verified that prospective buyers can make dysfunctional choice decisions under conditions of heavy informational loads. Finding that participants in his study exhibited the effects of "overload" when confronted with 10 or more alternatives in the choice set or with information on 15 or more attributes, Malhotra (1982) suggested that future investigations should attempt to more clearly

"determine the critical number of alternatives and attributes to information processing breakdown"; Miller's (1956) "magical number seven" is certainly an intriguing concept. There are, however, a number of reasons as to why it is unlikely that such a number can be identified in any marketing context and why this number alone would not be of much practical value.

The Multidimensionality of the Workload Construct

Although "overload" in the context of mental workload can be operationally defined with respect to increases in task performance error, there currently appears to be a consensus that there is yet no generally accepted definition of "mental workload" (cf., Chiles and Alluisi 1979; Wickens and Kramer 1985; Willeges and Wierwille 1979). The detection of "overload" is generally based on single-task performance measures, as when the "wrong" product is chosen in an information load task. There are also other measures of mental workload, including concurrent (aka dual-task, secondary, subsidiary) task performance measures, physiological measures, and self report measures (cf., Owen 1990a). This variety of measures alone would seem to indicate that mental workload is composed of many dimensions. Human performance researchers have recently made attempts to clarify various dimensions that may be involved in subjective perceptions of the workload construct, as in the conjoint approach of the Subjective Workload Assessment Technique (SWAT), which attempts to account for the workload dimensions of time load, mental effort load, and psychological stress load (e.g., Reid, Shingledecker, Nygren, and Eggemeier 1981; Tein 1989), or the NASA-TLX (Task Load Index) rating approach (Hart and Staveland 1988), which attempts to account for nine individual dimensions. The implication is that in various real-world marketing situations, "overload" is likely to occur at various points, depending on how various dimensions are affected at the time the marketing communication is received. The marketer would often not have control over all dimensions of workload, e.g., how much time the prospective buyer has to spend making product comparisons, which can affect the exact location of the overload "red line".

The Limited Resource Issue

There is substantial evidence of qualitatively different forms of processing mechanisms, and the mere observation of some quantitative threshold of "overload" is of limited value (cf., Owen 1991). From the perspective of attention theory, there is substantial evidence of multiple processing resources (e.g., Friedman and Polson 1981; Friedman, Polson, and Dafoe 1988; Isreal et al. 1980; Kantowitz and Night 1976; Navon and Gopher 1979; Sanders 1979; Wickins 1980, 1984; Wickens and Kessel 1980), each with its own "capacity" limitations, implying that "overload" may occur at different points, depending on what combinations of resources (e.g., mathematical, graphic, textual, oral) are engaged for any particular task.

Additionally, the "capacity" explanations of processing necessarily require the notion of automatism (Stelmach and Hughes 1983); there is evidence of an automatic mechanism of processing which does not consume from "capacity"-limited resources (e.g., Fisk and Schneider 1984; Schneider 1985; Schneider and Fisk 1983; Schneider, Dumais, and Shiffrin 1984; Shiffrin, Dumais, and Schneider 1981; Shiffrin and Schneider 1977), with the implications that there may be differences in the "overload" threshold for the processing of some kinds of information for some people and that new informational inputs will not be retained in memory. Related to the notion of automatism is evidence that processing can sometimes be a "skill" (e.g., Gopher in press; Hirst 1986; Hirst, Spelke, Reaves, Caharack, and Neisser 1980; Spelke, Hirst, and Neisser 1976), with similar implications. For example, "novice" shoppers of a particular product class may experience "overload" at a different point than "experienced" shoppers. The engagement of qualitatively different forms of processing resources will presumably result not only in different levels of an "overload" threshold, but may also result in qualitatively different outcomes with regard to learning information from a marketing communication.

Moderators of Processing Ability

A number of individual-specific traits may moderate "capacity" or other forms of processing interference that could lead to processing outcome errors (e.g., Gopher and Kahneman 1971). One capacity-based measure, concurrent task performance, has been associated with such individual traits as demographic (Stapleford 1973) and personality variables (Huddleston 1974; Huddleston and Wilson 1974). The effects of distraction also appear to be related to personality (Morgenstern, Hodgson, and Law 1974). Processing ability appears to be affected by the biological effects of aging (Kochhar 1979), apparently increasing from childhood through adulthood (Halford, Maybery, and Bain 1988), although further aging may negatively affect processing abilities (McDowd and Craik 1988). Additionally, a number of environmental factors could affect processing abilities. These might include food intake (Lisper and Eriksson 1980), noise (Finkelman and Glass 1970; Finkelman et al. 1977), sleep (Collins 1977), temperature and clothing (Vickroy, Shaw, and Fisher 1982), and perhaps even time of day (Malaviya and K. 1976). The overload "red line" could differ not only between individuals, but even within individuals, depending on environmental factors.

Heuristic and Peripheral Processing

From the perspective of persuasion and attitude change, there is also evidence of qualitatively different forms of information processing. There is evidence that people will sometimes engage in an objective or "systematic" mode of processing, but may at other times engage a more "heuristic" based mode of processing (e.g., Chaiken 1980; Chaiken, Liberman, and Eagly 1989). Related to this is evidence for the notion that people can sometimes engage a "central"

mode of processing, where issue-relevant information is elaborated upon, and can at other times engage a "peripheral" mode of processing, where non-issue-relevant information may be elaborated upon or where elaboration may not even be engaged (e.g., Petty and Cacioppo 1981, 1986). Although the engagement of qualitatively different modes of processing may result in similar levels of initial attitude changes, the persistence (Haugtvedt and Strathman 1990) and resistance (Haugtvedt 1989) of attitudes (i.e., delayed effects) may be very different.

There are two implications associated with this. The engagement of a "peripheral" mode of processing may require the use of capacity-consuming effort, as when some sort of heuristic is used, or may not require the consumption of much capacity, where a person can be influenced by the peripheral features of a communication without deliberately using some sort of decision heuristic. This would roughly correspond to what Owen (1990b) calls "controlled/peripheral" and "automatic/peripheral" processing. Whether or not "capacity" gets used will affect whether or not a person made a decision that was affected by "overload", since overload is presumably a capacity-based construct. Exactly how one would define the overload "red line" under these conditions is not clear.

The other implication is that there is more at stake than just the decision outcome. Exactly how increases in mental workload affect attitude change processes is at least as important as any immediate decision outcome of the effects of mental workload. The pre-purchase process associated with products such as houses, automobiles, life insurance, or complex, expensive appliances is likely to result in a high level of motivation to process information as well as a high level of information load due to the difficulty in comparing features between such products. It is possible, perhaps likely, that many prospective purchasers of such products would not make an immediate decision when comparing products, but would take several days to "think" about the merits of the products. What should be of more interest in situations of high mental workload, then, are differences in the nature of attitude changes under these conditions, which could affect a *future* product choice decision.

Issues of Practical Application

As a sort of bench mark, knowledge that consumers can compare five or ten attributes or alternatives before exhibiting the effects of "overload" (cf., Malhotra 1982) is useful. The problem in a marketing context is that a number of constraints get in the way of making good use of this as a precisely defined point. Even if one could identify the magical number that defines the "red line" point in the number of product alternatives and number of attributes that people can consider before exhibiting the effects of "overload", it would have little managerial use in many situations. If the prospect wants to look at ten houses, the real estate agent cannot stop him/her. If the government mandates information on product packaging for the sake of consumers' right to know, then the seller must

comply. If a life insurance agent is attempting to close a sale on a prospect, but the prospect is being deliberately "overloaded" with too much confusing information on too many policies by a competitor attempting to foil the sale, knowledge that the prospect is likely to have "overloaded" is, alone, of little value. However, an understanding of the process that leads to recall and to attitude change, attitude persistence, and attitude resistance under these conditions could be useful in the design of more effective marketing communication strategies.

DISCUSSION

The results of the marketing "overload" studies appear to support Miller's "magical number seven" as a rough benchmark. The debate resulting from these pioneering studies has also flushed out some crucial conceptual and methodological issues, providing a firm footing for future work on issues of the effects of mental workload in marketing situations. The preface to this interesting and practical subject has been written. Curiously, however, there has been very little work on the subject of consumer mental workload since the pioneering "overload" studies of the seventies.

The problem closing this issue at this point is that the identification of some quantitative threshold of "overload" has little practical use beyond providing a rough benchmark. This paper has discussed a number of qualitatively different processing mechanisms that can be engaged. The threshold might change, depending on how different kinds of informational inputs engage different combinations of processing resources, and depending on the processing skills of the person or population of message recipients. A number of other factors have also been discussed, such as individual differences, age, clothing and temperature, or time of day, which could affect an individual's ability or motivation to process a marketing communication. Any quantitative "red line" value that is identified as the outcome of a study could potentially be a mere artifact specific only to a particular experimental setting and may not be valid in other settings.

A more theoretically interesting and managerially useful issue regards the *quality* of processing under conditions of increased mental workload, regardless of the exact location of any overload "red line". The general purpose of a marketing communication is to inform and persuade, whether that communication be the labeling on a package, the appeals of a TV commercial, or an encounter with a salesperson. People do not always make some "correct" or "incorrect" decision choice when receiving a marketing communication; it is more likely that most marketing communications lead to the remembering of information and to changes in attitudes. Such learned information and attitudes are likely to affect some choice decision at a future time and are additionally, and importantly, likely to affect perceptions of product performance (i.e., satisfaction) after a purchase is made.

Even if one does consider the situation where a product choice decision is made at the point of the

marketing communication (as when comparing package labeling in a store), the purchaser does not make a simple "correct" or "incorrect" choice. There may exist one single objectively best choice for that particular individual, but what actually happens when the person makes a choice that results in the purchase of a product that was not the "correct" choice? Although too much information could lead to human error, what is the *quality* of whatever choice was made? It is unlikely that the purchaser in this situation can make only a "correct" choice or a *random* incorrect choice.

If we assume that a consumer will attempt to make a reasonable (satisficing) choice, even if they lack the ability to adequately process information due to "overload", then we cannot assume that they would make a random incorrect choice. It is quite possible that people use simplifying heuristics based on, say, "peripheral" clues to product quality, such as the appearance of the packaging material or the furnishings in an attorney's office (cf., Jacoby 1984; Olson and Jacoby 1972; Shostack 1977). It is also possible that people can be influenced by more subtle "peripheral" cues in the situation that they do not deliberately consider, as in the automatism that may be associated with stereotyping (e.g., Devine 1989). If one assumes that people do attempt to make "reasonable" decisions, and are influenced by peripheral clues or cues, would it not then be possible to predict what kind of decisional error would be made? Would it not be possible to influence the outcome of potential errors with different strategies in packaging, in personal selling, or other forms of communication?

Two information processing models which attempt to integrate issues of "capacity" with issues of consumer memory and attitudes are those of Bettman (1979) and Owen (1990b). Perhaps such models hold some insights regarding the delayed effects of consumer mental workload on such factors as memory and attitude. Work related to consumer mental workload has addressed such issues as automatism (Palmer and Jonides 1988) and heuristics (Formisano, Olshavsky, and Tapp 1982; Lussier and Olshavsky 1979; Payne 1976a, 1976b), and the recent line of research addressed by Keller and Staelin (1987) has addressed the issue of information quality, rather than quantity.

Attitude theories and capacity-based attention theories recognize the influence of motivation and ability on human information processing. Certainly, information load affects and is affected by both motivation and ability (cf., Muller 1984), which are perhaps greater confounds in real-world consumer situations than they might be in the settings of astronauts or airline pilots. A severe limitation to the concept and construct of mental workload as it is studied in human factors is that these researchers are concerned with human error at the time of a task without regard to the delayed effects that workload may have. The effects of mental workload on memory, on changes in attitudes, and on the quality of *future* decisions appears to be, importantly, an issue unique to the discipline of marketing.

The Influence of Level of Involvement on the Feature Matching Process in Consumer Preference Judgments

Alan Strathman, University of Missouri-Columbia
David S. Boninger, University of California-Los Angeles
Sara M. Baker, Ohio State University

ABSTRACT

Previous research has indicated that Tversky's (1977) feature matching model of similarity judgments can be applied to judgments of preference (Houston, Sherman, & Baker, 1989). However, this research has examined preference judgments only under conditions of low involvement. This study investigated the hypothesis that the feature matching process by which the features of the more recently presented product (the subject) drive the comparison of features with the earlier product (the referent) would be attenuated under conditions of high involvement. As predicted, under high involvement, the subject was preferred equally under unique positive and unique negative conditions.

INTRODUCTION

People are frequently in situations in which they must make preference judgments by comparing alternatives. Individuals contemplating a vacation may be faced with the task of determining which of two or more vacations they prefer. At other times they must make preference decisions between competing automobiles or alternative houses. Recent research indicates that, if one controls for the attractiveness of the alternatives, relative preference can be affected by the order in which the alternatives are considered. Houston, Sherman and Baker (1989) found that when people were asked to compare the desirability of alternatives, they were more sensitive to the unique information provided by the more recently presented alternative. Their results were consistent with predictions derived from a feature matching process (Tversky, 1977) and indicated that Tversky's model of similarity judgments can be applied to judgments of preference. The current research seeks to further our understanding of the role played by feature matching in consumer preference judgments and to determine whether the feature matching process will manifest itself under conditions of heightened involvement.

Feature Matching

Tversky (1977) presented a feature matching process that attempts to explain comparison processes in judgments of similarity. According to Tversky (1977), comparisons of objects involve a subject of comparison and a referent. In a comparison of the form "A is like B" (e.g., Ford is like Chevrolet) "A" is the subject, and "B" is the referent. Perceived similarity differs depending upon whether people are asked whether A is like B or B is like A.

In Tversky's model, objects may be represented as sets of features. These objects are assumed to have shared features (i.e., features belonging to both a and b) and/or unique features (i.e., features belonging to a but not b and features belonging to b but not a). It is argued that, in a similarity judgment task such as

judging the similarity of a to b, people naturally focus on the subject. They compare the features of the subject with the same features of the referent. According to Tversky (1977), the features of the subject are weighted more heavily than the features of the referent. Thus, "the features of the subject control the agenda of the comparison" (Houston et al., 1989, p. 122), and judged similarity is affected more by the unique features of the subject than the unique features of the referent. Tversky (1977) reported research with pairs of countries (e.g., U. S. A. - Mexico), pairs of figures, and pairs of letters to support the propositions of the feature matching process.

Houston et al. (1989) examined implications of the feature matching process for preference judgments. For each of several categories (e.g., automobiles, vacation spots) they constructed feature-based descriptions of alternative items or persons. The descriptions were constructed so they had either unique good and shared bad features or unique bad and shared good features. Overall desirability of the features used in each description was held constant making each alternative equally desirable. In Experiment 1, participants were instructed to try to form a general impression of each item or person. They were then shown a set of category descriptions. After people viewed the first item in each pair they were given a second item for each pair and asked to indicate their preference on a 12-point scale varying from strongly favor the first item to strongly favor the second item. It was expected that, by keeping participants unaware of the experimental task until they viewed the second item in each pair, the second item in each pair would become the subject of the comparison (cf., Agostinelli, Sherman, Fazio, & Hearst, 1986). Greater preference was shown for the first item when both the first and second item contained unique bad features than when both the first and second item contained unique good features. These results are consistent with use of a feature matching process in which the second item is the subject and the first item is the referent.

In Experiments 2 and 3, Houston et al. (1989) attempted to make the first item the subject of comparison. Although these attempts to manipulate the subject of comparison were unsuccessful, the feature matching process was replicated such that when both items had unique negative features the first item was preferred more strongly than when both items had unique positive features. To summarize, the Houston et al. (1989) results are consistent with the position that, when subjects are exposed to complete presentations of the items (i.e., all the features at once) they spontaneously form preference judgments by a feature matching process upon their exposure to the second item in a category.

Involvement

An important way to further our understanding of the feature matching process is to prescribe its limits. Research that has examined the role of involvement or personal relevance on persuasion has shown that increasing involvement increases the tendency of people to engage in a careful consideration of message arguments (Petty and Cacioppo, 1986). For example, Petty, Cacioppo and Schumann (1983) manipulated involvement by leading people to believe they would be able to choose a product as a gift to take home. The high involvement group was led to believe they would be able to take home a brand of disposable razor whereas the low involvement group believed they would be able to take home a product in a different product class. Subjects were then exposed to a series of ads including an ad for a disposable razor which contained either strong or weak product arguments. Data indicated that argument strength (i.e., whether the described product features were weak or strong) had a greater impact on attitude toward the product under high involvement than low involvement. This result is consistent with the position that subjects engage in greater elaboration of the message arguments under high involvement than low involvement.

In Houston et al. (1989), level of involvement was not manipulated and subjects were given no expectations that their task was self-relevant or had any important consequences. Thus, there is no evidence that suggests that feature matching, a low effort strategy, is prevalent in important contexts where the alternatives themselves or possible outcomes of the decision heighten the level of involvement.

We hypothesized that conditions of high involvement should motivate people to more carefully consider the information about the first product at the time that it is presented. Moreover, we expect that high involvement subjects will more thoroughly process that information than will low involvement subjects. When subsequently induced to make a preference judgment, they will be more likely than low involvement subjects to utilize the more thoroughly processed information in their decision making. In other words, greater consideration of information from the first product presented has the effect of equalizing the weights of the features assigned to the subject and the referent. Consequently, we expect that increasing involvement will moderate or eliminate the biasing effects of unique features of the second item in preference decisions.

Finally, we expect that these effects will be reflected in recall (Gati & Tversky, 1987). According to the feature matching process, the unique features of the subject drive the comparison process. If this is the case, one would expect greater recall of the unique features of the subject than of the referent. However, we hypothesized that if individuals in the high involvement condition are exerting enough effort to attenuate the feature matching effect, then their recall scores should parallel this. That is, these individuals should recall equivalent amounts of unique information from the first product as from the second product.

The following study was conducted in order to achieve three goals. First, because Houston et al. provide the only demonstration of the use of a feature matching process in preference judgments, our first step was to replicate their findings with vacation spots, a category they utilized. Next, we examined the use of a feature matching process under conditions of manipulated low involvement. If Houston et al. subjects were indeed uninvolved in the decision process, then data from subjects manipulated to be in a low involvement state should mirror the Houston et al. findings and our own replication. Finally, we examined the use of the feature matching process under conditions of high involvement.

METHOD

Subjects

Subjects were 146 students at Ohio State University who participated in partial fulfillment of a course requirement. Subjects participated in groups ranging in size from 10 to 25.

Materials

Subjects were presented with descriptions of two products for each of two product categories: vacation spots, and pens. In addition, subjects were presented with descriptions of two products from the soft drink product class, which was included only as a filler product for the manipulation of involvement. Each product description consisted of a list of six descriptive phrases (features). For example, features for vacation spots included "beautiful scenery", "overcrowded", and "reputation as a tourist trap." Features for pens included "expensive", "ink smudges" and "looks professional."

Pretests were conducted to create products with comparable sets of features. Each feature was rated for positivity and importance using a procedure similar to that of Houston et al. (1989). Pretest subjects were given a large list of possible descriptive phrases for one of the product categories. For each of the descriptive phrases, subjects were asked to rate on 9-point scales how positive they found the feature (1-negative, 9-positive) and how important they found that feature (1-not at all important, 9-very important).

Mean positivity ratings were then computed for each descriptive feature. For each product category, features whose mean positivity ratings were not statistically different and whose importance ratings were similar were chosen. For each product category, three lists of features were constructed. Each list consisted of three positive features and three negative features. The pairing of one set of two lists of features resulted in product descriptions that shared positive features but had unique negative features, while another pairing resulted in products which shared negative features but had unique positive features. Within each pairing, order of list was counter-balanced. This procedure insured that subjects were choosing between products which were evaluatively equal.

Procedure

The procedure in the present experiment was derived from the procedure employed by Houston et al. (1989). Subjects were randomly assigned to be in unique positive or unique negative conditions for vacation spots. These same subjects also participated in an additional condition in which involvement with the pen decision was manipulated.

Subjects were seated for the experiment in a manner which prevented interaction. They were told that the purpose of the experiment was to investigate how individuals formed impressions of products. Therefore, they would be presented with descriptions of three types of products.

At this point the manipulation of involvement occurred. This manipulation is modeled after the procedure employed by Petty, Cacioppo, and Schumann (1983). Subjects were told that in appreciation for their participation, they would receive a small gift. High involvement subjects were told their gift would be a pen and that they could choose their pen from among a variety of pens. In addition, subjects were told that the pen they would see described would soon be marketed in their city.

Low involvement subjects were told that they could choose their gift from among a variety of soft drinks and that the soft drinks they would see described would soon be marketed in their city. Therefore, these subjects were expected to be uninvolved with the pen descriptions (cf., Petty, Cacioppo, & Schumann, 1983).

Subjects were then presented with the first booklet which contained descriptions of three products, one from each of the product categories. Subjects were paced through the descriptions and were given 20 seconds to view each descriptive list.

After finishing with this booklet, subjects were given a second booklet. Subjects were told that the booklet contained descriptions for another brand in each of the product classes contained in the first booklet. Subjects were to view each of the descriptions and then state a preference for either the product they saw first or second for each of the product types. Preferences were expressed on a 12-point scale with endpoints labeled "strongly prefer first product" and "strongly prefer second product."

In addition to this preference scale, subjects responded to two measures designed to assess the effectiveness of the involvement manipulation. Subjects also responded to a series of ancillary measures and were asked to recall as much of the information concerning each of the pen descriptions as they could.

RESULTS

We first attempted to replicate Houston et al.'s findings. In addition, we tested two hypotheses: 1) subjects in a manipulated low involvement state would use the feature matching process in making their preference judgments as in Houston et al., and 2) use of the feature matching process would be attenuated for high involvement subjects.

Subjects expressed their preference for each product category on a 12-point scale (1 = strongly

prefer first product, 12 = strongly prefer second product). T-tests were conducted on responses to this scale for the vacation product category as a function of feature matching condition (unique positive features vs. unique negative features). This analysis revealed a significant feature matching effect, $t(135) = 2.87$, $p < .01$. These data replicate those of Houston et al. (1989) and indicate that individuals who viewed vacation spots with unique positive features preferred the second product ($M = 6.5$) more than individuals who viewed vacation spots with unique negative features ($M = 5.1$).

In order to check the effectiveness of the involvement manipulation, subjects were asked to indicate on two self-report measures how hard they were concentrating, and how much attention they were paying to the descriptions of the pens. A mean of these two measures was computed and served as our measure of involvement. A t-test of this measure comparing high involvement subjects to low involvement subjects revealed a significant difference, $t(127) = 2.08$, $p < .05$, indicating that high involvement individuals reported paying more attention to, and concentrating harder on the pen descriptions than did low involvement individuals.

Next, we examined preferences of low involvement subjects as a function of feature matching condition. As expected, this analysis clearly indicated that subjects who received products with unique positive features more strongly preferred the second item ($M = 6.8$) than did subjects who viewed products with unique negative features ($M = 4.9$), $t(135) = 2.21$, $p < .03$. Because these results parallel the Houston et al. findings and our own replication reported above, it seems likely that the Houston et al. study was conducted in a low involvement context.

Finally, we examined preferences of high involvement subjects as a function of feature matching condition. As predicted, t-tests indicated that individuals in the high involvement condition were no more likely to favor the second product when they saw products with unique positive features ($M = 5.9$) than when they saw products with unique negative features ($M = 5.2$), $t(135) = .90$, $p > .35$. Thus, the feature matching process was eliminated in a high involvement context.

In addition, subjects were asked to recall as many of the features from each of the pen descriptions as they could. We expected that under low involvement, recall of the unique features of the subject of comparison (i.e., the second product presented) would be higher than recall of the unique features of the referent. However, we expected that under high involvement, this recall difference would disappear. The number of unique features recalled from the first product was compared with the number of unique features recalled from the second product for high and low involvement. This analysis indicated that low involvement subjects recalled more unique features from the second product ($M = .59$) than from the first product ($M = .09$), $t(65) = 1.91$, $p = .06$. In contrast, high involvement subjects did not recall a greater number of unique features from the second item

($M = .63$) than from the first item ($M = .53$), $t(75) = .37$, $p > .70$.

DISCUSSION

The results of this study further attest to the role of Tversky's feature matching model in preference judgments while also increasing our understanding of the process and the conditions under which it may be attenuated. Under low involvement conditions, the process by which the features of the more recently presented product (the subject) drive the comparison and retrieval of features from the earlier product (the referent) was exhibited for both vacation spots and pens. For each category, two pretested, evaluatively equal brands were presented. In each case, if the subject had unique positive features it was preferred, but if the subject had unique negative features, the referent was preferred.

This study also elucidates conditions under which the feature matching process does not determine preference judgments. When making comparisons using the feature matching process, people may consider the features of the first product only once the features of the second product are presented. This allows the features of the second product to drive the comparison (Houston et al., 1989). If this tendency was eliminated, then the biasing effects of order that are necessary in the feature matching process might be greatly reduced. In accordance with this reasoning, we hypothesized that conditions of high involvement would motivate people to more carefully consider the information presented about the first product at the time that it is presented, thereby increasing the weights assigned to the features of the referent and making them more nearly equal to the weights assigned to the features of the subject. Under such conditions, the feature matching effect should be significantly attenuated.

In the present study, an examination of the effect of level of involvement supported this hypothesis. For low involvement subjects, the feature matching effect was significant, but for high involvement subjects, the effect was eliminated such that the subject was preferred equally under unique positive and unique negative conditions. This effect of involvement on feature matching may be understood in terms of Tversky's assumption that weights are associated with the features of each item. For low involvement, the weights assigned to the features of the subject are greater than those assigned to the referent. In fact, the weights assigned to the unique features of the referent may fall to zero such that those features are not considered in the comparison process and will not be recalled. However, under high involvement, the weights for the features of the subject and the referent are more likely to be equal and non-zero, thus increasing the overall recall.

Thus, the use of the feature matching process in making preference judgments appears to be limited to low involvement settings such as those in which the difference among the alternatives is considered relatively unimportant or the outcomes of the decision are not considered serious. It may be worth noting that a real-world manipulation of involvement may be

stronger than that accomplished in the laboratory. Such a manipulation should result in a pattern of data which is even more dramatic than the present data.

We also found support for the hypothesis that the influence of the process of feature matching on recall of unique features would be affected by level of involvement. Because the information about *both* products is considered more seriously under high involvement conditions, these individuals recalled an equivalent amount of unique information from the first product as from the second product. However, under low involvement more unique features were recalled from the subject than from the referent. Because this recall effect occurs with unique features only, a simple recency explanation is untenable.

These data are encouraging because they mirror the data concerning the effects of involvement on preference judgments. In both cases, differences under low involvement were significant whereas there were no differences under high involvement. Our hypotheses regarding the effects of involvement on preference judgments and on recall of unique features both stem from the more general prediction that the operation of the feature matching process is influenced by level of involvement. Thus, these parallel findings give us greater confidence that the results concerning the effects of involvement on the feature matching process are reliable.

If in fact high involvement subjects are engaging in feature matching, then the biasing by-product of the feature matching process may be reduced because all information is being considered. Alternatively, high involvement subjects may not be using a feature matching process at all. The recall data may be useful in distinguishing the feature matching process from a memory-based recall/accessibility process as has been suggested by Houston and his colleagues. If the feature matching process is not occurring under high involvement, then a more memory-based process may be functioning. In this case, subjects form evaluations of the products for the comparison task by using features of the products which are accessible in memory (Houston et al., 1989). If this memory-based process is utilized under high but not low involvement, then we would expect higher correlations between recall of unique features and preference under high involvement (Hastie & Park, 1986).

Analyses of the recall data lend tentative support to the above hypotheses. Correlations between recall of unique features and preference were computed for high and low involvement for unique positive and unique negative features. The correlations under high involvement were .16 and .15, while under low involvement, they were .07 and .06. These correlations approach statistical significance ($p = .17$) for high involvement subjects only. Although these data clearly are not conclusive, they do *suggest* the possibility that a feature matching process determines preference judgments in low involvement settings while a memory-based accessibility process determines preference judgments in high involvement settings. One goal of future research may be to more clearly resolve this issue.

The present study advances our understanding of the process by which people make preference judgments in a number of important ways. First, it affirms the surprisingly influential role of the feature matching process in individual preference judgments. When comparison alternatives are close on the evaluative scale and people are not especially motivated, the unique features of the subject of comparison will play an inflated and critical role in the preference judgment. This may occur in many real world settings in which information is serially presented such as when viewing successive advertisements from the same product class or when shopping in several stores for a product.

More importantly, our findings suggest an important limiting condition of the feature matching process. Individuals in high involvement settings engage in sufficient initial processing of comparison alternatives to wipe out the feature matching effect. Indeed, there is tentative support to suggest that instead they may be using a more memory-based process. Thus, the biasing process of feature matching may be less prevalent in important contexts where the alternatives themselves or possible outcomes of the decision heighten the level of involvement. This may be especially true in situations where the self is implicated or is an alternative in the comparison process. In such cases, we may expect more thoughtful and elaborative strategies to supersede the feature matching process.

A Spreading Activation Model of Consumers' Asymmetric Similarity Judgment

Ehsan Ulhaque, University of Texas at Arlington
Kenneth D. Bahn, University of Texas at Arlington

ABSTRACT

Consumers often make asymmetric similarity judgments which are explained via Tversky's contrast model. This paper attempts to explain asymmetric similarity judgments by using the spreading activation models of semantic and declarative memory. It is proposed that the time taken for activation to spread from one node to the next is related to, and gives rise to, asymmetric similarity judgment.

INTRODUCTION

An essential component in the study of marketing and consumer behavior is that of consumer judgment and choice processes. These judgment and choice processes are based, to some extent, on cognitive representations -- consumers' internal memory structures -- as well as information which is acquired externally (Bettman 1979; Johnson and Puto 1987). While a plethora of research had been conducted on what, how and why of external information acquisition, research on cognitive representations of consumers has been rather limited (Gardner, Mitchell and Russo 1978; Johnson and Puto 1987). This state of affairs is rather sad as cognitive psychology provides a number of research streams and models in the area of cognitive representation (Anderson 1983; Collins and Loftus 1975; Smith, Shoben and Rips 1974). This paper provides an indirect testing of cognitive representation of brands in the tradition of Gardner, Mitchell and Russo (1978) and Meyers-Levy (1989).

A second stream of research in consumer judgment and choice process has dealt with the idea of similarity and proximity judgment. However, similarity relations have generally been dominated by geometric models in which objects are represented by points in a Euclidean space (Shepard 1974). Tversky (1977) has proposed a contrast model in order to overcome the metric assumption of geometric models. One of the strengths of contrast models is its capability to explain asymmetric similarity judgments. For example, according to geometric model of similarity judgment if a consumer feels that coke is similar to pepsi than it follows that she must feel pepsi to be equally similar to coke. However, consumers do make asymmetric similarity judgments. Thus, a consumer may find coke to be very similar to pepsi and at the same time pepsi to be less similar to coke (Johnson 1986). While Tversky (1977) has provided empirical support for the contrast model he has not related it to the various models of cognitive representation. This paper is an attempt in this direction.

Specifically, a network model of declarative memory (Anderson 1983) is proposed. The nodes of this network are occupied by brands with their related network of attributes. When nodes are activated,

activation spreads to all other nodes connected to the activated node (Collins and Loftus 1975). The time taken for activation to spread from one node to another is hypothesized to be linked to similarity judgment. Asymmetric similarity judgment is proposed to be the result of differential time taken for the activation to spread from one node to another.

In the following sections we will first briefly describe the network model of memory. Then Tversky's contrast model of similarity judgment will be delineated. Finally, a conceptual model will be proposed to explain asymmetric similarity judgment via the network model of memory.

MODELS OF SEMANTIC MEMORY

Although various models of semantic memory have been proposed (e.g., Hierarchical-Network model of Collins and Quillian 1969; Feature-Comparison model of Smith, Shoben and Rips 1974; Spreading-Activation model of Collins and Loftus 1975) we will focus on spreading activation models. The reason being that the spreading activation, or network, models have better fared the scholarly scrutiny of various researchers (Chang 1986).

According to the spreading activation model of Collins and Loftus (1975), the concepts (or brands in this case) are represented in memory as nodes, and relations between brands are represented as associated pathways between the nodes. There could be multiple paths of various strengths and lengths between brands. For example, coke could be one such node in a consumer's memory while different attributes of coke (carbonated, cola, distinctive taste, etc.,) could be connected to the node 'Coke' by associated pathways. Another brand of soft drinks (e.g., pepsi) may share some of the attributes of coke (e.g., carbonated) while it may also have some unique attributes of its own. The attribute 'carbonated' is thus linked both to coke and pepsi. The more attributes two brands have in common, the more links there are between the two nodes, and the more related in memory the two brands will generally be. When a brand is activated, for example when attention is focused on coke, the activation spreads out in a decreasing gradient along the links emanating from the activated brand. This activation may reach the node 'Pepsi' via the attribute node 'carbonated'. When a path is found between two brands, i.e., two spreading activations intersect, a decision regarding them could be made (Collins and Loftus 1975). Cognitive psychologists seem to use the concepts of activation spreading from node 'a' and reaching node 'b', and spreading activations from node 'a' and node 'b' intersecting interchangeably (Ratcliff and McKoon 1981).

Anderson (1983) has proposed a similar process in his ACT* model of human memory. According to his model, brands or nodes have an activation value associated with them which reflect the

current importance, relevance, or availability of the node in memory. The links between nodes have weights associated with them which are determined by the strength of associations between the connected nodes. For example, if coke is regarded as the most popular soft drink then the link associating node 'Coke' to node 'soft drink' will have more weight associated with it reflecting the strength of association between the two nodes. On the other hand, if coke is not thought of as a food item then the weight of the link associating node 'Coke' to node 'food' will be relatively low, or there will be no such link. When a node is activated the spread of activation is modulated by the weights associated with each link, i.e., closely associated nodes produce higher activation transfer as compared to weakly associated nodes. Reder and Anderson (1980) found that the amount of activation spreading from a given node along a pathway is a function of the strength of that pathway relative to the sum of strengths of all paths emanating from that node.

Priming tasks have provided sufficient empirical support to network models of memory (Ashcraft 1989). In priming tasks a prime stimulus, which is presented first, influences some later process on a target stimulus which follows the prime. For example, in a lexical decision task (a task in which subjects have to respond whether a string of letters form a regular word or not) it was found that subjects took less time to recognize the target 'butter' as a regular word when primed by the word 'bread' than the time they took to recognize 'butter' as a word when primed by the word 'doctor' (Meyer and Schvaneveldt 1971). The spreading activation explanation of this differential response speed is as follows. The prime stimulus 'bread' activates the node 'bread' in the subject's memory. As 'bread' and 'butter' are related concepts, the link associated with the two nodes of bread and butter have a relatively higher weight associated with it. The activation spreads from 'bread' towards 'butter'. When the subject is asked whether butter is an English word the decision is facilitated as the node 'butter' is already activated because of the spread of activation from the prime 'bread'. On the other hand, as doctor and butter are not related concepts, therefore, when doctor is used as prime, activation does not spread towards butter, and consequently the lexical decision is not facilitated.

An important concept in Anderson's model is the 'fan effect' which means that performance of subjects on various tasks (e.g., lexical decision tasks as explained above) will slow down on any fact if that fact is but one of many that have been learned about a particular concept. The rationale is as follows. Given a fixed level of activation for a node the more links it has, the less activation is available for any one link. For example, if the node 'bread' is only linked to node 'butter' then all of the available activation of 'bread', when it is primed, will go towards 'butter'. Thus, the lexical decision for butter will be facilitated. However, if 'bread' is connected to 'breakfast' as well as 'butter' and 'sandwich', then only one third of 'bread's' activation can reach 'butter' as the activation will spread in all three links. Consequently, the

lexical decision for butter will not be as facilitated as when only one link was present. In a consumer behavior context, Meyers-Levy (1989a) have shown that brand memory for high frequency brand names is adversely influenced if their association sets are large - a phenomenon similar to the fan effect.

The concept of spreading activation has been used to explain mechanisms involved in such tasks as category exemplar production (Loftus 1973), semantic priming in lexical decisions (Neely 1977), episodic sentence and word recognition (Anderson 1983), and reading comprehension (Stanovich and West 1983). It has been experimentally found that the spread of activation is automatic as opposed to being under strategic control when the time duration between the prime and the target is less than 250 milliseconds (Neely 1977). Conscious processes, however, may take over at longer durations (Posner and Snyder 1975). It has also been found that the activation spreads beyond directly related concepts, although this 'mediated priming' effect is only evidenced in a pronunciation task (Balota and Lorch 1986). Although not in the context of spreading activation, priming paradigm has also been used in the area of consumer behavior. Thus, Herr (1989), Meyers-Levy (1989b) and Yi (1990) have documented the impact of priming on consumer information processing and judgment. This study will, however, use priming in order to model similarity judgment tasks.

CONTRAST MODEL OF SIMILARITY JUDGMENT

The theoretical analysis of similarity relations in marketing has been dominated by geometric models in which products, or brands, are represented by points in some coordinate space where the metric distance between the points reflect the similarities between respective brands (Green and Rao 1972). One result of such a dimensional representation is that the similarity between brand 'a' and 'b' (or Euclidean distance between them) remains the same whether one measures similarity of 'a' to 'b' or of 'b' to 'a'. Tversky (1977) has, however, argued that the metric assumption that underlie the geometric approach to similarity are often found lacking. He has developed an alternative feature-based approach to the analysis of similarity relations. According to his 'contrast' model, each brand is characterized by a set of features or attributes. For example, coke has attributes of being a carbonated drink, a cola drink, among others. The observed similarity between two brands is expressed as a function of their common and distinctive attributes. Thus, if brand 'a' (e.g., coca-cola) has a set of attributes 'A' and brand 'b' (e.g., shasta cola) has a set of attributes 'B' then the similarity between them is expressed as:

$$S(a,b) = \theta f(A \cap B) - \alpha f(A - B) - \beta f(B - A)$$

The model allows for a variety of similarity relations over the same set of objects through its flexibility of designating different values for θ , α , β as well as different functions f . Thus, in contrast to the dimensional model, similarity of 'a' to 'b' can be

FIGURE 1
A Model of Memory Network

different from similarity of 'b' to 'a'. The factors that contribute to the salience of a stimulus, i.e., intensity, frequency, familiarity, good form, informational content, etc., are reflected by the scale 'f' in the contrast model. Variations in similarity judgments because of the 'task' or 'context' effects are captured by the parameters θ , α , and β .

Tversky and his colleagues have published a few papers lending support to the contrast model. For example, Tversky and Gati (1978) have used the contrast model to explain asymmetric similarity judgments. They have shown that subjects' judged similarity of North Korea to China exceeds their judged similarity of China to North Korea. In a consumption context, Johnson (1986) has found that consumers rated the similarity of shasta cola to coca cola to be higher than the similarity of coca cola to shasta cola. Thus, coke is not as similar to shasta as shasta is to coke. Tversky and Gati (1978) explain this asymmetry via a focusing hypothesis and a relative salience effect in their contrast model. The focusing hypothesis states that if $S(a,b)$ is interpreted as the degree to which 'a' (subject) is similar to 'b' (referent) then in such judgments attributes of 'a' are weighted more heavily than attributes of 'b' (i.e., $\alpha > \beta$). The salience effect follows from the contrast model. With $\alpha > \beta$,

$$S(a,b) > S(b,a) \quad \text{iff} \\ f(B-A) > f(A-B)$$

or when the distinctive attributes of 'b' are more salient than the distinctive attributes of 'a'.

While the explanation provided by Tversky and Gati (1978) is reasonable, however, it is not grounded in the memory network models. For example, how are 'subject' and 'referent' cognitively represented and how features or attributes are given more weight than less. In the following section a memory network model of asymmetric similarity judgment is presented.

A SPREADING ACTIVATION MODEL OF ASYMMETRIC SIMILARITY JUDGMENT

Assume that 'a' (e.g., coke) is a node in the semantic memory. This node is linked to many attributes like carbonated, refreshing, dark color, sweet taste, distinctive bottle, etc., (Gardener,

Mitchell and Russo 1978). If A is the set of these attributes of coke then node 'Coke' has A different links emanating from it. Similarly, node 'b' (e.g., shasta) has B different links emanating from it. Now some of the attributes ($A \cap B$) are common to coke and shasta (e.g., carbonated, dark color), while some attributes ($A - B$ or $B - A$) are distinct to either coke or shasta (e.g., distinctive bottle, world-wide sales). Thus, the network structure might be represented as in Figure 1.

The focusing hypothesis of Tversky and Gati (1978) is proposed to be captured by a priming effect. According to Tversky and Gati when coke is the subject and shasta the referent, then the attributes of coke are weighted more heavily than the attributes of shasta. However, they also suggest that human subjects have a propensity to use directional statements such as "x is like y" where the subject 'x' always comes before the referent 'y' in similarity statements. A case can be made that the subject 'x' is acting as a prime for the referent 'y'. Thus, in a similarity estimation of coke to shasta, it is proposed that coke acts as a prime for shasta. 'Coke' becomes a source of spreading activation which reaches 'Shasta' via the common attribute links.

The salience of a stimulus depends on factors which include intensity, familiarity, frequency, informational content among others (Tversky and Gati 1978). All of these factors may safely be assumed to give rise to two phenomenon. Firstly, they will increase the steady state level of activation of a node (Anderson 1983). Secondly, they will increase the number of links emanating from a node as well as their strengths (Collins and Loftus 1975). Thus in the previous diagram, coke is more salient than shasta (coke has more links than shasta). Because of the 'fan effect', however, 'Coke' will be able to spread a lesser amount of activation to 'Shasta' via the common links as compared to that sent by 'Shasta' to 'Coke', assuming that the two have an equal amount of steady state activation level.

The process of asymmetric similarity judgments between coke and shasta can now be grounded into a proposed semantic network model. When a subject is judging the degree to which shasta is similar to coke, node 'Shasta' becomes the focused unit. Activation spreads from 'Shasta' via the mediating common attributes to 'Coke' (Balota and Lorch 1986). The strength of activation reaching 'Coke' depends on the sum of weights of the common

links between 'Shasta' and 'Coke' relative to the weights of all links emanating from 'Shasta'. The speed with which the intersection of activations from 'Shasta' and 'Coke' takes place, and the information about the level of activation (which is available to the subject; Anderson 1983) guides the subject to decide on the similarity of shasta to coke. A similar process occurs when the subject is determining the degree to which coke is similar to shasta. If we assume that the steady state activation level of shasta and coke are the same and also that coke is more salient than shasta, then because of the fan effect less activation will reach shasta from coke, as coke has many more links which also have greater strength, while more activation will reach coke from shasta. Because of this difference in activation transfer, the speed with which a critical level of activation intersection is reached will be more in the case when shasta is the prime than when coke is the prime (Anderson 1983). The information of this level of activation at the intersection is proposed to result in a degree of similarity judgment. According to the 'semantic relatedness effect' those concepts that are highly interrelated can be judged more rapidly in a lexical task than those with lower degrees of relatedness (Ashcraft 1989). Thus, speed of spreading activation and relatedness (or similarity in this case) are related. The more the activation spreads, the sooner the intersection, and consequently the more similar the prime concept is to the target concept. Thus, shasta will be reported as more similar to coke than vice versa. This asymmetric similarity judgment is exactly the same as that obtained by Johnson (1986). However, the proposed model presented in this paper provides asymmetric similarity judgment a grounding in memory network models. Based on the above logic we would hypothesize the following:

A more salient brand within a product category, when used as a prime, will slow the lexical decision or pronunciation task for a less salient target brand within the same product category. Thus, the more salient brand will be judged as 'less' similar to less salient brand.

On the other hand, a less salient brand within a product category, when used as a prime, will facilitate the lexical decision or pronunciation task for a more salient target brand within the same product category. Thus, the less salient brand will be judged as 'more' similar to more salient brand.

CONCLUSIONS

A spreading activation model of consumer's asymmetric similarity judgment is proposed. The model, if validated by empirical data, could lead to many interesting implications in the area of consumer's memory of brands and choice process. Firstly, it directly impacts on the contents of a consumer's evoked set. It seems that because of differential activation capabilities of less salient and more salient brands the composition of evoked set will depend on the 'cue' brand. If the cue brand is less salient then the probability of recall of more salient

brand will be high and so will be its probability of being a member of the evoked set. On the other hand, if the cue brand is more salient then the probability of recall, and hence membership in evoked set, of a less salient brand will be low.

Secondly, if according to this model priming has an important role to play in similarity judgment then an area of automatic and controlled similarity judgment might evolve. Posner and Snyder (1975) had shown that automatic priming precedes controlled processes. Thus, one may argue that in a low involvement choice process, where controlled processes are not dominant, automatic activation of brands may determine the similarity judgments among brands. This similarity judgment will in turn influence the choice. On the other hand, in a high involvement choice process, where controlled processes dominate, the automatic activation of brands will not determine the similarity judgments among brands and, consequently, the choice may turn out to be very different. Finally, this automatic or controlled similarity judgment may also impact brand substitution and brand switching behavior.

Schemata in Consumer Research: A Connectionist Approach

Tom J. Brown, University of Wisconsin-Madison¹

ABSTRACT

Schemata and related knowledge structures have figured prominently in consumer research in recent years, yet little consideration has been given to the processes through which schemata are retrieved from memory. In cognitive psychology, schemata have typically been considered frameworks of knowledge that are stored in memory and retrieved through a process of spreading activation. From a connectionist perspective, however, schemata are not stored at all. Rather, they are re-created as individuals need them; schemata are simply patterns of activation across a network of units connected in a constraint satisfaction system. A connectionist model of schemata is presented and demonstrated in a consumer context.

INTRODUCTION

Considerable research and theory in consumer behavior has been based on the notions of categories or schemata possessed by consumers (e.g., Cohen and Basu 1987; John and Sujan 1990; Loken and Ward 1990; Meyers-Levy and Tybout 1989; Sujan and Bettman 1989; Sujan et al 1986). According to the standard theory in cognitive psychology, schemata are stored frameworks of knowledge about some object or topic and are represented by nodes in semantic memory. Schemata are retrieved into working memory through the process of spreading activation (Ashcraft 1989).

Many cognitive phenomena, including schema development and retrieval, have been addressed in recent years from a different perspective, alternatively referred to as connectionism, parallel distributed processing (PDP) models, or neural networks. Such approaches, which feature formal mathematical models of cognitive processes, have enjoyed increasing popularity (Hintzman 1990). In contrast to the standard theory, connectionist approaches to schemata assume that schemata are implicit and created at the time an individual needs them. In short, schemata are not "things" stored in memory; rather, they are simply patterns of activation across a vast network of units. The connectionist approach offers a conceptually distinct model of schemata that approximates the physiology of the brain while demonstrating many of the recognized properties of schemata.

In this paper, one particular connectionist model of schemata retrieval based on a constraint satisfaction system is presented and applied in a consumer context. Data were collected with respect to a given product class (automobiles) in order to demonstrate the model.

A CONNECTIONIST APPROACH TO SCHEMATA

In general, connectionist models "assume that information processing takes place through the interactions of a large number of simple processing elements called units, each sending excitatory and inhibitory signals to other units" (McClelland et al 1986, pg. 10). These models are distinguished from traditional theories of learning and memory in several important ways. In general, they are more closely tied to the physiology of the brain. The brain consists of a large number of interconnected elements which appear to send inhibitory or excitatory impulses to other elements; moreover, these elements appear to update their excitations on the basis of these simple impulses (McClelland et al 1986).

In connectionist models, storage in memory does not involve the actual storage of semantic or episodic information in the form of nodes. Instead, the connection strengths or weights between units are stored, allowing information to be re-created at the time an individual needs it. Most connectionist models of information processing do not require the presence of a superordinate control function for organizing and storing information or guiding retrieval. Rather, the system learns of its own accord the connection strengths between units through the repeated processing of stimuli over time. Importantly, multiple patterns may be represented by the same set of units since it is not the units themselves that are important, but rather the connection strengths, or weights, between units.

The particular connectionist model presented in this paper is a constraint satisfaction model. The operation of the constraint satisfaction network in re-creating a schema provides perhaps the greatest point of contrast with the standard theory of schema retrieval. In a spreading activation model, activation moves from one activated node to other related nodes via connecting pathways (with the nodes themselves representing semantic memory). As the activation spreads from node to node, the schema is retrieved. In a connectionist constraint satisfaction model, all units are connected to all other units, and an activated unit may inhibit some units while exciting others. All the units may thus play a role in determining the final pattern of activated units. Moreover, this final pattern of activation across units may not be accounted for by a spreading activation model because units that are activated at some point may be inhibited (and ultimately de-activated) by other units in the network as constraints are satisfied.

The units in a constraint satisfaction model may be thought of as hypotheses about the presence of certain features or attributes. In a consumer marketing context, consider the schemata that individuals hold with respect to different types of automobiles. One unit might represent a hypothesis about the presence of high status or prestige. (In reality, the highly abstract attributes used in this example are themselves

¹The author expresses his appreciation to Professors Arthur M. Glenberg and Michael L. Rothschild of the University of Wisconsin-Madison.

likely to be patterns of activation across a great number of lower-level units.) This unit may be activated as part of a schema for certain types of automobiles (e.g., expensive sports cars), but not activated as part of a schema for other types (e.g., economy cars). The connection between two units represents a constraint between those units. If the units tend to co-occur (e.g., units representing high status and high price), then a positive weight is given to the connection between the units. If one unit tends to be activated while the other unit is not (e.g., units representing high status and vinyl seats) then a negative weight is "learned" by the system for the connection between the units. In some situations, there may be little regularity in the co-occurrence of units, leading to a connection weight approaching zero (e.g., units representing an airbag and leather interior).

By expanding the model to include multiple units, the workings of the constraint satisfaction network can be seen. Each unit receives excitatory inputs from units to which it is connected with positive connection weights, and inhibitory inputs from units to which it is connected with negative connection weights. The system will settle, or "relax", into a stable state where as many constraints as possible are satisfied, with priority given to those constraints (connections) weighted most heavily. In this model, the units that are activated in the stable state represent the relevant schema.

In addition to receiving inputs from other units, a unit may also receive input externally. This external input, or activation, represents external evidence that the feature represented by a unit is present, and may serve to set the system in motion. For example, the viewing of a print advertisement for the Ford Escort may be sufficient to re-create the full economy car schema for many individuals. In the following demonstration, it is assumed that the process of schema re-creation begins with an external stimulus.

Note also that some units have a higher likelihood of being activated because the feature represented by a unit occurs more frequently in the external environment. Similarly, some units are activated less frequently because the feature rarely occurs. Connectionist models of schemata normally introduce a bias into the model to account for this phenomenon. If a unit is usually activated, a positive bias is introduced; if a unit is not normally activated, a negative bias is introduced.

AN APPLICATION: A MODEL OF SCHEMATA FOR AUTOMOBILES

One application of schemata theory involves the features or attributes normally associated with a product. Meyers-Levy and Tybout (1989) identify a number of attributes of various beverages; Sujian (1985) considered the attributes associated with a 35mm camera. An automobile might also be represented by a group of attributes. Some attributes are concrete (e.g., power windows), while others are more abstract (e.g., high status). Table 1 presents a listing of 20 attributes that might be associated with

the automobile product category. These attributes were chosen for their diversity in concreteness/abstractness and for their ability to represent several types of automobiles. Note that some properties of automobiles (e.g., price) are shown as two attributes (e.g., high price, low price), since each unit in this simple constraint satisfaction network is binary (either on or off) and cannot represent multiple levels of continuous variables.

The Model

A connectionist approach to schema retrieval can be modeled mathematically. The model must update the activations on each of the 20 units in the system based on the inputs from other units, any external input, and the constant bias. Rumelhart et al (1986) provide the following model:

$$a_j(t+1) = a_j(t) + \begin{cases} \text{net}_j(1-a_j(t)) & \text{net}_j > 0 \\ \text{net}_j a_j(t) & \text{otherwise} \end{cases}$$

where $a_j(t)$ represents the activation of unit j at time t , an internal input is represented by setting $a_j(t)=1$, $\text{net}_j(t)$ represents the net input to unit j at time t , and

$$\text{net}_j(t) = e_j t + \sum_{i \neq j} w_{ji} a_i(t)$$

where $e_j(t)$ represents the bias, w_{ji} is the weight (constraint) on the connection from unit i to unit j , and $a_i(t)$ represents the activation of unit i at time t .

The system will reach a stable state with all units either turned on (a value of 1) or turned off (a value of 0). If the net input to a unit at time t exceeds 0, then the activation on that unit will be driven toward 1; otherwise, its activation will be driven toward 0. Note that this is an iterative model, and that only one unit may be updated at a time (although a truly parallel processing system would allow simultaneous updates). The model randomly chooses one unit at a time to update activation; this unit may not be selected again for updating until the remaining 19 items have been updated. Each cycle of updating all 20 units is considered one complete update.

Setting Connection Weights

The weights in the model represent the connection strengths between units. The weights will be positive when two units are mutually excitatory and negative when two units tend to inhibit each other. To obtain weights meeting these criteria, data were collected from 44 undergraduate students. Each subject completed a written questionnaire; all questionnaires were identical except for the order of the stimulus materials. Initially, subjects were presented with a list of the 20 attributes of automobiles shown in Table 1 and were instructed to indicate all attributes that applied to a general type of automobile. For example, approximately one-third of the subjects were told to consider a LUXURY SPORTS CAR and "to think of the typical automobile of this general type" and to complete the page by marking each attribute that they

"believe might in general apply to the automobile." Approximately one-third of the subjects began by considering the typical ECONOMY CAR, while the remainder initially considered the typical FAMILY CAR. When subjects had considered all 20 attributes for the first type of automobile, they repeated the process for the two remaining types of automobiles. Thus, each subject considered all three types of automobiles, for 132 total observations. The order of the presentation of the three types of automobiles was balanced to eliminate order effects.

Correlations were calculated across all observations for all pairs of attributes to obtain weights for use in the constraint satisfaction model. An attribute was coded "1" if a subject selected it; otherwise, the attribute was coded "0". Although the range of the correlations obtained using two dichotomous variables may be restricted, depending on the shapes of the distributions of the two variables (Nunnally 1978), the correlations obtained are useful measures of association. These correlations are shown in Table 1. For example, a leather interior is positively correlated with a high price ($r=0.77$); in the model, the unit representing leather interior is therefore connected to the unit representing high price by a connection weight of 0.77. Note that weights for four of the combinations (high price-low price; high status-low status; foreign-made-American-made; and, often needs repair-rarely needs repair) were set to -1.00.

Calculating Bias

In addition to the information used to estimate weights, subjects also provided information used to calculate the biases needed in the model. Subjects were asked to estimate for each attribute the percentage of cars that exhibit that attribute. These percentages are presented in Table 2, along with the biases for each attribute obtained by applying the following formula from Rumelhart et al (1986):

$$\text{bias}_j = -\ln \frac{p(x_i=0)}{p(x_i=1)}$$

Model Summary

Twenty attributes of automobiles were specified, each represented by a single unit; each unit represents the hypothesis that the feature is present and has value "1" when the model specifies that a feature should be present and value "0" when a feature should not be applicable. All units are connected to all other units and receive positive or negative impulses based on the connection weight and the current activation level of the impulse-sending unit. When the stable state is achieved, all units have activations of 0 or 1; the units that are activated represent the relevant schema.

A SCHEMA FOR HIGH STATUS AUTOMOBILES

Suppose that this system received strong external evidence that the hypothesis related to "high status" was correct, and that the activation on this unit

was accordingly set to 1 (and not allowed to change). How might the system respond? The unit that is activated begins to send positive impulses to those units with positive connection weights and inhibitory impulses to those with negative connection strengths. The system will ultimately settle into the best possible set of unit activations that it can achieve, given the constraints between units. This situation was modeled and is shown in Table 3. The entries in the table represent the activation levels of each unit at the conclusion of a complete update (e.g., the activation of the first unit, foreign-made, is equal to 0.25 once the model has completed the first update). Although the model required 105 updates to reach the stable state, only the first five and the last updates are shown. The model required updates 6-105 to bring the activation of unit 16 (advertised on national TV) to 0. This complete process was repeated 20 times to obtain a measure of the stability of the schema; this pattern was obtained 19 times. The schema for a high status automobile suggests an expensive, foreign-made automobile that might be special ordered from the factory, one that rarely needs repair, and has the following features: power windows, leather interior, and power steering. In addition, the automobile serves the basic purpose of providing transportation. This schema seems to reflect several of the attributes that might normally be associated with high status automobiles.

It is interesting to note the progression of the activity levels of individual units as the model proceeds through the update process. Some of the units (e.g., power steering and provides transportation) receive full activation on the first update while others (e.g., foreign-made and rarely needs repair) start slowly, building activation with each update. Many units which are initially off continue to remain off throughout the process. Other units receive some positive activation along the way but ultimately decrease to zero activation. The intermediate activations reflect the interactions among the units as they approach the stable state.

A SCHEMA FOR LOW STATUS AUTOMOBILES

It is interesting to next determine the resulting schema when unit 11 (low status) receives strong external stimulation. This external input was implemented and the model was allowed to run until a stable state was attained. Table 4 presents the ending activations for each of the six updates required to reach the stable state. The resulting pattern of activations was obtained each time that the simulation was run (20 times). A low status car might be described as an inexpensive American-made car with vinyl seats, a roomy interior, a small engine, and an AM radio; the car often needs repair (but parts are readily available). The car provides transportation and is advertised on national TV. It is interesting to note that this schema appears to be the "typical" automobile schema, since it represents the final stable state of the system when no strong external inputs are assumed (i.e., the system is allowed to run using the biases as the only inputs to

the system). The system was allowed to run 20 times with all initial activations set to zero; in 19 cases, this schema resulted.

OTHER EXAMPLES: COMBINATIONS OF EXTERNAL INPUTS

In many situations, it is likely that more than a single unit may receive strong external stimulation. Consider the situation in which the units representing "high status" and "American-made" both receive strong external evidence that the attributes exist. To demonstrate this situation, the activations on these units were set and held at 1; the model was then allowed to update in the normal way. The resulting schema was less stable than the earlier examples; two general schemata resulted. The first, which was produced on 11 of the 20 simulations, is shown in Table 5. The model took 16 iterations to reach the stable state. The resulting schema was of a high priced, high status, American-made automobile with features in accordance with its status and price. On 9 of the 20 simulations, the model produced a less grand schema: the automobile provides transportation, has a roomy interior, vinyl seats, power steering, an airbag has readily available parts, and is advertised on television.

DISCUSSION

Following Rumelhart et al (1987), several important properties of schemata are easily addressed within the connectionist approach. Several of the

properties relevant to consumer research are broadly considered in this section.

(1) *Patterns tend to complete themselves.* In order to retrieve a schema, it clearly is not necessary to receive external input for all units. As demonstrated, the interconnected system of constraints serves to activate those units, or attributes, that fit the schema. For example, when a "high status" automobile was indicated, the model settled into a solution with attributes that look very much like those appropriate for a high status automobile.

As another example, Sujana et al (1986) found that the stimulus of a salesperson was sufficient for people to bring up the clothing store salesperson schema. It was not necessary to get external input on such units as "...will tell me I look good in anything I've chosen to try on" or "...is probably selling on commission". Rather, the system settled into a solution in which these or other appropriate units were activated.

Much of the rationale behind brand extensions relies upon this principle. By attaching a well-known brand name to a new product, the marketer assumes that many of the units normally activated in the consumer's schema for the brand name will also be learned by the system in association with the new product. In this way, consumers may attach many associations to the new product as a result of the brand schema, without an extensive (and expensive) effort by the marketer to build the desired associations.

(20) rarely needs repair	0.00	0.15	0.52	0.77	0.90	1.00**

Units that are activated in the stable state are designated **.

They result simply through the process of re-creating the schema for the brand.

(2) *Knowledge at all levels can be represented in schemata.* In the automobile example, some of the attributes were very concrete, while others were very abstract, yet the model adequately represents all levels of abstraction. Consumers can thus be expected to incorporate higher level abstraction into their schema for a certain product. The image of a brand may often be represented in the brand schema along with more tangible elements of the physical product. For example, abstract advertising for Obsession perfume has been used to convey an image of the product.

(3) *Schemata are active processes, not static patterns stored in memory.* In this perspective, schemata are not stored at all; rather, the connection strengths between units representing hypotheses about features or attributes are retained. Over time, through the processing of schema-related information, the connection strengths may be altered. Advertising and promotion may serve to adjust some of the connection strengths between units. Advertising for a new product may be thought of as an attempt to increase the connection weights between a unit representing the product and units that tend to form a schema of products to consider for purchase (i.e., the consideration set). Similarly, connectionism provides an alternate explanation of the process through which a product is assimilated into an existing product class than does the schema-plus-tag explanation offered by Sujan and Bettman (1989).

One intriguing potential use for a connectionist model of schemata is the identification of specific schema elements or units to serve as the foci for advertising efforts. Suppose that a company offers a brand that is currently viewed as having low status and that the company desires to change this perception. With knowledge of the various weights between units in the system, it may be possible to identify a specific unit or attribute that, when activated, consistently activates the high status unit in the stable state. An advertiser could then focus communication efforts on this attribute. If the attribute does not currently exist for the brand, it may be added. It is possible that the addition of an inexpensive attribute might lead to dramatic changes in consumer perceptions of the product.

(4) *Some schemata are more rigid than others.* The units of some schemata seem to be much more tightly connected than those of other schemata. For example, the general schema for high status automobiles shown in Table 3 seems to be much more stable than does the schema for high status, American-made automobiles shown in Table 5. The high status schema is clearly defined, having resulted 19 out of 20 times it was modeled. However, individuals appear to hold a less clear schema for high status American cars since this particular schema is produced only about half the time.

The schemata formed for certain products (where the schemata might describe the attributes of the products at a basic level, or the positioning of the products at a higher level of abstraction) seem to be

very tight and rigid, while schemata for other products are much less so. For instance, consider the schemata formed for IBM personnel computers in comparison with schemata for Zenith computers. It is likely that the position of the IBM product is very clear and tightly formed, while that of the Zenith product is less rigid. One implication is that tight schemata might be more difficult to combat (from a competitive strategy perspective) or change in consumers' minds. This implication can be investigated from a connectionist perspective.

With this advantage for the company or brand with the strongest position, however, comes the possible disadvantage of inflexibility. For example, Coca-Cola's ill-fated attempt to change the product formula may have failed to a large extent because individuals held a clear conceptualization of what the product was "supposed" to be. New Coke may have simply been too great a departure from the tightly-held schema for the product.

CONCLUSION

A constraint satisfaction model of schemata based on connectionism has much to offer consumer research as a theoretical underpinning for research on schemata. In this paper, a brief overview of such a model has been presented and demonstrated. The results indicate that the model seems to capture the nature of consumer schemata for automobiles.

Priming and Implicit Memory: A Review and a Synthesis Relevant for Consumer Behavior.

Abhijit Sanyal, University of Massachusetts at Amherst

ABSTRACT

The idea of implicit memory have recently seen a resurgence of interest in the memory and cognition literature. A major issue is that of dissociations or independence between explicit and implicit memory systems. An ongoing and unresolved debate is how to reconcile the data with various theoretical frameworks. The findings and issues from the psychological literature are briefly discussed followed by some of these issues which could have relevance for consumer behavior.

INTRODUCTION

Schacter (1987) and Tulving and Schacter (1990) posit that there is now increasing evidence of yet another category of learning and memory which cannot be classified as belonging to any of the existing memory structures. This type of memory has been labeled as "implicit memory" (Graf and Schacter, 1985, 1987;). Consumer researchers should be aware of the progress and problems faced in this area as it might provide some insights into consumer decision making. The Wall Street Journal (McCarthy, pp B3; March 22, 1991) in a special report have also raised this issue and the subject may become increasingly important for advertisers and practitioners.

Implicit memory is revealed when previous experiences facilitate performance on a task that does not require conscious or intentional recollection of those experiences. This is to be distinguished from "explicit memory" which refers to conscious recollection of recently presented information found in traditional test of free recall, cued recall and recognition. A key issue in this area is that implicit and explicit forms of memory can be quite independent of each other (Graf and Schacter, 1985; Schacter, 1987) which is referred to as dissociation. In other words, implicit memory appears to be less affected by the kinds of interference manipulations that reduce retention in explicit tasks (Jacoby, 1983a; Graf and Schacter, 1985).

In this article I review some key aspects of implicit memory relevant to consumer behavior and discuss some possible areas of research.

IMPLICIT MEMORY AND PRIMING

Definitional and procedural aspects of Priming

The operative word "priming" has been used in various fields and sub-fields of psychology. Priming refers to the process by which previous experience increases the general accessibility of a conceptual category, thereby increasing the likelihood of that category being used to encode new information (Fiske and Taylor 1990). In social cognition, priming has been mostly exhibited with the usage of trait terms. Thus exposing people to positive or negative trait

terms (e.g., reckless versus adventurous) causes people soon afterwards to interpret ambiguous behavior (e.g., shooting rapids in a canoe) as correspondingly positive or negative depending on the trait being primed and its corresponding meaning (Higgins, Rholes and Jones, 1977; Bargh and Pietromonaco, 1982; Srull and Wyer, 1979, 1980).

Graf and Schacter (1985) introduced the concept of implicit versus explicit memory, which was more of a descriptive as opposed to a process distinction. They stated that "implicit memory is revealed when performance on a task is facilitated in the absence of conscious recollection; explicit memory is revealed when performance on a task requires conscious recollection of previous experiences". Thus performance on implicit memory measures is revealed only when priming occurs. It should be clarified here that priming does not always imply the operation of the hypothetical implicit memory system. Priming being an activation process can also underlie explicit memory (Ratcliff and McKoon 1988). In some of the literature however (Schacter, Delaney and Merikle, 1990) the term "priming" has been used interchangeably with implicit memory and is therefore a source of considerable confusion.

Priming experiments whether from social cognition or repetition priming typically consists of two (or three) stages with exposure to the prime (positive or negative trait terms; e.g., adventurous versus reckless) followed by the target stimulus in a seemingly unrelated context (reading about the un/ambiguous behavior of the targeted individual ; e.g., shooting rapids) An evaluative test of the individual (positive/negative) is thereafter taken to determine the extent of the priming effect (Higgins, Rholes and Jones, 1977). Caution is usually exercised in separating out the prime from the target with some intervening distractor task so as to ensure that subjects are unaware of the prime (Bargh and Pietromonaco, 1982).

The task flow in other priming studies is the same although researchers in this area combine the target stimulus and rating stages into two stages; study and test (Tulving and Schacter, 1990). In the first stage - the study phase, the subject is presented with a stimulus object. This stimulus object may comprise words (semantic and verbal) or line drawings of object, drawings of faces and so forth. In the second (test) stage which follows the first after an interval of maybe a few seconds to days or weeks, the subject is given reduced perceptual information about the object and asked to name or categorize it. These reduced cues may consist of initial letters or fragments of words, incomplete words or figures, originally presented faces in a more schematized form or tachistoscopic presentation of stimuli. Direct priming is a situation when the cues are the same as the stimulus. Priming is said to have been displayed if the probability of the identification of the previously encountered stimulus

object is increased. It is also evidenced if the latency measures for nonstudied control items. A magnitude of the priming effect is provided by the difference between performance on the target items and the nonstudied items.

Definitional aspects of Implicit Memory

Implicit memory should be defined (to avoid any ambiguity) in terms of unintentional or involuntary retrieval processes and the concept is restricted to those cases in which it is possible to demonstrate that test performance is facilitated by information acquired during a study episode without any recollective re-experiencing or awareness of remembering on the subject's part (Schacter, Bowers, and Booker; 1989). It should also be demonstrated that explicit memory performance is at or near chance levels, which in turn would imply that priming effects do not involve awareness of the study episode. This is discussed later under the "retrieval intentionality criterion".

The explicit/implicit memory distinction that Schacter and his colleagues have made is a widely used taxonomy. The above definition of implicit memory therefore can refer to two classes of phenomena (Dunn and Kirsner, 1989). The first consists of observable properties of the experimental situation, such as prior presentation of stimulus material, facilitation in performance and the nature of instructions viz., task characteristics. The second consists of unobservable mental events, such as conscious recollection which accompany the different forms of memory - a process perspective. It is possible therefore to distinguish between explicit and implicit memory tasks on one hand and processes on the other hand, although it is not clear whether the task distinction maps in any direct way onto the process distinction. A necessary assumption (the transparency assumption, Dunn and Kirsner, 1989) made in the literature in order to support "dissociation" effects is that there is a one to one mapping from task to process.

To mitigate the likely problems arising from this transparency assumption, Johnson and Hasher (1987) and Richardson-Klavehn and Bjork (1988) have used the terms direct and indirect tests to characterize the two classes of memory measures. Direct memory tests (recall, recognition) make reference to a target event and success is achieved when the respondent/subject gives behavioral evidence of knowledge concerning that event. Indirect tests require the subjects to engage in some form of cognitive or motor activity with no reference being made to prior events. The measures of interest in this case are shown to be facilitated in terms of task performance by relevant prior experience *even though no explicit reference was made to them*.

Richardson-Klavehn and Bjork (1988) have argued that there are a few major negative consequences of using the explicit/implicit memory distinctions to refer to both tasks and forms of memory. They use the terms direct/indirect to refer to tasks and methods of measurement. In the literature the terms implicit and explicit memory has been used interchangeably to refer to tasks and methods of

measurement or also to indicate hypothetical forms of memory - a term descriptive of mental content. Implicit memory can be a task-based definition (Schacter 1985) and it can also be inferred from dissociation between two measures of memory (Graf and Schacter, 1985). Similarly direct memory tests which have been defined as "conscious recollection" (Graf and Schacter, 1985) or "conscious awareness" (Roediger and Blaxton, 1987a, p 351) imply that in the test stage, awareness is based on task instructions and consequent intention to retrieve material from the study episode. This is a task based definition while subjective awareness is again a case of reexperiencing the episode, the existence of which is inferred from the data.

An assumption is usually made in the literature that a particular method of testing reveals only one underlying form of memory and therefore different methods of testing would indicate evidence of different forms of memory (Graf and Schacter, 1987). Different testing methods reveal different forms of memory *only* when dissociations between those methods of measurement are observed. Direct and indirect measures are sometimes influenced similarly by certain variables (Richardson-Klavehn and Bjork; 1988). In this case we do not know whether two different forms of memory are being affected or whether the same form of memory is being engaged by both types of tasks.

In the earlier definition of implicit memory given by Schacter and his colleagues, implicit memory is inferred from dissociation between explicit and implicit forms of memory. Thus if intentional retrieval is equated with explicit memory then this would rule out cases when subjects might become aware of a prior event without attempting to do so - a situation of involuntary explicit memory. Some untenable assumptions are necessary about the mental states or processes which ignores the complexity of such processes.

It is therefore suggested that the terms direct and indirect be used to distinguish memory tests which would be based on instructions and methods of measurement. This would make minimal a priori assumptions concerning the mental states and processes involved in performing the tasks. The terms explicit and implicit memory should be therefore used to refer to the effects of an episode that are expressed without awareness of remembering, and with awareness of remembering, respectively (Richardson-Klavehn and Bjork; 1988). An useful taxonomy adapted from Richardson-Klavehn and Bjork (1988) for only normal subjects is given below:

Schacter, Bowers, and Booker (1989) advise in using the retrieval intentionality criterion (RIC) to provide a non-circular, empirical testable way of distinguishing between explicit and implicit tests. This criterion consists of three key components: (1) the same nominal cues should be presented to subjects on implicit and explicit tests.; (2) only the implicit/explicit nature of test instructions should be varied, and (3) an experimental or subject variable should be identified that produces dissociations between implicit and explicit task performance. When

TABLE 1
Frequency with which a given form of memory contributes to performance in direct and indirect test

Type of test	Form of Memory		
	Explicit: Intentional	Explicit Involuntary	Implicit
Direct	Always	Occasionally	Sometimes
Indirect	Sometimes	Sometimes	Usually

an implicit/explicit dissociation is observed under these conditions, then only can the possibility that subjects use explicit strategies on the implicit test be ruled out.

It is suggested that the framework provided by Richardson-Klavehn and Bjork (1988) with regard to direct and indirect tests and the retrieval intentionality criterion (RIC) be used in future research. The above frameworks does not appear to have been used in consumer research and is a fruitful area of inquiry. As a starting point it can be useful to determine, using the RIC, whether the construct of implicit memory using the implicit memory measures can be replicated in the consumer research context. Nedungadi (1990) has used word completion - an implicit memory measure in one of his studies.

THEORETICAL ACCOUNTS:

In the social cognition literature the theoretical background assumed is mostly activation theory (detailed below) and the studies are at a more molar level without any debate regarding the appropriate memory system being used. There is however considerable turmoil regarding this issue in direct priming (see below) and the issue is analyzed at a more molecular level with no discernible agreement in the research community as to the appropriate theoretical (memory) framework.

Multiple Memory Systems View

Schacter (1987) has forwarded three main classes of theory to explain the distinction between explicit and implicit memory systems. The first of these is called the *multiple memory systems view*, and its major support arises from the observed independence or dissociation between explicit and implicit memory systems (Schacter, 1987)

These dissociations as Schacter (1987) Tulving and Schacter (1990) argue lead to the possibility of a single perceptual representation (PRS) which may exist separately from other memory systems and suggest that implicit and explicit memory performance are reflections of the operation of separate subsystems in memory.

These separate subsystems are characterized by different rules and operations and different candidate subsystems have been proposed as underlying the distinction (Squire; 1986). Squire and Cohen (1984) have argued that conscious or explicit recall is a

property of and supported by a *declarative memory system* that is involved in the formation of new representations of data structures. Implicit memory such as learning of skills and repetition priming effects are attributed to a *procedural system of memory* characterized by online modification of procedures or processing operations.

The distinction between episodic and semantic memory has also been invoked to account for this dissociation, (Tulving, 1972, Cermak et al., 1985; Kinsbourne and Wood, 1975; Parkin, 1982; Tulving and Schacter, 1982; Tulving, 1983). The episodic memory system is viewed as the basis for explicit recollection of specific events, whereas semantic memory is seen as responsible for performance on tasks such as word completion, lexical decision, and word identification which require subjects to make use of pre-existing knowledge of words and concepts. Other multiple memory systems have also been proposed to account for the observed data with regard to explicit and implicit memory systems (Johnson, 1985; Schacter and Moscovitch, 1984; Warrington and Weiskrantz, 1978).

Another related issue is that of the strong view versus the weaker account (Sherry and Schacter, 1987; Parkin, 1989). A strong view would argue that these systems are completely independent of each other and the operation of one exerts no influence on the operation of the other. A weaker account proposes that different systems exist but their outputs can influence the performance of each other. The results and arguments forwarded by Parkin (1989), Schacter, Delaney and Merikle (1990) favors the weaker version of a multiple memory system.

If performance on implicit priming tests is mediated by a single memory system then stochastic dependence between two implicit tests should be found. However results by Witherspoon and Moscovitch (1989) show stochastic independence between word-fragment completion and perceptual identification. These results are not consistent with the multiple memory systems view and one interpretation is to argue that the the degree of dependence between performances on direct or indirect memory tests is determined by the similarity (or dissimilarity) of information usage and of the different parts or component processes that the tests use.

Processing View

A second theoretical account is proposed by the *processing view* in which the interaction between encoding and retrieval is the focus (Jacoby, 1983; Roediger and Blaxton, 1987a, Hunt and Toth, 1990). This relies on the distinction between conceptually-driven (top-down) and data driven (bottom-up) processing. Conceptually driven processes reflect subject-initiated activities such as elaborating, organizing and reconstructing; data-driven processes are initiated by the information or data that is presented in test materials. The major argument is that information encoded via one of these general types of processes is best retrieved using the same or similar process. Thus most explicit tests emphasize concept-driven processing while most implicit tests draw on data-driven processing and performance dissociations between implicit and explicit tests are attributed to differences between conceptually driven and data driven processes. Hunt and Toth (1990) have reported some limitations in using this framework with regard to the effect of orthographic distinctiveness of words.

Activation View

The third class of theories are those espousing the *activation view*. Activation holds that priming effects on implicit memory are attributable to the temporary activation of preexisting representations, knowledge structures or logogens (Graf and Mandler, 1984; Morton, 1979). This activation is automatic and decontextualized and is not affected by any ongoing elaborative processing. An activated representation readily pops into mind on an implicit memory test but since it is decontextualized, does not contribute to explicit remembering of the episode. Priming studies in the social cognition area mostly use this class of theoretical framework (Fiske and Taylor, 1990).

As Schacter's (1987) review suggest, none of the three existing theoretical approaches can accommodate all of the available data. Another perspective suggests whether the current theoretical debate with regard to implicit memory is a spurious debate in the sense that the problem is impossible to solve (Snodgrass, 1989; Lockhart, 1989).

FINDINGS IN " PRIMING AND IMPLICIT MEMORY" RELEVANT FOR CONSUMER BEHAVIOR

In the next few pages I will make an attempt to briefly present what I feel are some of the relevant findings in priming and implicit memory that may be of some importance in studying consumer behavior.

Factors from studies in social cognition known to affect priming

Several factors in social cognition have been found to influence the accessibility of using a primed trait. In other words the effects of priming on dimensions descriptively or evaluatively related to the primed trait are increased (or assimilated) by: (a) increasing the number of trait-relevant items used during the priming task (Srull and Wyer, 1979; 1980); (b) decreasing the time interval between the priming

task and the presentation of information about the target character (Srull and Wyer, 1979,1980); (c) increasing time interval between the target character's information (behaviors) and the judgment (Srull and Wyer, 1980); (d) increasing the ambiguity of the target character's behavior (Srull and Wyer, 1979); (e) increasing expectations that category-relevant events will occur (Higgins, Kuiper and Olson, 1980); (f) increasing frequency of activation of the category (Wyer and Srull, 1980) and (g) increasing the strength of semantic relationships between the category and other activated concepts (Collins and Loftus, 1975; Warren 1972).

In the above it can be observed that the activation view of memory systems is used as a theoretical background. Consumer researchers have used some of the above factors in several studies eg., time interval effects (Wyer and Hong, 1990), ambiguity of the target's attributes (Herr, 1988).

Dissociations between implicit and explicit memory:

As stated earlier dissociation in performance on the two types of memory tests (explicit or implicit) has sparked significant research interest in implicit memory. An useful framework to review these dissociations is to think of them as arising from "subject variables" or "experimental variables". With respect to "subject variables" the two factors that have shown robust dissociations are (1) performances by amnesics on implicit memory as compared to recall and recognition measures and (2) age effects also called developmental effects. Many experimental variables also produce dissociations but the more important ones are retention interval, semantic encoding or the level of processing, and modality shifts between study and test. Other relevant factors of interest to consumer research including semantic priming and the specificity of priming effects, will be also briefly discussed.

Developmental Effects

Though recognition memory increases with age, priming effects can be as large as in 3-year olds as in college students (Gollin, 1962; 1966) Similarly elderly subjects have difficulty with recall and recognition, but their priming effects are indistinguishable from that of young adults (Caroll, Byrne and Kirsner, 1985; Mitchell, 1989).

Priming effects of nonverbal information are reasonably robust across age groups (Mitchell, 1989). Mitchell (1989), observed a robust facilitation of naming latency (as compared to explicit memory tests) in young and old subjects at different intervals between presentation of the prime and the target stimulus. Similarly Light and Singh (1987) have also found that although young subjects had a differential advantage over older subjects on recall and recognition, the two age groups performed equivalently on word completion and recognition. Studies by Gollin (1960, 1962), Parkin and Streete (1988), Caroll, Byrne and Kirsner (1985) all point to strong priming effects regardless of age of the subjects.

The robust priming effects across age groups has implications in terms of research of advertising and brand name effects on children and the elderly. The elderly consumer may have weak recall or recognition of ad message or contents but may be primed with the brand name or other memory based cues so as to influence judgment and choice.

Effects of retention interval:

Retention interval indicates the time interval between study and test or also between test and taking the final rating. Forgetting on implicit memory tasks is slower than forgetting on explicit memory tasks and the duration of priming effects in implicit memory can be as long as one year (Mitchell and Brown, 1988; Tulving, Schacter and Stark, 1982). Priming effects on implicit memory tests have been found to be greater for subjects who experienced a delay between the stimulus and the rating than other subjects who experienced a delay between the priming and the stimulus paragraph (Srull and Wyer 1980). It is therefore important that the prime and target stimulus occur in close temporal contiguity, as the effect depends on the target stimulus being encoded in terms of the prime. Implicit memory test performance have been found to decrease with wider gaps between a prime (study) and stimulus (test) (Fiske and Taylor, 1990). The wider gap possibly interferes with the process of encoding the stimulus in terms of the prime.

Priming effects have also been found to actually increase with greater time intervals between the target stimulus (test) and the rating, holding the time interval between the prime (study) and the stimulus (target) constant (Fiske and Taylor, 1990). Once a stimulus has been encoded in terms of the prime, then the longer it sits in memory linked to that particular prime, the stronger the prime's effects. This evidence suggests an encoding explanation for priming because the delayed rating must be less dependent on ability to use the initial prime itself as retrieval cue, since retrieval of the prime becomes more difficult over time. As the effect increases with time, it suggests that the details of the original stimulus are lost and the primed representation becomes relatively important.

Results by Musen and Triesman (1990) suggest that a single exposure to novel, nonverbal stimuli was sufficient to establish a long duration of perceptual priming as compared to recognition memory loss over the same time period.

Level of processing:

Level of processing (LOP) or semantic processing produces better recognition and recall (Craik and Lockhart, 1972; Craik and Tulving, 1975) but does not seem to affect implicit memory performance (Jacoby and Dallas, 1981). In Jacoby and Dallas (1981) manipulating the LOP of study words had no affect on repetition priming in perceptual identification (implicit memory test) but semantically processed words yielded superior performance on recall and recognition than phonemically or orthographically processed words. Null effects of

study LOP on repetition priming have been also found for word completion (Graf and Mandler 1984) lexical decision (Kirsner, Milech and Standen, 1983, Expts 2 and 3) picture naming latency (Caroll, Byrne and Kirsner; 1985, Expts 1-3) and perceptual identification of pictures (Caroll, Byrne and Kirsner; 1985, Expt 4). In all these studies, explicit memory tests showed a large LOP effect for the same study and test stimuli. Jacoby (1983) has shown that while generation (high LOP) produced better recognition memory than a reading task (low LOP), there were opposite effects in perceptual identification (implicit memory task) i.e., read tasks produced better performance than generate.

The LOP variable has been used in consumer research (Bettman and Sujun, 1987) but LOP variable effects on implicit memory tests have not to the knowledge of the author been used in consumer behavior.

Modality Effects

Under the processing view (Jacoby, 1983; Roediger, Weldon and Challis, 1989; Roediger and Blaxton, 1987, a,b), explicit tests emphasize elaborated, semantic information in memory and therefore are not sensitive to modality (visual versus auditory) differences. Most implicit tests being data driven, are quite sensitive to the modality match between study and test (Graf, Shimamura and Squire, 1985; Kirsner, Milech and Standen, 1983). The above is an issue of modality sensitivity across explicit and implicit memories.

A related issue is that of priming across modality within the same implicit test. Thus Jacoby and Dallas (1981) had subjects study words either visually or auditorily and then try to identify visually degraded words. There was substantial priming effects on the visual implicit test for visually studied words but not for auditorily studied words.

Winnick and Daniel (1970) found that recall was higher following study of a picture than study of the corresponding word, but priming effects on the word-identification test were greater following study of the word than study of the picture (see also Weldon and Roediger; 1987). This was further corroborated in lexical decision making (Scarborough et al. 1979) and fragment completion (Ellis and Collins, 1983). The more common pattern is to observe a gradient of priming - more priming within modality (A-A or V-V) than across modality (A-V, V-A), but significant priming even across modality (Bassili, Smith and MacLeod, 1989). This pattern also appears in word fragment completion (Roediger and Blaxton, 1987, a,b), word identification (Kirsner et al., 1983; Postman and Rosenzweig, 1956) and lexical decision (Kirsner and Smith, 1974; Kirsner et al., 1983).

Despite some inconsistencies and variabilities in the results it can be concluded that there is generally less priming from pictures to words and words to pictures than from words to words or pictures to pictures. In other words priming is reduced in intermodal conditions as compared to intramodal conditions. This also indicates that the physical form of a stimulus plays a large role in priming and is

consistent with the data processing point of view. The finding that studying familiar pictures enhances recall and recognition while producing little or no priming effects on word identification, fragment completion and lexical decision tasks, (Graf et al., 1985; Kirsner et al 1983) also indicates that form based information plays a different role in priming as compared to explicit memory. This is also consistent with the idea that most explicit tests are largely conceptually driven. The importance of form information of a stimulus is observed only for repetition or direct priming. In semantic priming or associative priming there is evidence of extensive and even complete transfer between pictures and words. (Vanderwart, 1984).

Semantic Priming and Brand Names

In a typical semantic priming experiment, the subjects perform a "lexical decision" task, in which words must be discriminated from nonword letter strings. Nonwords conform to the orthographic (spelling systems) rules of the language and therefore a subject has to semantically encode the word before being able to decide that it is a word. The speed and accuracy with which subjects classify words is taken as a measure of the efficiency of a semantic coding of the word. If a word is preceded by a semantically related cue (word or sentence), lexical decision for words proceeds more efficiently (Fischler, 1981; Meyer and Schanveldt, 1971, Morton, 1969; Neely, 1977).

Brand names provide labels by which firms identify and promote their products and services. The effect of a brand is of course not merely in the name but represents the rich configurations of symbols and meanings that are embodied by products (Levy, 1978). Brand names can be either everyday words used in the language (Tide, Dial, ...) invested with product attributes or they can also be constructed words (Sentra, Compaq, Accord) which are not in the normal lexicon of words. The multiple meaning of everyday words being used as brand names can be understood in terms of the literature on word meanings (imagery, vividness, meaningfulness, concreteness-abstractness, (Taylor, 1976) association set size, (Meyers-Levy, 1989), functional or usage based vs concept or symbolic (Park, Lawson and Milberg, 1989)).

A relevant question is at what stage does a constructed word become part of the mental lexicon of consumers and what role would priming play in understanding this transition. A constructed brand name entering the mental lexicon of consumers is of course a function of the firm's marketing investment and strategic acumen. An interesting question is whether multiple lexical representations exist for several meanings of a brand name - normal or constructed, only some of which are activated when a stimulus is presented. Morton's (1970) "logogen model" which explicitly defines a "logogen" as representing a meaning as opposed to a mere spelling pattern is an example of a useful framework for studying common words being used as brand names.

There are two findings that are often cited as evidence for support of the activation theory with regard to repetition priming for nonwords and therefore could be used for understanding brand name (constructed) priming effects. First repetition priming in amnesic patients is only short-lived (Graf, Squire and Mandler, 1984; Squire, Shimamura and Graf, 1987) and secondly amnesic patients do not show repetition priming for non-words. The first finding is consistent with the idea of an independent decay implied by the concept of activation and the second can be predicted from the notion that repetition priming should be found only with stimulus materials that have pre-existing internal representations.

This activation account is however inconsistent with the current debate in implicit memory research where there is evidence about the formation of implicit new associations which can be acquired, used or retrieved implicitly (Graf and Schacter's; 1985, 1987). If something has no prior representation in memory - such as the association between two unrelated items - and can be learned implicitly, it is obvious that the activation account cannot be sustained. Hayes and Broadbent (1988) suggest that even complex cognitive skills can be acquired through an implicit mode of learning. Lewandowsky, Kirsner and Bainbridge (1989) have suggested a sense-activation view to reflect implicit memory for new associations. Their data suggest that it is the re-instatement at the rating stage (after target stimulus or at the test stage) of the encoded *sense* of the word rather than the use of a new association between the cue (or context) and target that gives rise to implicit new associations.

Specificity of priming effects

The specificity of priming effects is an interesting issue worthy of future research. Is the phenomenon of priming based on the activation of some generic or abstract code that represents the target object's prototypical features or does priming reflect certain specific characteristics of the object encoded by subjects during exposure to the priming stimulus. Gollin (1960) found evidence that initial "training" on a fragmented version of a picture produced greater subsequent priming effects in identifying that fragment than initial training by exposure to the entire picture. Further Snodgrass and Feenan (1989, as cited by Schacter, Delaney and Merikle, 1990) have also shown that priming is greater when the same picture fragment is presented for identification during the study and test periods than when different fragments are presented. These results suggest that priming is based in part on a representation of the specific characteristics of objects presented for study and does not seem to rely on an abstract, generic code. However explicit memory processes may have played some role in these observed specificity effects. Warren and Morton's (1982) study suggests that priming may be based on the activation of a more abstract object representation and the contribution of explicit memory processes needs further scrutiny. Herr (1989) in a consumer research setting has also found evidence that the effect of priming seems to be

highly specific to the category primed. In his study only judgements of price were influenced by priming, while other evaluative measures taken at the same time on quality, reliability, and prestige were not influenced by the activated category of price.

The reason for this specificity is not exactly known but it may be found in a categorization theory explanation of the priming effect. This assumes also an activation view. Priming effects are mostly obtained at the same category level as the category primed. If priming takes place with the priming stimulus at a "prototypical features" level then the priming effects are unlikely to be specific but more abstract and generic. Another related issue worth exploring is the contribution of explicit memory processes to priming and how it relates to observed specificity effects (Warren and Morton, 1982; Jacoby, Baker and Brooks (1989).

MEASURES OF IMPLICIT MEMORY

An important issue is what are relevant measures of implicit memory and explicit memory. This discussion also has to be within the context of the earlier discussion on the retrieval internationality criterion (Schacter, Bowers, and Booker; 1989). Recall and recognition are the usual task based explicit memory measures. Stem completion, fragment completion, and perceptual identification are some of the implicit memory measures used. Perceptual identification or fluency is usually measured in terms of how well an item can be identified under impoverished conditions. Other implicit measures used are solving anagrams (Srinivas and Roediger; 1990). Schoen, Ciofalo and Rudow (1989) compared word fragment completion to an anagram solution word-completion task and found no differences between the measures suggesting that the anagram solution is an adequate measure of implicit memory.

IMPLICIT MEMORY AND JUDGMENT

What is the relationship between implicit memory tests and judgment? Bacon (1979), Begg et al (1985) have found that prior exposure to statements, or components of statements increases the truth rating of those statements. Lewicki (1986) presents an interesting aspect of the influence of implicit learning on judgment. This study focussed on the processing of covariation (among features) present in the stimulus material that could be implicitly learned. A latency of response measure which would result in increase of processing time for the questions considered relevant to the covariation was used. His results show that subjects had learned the rule implied by the covariation and used it in their subsequent judgments but were unable to articulate it later. A relevant question, is do consumers implicitly learn about covariations in their environment which influence their judgments and purchase behavior. Covariation assessment research (Bettman, John and Scott, 1986) shows consumers' estimate of covariation was accurate and unaffected by prior beliefs. Investigations at the implicit level of how covariations can affect judgment does not appear to have been carried out.

Research by Zajonc and his co-workers show that exposure to stimuli increases affective preferences for those stimuli (Zajonc, 1984; Zajonc and Markus, 1982). Their research centers on the finding that people can form preferences for stimuli in the absence of recognition memory. Zajonc interprets his results with the proposition that affective responses are independent of cognitive processing and affect can precede cognition. Lazarus (1982) however defends the cognitive-affective model and contends that the absence of recognition does not imply the absence of cognition. The debate between these two contending viewpoints depends on how each side defines cognition and affect (Anand and Sternthal, 1991). In consumer research Anand, Holbrook and Stephens (1988) have used a dichotic learning task to find support for the cognitive-affective model over the independence hypothesis. Heath (1990) has contested the independence of affect-cognition based on the results of Anand, Holbrook and Stephens (1988).

Research on recognition shows that two processes - labelled here as perceptual fluency and directed search, are used to determine recognition judgments. (Mandler, 1980; Johnston, Dark and Jacoby; 1985, Gillund and Shifrin, 1984). Perceptual fluency (PF) is usually measured in terms of how well an item can be identified under impoverished presentation conditions (Johnston, Dark and Jacoby; 1985) or the relative ease with which people can perceive a stimulus (Anand and Sternthal, 1988) and is an implicit memory measure. A directed search would involve the generation of contextual or episodic information related to the target stimulus.

Using a two stage priming framework and signal detection techniques Johnston, Dark and Jacoby (1985), presented subjects with a series of target stimulus items after which the recognition judgments of these old target items as well as new foil items were assessed. There were two measures of perceptual fluency - (1) the time taken to identify the word correctly since PF was inversely related to latency of identification; and (2) accuracy of identification. A two by two classification of actual exposure status and judged status was then used with: hit (old item judged to be old), miss (old item judged to be new), false alarm (new item judged to be old), correct rejection (new item judged to be new). If subjects relied only on perceptual fluency then the pattern of recognition outcomes would be hits > false alarms > misses > correct rejections. If they relied only on the search factor then perceptual fluency might not affect judged repetition status and perceptual fluency would vary across recognition outcomes in the following manner: hits = misses > false alarms = correct rejections.

Johnston, et al (1985) first experiment showed perceptual fluency for misses to exceed that for false alarms therefore indicating that the search factor was also in operation. In their second experiment they reduced the contribution of the search factor by using nonwords rather than words and found that recognition judgments were much more dependent on speed of identification than they were on actual old/new status. Their conclusion is that perceptual fluency plays a

significant role in recognition judgments and may be the basis of the feeling of familiarity.

Anand and Sternthal (1988) used a dichotic learning task to investigate the affect without recognition phenomenon. Using the same experimental framework as Johnston, et al (1985) they investigated how perceptual fluency influences judgments when search fails. If one subscribes to Zajonc's view, perceptual fluency is viewed as a function of stimulus repetition or objective familiarity with the greater the repetition, the higher the perceptual fluency and the more positive the affective judgments. If however you favor Lazarus's view that cognitive appraisal is a necessary condition of affective appraisal, then the greater the subjective familiarity of a stimulus the greater the perceptual fluency and the more positive the affect. If subjective familiarity was the dominant factor, affective responses would be more positive for false alarms than for misses. Anand and Sternthal (1991) results supports the dominance of subjective familiarity (but see Heath, 1990 for an alternative viewpoint). This would also imply that affect without recognition involves some sort of cognitive process, although this would again depend on the definition of cognition and affect (Zajonc, 1984; Lazarus, 1984)

Perceptual fluency is an implicit memory test and the previous discussion suggests that when directed search fails then perceptual fluency influences judgments. If one accepts some fallibility of recall and recognition then to what extent is implicit memory directing judgment? What are the likely effects for the elderly consumer where the age deficits that are obtained so consistently on direct tests are reduced or eliminated when indirect tests are used (Howard, in press). What independent variables can impact on the relative utilities of the perceptual fluency and search factors. One variable that may cause variations is item meaningfulness. Reliance on perceptual fluency has been greatest with nonwords (Expt 2; Witherspoon, 1984 as quoted in Jacoby et al 1985) whose item meaningfulness has been low and least with words (with high item meaningfulness) (Tulving et al., 1982). Decrease in item meaningfulness clearly reduces the utility of the search factor. It should be noted that item meaningfulness is possibly a "cognitive" variable and these arguments assumes that affect is based on cognition. Other variables worthy of interest are retention intervals (discussed earlier) and repetition lag (Tulving et al., 1982). Longer repetition lags may lead to lower utilization of the search factor and increasing dependence on the perceptual fluency factor.

CONCLUSION

Implicit memory is a reasonably robust framework for many applications in consumer behavior. If the idea of consumer memory is restricted to existing recall/recognition tests then consumer researchers maybe ignoring a potentially influential dimension of consumer evaluation and decision making.

The notion of consumer memory may thus need to be expanded to include the concept of implicit

memory. Researchers should be however aware of the major debates still remaining unresolved mostly with regard to the "correct" theoretical framework and with regard to the distinction between task and process. It is a still evolving and exciting framework rich with opportunities for use in consumer behavior.

Goal-Related Consumption and Extension Advertising: The Impact on Memory and Consumption

Brian Wansink, Dartmouth College
Michael L. Ray, Stanford University

ABSTRACT

Advertising which encourages a person to use or to consume a familiar product in a new situation is referred to here as *extension advertising*. This paper examines some of the delayed effects of extension advertising. In particular, it shows that these extension ads are more memorable when they explicitly make comparisons with either other products or with other situations. It also shows that regardless of the impact that these ads might have on a meal planner, their impact on actual consumption will be mediated by the attitudes of other family members.

Advertising which encourages a relatively new or different use of a product will be referred to as *extension advertising*. Arm and Hammer Baking Soda launched a very effective extension advertising campaign when it extended the use of baking soda from a baking product to a refrigerator deodorizing product. Similarly, the Florida Citrus Commission used an extension advertising campaign when it told consumers that orange juice was "not just for breakfast anymore," and could be extended into the afternoon, and after exercising. In general, extension advertising includes any advertising which encourages a person to consume a product in a situation in which it is generally not consumed, and extension advertising is defined with respect to a particular segment of consumers who do not use the product in this specific situation, or who do so very infrequently and only as a very secondary use of the product (Wansink and Ray, 1992).

In general, we commonly see extension ads which either compare or frame the target product with another product or with its use in another situation. Such framed ads can emphasize a frame of reference which encourages consumers to think of using the product either 1) with respect to the *other products* one conventionally consumes in that situation (product frame), or 2) with respect to the *other situations* in which one conventionally consumes this brand (situation frame). Though extension ads (such as the Arm and Hammer ads) need not contain any overt comparison or frame of reference (they can be "unframed"), this research shows that both situation frames and product frames will be more effective than unframed ads in causing one to remember an ad for eating a particular product in a particular situation. In addition, the research will argue that the consumption of that product will be influenced more by a meal planners perceptions of family preferences than by his or her own preferences.

BACKGROUND: CONSUMPTION FRAMING

A consumption frame refers to either the point of comparison used in an extension ad or to the point

of comparison used by a consumer when processing information about an extension. Even though consumption framing can be encouraged through the structure and content of an ad, it only has an impact when consumers perceive the frame.

An ad with a *product frame* is one that "positions" or compares the target brand with selected attributes of another product that is already favorably associated with that situation. For instance, such an ad (or commercial) might begin with a woman serving the conventional product (one that is strongly associated with the situation) in the target situation. She might say that benefit₁ and benefit₂ make it a reasonable choice for the situation. The scene would then change and she would be serving the target brand in the target situation. She says that just as benefit₁ and benefit₂ made the conventional product reasonable in this target situation, they also make the target brand reasonable for that situation. For instance, an ad that encourages consumers to eat Campbell's Soup with their dinner might compare some attributes of Campbell's Soup (e.g., quick and nutritious) with similar attributes of a product they conventionally consume with dinner (e.g., lettuce salad).

Whereas a product frame draws similarities between the target product and a conventional product, a *situation frame* draws similarities between consuming the target product in a new situation with consuming it in a more conventional situation. The basic situation-framed ad might begin with a woman serving the target brand in the situation in which it is most conventionally served. She might say that benefit₁ and benefit₂ make it an reasonable choice for the situation. The scene would then change and she would be serving it in the target situation. She says that just as benefit₁ and benefit₂ make the brand reasonable in this conventional situation, they also make it a reasonable choice for this target situation. For instance, an ad which encourages consumers to eat Campbell's Soup with their dinner might compare how eating it at dinner is similar to eating it in a more conventional situation, such as with lunch. By doing this, a situation frame emphasizes an additional situation in which the product can be consumed.

In contrast to these, an unframed ad would draw no similarities with other products or other situations. The basic unframed ad might begin with a woman serving the target brand in the target situation. She would simply say that benefit₁ and benefit₂ make it an reasonable choice for the situation. Essentially the arguments she gives (i.e., the attributes she mentions) for eating the target product in the target situation are identical to those she would have given in either the product frame or the situation frame. The only differences are the points of comparison that are suggested (or that are not suggested).

HYPOTHESES

Consumption Framing and Memory

One's actual consumption of the target product in the target situation not only depends on how the extension ad influences one's attitude toward the extension (A_{ext}) but also on whether it affects one's ability to recall or evoke the product in the appropriate consumption situation. Indeed, the cued recall of the product in the target situation is a necessary condition of consumption.

Though product frames and situation frames encourage different types of comparisons and different types of thinking, they should both be more effective than unframed ads in increasing the number (and strength) of associations that are made between the target product and the target situation. Whereas a product frame should increase the number of associations made between the target brand and a product that is already associated with the situation, a situation frame should increase the number of associations made between the new situation and more conventional situations in which the brand is consumed.

Since one's ability to recall or to evoke a brand is dependent on the number and on the strength of associations between the brand and the situation (Nedungadi 1990), the more associations that an ad can encourage a person to make between the target product and the target situation, the more likely one will recall that target brand when given that situational cue at a later date (Keller 1991). Therefore . . .

- H₁: When compared with an unframed ad, framed ads (i.e., product frames or situation frames) will generate greater recall when given a situational cue.

Extension Advertising and Consumption

Though this study focuses solely on the long-term impact of extension advertising, such advertising does have immediate impacts on one's attitude toward the extension (A_{ext}) and on beliefs (b_i) about the product and on evaluations (e_i) as to whether these beliefs are relevant in a particular situation. As is consistent with Fishbein and Azjen (1975), A_{ext} can be approximated as $\sum b_i e_i$. It has been argued by Azjen and Fishbein (1980) that any lack of correspondence between attitudes and behavior (i.e., A_{ext} and actual consumption in that situation) can often be attributed to external factors, such as to what others (such as family members) think about the behavior (behavioral norms -- bn_i) and the degree to which abiding by these people's thoughts is important to a person (motivation to comply -- mc_i). This less-than-perfect relationship between one's attitude and one's actual behavior is particularly vivid when meal planning is involved (Rudell 1979; Krishnamurthi 1983). As a result, we see meal planners who love liver and onions, but who would never serve this at their home because no one else would eat it.

Nevertheless, research has suggested that a researcher may be able to more effectively predict consumption behavior by taking these attitudes of relevant others (such as family members) into account (Pantzar 1988). Ajzen and Fishbein (1980) viewed this component as the perceived social norm (SN) and modelled it as the summed cross-product of behavior norms (bn) and one's motivation to comply (mc) with these norms ($\sum bn_i mc_i$). The social norm of serving Campbell's Soup for breakfast would consist of what a meal planner believed his or her family would think of it (bn_i) as well as the degree to which he or she cares about what family members think (mc_i). When these norms are specific to a certain extension situation (e.g., serving soup for breakfast), they are modelled as $\sum bn_{ext} mc_{ext}$.

Though Axelson, Brinberg, and Allen (1986) found that the correlations between SN and behavioral intentions were very low for both college students ($r=.10$) and for families ($r=.23$), SN may be of predictive value when combined with attitude information. In this instance, we should find that the social norms of a family can profoundly mediate the impact of the meal planner's A_{ext} on actual consumption. Regardless of how effective an extension ad is in changing the A_{ext} of a meal planner, if he or she does not think family members will like it, he or she will be unlikely to serve it. In summary,

- H₂: The perceived social norms within one's family will mediate the relationship between a meal planner's A_{ext} and actual consumption.

METHODOLOGY

The goals of the main study were 1) to determine how various frames impact one's memory, and 2) to determine how subsequent consumption is mediated by family considerations.

Subjects and Design

Adult subjects were recruited through PTA groups, and six dollars were donated to the respective organization for each of the 219 group members who participated. The age of the subjects ranged from 26 to 67 with 83 percent being between the ages of 30 and 45. The majority (86 percent) of these subjects were not employed outside the home. Their educational backgrounds were heterogeneous.

The basic experiment was a 4 x 3 x 2 between-subjects design with four levels of framing (product frame, situation frame, no frame, and a "no ad" control condition), three brands (Campbell's Soup, Jell-O Brand Gelatin, and Ocean Spray Cranberry Sauce), and two levels of appropriateness (appropriate extensions and less appropriate extensions). The products and their relative appropriate and less appropriate extensions were determined in a prestudy. In essence, the last two factors (brands and appropriateness) were included for generalizability and will not be factors which will be individually analyzed.

Procedure

Upon beginning the experiment, the subjects were told to take alternate seats, and they were given a closed packet of materials which contained a cover sheet of instructions and a number of consecutively labeled booklets. The subjects were told they were going to be comparing how understandable transcripts of commercials were to storyboards of commercials. They were then asked to read through a transcript for the target brand in a natural way, write their thoughts and feelings about it, answer the questions which followed it, read an unrelated storyboard, and to answer more questions. The objective of the cover story was to insure that subjects would process and comprehend information in the ad without unduly focusing on directly evaluating the product. They were last asked demographic questions and questions related to the manipulation checks. Three months after their involvement in the study, they were called and asked about their memory of the target product and their consumption of it.

Measures

After writing down their cognitive responses, subjects were asked a couple of questions which served as a basic set of manipulation checks regarding the frame. These questions were quantitative processing measures which used a Likert scale to rate ("Strongly Disagree" = 1; "Strongly Agree" = 7) the degree to which subjects focused on the brand or on the situation.

Following this, a measure of A_{ext} was taken by asking subjects to indicate (on a seven-point scale) whether a particular extension was "Bad-Good," "Unappealing-Appealing," "Inappropriate-Appropriate," and "Unreasonable-Reasonable." The Cronbach's alpha (.921), was high enough to enable A_{ext} to be analyzed as the average of the four items (Nunnally 1967). Make this consistent with past research on multi-attribute models).

All subjects were then asked how many times in the past year they consumed the basic product category and the percentage of times they consumed the target brand, and they were asked the degree to which they conformed to the consumption attitudes of their children and spouse ("need to comply") and how their children and spouse would feel about eating the target brand in this extended situation ("social norm"). As has been recommended (Fishbein and Ajzen 1980), these measures used a seven-point Likert scale ("Strongly Disagree" = 1; "Strongly Agree" = 7).

To determine a subject's memory of the brand and their reported consumption of it, subjects were telephoned roughly three months after they were involved in the experiment. They were given the appropriate situation cue for the ad they saw (breakfast, snack, dinner) and were asked if they could recall the brand in the transcript. They were then asked how many times (since the experiment) they consumed the target brand in the relevant extension situation. Though such measures are not without the typical flaws and biases associated with self-report measures of consumption (Jones 1985), they were

taken with the hope of adding richness to the study and adding credibility to the results.

Stimuli

Each subject saw a professionally edited ad (in the form of a transcript) for one of three brands. In total, there were 18 different ads: There were three different frames (product-, situation-, and un-framed ads) for each of the three brands (Campbell's Soup, Jell-O Brand Gelatin, and Ocean Spray Cranberry Sauce) and for each of two extensions (appropriate and less appropriate). Though this study only examines the difference between the framing conditions, by using multiple brands and a wide range of extension appropriateness, we are able to strengthen the generalizability of this study.

The eighteen hypothetical ads mentioned above were presented in the form of transcripts and each contained the two claims that were determined for each brand through the preliminary studies. The initial drafts were professionally edited by a copywriter who had significant experience with consumer products, and they were then subsequently re-edited to eliminate all irrelevant variation between conditions. These transcripts used either a product frame, a situation frame, or no frame.

The basic *un-framed* transcript begins with a woman serving the target brand in the target situation. She mentions why benefit₁ and benefit₂ make the brand a reasonable choice for the situation. The commercial then ends with a slogan containing 1) the target brand, 2) this target situation, and 3) the two benefits.

The basic *product-framed* transcript begins with a woman serving the conventional product (one that is strongly associated with the situation) in the target situation. She mentions why benefit₁ and benefit₂ make it a reasonable choice for the situation. The scene then changes and she is now serving the target brand in the target situation. She says that just as benefit₁ and benefit₂ made the conventional product reasonable in this target situation, they also make the target brand reasonable for that situation. The commercial then ends with a slogan containing 1) the target brand, 2) this target situation, 3) the two benefits, and 4) the conventional product.

The basic *situation-framed* transcript begins with a woman serving the target brand in the situation in which it is most conventionally served. She mentions why benefit₁ and benefit₂ make it a reasonable choice for the situation. The scene then changes and she is now serving it in the target situation. She says that just as benefit₁ and benefit₂ make the brand reasonable in its conventional situation, they also make it a reasonable choice for this target situation. The commercial then ends with a slogan containing 1) the target brand, 2) this target situation, 3) the two benefits, and 4) the conventional consumption situation.

RESULTS

Manipulation Checks and Overview of Analyses

Recall that this study's focus is to determine the impact that extension advertising has on consumers who are already "users" of a brand. A "user" was liberally defined as someone who had consumed the target brand *at least once in the past year*. This measure of usage also turned out to be highly related to conservative measures of brand loyalty (Jacoby and Chestnut 1978), since the typical individual in this study consumed the target brand 84 percent of the time he or she used a product from that particular product category. The subjects' prior consumption of each brand was similar across all the conditions.

The manipulation of the product frame and the situation frame appeared to be successful. Quantitative measures of processing ("I compared serving . . .") were taken on 7-point scales. They indicated that the subjects seeing situation frames "compared" the conventional situation and the target situation to a greater degree than did those subjects who saw unframed ads [$F(1,98) = 14.6, p < .01$] or to those subjects who saw product frame ads [$F(1,96) = 39.8, p < .01$]. Similarly, subjects seeing product frames compared the target brand and the conventional brand to a greater degree than did those subjects who saw unframed ads [$F(1,97) = 9.3, p < .05$] or to those subjects who saw situation frame ads [$F(1,98) = 12.4, p < .01$].

Though the hypotheses were assumed to be generalizable across all three brands and across both levels of "appropriateness," it was necessary to determine if the results for each of the brands were indeed similar enough to justify this. In general, the three brands involved in the study all exhibited similar patterns with regard to how subjects reacted toward them in both the frame and appropriateness conditions. A 3-way ANOVA (Brand by Frame by Appropriateness) was conducted on a number of key dependent variables, and the results indicated that there were mean-level differences between the brands but no significant interactions. The results indicated that there were also mean-level differences between the two levels of appropriateness but that there were no interactions. Because the basic patterns of the data were similar, the analyses were combined and each brand and each level of appropriateness was represented by a dummy variable in the analyses in order to account for their mean-level difference in response. Wansink (1990) provides a detailed reporting of this procedure.

Memory and Consumption

Subjects were phoned approximately three months after they participated in the experiment, and they were asked about their recall of the target brand and how many times they consumed the target brand in the relevant extension situation. Of those 219 people originally participating in the study, 181 agreed to provide information regarding this consumption.

There were two objectives when collecting the delay data: 1) To determine if framed ads promote cued

brand recall better than unframed ads (H_1), and 2) to determine the extent to which actual consumption is influenced by the social norms of one's family (H_2).

When given the relevant situation cue, 73 percent of those people who saw product frames were able to recall the target brand. This was significantly different than the 42 percent recall of the people who saw unframed ads [$F(1,84)=7.34; p<.01$] and directionally different from the 58 percent of those who saw situation frames. (See Figure 1). A linear contrast showed that framed ads (situation frames and product frames) were more effective than the unframed ones ($p<.05$). Though this finding was hypothesized (H_1), it was inconsistent with the cognitive responses of the subjects, for framed ads did not generate more cognitive responses than unframed ads. It may be, however, that the thoughts that were generated by framed ads stimulated associations that were stronger or more relevant than those stimulated by unframed ads.

When examining the general impact that these ads had on actual consumption, it was hypothesized that the correlation between A_{ext} and reported consumption ($r=.24$) would be greatly moderated by the social norms of one's family (H_2).

Measures of social norms (SN) were obtained by calculating the summed cross-product of behavior norms (bn_i) and one's motivation to comply with these norms (mc_i) (Ajzen and Fishbein 1980). The norms consisted of a two-item score which asked subjects whether their spouse would approve of consuming the product in this situation (1="Strongly Disagree"; 7="Strongly Agree") and whether their children would approve.

Given this measure of SN, a regression of SN, A_{ext} , and one's prior consumption frequency of the brand was conducted on actual extended consumption. Having included both appropriate and less appropriate extensions in the study should raise the variance of social norms, thus allowing us to effectively examine when SN are significant and when they are not. To test this, one regression was conducted using only the appropriate extensions, and a second regression was conducted using only inappropriate extensions. The results confirmed H_2 , for these regressions indicated that SN was insignificant when the extension was appropriate but significant when it was inappropriate ($t=2.35; p<.05$).

Regardless of whether an extension ad influences A_{ext} , it still had a minimal impact on consumption if a meal planner thought his or her family would dislike it. Though changing the A_{ext} of the meal planner is an important precondition to changing consumption, this analysis shows it is not sufficient, for one must also consider the A_{ext} of their family.

GENERAL DISCUSSION

Overview and Implications

Recall that people who saw product frames were more likely to recall the brand when provided a situational cue three months later (Table 1).

FIGURE 1
Impact of Consumption Frames on Cued Recall
(3 Month Delay)

Specifically, when cued with the extension situation (corresponding to the transcript they had seen three months earlier), 73 percent of the subjects recalled the target product. As mentioned earlier, this was significantly different than those who saw unframed ads (42 percent) and directionally different from those who saw situation frames (58 percent), and it provides evidence for the contention that various comparisons can have a strategic impact if they serve to influence a certain cognitive process, such as memory.

Regardless of the impact that an extension ad has on a meal planner's memory, this research shows that such an impact need not affect subsequent consumption . . . especially when a meal planner is concerned about what family members might think. Such a finding is of important managerial interest since it indicates that the most memorable commercial might not be the most effective commercial if it is targeted only toward the "decision maker" or meal planner and is not also targeted at other family members. As a result, one might want to use a "pull strategy" by advertising the extension in a clever way to children, thereby encouraging them to remember it and to request it. Conversely, an advertiser might also try to provide the proper "excuse" the meal planner might need to overcome any objections family members might have.

Limitations and Future Research

Great care was taken to make the ad transcripts as comparable as possible (except on the relevant manipulations). The subjects rated all the transcripts as being equally clear and as requiring an equal amount of concentration. The reading of these transcripts, however, was performed in a high involvement context. Nevertheless, if a person is highly involved with a stimulus, there appears to be no reason why the same principles operating here would not work in a television campaign, a print campaign, or even on the back of a brand's package. In a low involvement scenario, however, it may be that a product frame can successfully associate the brand with the largest number of situational cues, thus providing positive conditioning (with a high number of exposures) between the brand and the situation (Petty and Cacioppo 1981).

The focus of this study was on brand loyal consumers. Extension ads, however, are likely to have little or no impact on those individuals who are not interested in the product category, or who are brand loyal to another product. Nevertheless, extension ads *may* have an impact on nonusers who have not yet been introduced to the product category, and these ads may have a differential impact on heavy and light users. It may be that heavy users are more predisposed toward extensions and may thus respond differently to frames because they would be less likely

to counterargue against a product frame which suggests a substitution (Wansink and Ray 1992).

SUMMARY

For mature brands which are the market leaders in their category, increasing category volume is likely to be a much more cost-effective strategy for building sales than would be the strategy of increasing market share. Extension advertising provides a viable way to increase category volume since it encourages a person to use or to consume a familiar product in a new situation, referred to here as *extension advertising*.

This research suggests that the different comparisons made in such ads form or strengthen the associations one has between a product and a situation. In particular, this paper shows that these extension ads are more memorable when they explicitly make comparisons with either other products that are currently used in the target situation, or with other situations in which the target brand is used. In addition, however, this research also shows that regardless of the impact that these ads have on a meal planner's memory for an ad, their impact on actual consumption will be mediated by his or her perception of what what other family members would think.

Some Measurement Issues in Consumer Research

Ved Prakash, Morgan State University

INTRODUCTION

The purpose of this paper is to discuss the issues raised by the three papers accepted by the Association for Consumer Research for presentation in the session on "Measurement Issues". First, a broad criteria for discussion of measurement issues is presented and then each of the papers is discussed. This discussion concludes with suggestions for applications of some of the concepts presented in one of the papers. The papers under discussion are as follows:

- 1) Gabriel S. Haberland and Peter A. Dacin, "The Development of a Measure to Assess Viewers Judgements of the Creativity of an Advertisement: A Preliminary Study".
- 2) Paul L. Sauer, Peter R. Dickson and Kenneth A. Lord, "A Multiphase Thought Elicitation Coding Scheme for Cognitive Response Analysis".
- 3) Jonathan E. Brill, "Scales to Measure Social Power in a Consumer Context".

To begin with, it would be useful to lay down some criteria for evaluation of measurement issues. For a sound measurement of constructs in consumer research three criteria may be useful. First, the purpose of the research problem ought to be meaningful and significant; the construct being developed should be conceptually sound. Secondly, the constructs that are developed ought to be rigorously measured. The measures should meet the tests of reliability and validity. Special attention needs to be paid to the requirements of validity suggested by Campbell and Fiske (1959). Reliability is also an important consideration that is often ignored. Peter (1979) reported that only 5% of the studies assessed the reliability of the measures employed. Third, for the purposes of consumer research it would be desirable to show relevant applications with some concrete examples preferably with empirical data. These applications should show effectiveness of the measures in a real life situation different from the one used in an experimental setting for testing the constructs developed. With these guidelines in view we may now proceed to discuss the three papers mentioned above.

Haberland and Dacin Paper

Haberland and Dacin's paper is very clear in its purpose i.e. to develop a valid construct of creativity in advertising from viewer's point of view. The authors make some new contribution to the consumer behavior literature. The concept of creativity has long been researched in the psychological literature, and has been intuitively practiced by the advertising industry, but it has not been *objectively* tested in an advertising setting. The April 15, 1991 issue of the

Marketing News has many articles on the concept of advertising creativity from the practitioner's point of view. Dacin and Haberland have drawn extensively from the literature in various fields: Advertising (Hinderyckx 1991, Trout and Ries 1989) and Psychology (MacKinnon 1962, Bruner 1962, Jackson and Messick 1965). Based on these studies, Haberland and Dacin deduce four dimensions for measurement of creativity in advertising i.e. 1) originality or innovativeness, 2) meaningfulness, 3) reformulation or modification of consumer attitudes, and 4) condensation i.e. simplicity in packing a lot of information in a few words; parsimony could be another word for it especially considering the time compression and high rates of inserting advertisements in the media.

Haberland and Dacin have done a satisfactory job of collecting 42 items relating to creativity and reducing them to 16 purified items. For these 16 items, the reliabilities as reflected in the coefficient alphas are acceptable e.g. at the overall level (.92), and for the individual dimensions, .87 for originality, .77 for meaningfulness, .77 for reformulation and .66 for condensation. These four dimensions are confirmed by the results of factor analysis as indicated in Table 2. The assessment of convergent and discriminant validity on the multitrait-multimethod matrix (MTMM) as suggested by Campbell and Fiske (1959) and as displayed in Table 3 is well done except that for divergent validity the choice of the divergent measures humor and attitude toward the brand is debatable. Conceptually, humor can be an essential part of a creative advertisement and therefore the two constructs are not independent. Also some of the items that are used to measure attitude toward the brand can also be included in the measure of creativity of advertisement. There is a further question regarding the reliabilities of Method 2 in the MTMM where single-item 10 point scales are employed (as different from multi-item Likert and Semantic Differential scales in method 1). Psychometrically, single item scales have been found to be less reliable than those based on multiple items (Nunnally 1967; Peter 1979, p. 16).

Evaluation of Haberland and Dacin paper on the third criterion that I mentioned at the outset led me to some disappointment. Even though the authors have developed a valid measure of creativity, they have not reported any empirical results obtained from a real life situation to test the effectiveness of this measure. Their claim that, "while creativity is currently measured by advertising professionals and brand managers, our measure focuses on viewers' judgements of the creativity of the advertisements", is an exaggeration in the absence of an evaluation of the effectiveness of this measure in a real life setting. It is hoped that the authors would be doing further research into the real life application of this measure of creativity and reporting results in the literature.

Sauer, Dickson and Lord Paper

Sauer, Dickson, and Lord's paper entitled, "A Multiphase Thought Elicitation Coding Scheme for Cognitive Response Analysis", has a well defined purpose and is based on a sound review of the existing literature. The main purpose of their paper is to improve upon an earlier coding scheme developed by Dickson and Sauer (1987). This improvement is accomplished by incorporating the suggestions of Brucks et al. (1988) with respect to the categorization of cognitive thoughts. The study of verbal protocols in marketing was pioneered by Wright (1973) who suggested three main categories for dividing verbal thoughts: support arguments, counterarguments and source derogation. Bettman and Park (1980) further refined the method of analysis and division of verbal protocols according to brand, advertisement etc. Cacioppo, Harkins and Petty (1981) divided verbal thoughts into three major categories: Target, Origin and Polarity. Brucks et al. (1988) added a fourth dimension i.e. Relevance to the three dimensions suggested by Cacioppo et al. (1988). Brucks et al. tested the application of their coding scheme to determine the cognitive structures of children's responses to television advertising.

In the current paper Sauer et al. seek validation of their scheme of coding verbal thoughts (toward the choice of a Sony Compact Disk player). These authors have done a good methodological analysis by classifying verbal responses into four categories: Type (Fishbein - Ajzen 1975, Unidimensional Tripartite theory), Target of Thoughts (Cacioppo, Harkins and Petty 1981), Self-Relevance of Thought (Markus 1980) and Polarity of Thoughts (Cacioppo, Harkins and Petty 1981). Tables 4, 5, 6 in their paper indicate the crosstabulations of the responses into various categories i.e. Target by Polarity, Target by Type, and Target by Self-Relevance. There is a good deal of similarity in the results obtained with those of Brucks et al. (1988). These results indicate associative links in the pattern of thinking in cognitive processing. Sauer et al. go a step further by aggregating response dimensions and applying the McKenzie et al. (1986) cognitive structure model to the experimental data. The results show that Type and Relevance are the predominant categories in their research data.

With respect to real life applications of this scheme, I would look forward to any results that might be reported by these authors in future. In my overall evaluation, this study was too methodologically driven and less space was devoted to conceptual explication to real life consumer and advertising issues.

Brill's Paper on Social Power

Brill's paper entitled, "Scales to Measure Social Power in a Consumer Context", attempts to construct a scale to measure the concept of social power. In this paper social power is defined as the degrees of "influence" and "resistance". Brill concludes, "It has been argued that power is an attributed outcome deriving from a social actor's dependency on another within a specific context or social situation.

Specifically, it is dependency not power, that has been posited to influence interpersonal behavior". A reading of the literature showed me that the topic of power has been extensively researched in the retailing literature in the context of inter and intra-channel relationships ((see Gaski (1984) for a review of the extant literature on channel power, conflict and contravailing power; El-Ansary and Stern (1972); Etgar 1978; Lusch, and Brown ((1982)). This literature in turn was based heavily on Social Psychological literature ((see Dahl (1957), where power has been defined as "the ability to evoke a change in another's behavior"; French and Raven (1959) identify five sources of power in terms of rewards, penalties, expertise, referent and identification; Thibaut and Kelley (1959) define power as, "an individual's power over another derives from the latter's being dependent upon him"))).

Even though Brill has made a good and well-intentioned effort to measure "the concept of social power in a consumer context", I am a bit disappointed. First, from a conceptual point of view not enough explanation has been provided on the significance of the concept of social power and how this concept is different from the existing concepts being utilized in consumer behavior literature. Only a few lines in the second paragraph in the introduction section provide some justification for a study of social power in consumer behavior where Brill States, "yet, research emphasizing power relationship between retailers and consumers, the buyers and sellers at the end of many marketing channel systems, is relatively uncommon. And, even when these power relationships are considered, the focus is typically on the retailer with little, if any, regard paid to power associated with consumers". It would have been more desirable to elaborate on the importance of social power in a variety of consumer settings and to develop a model and suggest some hypotheses in a given context. The concept of social power is not new in consumer behavior. Fishbein and Ajzen's (1975) extended model of behavioral intention is relevant here, especially the concepts of social norms and motivation to comply. The latter concept is similar to the idea of social resistance mentioned by Brill. There is a whole lot of related literature on reference group, personal values, attributions, consumer complaint behavior (CCB) from where information on social power and related concepts could have been drawn. Instead, Brill uses a lot of space in the paper on the discussion of the definitions of power as found in the psychological literature. Perhaps, Brill should have presented a conceptual model in consumer context. It would have been better for Brill to expand on the interdependent relationship between the retailer and the consumer. Even though Brill tries to develop a general concept of social power, he does not seem to rise above the retailing context. There seems to be some confusion whether the intended context of Brill's future application is retailer-consumer relationship or some other possibilities in consumer research e.g. consumer complaint behavior. This same conceptual flaw is evident in the discussion of the potential applications of the measure of social power in the

section of the paper on research applications. More elaborate, imaginative, treatment could have been given to potential applications.

Let us now evaluate this paper from a methodological point of view. For operational purposes the construct of "Consumer Power" (or social power) is broken down into four sub-scales: Social Influence (SI), Social Resistance (SR), Consumer Influence (CI), and Consumer Resistance (CR). Conceptually social resistance and consumer resistance are not the same, just as social resistance and consumer resistance are not the same. When we look at the "consumer power" and "consumer resistance" items given in the appendix to the paper, many of the items can also be found in a scale of consumer discontent (Lundstrom and Lamont 1976) or a scale of consumer alienation (Allison 1978). In his paper, Brill does not clarify how the pool of (39) items for his study was developed for these four subscales mentioned above. Brill, however, does mention the source of two other scales used for validity check i.e. Powerful Others Control (POC) and Internal Control (IC); for these 2 scales, 24 items were borrowed from Levenson (1974) who in turn based them on Rotter's (1966) Internal-External Locus of Central Construct. Alpha reliability coefficients for SI (.87), SR (.62), CI (.66), CR (.75) were reported. Relatively low reliabilities for SR and CI are justified by Brill on the ground that each scale has the desirable characteristic of having items with large standard deviations. This reasoning along with the conclusion that "these two scales would seem to offer high discriminatory power" is not very convincing. The analysis of convergent and discriminant validity following the display of Table 2 is very confusing. This analysis did not seem to rigorously follow the guidelines suggested by Campbell and Fiske (1959) by the multitrait-multimethod matrix (MMTM). A better presentation and discussion of the validity analysis would have been desirable.

In the discussion of limitations of the study, Brill seems to think that having a convenience sample is a serious limitation. This is not necessarily true. As Calder, Phillips and Tybout (1981) point out that if the purpose of a study is theory development and testing of hypotheses, convenience sample or a laboratory study is preferable to a representative sample or a field study (where the goal is generalizability). Since theory development is the main purpose of Brill's paper, convenience sample is not a serious limitation. It is the other conceptual and methodological weaknesses pointed out here that Brill should be concerned with.

Finally, as I mentioned earlier, in the area of giving concrete examples of potential applications of the scales developed, Brill's paper could have been more imaginative. I will now present one example of my own for a potential application of the concepts of consumer influence and consumer resistance in the area of consumer complaint behavior (CCB). The CCB literature shows that there are three main methods of expressing complaints: Voice, Private Party and Third Party (Singh 1988). The main antecedents CCB are: the intensity of dissatisfaction, attitude toward

complaining, expectancy-value of complaining, and power experience complaining. We could add one more antecedent to the CCB i.e. consumer influence - consumer resistance, i.e. how much leverage the consumer has over the retailer or the manufacturer in getting redress for the complaint. This is especially true for voicing and third party action. The resolution of consumer complaints could be a net result of the relative power of the two parties i.e. the seller and the consumer. Also, there seems to be some overlap between the items included in the consumer resistance construct developed by Brill and the attitude toward the act of complaining widely used in CCB literature (Richins 1983a, 1983b; Singh 1990). Perhaps, a judicious combination of items from the two scales could be very useful to the multidimensional conceptualization of the CCB.

CONCLUSION

I have discussed three papers on the three useful criteria: a) the conceptual soundness and significance of the construct being measured, b) methodological rigor in applying tests of reliability and validity, c) the presentation of empirical data to show some real life application of the constructs developed. All the three papers have made useful contribution to consumer research e.g. Haberland and Dacin in the area of creativity in advertising, Sauer et al. in developing a coding scheme for cognitive thoughts and Brill on social and consumer power. All the three papers were however deficient on the third criterion I laid out i.e. empirical data on some real life application. I hope that they would be doing so in future. I found Haberland and Dacin paper and Sauer et al. particularly sound conceptually and methodologically. I found Brill's paper a little weak conceptually and methodologically. It is hoped that these suggestions would be useful for researchers in the area.

The Development of a Measure to Assess Viewers' Judgments of the Creativity of an Advertisement: A Preliminary Study

Gabriele S. Haberland, University of Wisconsin-Madison

Peter A. Dacin, University of Wisconsin-Madison

ABSTRACT

Advertising professionals have traditionally placed a high value on creativity, yet recently some have begun to question the importance of creativity in advertising. This paper attempts to lay the foundations for the systematic evaluation of viewers' reaction to creative and less creative ads, by developing and testing a measure of viewers' judgments of the creativity of an advertisement. Our exploratory study shows this measure has good psychometric properties and the ability to classify ads a priori as more or less creative. Consequently, we feel that our measure could allow researchers to investigate responses to ads that differ in their level of creativity, and study the factors that contribute to the production of creative ads.

INTRODUCTION

For many advertising professionals creativity is the lifeblood of their profession. Advertising agencies have "creative departments," the advertising profession has coveted awards for creative advertising, and the advertising literature has traditionally stressed that good campaigns need to be creative (Bernstein 1974, Whittier 1955). Yet there are also critics who allege that the emphasis on advertising creativity is contributing to the demise of advertising. Trout and Ries (1989) argue for dethroning the "God of Creativity" to make way for more emphasis on positioning as the objective of good advertising, and other experts advocate emphasis on product benefits, not creativity, as hallmark of successful advertising campaigns (Hinderyckx 1991).

However, no reliable measure of advertising creativity exists and thus conjecture plagues the debate over the importance of advertising creativity. Currently advertising creativity is typically assessed by agreement among advertising professionals or brand managers. Furthermore, this assessment often occurs after the airing of a campaign when its success or lack thereof is known. As a result, the arguments of creativity advocates that campaigns which win creativity awards are by and large also highly successful (Fallon 1989, Kagan 1989) are weak, since creativity judgments are often not entirely independent of knowledge about success. More importantly, whether viewers also consider these advertisements to be creative never enters into these judgments. It is our belief, however, that in order to investigate the relationship between creativity and advertising effectiveness the viewer's judgments of creativity must be taken into account. Therefore, a measurement of advertising creativity from the viewer's perspective is necessary.

The focus on awards in the advertising industry also implies that an object is either creative or not. While this may be a useful perspective for award granting, we believe that it is more likely that

advertisements vary in degree of creativity. Current measures do not capture this continuum. Creativity adversaries often argue that not all effective ads win awards for creativity, yet this does not mean that effective ads are not creative. For example, Trout and Ries (1989) point to advertisements which, while highly successful in stimulating sales, received no creative acclaim. However, these ads may still be very creative, although not sufficiently creative to win awards.

Given that many of these problems stem from our inability to reliably and validly assess the creativity of advertisements, our objectives are two fold. First we want to address the problem of identifying creativity by developing a definition of creativity in advertising based on the literature on creativity. Second we want to undertake a preliminary operationalization of this definition resulting in a valid and reliable measure of creativity that reflects its underlying dimensions.

To this end, we begin with a review of the relevant literature in psychology and advertising, assessing existing perspectives on creativity. Then, we integrate these perspectives into a multi-dimensional definition of creativity that serves as a useful basis for identifying creative advertisements. Next, we undertake an initial assessment of reliability and validity of the measure and, finally, we report our findings.

LITERATURE REVIEW

Developing a measure of creativity requires a definition of the construct and specification of its domain (Churchill 1979). To do this, we begin with a review of extant approaches to creativity focusing on both the definitions and measures that have been used.

A noted feature of research on creativity is that there is a long history of disagreement about the preferred approach to understanding the construct (Amabile 1983). Three approaches are found in the literature. These are: (1) identifying traits of creative people, (2) identifying the processes necessary to bring about creativity and, to a much smaller degree (3) identifying characteristics of creative outcomes. We feel that none of these approaches alone is adequate to understand creativity. Rather, we believe that it is necessary to draw from all three approaches. To do this, we review the definitions of creativity in each of the three perspectives.

Barron (1955) represents an early approach to creativity. His focus was on identifying the personality traits that lead to creative responses among individuals. He categorized the responses of individuals to various problems as either creative or uncreative and then compared the personality traits of the two groups, noting any differences. The definition of creativity used by Barron to categorize responses consisted of two components—originality and

adaptiveness to reality. Originality referred to an "uncommonness" of a response in relation to responses of others. Adaptiveness to reality, occurred when an individual provides an objectively correct solution to a problem which permits such assessment, or when an individual provides an appropriate response based on consensus among experts. Mac Kinnon (1962) later added a third component—a creative output needs to be developed and elaborated, it has to be more than a one time original insight.

The second approach to creativity appears in a series of studies that attempt to identify stages of the creative process, and the factors that set this process apart from other processes (e.g., Newell, Shaw and Simon 1962). In this approach the definition of creativity is a special type of problem solving behavior that applies to situations that are complex and require novelty (i.e., could not be expected from previous information) and unconventionality (i.e., modification or rejection of previous solutions), and is characterized by the use of heuristics rather than algorithmic approaches. Therefore, according to this definition, creativity is not relevant in all facets of life.

Bruner (1962), takes a somewhat different view of creativity from the previous ones in that, to him, creativity is not a characteristic of an output or a process, but rather the reaction produced in the receiver of the output. He defines creativity as "an act that produces effective surprise." Bruner argues that one important aspect of surprise is unexpectedness that produces wonder or astonishment. Unexpectedness, in contrast to novelty and originality, is dependent on the situation and does not have to be rare, infrequent or bizarre. In addition, he argues that a second important aspect of effective surprise, is the "quality of obviousness." Creativity should produce a "shock of recognition, following which there is no longer astonishment"—the unexpected has to matter to be meaningful.

These approaches to creativity tend to incorporate definitions that focus on only one or two dimensions. However, authors who follow the third approach, attempting to identify characteristics of creative outcomes, use multi-dimensional conceptualizations of the construct. For example, in their definition Jackson and Messick (1965) identify four underlying dimensions: unusualness, appropriateness, transformation and condensation. Unusualness or novelty refers to uniqueness or infrequency against a norm. Appropriateness can be either external (referring to the degree to which a product fits the demands of the situation), or internal (the degree to which an output is consistent in its parts). Thus, appropriateness requires an evaluation of fit in the context for which the output was developed. These two dimensions are common to most conceptualizations of creativity.

Jackson and Messick's two other dimensions, however, are more abstract, harder to grasp, and rarely appear in other definitions of creativity. Transformation denotes the degree to which an output has the potential to force someone to view reality in a new way. It must be judged relative to the strength and

nature of the constraints that are transcended. Condensation refers to the degree, to which a product achieves simplicity and summarizes the essence of a situation. A condensed outcome conveys a lot of meaning, provides a richness of interpretation and is appropriate for many aspects or situations.

Similar to Bruner, Jackson and Messick hypothesize that each of these dimensions evokes a different response in the listener or viewer of creative output. Unusualness evokes surprise, which is highest upon exposure and diminishes as the listener or viewer assimilates the object or event into their experience. Appropriateness leads to satisfaction—a recognition that the output is complete or sufficient. The presence of transformation stimulates the listener or viewer to alter their conventional way of perceiving or thinking about the world. Condensation leads the listener or viewer to deliberately, carefully and repeatedly examine the output.

Despite the existence of multi-dimensional conceptualizations of creativity, many researchers continue to operationalize the construct as a broad overall judgment by simply asking individuals whether they think something is creative (e.g., Amabile 1983). While these measures sometimes show high inter-rater reliability, they add little to our understanding of the construct. We believe that these broad judgments can not capture all the dimensions of the construct. The high reliabilities may simply reflect respondents making creativity judgements based only on the originality or novelty dimension. Consequently, individuals who adopt this perspective for producing creative output will find themselves working on a hit or miss basis. This is especially true for advertisers who, when attempting to produce creative campaigns, would benefit from an understanding of how all the underlying dimensions of creativity contribute to the effectiveness of an advertisement. Furthermore, since advertising effectiveness depends on viewers' judgments, a measurement of advertising creativity from the viewer's perspective is necessary.

CREATIVITY IN ADVERTISING

Just as a poem, painting or theory is an output that can be judged on creativity, these judgments can also be made about advertisements. Thus, specifying an advertisement to be a creative outcome allows us to use the previous literature base to develop a multi-dimensional definition and measure of creativity in advertising.

Based on our previous literature review, we conceptualize the creativity of an advertisement as the extent to which it is: (1) original and unexpected (2) appropriate and meaningful in an advertising context (3) requires the viewer/listener to (re)formulate or modify their attitude towards an advertised product or service and (4) is condensed, that is, it is simple, yet conveys a lot of meaning and offers a richness of interpretation.

Similar to Bruner (1962), and Jackson and Messick (1965) we also assume that a creative ad evokes several responses in the viewer. Specifically: unexpectedness leads to surprise: appropriateness and

meaningfulness lead to a satisfaction with the message; reformulation leads to examination of the previous way of thinking about a product or a product class; and condensation leads to deeper thinking about the ad and to the formation of associations based on ad content.

Furthermore, this approach leads us to believe that it is possible to measure the creativity of an output at two levels. The first level involves a judgment of how unusual, appropriate and condensed an output is and to what degree it embodies transformations. The second level assesses the presence of a corresponding affective response in the listener or viewer. Therefore, we believe that it is possible to operationalize all dimensions of creativity at two levels: (1) the cognitive or evaluative level, which calls for direct assessment of the presence of the criteria (i.e., by asking a subject for their judgment of the originality of an advertisement) and (2) the affective level which calls for an assessment of a subject's affective reactions (e.g., surprise) upon seeing the ad.

The first dimension is common to most existing definitions of creativity. While this is generally assessed against a norm established by the researcher (e.g., infrequency relative to a sample or population), this notion is irrelevant in the advertising context. Rather, we believe that each viewer, based on their lifetime experience with advertising, has certain expectations for advertisements. To the degree that an advertisement deviates from this expectation, the viewer is more likely to call an ad original or novel. However, as we previously argued, originality alone does not constitute creativity.

The second dimension, appropriateness/meaningfulness, is also important. In an advertising context, this definition implies that although a viewer may judge an ad to be unexpected, original, or "out of the ordinary," the advertisement is not necessarily creative unless it also conveys some meaning about the advertised product.

The third dimension, reformulation, is based on the existing dimensions of transformation (Jackson and Messick 1965), and unconventionality (Newell, Shaw, and Simon 1962). It represents the necessity of the viewer/listener to (re)formulate or modify their attitude towards an advertised product or service. In an advertising context, this dimension is difficult to isolate. It requires not just the form of an ad to be novel, but also its content. It also requires that the information provided is meaningful and provides some new or contrasting information the consumer did not know or did not consider.

The fourth dimension—condensation—is one previously proposed by Jackson and Messick (1965) only. However, it is relevant for an advertising context in which advertisers generally strive for a simple message that is rich in the information conveyed.

DEVELOPING THE MEASURE AND METHOD

In developing the measure, we first generated a set of items based on the four dimensions of our definition. We used several sources to generate these items including the literature reviewed above, textbooks and, journal articles in advertising which often contained colorful statements by advertising practitioners. From the large pool of items that initially resulted, we selected 10 – 12 items for each dimension that in our view best captured the dimension.

Next, we developed an initial questionnaire. We operationalized items as either Likert or Semantic Differential scale items in order to allow for variety in an otherwise lengthy questionnaire. We worded some scale items positively and some negatively to prevent subjects from rapidly marking the same box for all items. Furthermore, items were randomly ordered to mix dimensions. We then pretested this questionnaire for understanding and made some minor changes as a result. The resulting items for each dimension appear in Table 1.

In order to assess the validity of the measure with a multitrait-multimethod (MTMM) approach (Campbell and Fiske 1959), we needed a second measure of creativity, using a maximally different method to assess the construct. In practice, however, the use of very different methods is difficult. For example, in this study, since all measures needed to be collected by means of a questionnaire both our measure and the alternative measure of creativity were self-report measures, thus, limiting the difference between methods. To introduce some difference, however, we decided that our alternative measure would ask subjects to directly judge the creativity of the ad on a 10 point scale. This seemed sufficiently different from our indirect "dimensional" approach, in which the word creative was never explicitly mentioned. The direct judgment also corresponds to the widely used practice of assessing creativity by independently asking experts for their judgment without providing them with explicit criteria to use.

Use of the MTMM approach also requires the measurement of at least one other construct, which should be independent from creativity, but assessed using similar methods. We decided on two constructs—how humorous the advertisement was, and attitude towards the advertised brand.

We measured humor in two ways. The first measure consisted of two Likert (the advertising makes you smile, the advertising is amusing) and two Semantic Differential Scale Items (dry/entertaining, funny/serious). The second measure consisted of a 10 point scale asking respondents to judge how humorous the ad was. We recognize that the choice of humor does not meet the ideal criteria for the MTMM, since humor and creativity of an ad are not completely unrelated, very creative ads are often also amusing. However the reverse need not be the case.

We also chose to measure attitude towards the brand because it is a construct for which generally accepted measures exist in the literature. Several researchers have used the same four item Semantic

TABLE 1
Initial Likert and Semantic Differential Items to Assess Creativity

Item No.	Item Content	Dimension
1.	This advertisement does tell you why you should buy the product.	Meaningfulness
2.	This advertisement is very similar to other ads for this type of product.	Originality
3.	This advertisement does <i>not</i> change your view about the product.	Reformulation
4.	You hardly know what is advertised.	Meaningfulness
5.	This advertisement makes you think how the product may be useful for you.	Condensation
6.	The advertising message is <i>not</i> easy to remember.	Condensation
7.	The advertising is unique.	Originality
8.	I never thought about the product in the way the advertisement presents it.	Reformulation
9.	You get a good idea what the product is like.	Meaningfulness
10.	There is so much in this ad that you want to see it again.	Condensation
11.	I <i>don't</i> see the point of this advertisement.	Meaningfulness
12.	The ad uses a simple but powerful way to get the message across.	Condensation
13.	This advertisement stands out.	Originality
14.	This advertisement was meaningful for me.	Meaningfulness
15.	This advertisement showed me the product has certain advantages I did not know before.	Reformulation
16.	This advertisement is really "out of the ordinary".	Originality
17.	This advertisement makes you want to buy the product.	Reformulation
18.	This advertisement makes you see the product in a new light.	Reformulation
19.	This advertisement brings a lot of thoughts to my mind.	Condensation
20.	The information given is difficult to summarize.	Condensation
21.	The advertisement is not at all imaginative.	Originality
22.	I never thought of this aspect of the brand before.	Reformulation
23.	I was astonished when I first saw this advertisement.	Originality
24.	This advertisement is intriguing.	Originality
25.	This advertisement does not have anything to do with me or my needs.	Meaningfulness
26.	This advertisement knocks your socks off.	Originality
27.	interesting/uninteresting	Condensation
28.	commonplace/surprising	Originality
29.	personal/impersonal	Meaningfulness
30.	boring/stimulating	Reformulation
31.	succinct/diffuse	Condensation
32.	haphazard/thoughtful	Condensation
33.	novel/conventional	Originality
34.	satisfying/unsatisfying	Meaningfulness
35.	involving/uninvolving	Reformulation
36.	shallow/profound	Condensation
37.	unfamiliar/familiar	Originality
38.	useful/useless	Meaningfulness
39.	changes your view/ does not change your view	Reformulation
40.	expected/unexpected	Reformulation
41.	good/bad	Meaningfulness
42.	routine/imaginative	Originality

Differential Scale (good/bad, poor quality/high quality, unpleasant/pleasant and like very much/dislike very much) to assess respondents' attitudes towards the advertised brand. The reported reliabilities (coefficient alpha) are generally high, 0.88 Mitchell and Olson (1981), 0.91 Edell and Staelin (1983), 0.92 Mitchell (1986). Again, brand attitude is not entirely independent of creativity, since a creative ad may induce people to view a product more favorably. However, attitude has many determinants

besides exposure to one advertisement (e.g., product experience).

Since it is more difficult to distinguish among related than unrelated constructs, one advantage of using two constructs related but conceptually independent from creativity is that this allows for a stricter test of construct validity. We pretested the questionnaire with the measures of creativity, humor and brand attitudes. No changes were necessary.

DATA COLLECTION AND ANALYSIS

We collected data in the main lobby of a student union at a large Midwestern university. Most respondents were students. Respondents were recruited at random and asked to watch a TV commercial on a video monitor and then fill out a questionnaire about this commercial. In all, we used 38 different TV commercials, recorded either from network broadcasts or agency tapes. We selected ads that we believed reflected a wide spectrum of creativity, ranging from "slide type" ads for a special sale at a local store to a national beer campaign that won a CLIO award. Respondents watched one commercial and then filled out the questionnaire.

We needed a minimum of 100 subjects since an item analysis requires 5 to 10 times as many subjects as items (Peter 1979). In total, 102 subjects completed the study.

Our data analysis had three objectives. First, it would assess the reliability of our measure. Second, it would suggest how to purify the measure through deletion of items with poor psychometric properties. Third, it would also provide a preliminary assessment of the validity of the proposed measure.

Assessing Reliability and Purifying the Measure:

As a first step, we calculated reliabilities for each of the four dimensions. This resulted in the following coefficient alphas: 0.91 for originality, 0.80 for meaningfulness, 0.79 for reformulation, and 0.69 for condensation. The overall reliability of the measure was 0.93 based on a formula for the reliability of a linear combination of measures (Nunnally 1978). This is somewhat higher than any of the dimensional measures, since the overall measure is also longer than any dimensional measure and errors are more likely to cancel each other.

From a practical standpoint, however, a 42 item measure of a construct is long and cumbersome. The length of this questionnaire could be detrimental to the purpose of any future study of creativity. Faced with many questions about one short advertisement, subjects may try to make consistent statements about the ad rather than actually evaluate it. We, therefore, decided to attempt to purify the measure and shorten it without sacrificing its reliability.

A plot of the correlation of items with their corresponding total dimension scores did not reveal any large gaps that indicate cut-off points beyond which we could eliminate items. Consequently, the choice of how many items to eliminate would be somewhat arbitrary. Since the reliability of the overall measure was very high, we felt that we could eliminate several of the least reliable items and maintain a high degree of reliability. Therefore, we decided to halve the number of items, retaining five items per dimension. One reason for this was that the equal number of items would allow for an equal influence (i.e., equal weight) of each dimension on the total score.

Elimination of items based strictly on statistical analysis (i.e., low reliabilities), however, may be inappropriate. There is a danger that this could

alter the domain of the construct being sampled. For example, this might result in the elimination of items that capture any different aspects of a dimension, and thus a scale of items that are identical to one another except for minor differences in wording. To ascertain whether this bias was present we carefully examined each item before deciding on its elimination.

The biggest difference in each dimension was among items designed to assess respondents' cognitive evaluation and those designed to assess their affective reaction. For example in the case of the originality dimension, respondents evaluated whether the ad was unique (cognitive evaluation) and whether it had made them surprised or astonished (affective reaction). Therefore, we wanted to maintain both cognitive and affective items for each dimension. Fortunately, the items that remained after we eliminated other items on a statistical basis allowed for this.

In several cases an inspection of the items made it clear why they had fared relatively poorly in the statistical analysis. For example, one item "familiar/unfamiliar", appeared to be ambiguous since some subjects seemed to interpret it to refer to uniqueness (originality) while others used it to indicate that they had seen the ad had previously. In other cases the wording of items seemed to be too strong to be meaningful in the advertising context (e.g., "the ad that knocks your socks off"). Consequently, we felt comfortable eliminating those items suggested by the statistical analysis.

The purified 20-item measure had a reliability of 0.94, with the following coefficient alphas for the four dimensions: 0.90 originality, 0.81 meaningfulness, 0.80 reformulation and 0.74 for condensation. No deterioration of reliabilities occurred despite the extensive shortening of the measure.

After purification, we factor analyzed the data using principal components as suggested by Churchill (1979). Factor analysis was appropriate because the three criteria of appropriateness for its use as listed by Stewart (1981) were met. First, the correlation matrix showed that the correlations among most variables were at least moderately high. Second, the plot of eigenvalues of the correlation matrix did have two breaks after the first and the fourth eigen value. Third, all communality estimates (four-factor solution) were at least moderately high (at least above 0.49). The results, therefore, met all of Stewart's criteria.

In deciding how many factors adequately captured the covariation in the data, we used the roots criterion. This calls for the extraction of all factors with eigenvalues larger than 1. In the present case, this resulted in a four-factor solution supporting our a priori hypothesis of four underlying dimensions. We then rotated this solution to facilitate interpretation of the factor loadings. We performed varimax, quartimax and equamax rotations and compared their solutions. All three techniques led to similar conclusions. Consequently, for the sake of efficiency we base the following discussion on the varimax rotation only. The result of this analysis is shown in Table 2.

TABLE 2
Results of Factor Analysis (Varimax Rotation)

Item No.	Item Content (a priori Dimension)*	Factor Loadings			
		F ₁	F ₂	F ₃	F ₄
7.	The advertisement is unique (O)**	<u>.82</u>	.21	.01	.23

*Key to dimensions: O=Originality, M=Meaningfulness, R=Reformulation, C=Condensation
** These items were retained in the final measure of creativity

Table 2 suggests that the four factors obtained in the analysis corresponded to our a priori hypothesized dimensions. Five items had high loadings on the first factor and all five belonged to the dimension originality. Therefore, factor 1 represented originality. On each of the other factors, we found at least four items to load much higher than the remaining items. Again, in each case these four items corresponded to our a priori specified dimensions. All four items for factor 2 belonged to meaningfulness, all four items for factor 3 belonged to condensation, all four items for factor 4 belonged to reformulation. The factors therefore represented these dimensions well.

Among the remaining items, items 10 and 35 correlated higher with originality than with their intended dimension and item 14 correlated moderately with several dimensions. After considerable discussion, we decided to eliminate these items.

While most of the remaining items loaded highly only on one factor, three items did not perform well in the rotation. Items 41 and 27 loaded highly on both the dimensions they were intended to measure as well as originality, and item 17 loaded high on both reformulation and meaningfulness. We felt that one reason for this was that these items assess a more

affective reaction to the ad and, therefore, unlike the more cognitive based items, tended to be related to more than one dimension. However, since all three items are theoretically important aspects of our construct and would lead to an underrepresentation of an affective component if we eliminated them, we retained these items in our measure.

The purified 16 item measure had an overall reliability of 0.92 with the following coefficient alpha's for each dimension: 0.87 for originality, 0.77 for meaningfulness, 0.77 for reformulation, and 0.66 for condensation. Since this is a preliminary attempt at developing this measure, one must keep in mind that these reliability figures are at this point no more than first estimates. Reliability can only be established over several different samples and occasions. Any one occasion contains too much measurement artifact to warrant a final conclusion. In this study the problem is even more severe, since we have significantly shortened the questionnaire items can now be said to appear in a different context. This may affect reliability scores.

TABLE 3
Multi-Trait Multi-Method Matrix For Measure of Creativity

		Method 1 (Multi-Item)			Method 2 (Single-Item)		
		Creativity	Brand Attitude	Humor	Creativity	Brand Attitude	Humor
Method 1							
Multi-Item	Creativity	(.922)					
Likert & Semantic Differential	Brand Attitude	.370	(.881)				
	Humor	.618	.206	(.804)			
Method 2							
Single-Item	Creativity	.794	<u>.193</u>	<u>.620</u>			
10 point Scale	Brand Attitude	<u>.406</u>	.652	<u>.255</u>	.308		
	Humor	<u>.463</u>	<u>.167</u>	.778	.519	.221	

Note: Reliabilities (Coefficient Alpha) are parenthesized. Entries in the validity diagonal are bolded. Entries in the heterotrait-monomethod triangles are italicized. Entries in the heterotrait-heteromethod triangles are underlined.

Assessing the Validity of the Measure:

We assessed two aspects of construct validity: convergent validity and discriminant validity. Since no established theories exist with respect to creativity in advertising, we could not assess nomological validity.

We based our assessment of convergent and discriminant validity on the multitrait-multimethod matrix method (Campbell and Fiske 1959). The matrix, shown in Table 3, consists of the intercorrelations among each of several traits measured by each of several methods.

Evidence of the convergent validity occurs in the entries in the validity diagonal which represent the correlations between different measures of the same trait. The entries of 0.794 for the creativity measures, 0.652 for the attitude measures and 0.778 for the humor measures are fairly high and indicate that for each construct the two different methods seem to measure the same thing. This suggests the presence of convergent validity for the measures of each construct.

A closer analysis shows a very high correlation (0.862) between the score for the originality dimension and the single-item alternative measure of creativity. Furthermore, this correlation is higher than all other correlations between dimension scores and the one-item measure, as well as between the one-item measure and the overall multi-item measure (0.794). This suggests, as we previously suspected, that when subjects are asked to directly judge the creativity of an ad, they rely more heavily on originality than any other of the hypothesized dimensions. To the extent that the other dimensions are equally important aspects of creativity, the multi-item measure is then a more valid measure of the construct.

We assessed discriminant validity using the three criteria suggested by Campbell and Fiske (1959). First, we examined whether the entries in the validity diagonal were higher than the correlations that lay in the same column and row of the heterotrait-heteromethod triangles. This is necessary to demonstrate that the two creativity measures have more in common with one another than with other measures which neither assess the same trait, nor use the same method. Our data met this requirement even though the heterotrait-heteromethod triangle correlations were fairly high. These high correlations suggested that creativity, humor and attitude toward the ad may not be as independent as ideally desired for use of the MTMM matrix. This is particularly true of the measure of humor.

Second, we investigated whether the validity coefficients (entries in the validity diagonal) were higher than the correlations in the heterotrait-monomethod triangles. This would indicate that alternative measures of the same construct are more closely related with each other than with measures of other constructs employing a similar method (scale). Again our data met this criterion even though correlations between creativity and other constructs are high.

Third, we examined whether the same pattern of correlations existed in the heterotrait-monomethod and heterotrait-heteromethod triangles. This would tell us whether creativity measured by either method has the same relation to other constructs. In general the data meet this criterion. When we ranked the correlations in each triangle by size, the correlations between creativity and humor were always the largest. The second largest correlations generally occurred between creativity and brand attitude, with one

exception. In the upper right heterotrait-heteromethod triangle, the correlation between humor and brand attitude was slightly higher than the correlation between creativity and brand attitude.

CONCLUSION

Developing a definition of an abstract construct such as creativity, is an important contribution to the debate among advertising professionals about the importance of developing advertisements that are creative (e.g. Trout and Ries 1989, Beaver 1989). As in many controversies, a part of the differences in opinion may be attributable to a different understanding of the focal concept. Indeed one of the proponents of creativity (Beaver 1989) has suggested that the problem is not creativity per se, but the narrow view of creativity held by some professionals who consider only the executional elements of an ad as creative, rather than evaluating the advertisement holistically.

To move this debate from the realm of polemics to scientific investigation, it is necessary to develop a clear understanding and a valid measurement of the creativity of an advertisement. The definition developed for this study, identifies dimensions that we believe are necessary to evaluate creativity. Consequently, our approach may provide additional guidance to advertisers who strive to develop creative ads.

Based on this definition we developed a measure of the creativity of an advertisement that allows us to tap creativity assessments of more than one constituent group. We feel that much of the controversy around the importance of creativity of advertisements may stem from differences in perspectives employed. While creativity is currently measured by advertising professionals or brand managers, our measure focuses on viewers' judgments of the creativity of advertisements. Assessments by advertising professionals may often be overly focused on the novelty of executional elements, for which they see themselves as responsible. Since a viewer's reaction to creative ads is at the heart of the debate among professionals, it seems that the viewer's judgments of creativity should be the most relevant assessment of advertising creativity. As such, our measure may be helpful for identifying whether viewers will also judge a campaign to be creative.

Data we collected showed our measure to be both reliable and valid. Furthermore, we were able to retain good psychometric properties for the measure even with a substantially shortened version. While the long form of the measure may be useful for theoretical/academic based research, we feel that at a practical level, the short form of the measure would be easier to administer and would be just as applicable in the selection of advertising campaigns.

Our analysis also showed that our measure may be a more valid way of assessing creativity than directly asking viewers to judge creativity. Direct single-item measures of creativity appear to rely mostly on one dimension of creativity: originality/novelty. In our view originality and creativity are not synonymous. As the literature and

our analysis demonstrated, originality is only one aspect of creativity, albeit an important one, and our multi-dimensional measure seemed to capture a number of other relevant aspects of creativity.

While our study provided some good initial results, additional studies are required to confirm the measure's psychometric properties. For example, our conclusions are limited since all our measures of constructs employed paper and pencil methods, rather than highly different methods such as ideally required by the MTMM approach. Furthermore, we based our selection of items for the shortened measure on data from only one sample of respondent. Consequently, it is important to investigate whether these findings replicate across other samples.

In sum, the ability to measure advertising creativity is important since it enables advertisers to investigate viewer's reactions (e.g. memory, attitude towards ad, brand, and purchase) to ads which differ in their level of creativity. In turn, this allows for an assessment of the importance of creativity in advertising campaigns. For too long creativity has been seen as a concept that everybody intuitively understands, yet one which defies clear definition. We attempted to shed some light on the construct by undertaking a preliminary step toward developing a definition and measure of the creativity of an advertisement. We hope this will encourage others to follow.

A Multiphase Thought Elicitation Coding Scheme for Cognitive Response Analysis

Paul L. Sauer, Canisius College
Peter R. Dickson, Ohio State University
Kenneth R. Lord, University at Buffalo (SUNY)

This paper proposes a four-phase thought elicitation coding scheme for use in cognitive response analysis as frequently used in the investigation of cognitive structure. The coding scheme, derived from recent multidimensional coding developments in the cognitive response literature, simplifies the dimensionality of past work to yield codes which can be aggregated to yield complex indicators of cognitive structure constructs. Comparative analysis across dimensions reveals associative links in the pattern of thinking during cognitive processing. Codes are applied to experimental data to illustrate an application to an extant structural equation model of cognitive structure.

INTRODUCTION

The richness of the full content of a person's thoughts while processing product information is never completely captured in measures employed in experimental design. The more structured the measures, the more directed the responses and the greater the chance for content bias. In some designs, therefore, it may be preferable to use less structured measures to capture as much of the content of thoughts as possible, then to refine the measure by detailed coding of thoughts. Of course, less structured measures such as thought elicitation tasks are not without the potential for bias due to factors such as task- rather than stimulus-based elaboration or demand effects; nevertheless they would seem to be preferable in situations requiring detailed cognitive structure or process information.

A difficulty in developing coding schemes is that a large number of categories may be required. The greater the number of possible coding categories, the lower the inter-judge reliability in coding thoughts is likely to be. Multi-phase coding schemes designed to capture multiple dimensions, and thus eliminate the need to use a large number of categories within a single dimension, are beginning to appear in both the cognitive process (e.g., Brucks, Armstrong and Goldberg 1988; Dickson and Sauer 1987) and choice protocol (Park, Iyer and Smith 1989) literatures. The purpose of this research is to suggest a coding scheme for cognitive processes based on the dimensions proposed by Dickson and Sauer (1987) and developed further by Brucks, et. al. (1988).

The cognitive process approach involves collecting cognitive responses in a thought elicitation task. Both Brucks et al. (1988) and Dickson and Sauer (1987) have proposed separate sets of codes for various dimensions of the cognitive process including: counter and support arguments in cognitive responses (Wright 1973; Batra and Ray 1983); cognitive structure (Fishbein and Ajzen 1975; Ostrom 1969); target, origin and polarity of thoughts (Cacioppo, Harkins and Petty 1981); and, relevance of

thoughts (Brucks et al. 1988). We refine the coding scheme of Dickson and Sauer (1987) to conform more closely to that proposed by Brucks et al. (1988) and demonstrate how it can be applied to a cognitive process model of the form proposed by McKenzie, Lutz and Belch (1986) to capture ad versus brand effects.

TARGET AND CODING

A thought elicitation is defined here as any open-ended, unconstrained (but potentially directed) response task in which subjects record thoughts generated while processing treatment information. Thought elicitations are frequently used in marketing to capture cognitive responses to treatment variables such as advertisements in cognitive process analysis.

A distinction should also be made with respect to the timing of elicited thoughts. If responses are recorded *during* a subject's exposure to treatment in thought elicitation tasks, the task is *concurrent*. If responses are recorded *after* the treatment, the task is *retrospective* (Ericsson and Simon 1984).

Two aspects of experimental designs using thought elicitations include the targeting of thoughts and the coding of the thoughts elicited. An undirected task may require subjects to list all thoughts generated at the time of exposure to a treatment stimulus, without reference to a specific focus or "target", leaving the researcher with the task of categorizing thought targets. A thorough coding scheme when applied to thoughts elicited in this way should reveal any such targeting of thoughts. Alternatively, a target, such as the brand being advertised, may be designated by the researcher as a specific focus of thinking for each subject prior to the thought elicitation task.

The target of the thought elicitation is an important component of the wording of thought elicitation task instructions to subjects. The target may influence both the net valences and strength of responses with respect to various targets such as brands, products and advertisements. Little is known about the effects of manipulating the target in thought elicitation tasks, as more attention has been paid in the past to developing elicitation coding schemes than to manipulation of targets in task instructions.

Coding schemes applied to elicited thoughts represent thoughts as measures of cognitive responses which have been shown to influence the cognitive structure of subjects (McKenzie, Lutz and Belch 1986). As such, their usefulness is constrained by the extent to which they can, in a reasonably comprehensive and accurate manner, reveal the relevant dimensions underlying cognitive structure. Criticism has been made of the possible confounding when valence is a primary coding criterion (Droge 1989). A similar

argument may be made in situations where dimensionality is not explicitly captured in the coding scheme. The McKenzie, Lutz and Belch (1986) study, for example, used the simple counter and support argument coding system introduced by Wright (1973). Batra and Ray (1983; 1986) improved this scheme by expanding the number of categories used by judges to code thoughts. Perhaps the most extensive single-dimension coding scheme has been developed by Bettman and Park (1980) for use in choice protocols. A problem with the Bettman and Park scheme is that the judging task may be difficult to apply because of the large number of codes in only one dimension. Park, Iyer and Smith (1989) deal with this in choice modeling by proposing a multi-dimensional coding scheme. Similar multi-dimensional coding schemes are being developed which apply to issues unique to the study of cognitive processes (e.g., Brucks et al. 1988; Chattopadhyay and Alba 1988; Dickson and Sauer 1987; Hastak and Olson 1989; Johnson 1989; Keller 1991). The use of multi-dimensional or multi-phase formats helps to improve judging accuracy and increase inter-judge reliability.

Development of multi-dimensional cognitive response or thought elicitation codes often flows from the theoretical purpose of the research being conducted. Ideally each dimension should exclusively represent a unitary, unambiguous construct free from any potential confounds with concepts tapped by other dimensions (i.e., a lowest common denominator) and should not include codes which overlap codes in other dimensions. Such overlap may only increase confusion in judging and reduce inter-judge reliability.

In cognitive response research, dimensions which have been used or proposed include focus or target, valence or polarity, level of abstraction, origin, saliency, emotionality, and relevance. Keller (1991) proposes and Chattopadhyay and Alba (1988) specify the level of abstraction as including four codes for classification: (1) factual details; (2) single-fact interpretations; (3) abstractions; and (4) global abstractions. Chattopadhyay and Alba (1989) find that their four-code scheme captures variation in dependent measures which the simpler counter-support argument scheme of Wright (1973) does not. More categories of codes will obviously capture a greater and greater amount of variance. Parsimony considerations, however, dictate that reason be used to limit the number of categories. The most extensive schemes for coding cognitive responses in the form of thought elicitation for cognitive process analysis are offered by Brucks et al. (1988) and Dickson and Sauer (1987).

Cacioppo, et. al. (1981) suggest three dimensions to capture cognitive responses - polarity, target, and origin. Brucks et al. (1988) further develop this by adding relevance (to the product class) as a screening code designed to eliminate non-product directed thoughts which add to unexplained variance. In the application of their codes, Brucks et al. (1989) elect to aggregate coded responses into fewer categories in performing analysis. The ability to perform such an aggregation is a desirable feature of a

well-developed baseline coding scheme. Brucks et al.'s (1988) categories and subcategories are shown in Table 1. Brucks et al. (1988) apply their coding scheme to a model of children's uses of cognitive defenses. In this application, high levels of inter-judge reliability are achieved, ranging from 77% for the target group to 95% for the relevance group.

While this coding scheme is superior to previous attempts, it does not achieve a lowest common denominator of dimensionality. This is obvious with respect to two sets of codes. First, both beliefs and feelings are aggregated into one code in the target dimension for product, product class, and advertisement. Second, references to self are contained in the general category for target when a separate dimension for self may be prove useful. Such coding does not harm the outcome of the Brucks et al. (1988) study because aggregation across codes is used to form coded categories for analysis.

An alternative coding scheme proposed by Dickson and Sauer (1987) develops dimensions from cognitive theories, thereby attempting to reveal not only constructs or targets, but also links between these constructs. These links may be captured, it is argued, in the organizational thoughts expressed in the elicitation. A coding scheme sensitive to these organizational thoughts is needed to measure them. Three theories are used in developing this scheme: (1) the theory-based tripartite coding scheme (Ostrom 1969); (2) the attitude theory of Fishbein and Ajzen (1975) expressed as a means-end model of attitude (Rosenberg 1956; McGuire 1969); and, (3) involvement/centrality theory of self (Markus 1980; Rogers, Kuiper and Kirker 1976). The resulting coding scheme is shown in Table 2.

The most striking difference in this coding scheme compared to other schemes is found in the codes for phase 3 where links between single entities such as products and benefits are assigned a unique set of codes. Nevertheless this may be counterproductive as it results in duplication of categories across codes in different phases and therefore makes meaningful aggregation of the type employed by Brucks, et. al. (1988), Keller (1991) and others difficult to accomplish. Another problem is that in phase 1 the lowest common denominator principle is not applied. This is why attribute and affective reaction, for example, are duplicated for each of product, brand, and advertisement. Similarly, product, brand and ad are duplicated in phases 1 and 2. This duplication stems from the motivation to achieve a set of codes which derive directly from existing theory. While it is important to be sensitive to theory in developing codes, it may be counterproductive to allow theory to dictate codes for a single phase.

As long as all dimensions incorporated in a theory are captured in a series of coding schemes which apply the principle of lowest common denominator to each base dimension, the theory can be tested using responses aggregated across appropriate codes.

TABLE 1
Brucks et al.(1988) Cognitive Response Coding Scheme

1. Relevance
 - a. Relevant: Connected to ad or product class
 - b. Irrelevant: Not connected to product or ad
 - c. Monitoring: Product/ad not appropriate for self
2. Target
 - a. Product: Belief and feelings
 - b. Product Class: Belief and feelings
 - c. Advertisement: Beliefs and Feelings
 - d. Ad Communicators: Thoughts about actors or voices
 - e. Product/ad combo: Target not distinguishable
 - f. Self: Thoughts about self
 - g. Other people: Thoughts about
 - g. Advertising in General: Thoughts
 - h. Other: Not classified above
3. Origin
 - a. Message-oriented: No Prior Knowledge
 - b. Modified message-oriented: Ad memory + prior knowledge
 - c. Recipient-generated cognitive: prior knowledge
 - d. Recipient-generated emotional: express affect
4. Polarity
 - a. Positive
 - b. Negative
 - c. Neutral

A TEST OF THE DICKSON-SAUER CODING SCHEME

Brucks et al. (1988) have successfully applied their coding scheme to thought elicitation in a cognitive response study. No similar attempt was made to apply the Dickson-Sauer coding scheme. To evaluate the Dickson-Sauer scheme we asked two judges to code thoughts elicited during an experiment involving exposure to an advertisement. In the experiment approximately 90 students enrolled in undergraduate and graduate (master level) marketing courses volunteered as subjects. Ad exposure involved projecting a slide image onto a large screen at the front of the room as well as placing a black and white copy of the ad in the task booklets. The ad in the booklets enabled subjects to read all of the ad message clearly, while the projected ad was designed to create the overall copy effect desired by the ad creator. After exposure to the ad subjects were instructed to write down in the booklets provided all thoughts they had while reading it.

Two independent judges separately coded the thought elicitation responses using the codes in Table 2. Response content and volume revealed conscientious and in-depth responses by subjects. The level of inter-judge agreement, however, was extremely low (less than 40%). This occurred in spite of the fact that the judging task was subdivided into three phases to simplify it. Each phase with subdivisions had been intended to provide judges with a mutually exclusive and exhaustive set of

subdimension categories within each primary dimension. Such was not the case.

A comparative analysis of thought unit by thought unit coding revealed definitional ambiguity with a high lack of non-exhaustiveness, particularly along the second dimension of involvement/centrality. Thought unit divisions were determined by one judge and confirmed by the other. Each thought unit contained one and only one item of thought or information. It usually was a sentence or a part of a sentence linked to another part by a conjunction, a comma, or a semicolon. Thus inter-judge correlation should not be affected by double content thought units. The Dickson-Sauer coding scheme was not considered for further testing because of the confounding nature of the codes. To attempt to apply a coding scheme with such a low level of inter-judge reliability to a model of construct relationships, such as an attitude model, ignores the basic issue of measurement quality. In this case it would be misleading to apply measures to a model and to report model results.

REVISED CODING SCHEME

Revised coding categories were developed in an attempt to ensure mutually exclusive and exhaustive subdivisions within lowest common denominator dimensions, while still attending to the theoretical richness intended. The resulting phases of coding with subdimension categories are shown in Table 3. This coding scheme eliminates confounding in the Dickson-Sauer codes while remaining attentive to the

TABLE 2
Dickson-Sauer Three Phase Coding Scheme

- Phase 1: Tripartite Theory
1. Product
 - a. Attribute descriptions
 - b. Belief statements
 - c. Affective reactions
 - d. Behavioral intentions
 2. Brand
 - a. Attribute descriptions
 - b. Belief statements
 - c. Affective reactions
 - d. Behavioral intentions
 3. Advertisement
 - a. Attribute descriptions
 - b. Affective reactions
- Phase 2: Involvement/Centrality Theory
1. Product - elaboration personal past use
 2. Brand - elaboration personal past use
 3. Benefit personalized
 4. Usage consequence personalized
- Phase 3: Means-End Theory
1. Product-attribute link
 2. Brand-attribute link
 3. Product-benefit link
 4. Brand-benefit link
 5. Attribute-benefit link
 6. Product-attribute-benefit link
 7. Brand-attribute-benefit link
 8. Attribute-benefit-intention link
 9. Product-attribute-benefit-intention link
 10. Brand-attribute-benefit-intention link

Source: Dickson & Sauer (1987)

desire for a theoretical base for the development of codes. The coding scheme is more similar to the Brucks et al. (1988) scheme, but also improves on some confounding in that coding scheme (e.g., beliefs and feelings). It is better to simplify codes in each dimension and to aggregate across dimensions in capturing more complex response groups.

To illustrate how this coding scheme applies the "lowest common denominator" principle, consider the combinations which can be constructed to arrive at single-category codes proposed by other researchers. The original dimension codes used by Brucks et al. (1988) can be formed by combining the phase 1, 2, and 3 codes in this scheme. Similarly the relevance dimension can be captured by aggregating across phase 2 and 3 coded values. Therefore, none of the richness of the Brucks et al. scheme nor the theoretical motivation of the Dickson-Sauer scheme is sacrificed, except for the coding of links in the Dickson-Sauer

scheme. Links of this type, however, should span several thought units which would each be coded separately. Ideally a separate set of codes could be used to identify links denoting timing sequences of recorded thought units.

To test the new four-phase coding scheme, thoughts elicited from subjects in a second experiment were coded using the codes in Table 3. Subject were again given time to read the ad for a Sony Compact Disk Player, then instructed to list the thoughts they had while reading the ad. There was no difficulty in applying the codes as there had been when using the Dickson-Sauer scheme. The level of inter-judge agreement was approximately 82 percent. Differences between judges were eliminated through discussion moderated by a disinterested third party. In addition, structured measures of attitude and behavioral intention were taken. Results of comparative analysis

TABLE 3
Revised Four-Phase Coding Scheme

Phase 1:	(TYPE) Unidimensional Tripartite Theory (Fishbein-Ajzen 1975)
1.	Expressions of intentions or non-intentions
2.	Expressions of feelings (attitudes) toward product or ad
3.	Expressions of usage consequences
4.	Expressions of beliefs
5.	Expressions of thoughts not in 1 through 4
Phase 2:	TARGET of Thoughts (Cacioppo, Harkins and Petty 1981)
1.	Product
2.	Brand
3.	Advertisement
4.	Other (including self)
Phase 3:	Personal (Self) RELEVANCE of Thought (Markus 1980)
1.	Personalized to self
2.	Personalized to other
3.	Depersonalized - 3rd person
Phase 4:	POLARITY of Thought (Cacioppo, Harkins and Petty 1981)
1.	Positive
2.	Neutral
3.	Negative

across phases for the coding of this judge are presented in the following section.

RESULTS - COMPARATIVE ANALYSIS

The comparative analysis seeks to determine if there was any relationship between the types of thoughts found in one phase of coding and types of thoughts found in another phase of coding. Simple crosstabulations were generated. All relationships in the crosstabulations were tested using the Chi-square statistic and all were found to be highly significant at the 99% level of confidence. In Table 4 the crosstabulation between POLARITY and TARGET is displayed. The pattern of frequencies in cells indicates that brand thoughts tend to be either positive or negative with bias toward the positive. Two out of three thoughts about the ad tend to be negative while thoughts about the product and other (unrelated to brand, product, or ad) thoughts are predominantly neutral.

The crosstabulation between TARGET and TYPE of thought is shown in Table 5. Thoughts expressing intent or affect concern the brand or ad rather than the product. Recall (belief thoughts) are the dominant type for the product and occur at an 8 to 1 ratio for affect thoughts about the brand and a 4 to 1 ratio for affect thoughts about the ad. This implies that on average there are 8 salient brand attributes and 4 salient advertisement attributes which are instrumental in forming attitudes.

Finally, consider the crosstabulation of TARGET by self-RELEVANCE in Table 6. Very few of

any thoughts concerned an "important other" person, reflecting perhaps a relative inconsequentiality of the product relative to social consequences among the student subjects or their "me" generation values. While brand and product thoughts tend to be evenly divided between self and depersonalized, ad-targeted thoughts are oriented toward the self as opposed to depersonalized by a two-to-one ratio.

Though comparative analysis shows how coding dimensions might relate to one another, there is no conclusive evidence to indicate the nature of theoretical structure. Rather, aggregation across dimensions (e.g., McKenzie et al. 1986) reveals the flexibility of this coding scheme. A example of such application is provided in the following section.

COGNITIVE STRUCTURE & PROCESS APPLICATIONS

The theoretical richness of a multiphase coding scheme offers an enhanced ability to detect and empirically validate the processes assumed to underlie cognitive structure models. For example, a large stream of research demonstrates the existence of central and peripheral routes to persuasion (Elaboration Likelihood Model) determined by the level of elaboration (c.f. Petty, Cacioppo and Schumann 1983). But empirical evidence of the actual process of affect transfer (a common explanation of peripherally induced attitude formation) has been elusive. As a demonstration of the multiphase coding scheme's ability to effectively reveal such process information, the data described earlier are submitted to

TABLE 4
TARGET by POLARITY

TARGET	POLARITY		
	Negative	Neutral	Positive
Brand	128	90a	173
Product	10	105	1
Ad	269	77	79
Other	1	27	0

Chi-square = 387.6 df = 6 p = 0.000

Ad	282	0	143
Other	3	0	25

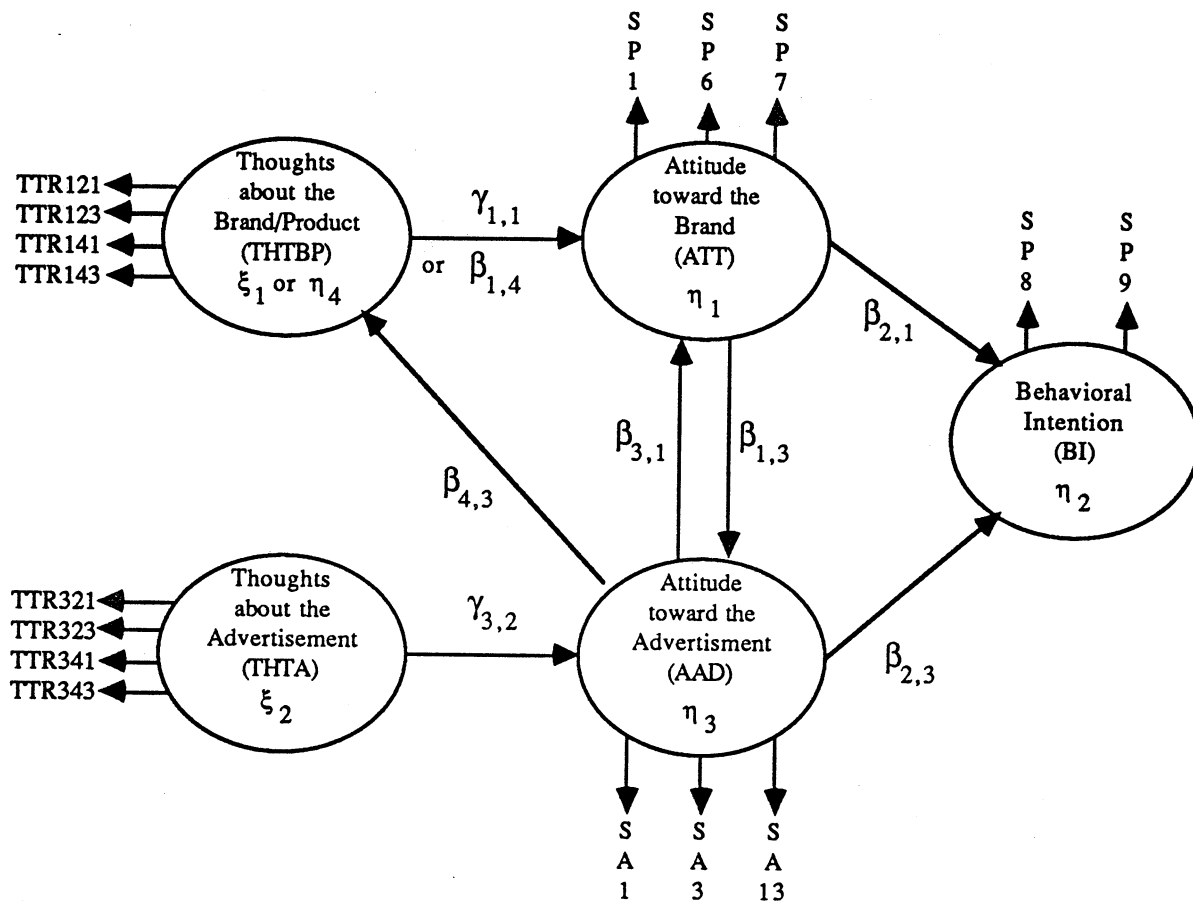

Chi-square = 56.1 df = 6 p = 0.000

a factor structure investigation and applied to a previously published structural equation model of theoretical relevance. We used the codes in Table 3 to develop valence measures of varying specificity. In order for thought elicitation to provide usable cognitive response measures it is necessary to obtain a sufficiently large number of responses in each cell of the coding cross-classification. A set of cross-tabulations was generated for various combinations of the four coding dimensions. Based on these cross-classifications, certain codes were eliminated from use in ELM analysis. Few instrumentality thoughts oriented toward purchasing or using the product (TYPE=3), thoughts of intent toward the product (TYPE=1), or thoughts related to an important other (RELEVANT=2) were generated. By eliminating these categories with low cell counts and by not considering other (TYPE=5), unrelated (TARGET=4) thoughts for the present, the possible combinations were reduced to 12 (TARGET=ad, brand, product; RELEVANT=self, 3rd person; and TYPE=affect, recall). These categories provided the basis for net valence calculations.

To determine the loading patterns of cross-coded valence data, a common factor analysis was run in which an oblique rotation was used to determine factor structure. Results indicate that RELEVANCE and TYPE dominate loading patterns. This implies that perhaps method factors are causing brand and ad thoughts to have common valence patterns within a common TYPE and RELEVANCE category. Valence structures of thoughts are more likely to differ if (a) thoughts relate to self or are depersonalized, but not both; and (b) thoughts are affective or recall facts, but not both. This may explain why the ELM works well. Subjects appear to readily transfer valence from brand to ad and vice versa - an affect transfer phenomenon which can account for attitude change in the absence of message elaboration (i.e., the peripheral route) - but not between self and a 3rd person or between affect and recall.

To further reveal the revised coding scheme's ability to capture detailed structure and process information, we applied it to a test of the alternative causal models developed by McKensie, Lutz and Belch

FIGURE 1
A_{ad} Mediation Models

Model	β Paths Include	χ^2	df	p =	GFI
A	$\beta_{1,3}; \beta_{2,1}$	670.1	99	.000	.723

*all models include $\gamma_{1,1}$ (or $\beta_{1,4}$) and $\gamma_{3,2}$

(1986) to explain the mediating role of attitude toward the ad. Consistent with their approach, we initially tested models in which only TARGET was used to code thoughts. The LISREL technique was unable to estimate the parameters for any of the tested structural models developed by McKenzie et al. (1986). McKenzie et al. (1986) used three indicators for three dimensions of ad-related cognitive responses in their models. Though they agree that this separation "makes sense," they provide no theoretical or statistical basis for accepting this structure in their measurement model.

An improvement in estimation and fit is possible if thoughts are classified by both TARGET and TYPE. Given the results obtained in the exploratory factor analysis, it makes sense to subdivide thoughts by TYPE to determine more accurately the effect of each TYPE thought on the thought valence construct for each TARGET.

Finally, a third level of coding was added using the RELEVANT code. Model fit can be seen in the Figure. This represents considerable improvement in model fit over models in which we used only two (target and polarity) or three (target plus type plus

polarity) dimensions to generate coded net valence values for the indicator variables. The Figure shows that model C (dual mediation hypothesis) fits best, but that model D (independent influences hypothesis) has statistical problems.

By utilizing all four coding dimensions the measurement component of the ELM structural equation model is able to allocate different weights to each of the indicator variables, and thus improve model fit. The ability of the measurement model to be sensitive to these different dimensions is possible only if a multidimensional coding scheme of the type proposed here is utilized.

Scales to Measure Social Power in a Consumer Context

Jonathan E. Brill, Temple University

ABSTRACT

Although the concept of social power is frequently used in social science research, its conceptualization is not consistent. Based on a literature review analyzing benefits and drawbacks of two dominant conceptualizations of power, the argument is made that power may be appropriately measured using attributions made by an involved social actor. It is argued that these attributions have an underlying two dimensional factor structure framed by one or more applicable social contexts. These ideas are extended to a retail shopping context to develop scales for measuring consumer power. The resulting scales are shown to (1) be valid, (2) have acceptable levels of reliability, and (3) be supportive of the two dimensional conception of power advanced. Potential applications for using the scales in consumer research and limitations of this study are discussed.

INTRODUCTION

It is widely recognized that exchange theory has been a dominant paradigm in the development of marketing thought (Bagozzi 1975, 1979). As power is a core concept inseparable from the ontology of social exchange theory (Blau 1964), it is clearly an important variable to be considered in the study of behavioral relationships between social actors operating within a marketing system. Dixon and Layton (1972), in discussing the role of power in marketing channel systems, have argued that power relationships are necessarily derived from the interdependencies that must exist between marketing actors if the channel system is to survive, and that these interdependencies are responsible for inducing marketing exchange partners, presumably with inherently conflicting objectives, to engage in cooperative behaviors.

Consistent with this reasoning, many researchers have emphasized the role of social power in marketing channel systems. In fact, much of the work in this area has been reviewed by Gaski (1984) who, through a synthesis of research results, has proposed a theory of power and conflict among distribution channel buyers and sellers. Yet, research emphasizing power relationships between retailers and consumers, the buyers and sellers at the end of many marketing channel systems, is relatively uncommon. And, even when these power relationships are considered, the focus is typically on the retailer with little, if any, regard paid to power associated with consumers (e.g., see Porter 1974).

Clearly, then, the potential for explaining interpersonal behavior styles of retailer representatives and consumers through exchange theory remains largely unexplored. It follows that use of a well defined conception of power and appropriate instruments to measure the power construct will be essential to this work. Unfortunately, however, there seems to be little consensus regarding the

conceptualization of power and its measurement, a situation that has been lamented by many (e.g., see Cartwright 1959; Pahng 1989), and published scales to measure the social power commanded by consumers appear to be absent from the literature.

TOWARD A THEORETICAL CONCEPTION OF POWER

Definition and Elaboration

Although power has been defined inconsistently, two general approaches to its conceptualization seem to be dominant. These may be referred to as the "power as a resource" and "power as an attribution" perspectives.

Perhaps the more common of these is the power as a resource perspective. Proponents of this view include Dahl (1957), French and Raven (1959), Rollins and Bahr (1976), and Tawney (1931), among others. In this view, power is conceived as an inherent characteristic or quality possessed by a social actor, a definite potential or capacity which may be used to influence or even control the behavior of others in some manner within some context.

Pahng (1989, p. 74) has noted that this conceptualization of power has been attacked in the literature, often quite strongly, being "... criticized as ambiguous, unscientific, and unmeasurable." Cross (1969), one of the more outspoken critics, has provided a particularly clear presentation of the crux of the case against the resource conception. He noted that the measurement of power as a resource relies upon the description of outcome events occurring between social actors. That is, an amount of power is associated with a social actor because the behavior of another is observed to be consistent with the first actor's wishes rather than his or her own. When such measures are then used as predictors of behavior, as is typical in empirical studies involving the power construct, an intolerable dilemma is created; if power is to be attributed in terms of behavioral outcomes and then used to predict behavioral outcomes, what results is tautology.

An additional problem of the conceptualization of power as a characteristic of an actor is that it may stand independent of the crucial idea that power arises as the consequence of dependency. This point has been emphasized by Thibaut and Kelley (1959, p. 124) who have noted that "an individual's power over another derives from the latter's being dependent upon him." Furthermore, Emerson (1962) has observed that power is specific and peculiar to social actor dyads, even when social groups are considered, since it is not uncommon for one individual to act dominantly toward a second party but subserviently toward a third who may act subserviently to the second. When power is viewed as a resource with definite magnitude or potential strength, such intransitive relationships must be prohibited for they are logically impossible.

Because of these shortcomings, the other conception, power as a perceived or attributed characteristic of a social actor, seems more sound conceptually. Though similar to the power as a resource conception in that it too posits that power is related to interpersonal or social influence, the power as an attribution perspective entails a key difference: it specifically recognizes that power is an aspect of the relationship between social actors, not a characteristic of a social actor. In other words, power perceptions are derived from the deference one shows another because of his or her dependency or reliance upon the other to behave in a desired manner. Hence, people do not possess power; they are empowered by perceptions of the interpersonal dynamics experienced in relationships.

This conception of power is bolstered by the work of selected social psychologists who have been concerned with power measurement. For example, in studying the processes of social influences in groups, Lippitt, Polansky and Rosen (1952) have not only implied that attributed power is real power, but they have further suggested that attributed power is a valid and reliable measure of social power. Additional empirical support for this proposition has been provided by Tagiuri, Bruner and Blake (1958), while conceptual support is apparent in the literature on negotiation processes (Bacharach and Lawler 1981; Pruitt 1981). Furthermore, it is particularly instructive to note that, when measuring power in studies of channel relationships, it has been common practice (e.g., see El-Ansary and Stern 1972; Etgar 1977, 1978; Hunt and Nevin 1974; Lusch and Brown 1982; Wilkinson 1974) to use measures of influence which the survey respondent has attributed to other parties involved in the channel network.

A critical difference between these two power perspectives is the comparative ease with which the power as an attribution is able to account for the role of social contextuality in power measurement. The power as an attribution view clearly presumes that power has a dynamic property. To be sure, power is often volatile and, sometimes, even fleeting since it is subject to readjustments as circumstances change or the context of a relationship evolves. In contrast, the conception of power as a characteristic resource seems inconsistent with power variances of social actors across relationships and time. Indeed, to retain this theoretical view, one must posit that a social actor has a specific power resource for every conceivable social relationship under every conceivable social circumstance. Hence, the power as an attribution conception offers greater potential than the power as a resource view for the development of parsimonious models incorporating the power construct.

Still, the belief that power in relationships is subject to change does not forbid one to posit that power attributions have a tendency toward stability over time, particularly when a relationship is ongoing. After all, if power attributions in a social relationship are the consequences of interpersonal behaviors, then the stability of power attributions should be similar to the stability of interpersonal behavioral patterns exhibited by the parties involved

in the relationship. To suggest stability in power attributions, then, is to rely only upon the idea that people have propensities to exhibit behavioral traits, or personalities, in their interpersonal behaviors. This point, of course, is critical to empirical research concerned with power, for it is only because of its tendency toward temporal stability that power measures useful for studying social relationships may be developed at all.

Consequently, a workable definition of power now may be advanced: power is the *perceived* ability or potential of a social actor to *influence or control* the behavior of another *within a given relationship or context*. Furthermore, it is an outcome of social dependency. It is dependency, not power, that may be viewed as an antecedent condition for predicting behavior. Power, then, can be a useful scientific construct only when it is employed as an indicator for social dependency.

Extending this to a consumer context, a consumer's power over a retailer or its sales agent is derived from the retailer's desire for the use or ownership privileges over the money resources commanded by the consumer. Likewise, a retailer's power over a consumer derives from the consumer's dependency on the retailer as a source of supply of those products and/or services which he or she may desire. As such, the interdependency existing between retail exchange partners leads to their attributed powers with respect to each other.

Furthermore, although much of the ascendancy granted by each party is purely economic in nature, some aspects of this ascendancy are purely social, governed by the institutionalized structure specified by the shopping norms and customs peculiar to the society in which the parties hold membership. Hence, power relationships between retail agents and consumers have multiple contexts, one which is socially instituted in a cultural sense and another which is instituted by the marketing (or economic) system that specifies the rules for exchange transactions.

Dimensionality of the Power Construct

It has become commonplace for researchers to develop operationalized measures of power that posit that power is a five dimensional construct (e.g., see John 1984). This practice would seem to have its roots in the taxonomy of relationships from which social influence may be derived as identified in a landmark essay by French and Raven (1959). According to their taxonomy, there are five bases from which power is derived. These include the ability to reward another ("reward power"), the ability to coerce another ("coercive power"), the occupation of an instituted position ("legitimate power"), the ability to furnish one's expertise to another ("expert power"), and being popular or widely respected so that others wish build associations or connections with you ("referent power").

Nevertheless, use of such a scheme for dimensionalizing and measuring power perceptions seems ill advised. Certainly, the French and Raven taxonomy is useful for understanding the antecedents

of dependency which give rise to power perceptions attributed to social actors. But it is essential to recognize that French and Raven (1959) themselves were careful to state that they have only described the bases from which power perception arise, not the dimensions of power itself.

In fact, a scheme for understanding antecedents is not necessarily appropriate for dimensionalizing a construct for measurement purposes. Among the foundations of test and measurement theory is that indicator measures of underlying constructs must have the property of being essentially unidimensional (Anderson and Gerbing 1988). It is this necessary condition, then, that makes adoption of the French and Raven (1959) taxonomy inappropriate as a framework for power measurement; the five bases of power are clearly not mutually exclusive. Reward power, for example, is not logically necessarily distinct from the other power bases -- say, for example, expert power -- inasmuch as the sharing of expertise by one party may rightly be considered reward influence rather than expert influence by the recipient.

An alternative scheme that seems workable is one based on the idea that the outcome of power is some degree of behavioral or fate control (Thibaut and Kelley 1959). Clearly, a social actor may attempt to control outcomes in only one of two ways. Either one may attempt to exert the influence one perceives he or she has over others, or one may attempt to resist or deflect the efforts of others to use the influence that he or she attributes to them. Hence, from this it follows that, within in any given context, power should be conceptualized as having two dimensions, influence and resistance. Influence Power, then, may be defined as the potential or ability that a social actor *perceives* he or she has, in general and within a given social context, to control the behavior of another. Similarly, Resistance Power is the potential or ability that a social actor *perceives* he or she has, in general and within a given social context, to deflect influence attempts perceived to be made by another. Integrating this dual dimensionality with the idea that power relationships between consumers and retail agents have both socially instituted and marketing system instituted aspects, it follows that it is appropriate to operationalize the consumer power construct as one consisting of four subscales: Social Influence (SI), Social Resistance (SR), Consumer Influence (CI), and Consumer Resistance (CR).

DEVELOPMENT OF CONSUMER POWER SCALES

In developing these four scales, psychological test construction procedures consistent with those outlined by Anastasi (1988) and Jackson (1967) have been followed. The first step was development of specific test item sets for each of the four scales. Second, statistical analyses evaluating the properties of items included in each set were performed to maximize and assess reliabilities of the scales. Finally, correlational analyses of the resulting scale measures with existing, conceptually related scales were undertaken to assess external validity.

Measures

All test items were constructed using a balanced six-point Likert scale ranging from Agree Strongly (1) to Disagree Strongly (6). Items included in the original SI pool were developed to reflect only the hypothesized influence dimension of power within a nonspecific social (i.e., "purely social") orientation. Care was taken to ensure that the wording of these items did not imply any specific social circumstance. In contrast, items included in the CI pool were created to suggest images of the influence dimension of power within a retail purchase setting. The wording of these items was designed to evoke images of buying products or services and dealing with retail salespeople. The items included in the SR and CR pools were developed in similar manners, except that the focus was placed on the hypothesized resistance, rather than influence, dimension of power within these two contexts. Finally, items intended for each pool were subjected to examination by colleagues and subsequently revised in an effort to ensure their face validity. These procedures resulted in the creation of 60 test items -- 19 for SI, 20 for SR, 13 for CI, and 8 for CR.

The measures chosen for use in the validity check analysis were the Powerful Others Control (POC) and Internal Control (IC) subscales of the 24 items measuring Internal-External Fate Control developed by Levenson (1974). Levenson's (1974) instrument includes three 8-item subscales, the third being Chance Control (CC), and represents a refinement to Rotter's (1966) 29-item Internal-External Control scale in that the items use a six-point (continuous) response set rather than the dichotomous Agree-Disagree/Unsure one chosen by Rotter. In addition, Levenson (1974) provided evidence suggesting that locus of control is a three dimensional construct rather than unidimensional, as Rotter (1966) had conceptualized it to be. The locus of control construct, particularly the POC dimension, has often been closely associated with, or even equated to, social dependency (Lachman 1986).

Given this, the nature of correlational results among the SR, CR, SI, CI, POC, and IC scales can be anticipated. As its name implies, the POC subscale is a measure of the influence that one perceives others have over him or her. Consequently, it is expected that this measure would be strongly associated with measures of one's perceptions regarding one's ability to resist influence attempts by others (e.g., the SR and CR scales) and weakly associated with measures of one's perceptions about one's ability to influence others (e.g., the SI and CI scales). Reasoning in a similar fashion, since the IC scale is intended to measure one's perceived ability to influence or direct one's own behavior, it should be more strongly related to the SI and CI than the SR and CR scales. Hence, empirical results consistent with these expectations would provide evidence of discriminatory and convergent validity of the SR, SI, CR, and CI scales.

Sample

Because of the preliminary nature of scale development work, respondent selection and recruitment relied upon convenience sampling techniques. First, the cooperation of 88 undergraduate and graduate students enrolled in the business and education schools of a major northeastern university was enlisted. Second, an additional 96 community dwelling adults were recruited to participate using a snowballing method. Selected characteristics of the total sample of 184 respondents are reported in Table 1.

Analyses and Results

The analyses began with an exploratory factor analysis having two purposes, to confirm the hypothesized dual dimensionality of power and to eliminate items that failed to reflect only a single power dimension. To do this, the item pools associated with each social context were combined, and separate exploratory analyses were run for the purely social and consumer item pools. Specifically, the CI and CR items were combined to form a pool totaling 21 items, and SI and SR items were combined to form a pool of 39 items.

In both analyses, results of the scree test and forced factor trials suggested the presence of two factors. For the consumer items pool analysis using a two factor solution with a varimax (orthogonal) rotation, 17 of the 21 items loaded primarily on one factor and, in all of these cases, the pattern was consistent with the hypothesized influence and resistance dimensions. Likewise, for the social items pool analysis, 26 of the 39 items loaded primarily on one factor and again, among these, the hypothesized pattern was observed. Those items not loading clearly

on a single underlying factor were eliminated from further analysis to ensure unidimensionality of each scale, and the items corresponding to the influence and resistance dimensions were again separated for further analysis. This procedure and its corresponding results, like the earlier item drafting and revision process, provide strong evidence of the substantive validity of four distinct scales, each representing one of two power dimensions in one of two social contexts.

Further reductions in the number of items included in each scale were managed by computing corrected item-total correlations and eliminating those items with insignificant correlations, a procedure recommended when item and total score measures are both continuous (Norusis 1988). Each scale was reduced by removing the item with the smallest correlation coefficient in an iterative manner until all items exhibited corrected item-total correlations of .30 or greater. Because this criterion is four times the correlation standard error and it is standard practice to accept all items exhibiting a corrected item-total correlation greater than twice this standard error (Crocker and Algina 1986), the degrees of interitem consistency for each scale have been nearly maximized without risking wholesale eliminations of items.

These procedures resulted in the creation of a six item CI scale, an eight item instrument for CR, an eleven item scale for SI, and a five item instrument for SR. Computed values of Cronbach's alpha were .66 for CI, .75 for CR, .87 for SI, and .62 for SR. Although the reliabilities of the CI and SR scales are somewhat low, each scale has the desirable characteristic of only including items with relatively large standard deviations. Jackson (1967) has noted scales

TABLE 2
Correlations Between Scales

	CR	CI	SR	SI	POC	IC
CR	—	.000d	.000h	.000e	.000f	.000d
CI	.2486	—	.000e	.000b	.478b	.001a
SR	.5280	.2886	—	.000f	.000g	.000d
SI	.2778	.5553	.3568	—	.040c	.000a
POC	.3369	-.0042	.3078	.1326	—	.013c
IC	.2721	.2442	.2788	.3429	.1671	—

Note: Pearson correlation coefficients are reported in the lower triangle, while probabilities and sample sizes associated with these coefficients appear in the upper triangle. Sample sizes are denoted as follows: a = 174; b = 175; c = 176; d = 177; e = 178; f = 179; g = 180; and h = 181.

incorporating items featuring wide variances are desirable because the observed reliabilities are not a consequence of the inability of the items to indicate good separation among subjects. Consequently, these two scales would seem to offer relatively high discriminatory power. The items included in the final versions of each scale, along with selected reliability statistics, appear in the Appendix.

Finally, external validity of each scale was examined in order to confirm that the scales measure what they are intended to measure. Convergent and discriminant validity was assessed by computing correlational results of all scale measures with each other and with the POC and IC subscales. Table 2 shows these results.

The relatively high positive correlations observed between the CR and SR scales ($r = .53$) and the CI and SI ($r = .56$) support the contention that these scale pairs measure the resistance and influence dimensions of power, respectively. Furthermore, in keeping with the weak positive relationship observed between POC and IC ($r = .17$), considerably weaker relationships between all pairs of resistance/influence scales (SR-CI, $r = .29$; CR-SI, $r = .28$; SR-SI, $r = .36$; CR-CI, $r = .25$) were observed as well.

In addition, both influence scales were positively correlated with the IC scale (CI, $r = .24$; SI, $r = .34$). It is also noteworthy that the relationship between the IC and SI scales was found to be stronger than that between the IC and CI scales; this too was to be expected in that the IC scale is a measure of social, rather than consumer, influence. Furthermore, little or no relationship was to be expected between the POC and the SI and CI scales because the correlation between POC and IC is weak ($r = .17$). Once again, the results were supportive (POC-CI, $r = -.004$; POC-SI, $r = .13$). In summary, then, these observations all lend support to claims of convergent and discriminant validity of the four power scales developed.

DISCUSSION

Research Applications

The results of this study support two important ideas about social power. First is that power is measurable when it is conceptualized as an attributed, as opposed to an inherent, characteristic of a social actor. Second is that, within any given social context, power may be viewed as consisting of two underlying dimensions, which might be labeled "influence" and "resistance".

Furthermore, it has been argued that power is an attributed outcome deriving from a social actor's dependency on another within a specific context or social situation. Specifically, it is dependency, not power, that has been posited to influence interpersonal behavior. This conceptual orientation, in combination with the present empirical results indicating adequate scale reliabilities and external validity, suggests that the power scales developed here may be useful for operationalizing the power construct in analyses of latent variable models of consumer interpersonal behavior.

Although one or more measures of locus of control (e.g., Levenson 1974; Rotter 1966) may be used to operationalize social dependency, such measures are general in nature and lack a contextual sensitivity. The General Systems Theory paradigm (e.g., see Berrien 1968; Miller 1955; von Bertalanffy 1968) reminds us of the importance of accounting for environmental influences and contextuality in the construction of theory; hence, it is proper that models of consumer behavior employ measures that reflect the influences of the social circumstances peculiar to the shopping and consumption planning experience. The scales developed here offer the opportunity to incorporate measures of power for use as a context sensitive indicator of a consumer's social dependency within a retail shopping environment and, in this respect, they represent an important addition to the social scientist's model building tool box.

APPENDIX

Note: Items eliminated in the analyses are available from the author.

CONSUMER POWER ITEMS

	Item Mean	Item S.D.	Corrected Item-Total Correlation
Consumer Influence (N = 178, $\alpha = .66$)			
I hate haggling with a merchant.	2.90	1.63	.3906
When I shop, I generally get salespeople to wait on me hand and foot. (R)	2.53	1.40	.4719
Salespeople who wait on me had better listen to me if they want my business! (R)	4.18	1.41	.3304
When I go shopping, it seems like salespeople will do almost anything for me in hopes of making the sale. (R)	3.35	1.38	.4394
Merchants often seem as if they could care less about having my business.	4.10	1.30	.3119
When buying a car, I know how to negotiate a favorable price. (R)	3.72	1.54	.3935
Consumer Resistance (N = 181, $\alpha = .75$)			
It often seems like salespeople know that I'm a real push-over.	4.75	1.19	.4423
I generally believe whatever a salesperson tells me about a product in which I'm interested.	4.40	1.39	.4511
I can honestly say that it's been ages since I've let a salesperson manipulate me into buying something I didn't really want. (R)	4.90	1.30	.4007
Salespeople have little ability to persuade me. (R)	4.30	1.25	.4600
I often feel that, as a consumer, I am a pawn of big business.	4.17	1.41	.3829
When a merchandiser and I don't agree about something, I'm usually the one who ends up giving in.	4.95	1.13	.4406
Sometimes I feel that a good salesperson could sell me the Brooklyn Bridge.	5.35	1.19	.4986
When I ask for help in choosing a product, I usually end up buying whatever the salesperson suggests.	4.51	1.26	.4836

SOCIAL POWER ITEMS

Social Influence (N = 179, $\alpha = .87$)

I know how to talk a good game. (R)	4.39	1.35	.4682
Because of my way with people, I have been able to accomplish things that many others cannot. (R)	4.21	1.39	.4694
It just seems like I'm a natural leader. (R)	4.04	1.34	.7406
When in a group, I frequently find that I assume a leadership role. (R)	4.13	1.36	.7903
I almost always make a good impression on people I meet. (R)	4.90	.94	.3982
People usually comply with my wishes when I make requests of them. (R)	4.52	.96	.4293
I can usually convince people to see things my way. (R)	4.48	.98	.5812
I rarely seem to be able to influence the behavior of others.	4.41	1.21	.4549
When with others, I generally prefer to assume a leadership role. (R)	4.08	1.27	.7006
Quite often, I find I am able to convince others to do something that I know they would rather not do. (R)	3.49	1.27	.5254
People often look to me for leadership. (R)	4.31	1.24	.7179

APPENDIX (CONTINUED)

Note: Items eliminated in the analyses are available from the author.

	Item Mean	Item S.D.	Corrected Item-Total Correlation
Social Resistance (N = 184, $\alpha = .62$)			
I almost always do whatever I'm told.	4.16	1.44	.3276
Unless I really want to, I rarely do what people ask me to do. (R)	3.37	1.46	.3311
I allow people to convince me to do things I am not eager to do more often than I really should.	4.32	1.45	.4546
I find it hard to say no to people.	3.67	1.56	.4259
I often do things I'd rather not just to please others.	4.20	1.44	.3675

(R): Reverse scored item.

Study Limitations

It is essential to recognize that, due to the complexity and breadth of the research issue, the focus of this study was intentionally limited in two respects. First, the focus has been placed on measuring power attributed to the consumer with no consideration of retail agent power. Secondly, scale development efforts have been limited to consumer power perceptions attributed by the consumer. Certainly, the development of measures for power attributed to consumers by retail agents and for power attributed to retail agents by both consumers and retail agents are relevant to interpersonal behavior studies of retail market exchanges. Hence, further scale development efforts to measure these perceptions of retailer-consumer power relationships are to be encouraged in future studies.

The use of convenience sampling is also a limitation of this study. The failures to have obtained a probability sample and to have achieved consistently high levels of internal consistency among all four subscales threaten the generalizability of the findings. In view of the facts that power is an essential concept in the ontology of the exchange paradigm and that exchange is central to marketing behavior theory, further research and scale refinement efforts to improve or extend the present scales seem warranted.

Insider versus Outsider: Reflections of a Feminist Consumer

Julia M. Bristor, University of Houston

ABSTRACT

Feminist critiques of the social sciences have shown that the perspectives and problems of women have frequently been overlooked or misinterpreted. Although in consumer research the consumer is assumed to be a female, this may be based on outdated stereotypes. This paper uses introspection as a technique to explore some consumption experiences of a feminist.

INTRODUCTION

Many women scholars, including myself, struggle with a tension born from being an insider and an outsider in our respective scholarly disciplines (Westcott 1979). I am a consumer research insider because I am educated and trained in the theories and methods of consumer research. I am a consumer research outsider because I am a female, and the discipline, like other social sciences, is by definition, both masculine and male dominated (Jordanova 1980; Keller 1978). In critically examining the discipline from the outside, I am also intimately familiar with the inside, and thereby oppose myself (Westcott 1979). As a result of such tensions, numerous feminist analyses have emerged that explore ways in which distinctly male perspectives on masculine experiences have shaped the scientific process and products of inquiry, for example, in sociology (Smith 1974); psychology (Sherif 1987); and organizational theory (Calas and Smircich forthcoming).

The purpose of this paper is to explore some of my consumption experiences. At the outset, I must point out that I am not a "normal" consumer since I am a consumer researcher who spends a great deal of time thinking about my own and others' consumption. I am also a feminist. Thus, here too, I struggle with the tensions of being both an insider and an outsider. It stems from my belief that many marketing practices contribute to and/or maintain the lower status of women in our society (Cott 1987; Friedan 1963). In my discussion of consumption, I will elaborate some of the tensions that I experience as a feminist consumer. First, however, it is necessary to provide a backdrop for them with a brief discussion of two key issues, research values and method.

RESEARCH VALUES

The first issue, and one that is fundamental to this endeavor, involves my research values. Although post-positivists freely admit that the research process is not value-neutral (cf. Lincoln and Guba 1985), research based on post-positivism rarely spells out specific motivations. Thus, I begin by being very clear about mine. I am a feminist. Although there are many types of feminism whose ideological commitments vary significantly, from liberal feminism, to radical feminism, to postmodern feminism (cf. Bristor and Fischer 1991b), most feminists would agree on two points. First, they agree that gender is socially constructed and is fundamental

to a person's life experiences (cf. Harding 1986). Thus, although the issue of whether gender differences arise from social factors, or are "hardwired," is unresolved, it is generally agreed that men and women have very different experiences (cf. Daly 1978; Gilligan 1982). This is much more than an academic issue. In a recent legal case, it was recognized that men and women think differently in the same situation (Hayes 1991). Second, feminists agree that our society is patriarchal. As a result, women -- their concerns, experiences and voices -- have been systematically overlooked, discounted and misinterpreted by those in powerful positions in institutions such as business, science and politics. It is because of this that I, and many other feminists, am motivated to study women and women's issues.

There are many potential explanations as to why women have historically been assigned lower status than men. One, which has been written about extensively elsewhere (cf. Harding 1986; Jordanova 1980, Keller 1978), relates to the historical development and practice of science and its influence on other institutions. Briefly, science has contributed to women's status in at least two ways. First, science has historically been closely associated with masculine characteristics and clearly differentiated from feminine characteristics. For example, consider the following word-pairs: hard/soft; rational/emotional; thinking/feeling (Keller 1978); subject/object; quantitative/qualitative; practical/fanciful; factual/symbolic; and reality/fantasy (Belk 1991). In each case, the first term is associated with masculine characteristics and with ideals of science; the second is associated with feminine characteristics and is distinctly differentiated with ideals of science. In Western society, the terms are not equally valued. What is masculine and scientific is valorized; what is feminine and non-scientific is devalued (Keller 1978). Among other unfortunate results, this has led to assumptions and stereotypes concerning women's and men's "natural" characteristics. On this basis, women have been historically excluded from scientific and other public roles, and have not been accorded epistemological status as knowers (Harding 1986).

The second way that science has contributed to women's inferior status is through its hallmark, objectivity, which has perpetuated the myth that scientific knowledge is universal and unbiased. Post-positivist critiques of science (cf. Anderson 1986; Lincoln and Guba 1985; Peter and Olson 1983) have shown convincingly that scientific knowledge is not value-neutral; feminist critiques of science have identified specific ways in which the methods and products of science are gendered (cf. Bristor and Fischer 1991b; Eichler 1988; Harding 1986; Millman and Kanter 1975). As a result of these two factors, what has been assumed to be universal unbiased knowledge produced by an objective science, is actually knowledge about men and men's problems produced by a masculine science.

Based on such conclusions, many feminist scholars are interested in revising and rewriting their discipline's knowledge base in a way that more accurately represents the problems, perspectives, and experiences of women. Such an endeavor is challenging for two reasons. First, many aspects of women's lives may not be as accessible as men's. Historically, as production and consumption were decoupled along with the separation of workplace and home, men assumed roles in the public sphere; women assumed roles in the private sphere (cf. Firat 1991; Gordon and McArthur 1985). Social scientists have generally put greater emphasis on the public than the private, so many aspects of women's lives have been overlooked (Millman and Kanter 1975). Further, the longstanding bias toward the observable in the social sciences has resulted in behavioral research focus -- on the assumption that there is a good fit between consciousness and activity. Especially where women are concerned, this may be problematic as their activities have been very constrained by gender role prescriptions and thus may not fit well with consciousness (Westkott 1979). As Westkott (1979) points out, to ignore women's consciousness is to miss out on the most important area of women's creative expressions of self in a society which denies that freedom of behavior.

The second reason that studying women is a challenging endeavor is that the field is still dominated by a masculine research perspective. This is not to say that all consumer researchers are male, but that historically acceptable scientific methods are gendered. Although this has changed in the last decade, the field has been dominated by quantitative methods which are underwritten by a masculine perspective; qualitative methods which are seen as reflecting various feminine characteristics are not considered legitimate science (Belk 1991). Thus men and women are socialized to practice masculine science (cf. Simeone 1987). This is also not to say that women have been ignored in consumer research. To the contrary, much research has proceeded on the assumption of the consumer as female (Fischer and Bristor 1991). However, Eileen Fischer and I have argued that this assumption is based on outdated stereotypes of gender and gender relations. Therefore, many research questions may not appropriately reflect women's concerns and experiences.

Given these challenges, the task at hand is to learn more about women -- their problems, concerns, experiences, emotions, etc. Also given these challenges, traditional quantitative methods may not be especially effective (Millman and Kanter 1975; Personal Narratives Group 1989). However, in suggesting that more qualitative, post-positivist approaches may be appropriate, feminist scholars rarely claim a distinct feminist method *per se*. Rather they advocate the use of post-positivist methods to better define research problems from the perspective of women's experiences and develop explanations that address the needs and wants of women (as opposed to others such as policy makers, marketers) (Harding 1987). As a *starting* point, introspection seems well suited to the task.

METHOD

It is a rare consumer researcher who does not think about her or his own consumption experiences. Yet we rarely read about them in the academic literature because when the subject and object are inseparable, it is difficult to ignore the emotional and experiential aspects of consumption. The inclusion of emotion in our papers is generally seen as inconsistent with scientific procedure (Holbrook 1990). As various critiques of traditional science have pointed out, objectivity is a masculine characteristic associated with science which emotion is a feminine characteristic (cf. Belk 1991; Harding 1986; Holbrook 1990; Jordanova 1980, Keller 1978). Further, the premium placed on rational, logical activities may help explain why consumer researchers have frequently overlooked emotion and experiential aspects of consumptions as legitimate consumer research topics (Holbrook 1990; Holbrook and Hirschman 1982). The net result is that emotion and the more feminine aspects of human experience are frequently not integrated into the practice or reporting of research. Like Holbrook (1990) and Holbrook and Hirschman (1982), I believe that we need to recapture these dimensions for a more complete understanding of consumption.

To more fully understand consumption, we do need more research on consumption experiences and emotions. Yet because consumer research does have masculine underpinnings (Belk 1991; Bristor and Fischer 1991b; Holbrook 1990), and because women may have very different consumption experiences (cf. Millman and Kanter 1975), traditional research methods may be insufficient when considering women's issues. Other approaches are necessary. One approach is to use of bigender research teams, as was suggested by Janeen Arnold Costa the 1991 Gender and Consumer Behavior Conference. Bigender teams help overcome the fact that male and female researchers may observe and learn very different things about a given phenomenon (cf. Warren 1988). Another approach is to use introspective techniques (Cook and Fonow 1986).

Introspection, or the conscious awareness or self examination of experiences can be used as a technique for examining emotion as a product of individual processing of meaning, as well as socially shared cognitions (Ellis 1991). Thus, Ellis (1991) suggests that introspection is a way to generate interpretive materials for the self and others to better understand lived experiences of emotion. In some cases, introspective techniques provide an opportunity to study unique biographies and life experiences, and to take advantage of situational familiarity (Brown 1991; Reimer 1977) or a complete membership role (Adler and Adler 1987).

Given forementioned difficulties of studying women, female introspection may be a useful way to generate research questions that may be less apparent from a male perspective. As Ellis (1991) notes, who better knows what questions to ask than a social scientist who has had the experiences of interest? On the other hand, introspection has potential liabilities as well. Problems associated with auto-ethnographies

may apply to introspection as well (Hayano 1979). Further, some researchers may be uncomfortable with introspective techniques because the subject and object are, by definition, inseparable. Some may also be opposed to introspection as an end in itself because then there is no attempt to generalize or validate against others' experiences. So little has been written about introspection (see Ellis (1991) for the most comprehensive treatment) that many issues remain to be addressed. My position is that introspection, particularly interactive introspection, where a researcher works back and forth with others to study the emergent experiences of both parties (Ellis 1991), can be a useful *starting point*. However, I see introspection as one component of a research program that is supplemented by other methods which, while still adept at focusing on the more feminine aspects of experience, use larger samples.

WOMEN'S/FEMININE EXPERIENCES

When I was first asked to participate in this special ACR session, I was asked to use introspection to describe my experiences as a feminist consumer, with the added suggestion that if I were going to explore some of the negative aspects, some of the positive aspects would be appreciated as well. After a couple of days of struggling, I finally realized that many of my consumption experiences were in direct conflict with my feminist value system. Further, in talking to other feminists, I've discovered that my feelings and emotions are shared by others. So while I am quite uncomfortable with personal-disclosure and self-introspection, there are two reasons why I see it as a valuable starting point. First, while I do not pretend to speak on behalf of all women, or even all feminists, I have discovered that I am not unique in my reactions to certain marketing activities. Second, since traditional consumer research has largely ignored feminist perspectives and concerns, my introspection as a feminist can be used to suggest research issues for broader investigation. For this paper, I have chosen to focus on two consumption areas: marketing and politics. Concerns about a third consumption area highly relevant to me, consumer research, are described in Bristor and Fischer (1991a; 1991b).

Marketing

Marketing is a pervasive institution in our society. I was so fascinated by it that I chose to study it as my profession. As a feminist, however, I do not like everything that marketers do. In particular, I think many marketing actions are based on a traditional white, middle class, male ideology about gender and appropriate gender roles. This ideology is shared and transparent, as air is to humans and water is to fish. It's only noticeable when one tries to breathe in the other's environment. Likewise, as a feminist, the male ideology is evident because my perspective is so different. Although the ideology has arguably contributed greatly to the notion that in the U.S. one can get "ahead" through individualism and hard work, it may be less true for women than white middle class men (Anderson forthcoming; Faludi 1991; Morrison et

al. 1987). Thus, while from a male perspective, certain actions may be seen as neutral, others may see the same actions as imposing unwanted conditions and constraints. The result is a contribution to and reinforcement of the lower status of certain groups such as women. While I'm not arguing that marketers bear sole responsibility for social conditions, their actions are not a neutral reflection of them either. To show how this might happen in marketing, I will use three illustrations: the beauty industry, advertising, and products marketed to girls.

Beauty Industry: My first example of male ideology is the mega-billion dollar beauty industry. This is the industry that implores women to: keep up with the latest fashions; be thinner; have perfect breasts; apply makeup and other cosmetics; remove body hair and so on. As a feminist, I am caught between my desire to participate and my intellectual recognition that beauty is largely a male social construction. Thus, regardless of the historical context, definitions of beauty are based on male notions, for male use and consumption. Although use of the traditional appeals to women that they should use beauty products to appeal to a man (e.g., "Gentlemen Prefer Hanes") have lessened in favor of more self-indulgent messages, the change is quite superficial. The industry, with a few notable exceptions such as Liz Claiborne, Anita Roddick (The Body Shop), and Estée Lauder, is largely controlled by men. This construction of beauty is closely linked to constructions of femininity and has several potentially negative consequences for women. First, the constructions of beauty are superficial and have little to do with qualities such as morals, ethics and compassion that might make our planet a better place for humanity. Second, women constantly receive the message that we are fundamentally flawed: we are too fat, our breasts are too small, our eyes are too close together, or too far apart, our eyebrows are too unshapely, our complexion is too uneven, and so on. As an example, Maybelline has an advertising campaign for its product line in the October, 1991 issue of *Vogue*. Each ad begins by defining certain beauty standards, for example for eyelashes. Then, they cast doubts on whether a woman could meet the standard naturally. Maybelline, of course, offers the solution. Although such messages convey standards that are unnatural and unrealistic; they are rarely challenged. Thus, when a woman doesn't measure up, it's not the fault of the product or the standard. It's hers.

Third, achieving these beauty standards may have emotional and physical consequences (Chapkis 1986). Too many women suffer low self esteem, negative and distorted body images, and feelings of inferiority that are reinforced by media images of ideal, and usually unnatural, women. Too many products are potentially dangerous because they contain ingredients such as formaldehyde, harmful dyes, and allergens. Too many women suffer from eating disorders such as anorexia and bulimia. Too many women suffer foot and back problems caused by shoes with high heels and/or unnatural shapes (i.e., severely pointed toes). Thousands of women may now

be experiencing serious health problems due to breast implants. To suffer such consequences in the name of beauty seems very sad to me. Yet, it seems easier than to do so than reconstruct notions of beauty.

Fourth, these notions of beauty create a lose-lose situation for me and many women. On the one hand, I stand to lose if I *do* buy into beauty industry rituals. If I wear makeup, polish my nails, and engage in related beauty rituals, I highlight my femininity. But in light of the bipolar gender dichotomies referred to above, the more I feminine and "womanly" I am, the harder it will be to be viewed as a competent researcher and college professor. Further, if I follow current fashion, which currently includes spandex, tight clothing and short skirts, I feel fashionable and attractive, especially since my figure is trim and my muscles highly developed from years of running and aerobics. But since my looks may also be read as provocative, I may receive unwanted attention, such as whistles, stares, and touches from those who seem to view me as an object of public consumption. Worse, I like many women, fear the possibility of violence. And then, if the worst were to happen, I fear that the blame would be placed on me. On the other hand, I also stand to lose if I *don't* buy into beauty industry rituals. It's impossible to avoid the message of advertisers and others telling me that without performing certain beauty rituals, I don't measure up. Further, it might have very real economic and legal consequences. If I refuse to wear makeup, I might risk being fired from certain jobs, as happened to Teresa Fischette at Continental Airlines (Reidy 1991).

In using these examples to show how participating in various beauty rituals creates conflict for me as a feminist, I want to be clear that I am not opposed to beauty, or aesthetics -- for myself, and certainly for others. The tension arises because so many women, including myself, have been socialized to participate in beauty rituals mainly for the gratification of others. Regardless of whether I set my own standards and/or participate solely for my own gratification, others may interpret my actions differently.

Advertising: My second example of male ideology is advertising. Sexism in advertising is an issue that has received critical attention over the last couple of decades. Indeed there has been a great deal of positive response from advertisers. Perhaps, however, in contrast to many others' views, I do not see sexism as a problem that is on the verge of extinction. Certainly, the use of blatantly negative stereotypes of members of certain groups, like women and blacks has diminished dramatically, but much more subtle and unrecognized forms of sexism still exist. These forms include portrayals of men as producers and breadwinners with responsibilities in the public sphere, and of women as mothers and wives, consumers and shoppers, with responsibilities in the private sphere. Men are also portrayed as dominant and aggressive; women as supporting and passive. What's wrong with these images? Several things. First, they contradict the experiences of the many men who participate in household activities and even more women who work both inside and outside the home.

For example, a recent study reported that 19% of men cook meals and 28% grocery shop (*Research Alert* 1991).

The second thing that is wrong with these images is that they reinforce outdated stereotyped of male-female relations where men are the experts, the bosses and the decision makers, while women are the passive and unquestioning followers. As an illustration, over the last several months in the Houston area Volkswagen has been running a couple of radio ads for their Fahrvergnügen campaign. The ads generally start with a woman named Helga singing. Suddenly Helga is aggressively and abruptly cut off by the spokesman who proceeds to provide the substantive product information. When he is done (and of course *he* decides that too), he issues a recall command to Helga. Depending on the version of the ad, it is to finish the music, or move over so he can drive. In other words, the important task of providing product information is clearly men's work; the supporting, accessory roles are clearly women's work. Apparently Helga isn't even competent to drive.

The third thing that is wrong with these images is that advertising appeals targeted to women often contain exploitative stereotypes of women as self sacrificing nurturers and caretakers of their husbands and children. I'm not implying that a caring wife and mother are undesirable roles. But neither are a caring husband and father and there is a dearth of such male advertising images. Such appeals reinforce outdated gender roles by implying that a woman's identity, sense of accomplishment and creative outlets are derived from the private sphere -- her relationship to her husband and children (Friedan 1963). Men, are rarely shown as the key player in domestic scenes; by implication, they are out in the public sphere working and producing an income so their wives will be able to consume. *The Wall Street Journal* (1991) recently reported that Stuart Tobin, who handles most of his family's shopping, household chores, and childcare is boycotting certain advertisers who specifically target "mom". "How do I perceive these commercials? That I'm inadequate and inept at taking care of kids? Not only are they offensive, but they're dumb. They aren't talking to me, when they should be," (pg. B8). Believe me Stuart, I agree with you. Of course if I boycotted all the products of advertisers who portrayed women as inadequate, I'd have a lot more money in the bank! Advertisers need to portray both men and women in much more positive and less stereotypical ways. Wouldn't it be great if more ads portrayed men as caring husbands and fathers (doing something more than displaying laundry ineptitude)? Wouldn't it be great if more ads portrayed women in the public sphere, as competent professionals?

The fourth thing that is wrong with these images is that violence and domination are all too prevalent. It's far more than a feminist issue, but much is directed at women. As one example, Bijan has a three page spread in the October issue of *Vogue* which incorporates several images and symbols of violence. On the first page is a photograph of a women's perfume and a men's cologne bottles linked together by handcuffs. The perfume bottle and cologne bottle

are each shaped like a hollow doughnuts containing perfume. Their caps differ in one important respect however. The cap of the women's bottle has a hole in it which is very suggestive of a vagina. The cap on the men's bottle is round like the tip of a penis, and ridged like a screw. However, for it to fit into the hole in the perfume bottle cap would require force because it is substantially larger. The text extends the theme of domination: "a woman who had all the right moves...and a man who know exactly what he wanted..." This theme is continued on the next two pages. On the next page, a red-lipped and nailed, sultry but lifeless, woman named Nikki is wearing handcuffs. She is holding a card above her large, semi-exposed breasts indicating that she has been arrested by the New York Police Department for wearing Bijan. The text reveals that she is being held with out bail and that her one phone call was to 1-800-99-BIJAN. Is the message that if a woman wears Bijan, she can experience bondage, arrest, etc? Is the message that the not-so-innocent get what they deserve? Are these outcomes supposed to be desirable? To me, they are horrifying.

Products Marketed to Girls: My third example of male ideology involves products aimed at young girls which reinforce the same stereotypes that I have been describing. More than any other example perhaps, these are disheartening because if our society is ever to change, we must change the way we socialize, educate and raise children (Dinnerstein 1976). Previously, Eileen Fischer and I (Bristor and Fischer 1991a) pointed out that Barbie dolls, if enlarged to life size, are estimated to have a 44" bust (McKillop 1990). What kind of message does this send to girls about their own bodies? How does such an image affect the self esteem of a developing girl? Why doesn't Ken have similarly exaggerated sexual organs? We also described Parker House's new game called "Careers for Girls" which included career possibilities such as supermom, fashion designer and college grad. Noticeably absent were any careers reflecting substantial power, leadership, or policy making activities (Ellerbe 1990). College graduate as a *career*? Supermom? Would the game's developers consider superdad to be a suitable career for boys?

Politics

The other area that I wish to discuss with respect to my consumption experiences is politics. Politics may not be the most salient type of consumption, but politicians are nothing if not marketers, and we, willing or unwilling, are consumers. For me, the recent U.S. Senate hearings to confirm Judge Clarence Thomas to the Supreme Court were a very painful example of political consumption. The confirmation process may have had several flaws; my focus is on one particular aspect that further the notion of a male ideology. The hearing process was a graphic example of how women's voices may be discounted if they are different from men's. (I fully recognize that men can also be victims, but will focus on the more common situation of women as victims.) In sexual harassment cases, it is generally problematic when women's experiences, perspectives and feelings

do not mirror men's. Women who do talk about their experiences face several risks. They may not be believed or seen as credible "witnesses" to their own experiences; their complaints may be treated in a joking fashion or trivialized; and their character may be attacked. Being a sexual harassment victim is terrible; the price of being a victim for the second time as a result of complaining, testifying or taking other public actions is enough to consign many women to silence. Unfortunately, this may have the effect of silencing others who would describe their own experiences.

The hearings were especially difficult for me because they revived a lot of recent memories of my own. In a previous job, I experienced sexual harassment over a long period of time. As I began to realize the problem had to do with my sex and gender, I tried to explain the problem to my superiors. My motivation, albeit naive, was that we were all rational, intelligent and educated individuals and that if I just explained the problem and how I felt, they would take steps to stop it. Instead, I was met with denials and suggestions that the problem really did not exist. There usually was an alternative explanation for each incident and it was implied the I was oversensitive, overemotional, but humorless woman. On the few occasions that a problem was acknowledged, I was also told that the people involved weren't going to change, so I would just have to put up with the problem. In my frustration, and to do a sanity check, I began to keep a log of incidents. After a particularly upsetting series of events, I decided to use my own experiences as the basis of an essay that explored the particular form of sexual harassment I was experiencing, the "hostile environment" or "chilly climate" (Bristor 1990). In writing the essay, I examined my data, in a systematic fashion. In spite of my knowledge that the problem was harassment, not my overactive imagination, I was astonished to discover how clear the emergent patterns were. While any one isolated incident had an alternate explanation, as a dataset, there was none. In a sense, my experiences have been validated by the many women who have read my essay and commented that they have had very similar experiences, both as a victim of sexual harassment, and when they have chosen to seek a remedy.

Although the exact nature of sexual harassment differs from woman to woman, Hill's, there are many similarities in the experiences of describing them to those in power. Regardless of the timing, for example I sought remedy as incidents occurred, and Anita Hill was compelled to testify long after the fact, the pattern of reactions was quite similar. Specifically, reported events are strongly denied, even though the loudest voices often have no direct involvement in the alleged incidents. It is thus very difficult for the woman to be believed. In many cases, the only women who *are* believed are the ones who deny that they have experienced harassment, suggesting that if it didn't happen to them, it didn't happen to anyone. The situation can then treated be "democratically" as a vote, and on the basis of majority rule, the victim's complaint "loses". If the victim has not been silenced

by this process, and continues to speak out about her experiences, her character comes under scrutiny and doubts will be cast on her sanity and emotional stability. Yet, similar doubts are rarely raised about the harasser. In my case, this continued to happen even after a substantial legal settlement had been reached: "You have to differentiate between the way she experiences things and the way they might have happened," said one dean in a newspaper article (Bass 1990, pg. C1). "I would say she has a very different perception of those incidents than other(s)," said another. As an example of such an "incident", I frequently experienced certain colleagues touching me without my consent, for example rubbing their hands against my rear end. When I described this as inappropriate conduct to one of my deans, in a conversation witnessed by the sexual harassment advisor, his response was that I was misinterpreting a friendly gesture. A friendly gesture? What a convenient way to appropriate both my body and my feelings of violation!

After experiencing harassment personally, hearing about similar experiences from dozens of other women, and watching Anita Hill's case emerge publicly, I have two conclusions. First, the experiences and voices of women are not given equal value or epistemological status. Second, victims of sexual harassment pay at least twice -- the first time when they go through the experience, and the second time when they attempt to speak the truth -- for whatever reason.

CONCLUSION

This paper has described some ways in which prevailing male ideology that underwrites various marketing actions creates conflict for me as a feminist consumer. In my criticisms of certain actions, I am not suggesting that marketing is a hopeless institution. What I am suggesting is that women's experiences and perspectives should be listened to more carefully. Being different should not be grounds for automatic dismissal or discreditation. From a purely pragmatic standpoint, women have tremendous spending and voting power. Those marketers who better understand the wants and needs of women, although this is not to suggest that women represent a homogeneous group, will have an edge over those who continue to impose old stereotypes and ideals.

Reflections of a Black Middle-Class Consumer: Caught Between Two Worlds or Getting the Best of Both?

Jerome D. Williams, Pennsylvania State University

Consumer behavior studies traditionally have treated Blacks as a homogeneous, monolithic group. However, the Black community, like the white community, has always shown evidence of diversity and stratification. Even during the period of slavery, there were social distinctions among slaves based on where they worked, e.g. in the fields or in the plantation house (Pinkney 1969). However, as noted by several researchers (Robinson and Rao 1986; Reid, Stagmaier, and Reagan 1986; Williams 1989), most consumer behavior studies have concentrated primarily on low-income Blacks, generally women, in urban areas, and often have generalized the results to all Black consumers. Within the next few years, though, it is projected that over half of all Black workers will be middle-class, casting them into critical roles as consumers of goods and services, in addition to becoming the focus of greater research attention.

Both empirical and ethnographic studies have fallen victim to this fallacy of focusing on the low-income Black consumer. For example, one empirical study on perception of television commercials compared children from white middle-class schools and neighborhoods with children from Black inner city schools and neighborhoods to reach conclusions about the differences between Blacks and whites (Donohue, Meyer, and Henke 1978). This obviously was more of a class difference than ethnic group difference. In an ethnographic study the ghetto community was advocated as the setting to pursue research on the effects of ancestry and kinship on consumption practices among Blacks since the researcher argued the ghetto community represents the most typical setting for the Black community (Hirschman 1985).

Another research approach, one that has received little attention but which offers an opportunity to explore the diversity among Black consumers by gaining a more in-depth understanding of how an individual really feels about many of the consumer behavior concepts based on traditional approaches, is introspection. Surprisingly, in spite of a number of studies of Black consumer behavior, we have little idea of how the many consumer behavior concepts become personalized and function within the individual. This paper aims to provide some clues as to this functioning by taking my own experiences in life as a Black middle-class consumer as text and focusing on the consumer behavior process as an internalized cultural product, following McCracken's (1986) model and Gould's (1990) adaptation of it. Although such a technique has been used previously in consumer behavior by Holbrook (1988) and Gould (1991), it is still relatively new. This paper provides a further exploration of the technique.

I will first provide a personal backdrop so the reader will have a better appreciation and understanding of the influence of my background on

my assessment. Then using this personal backdrop, I will provide an introspective analysis of four issues related to Black consumer behavior.

ONE MIDDLE-CLASS BLACK CONSUMER'S VIEW OF THE WORLD

As a child growing up in the world of inner city Philadelphia, I didn't think much about being "Black," let alone about being a Black consumer. Everyone around me was Black -- my classmates, my teachers, my neighbors, the customers in the stores where my parents shopped, and even the employees in the store. Now as an adult I think a lot about being Black. Only in my current world just about everyone is white -- my university colleagues, my students, my neighbors, the customers I encounter in the stores where I shop, and even the employees in the store.

On the one hand this sensitivity as an ethnic minority in a majority culture should be expected. As noted by Royce (1982), minorities in general are more self-consciously aware of themselves as minorities while whites do not tend to think of themselves as distinctly part of a particular ethnic group. On the other hand, based on my experience of attending a predominantly white, prestigious Ivy League school (University of Pennsylvania), being the captain of the track and cross country team composed primarily of white teammates, working ten years for a predominantly white Fortune 500 corporation (General Electric Company), living in predominantly white communities (10 years in Colorado and four years in State College, PA -- both with approximately a 3% Black population), and teaching at a predominantly white university (Penn State University), you would think by now I certainly would have become acculturated and assimilated into mainstream Anglo-European society, and totally comfortable with my role as a middle-class Black in a predominantly white environment.

However, I often wonder if I am caught between two worlds, never being fully accepted in one and having come too far from the other to ever again be fully a part of it. As a middle-class Black consumer, I often reflect on the degree to which I have fallen victim to being caught in a dual identity crisis. As articulated by Woodson (1933) and Cruse (1967), this means trying to be a mainstream American and a Black American, resulting in not being wholly either. This dilemma was expounded on by Park (1931) in his concept of the "marginal man" and DuBois (1907) in his concept of "double consciousness." Both stressed the "twoness" of being an American and being Black and the perpetual conflict between these two social roles.

Although I have not fully resolved that identity crisis, I have rejected the common assumption that there is a decrease in ethnic identity as Blacks move up the socioeconomic ladder to middle-class status, at least as I perceive my ethnic identity. I consider

myself a "multicultural," an ethnic minority living in two worlds, and getting the best of both. According to Frazier (1957), the more middle-class or bourgeois Blacks are, the more they attempt to emulate whites and their value system, and the weaker their ethnic or race commitment becomes. I partially accept the first part of Frazier's hypothesis in my case, i.e. accepting middle-class values. I find nothing wrong in espousing the values of mainstream society, certainly if those values mean wanting to live in an upscale neighborhood, drive a late model automobile, send your children to the best schools, etc. In my view, accepting one set of values does not necessarily mean rejecting another set. A multicultural individual is able to feel comfortable with both mainstream and his/her ethnic values.

In fact, in one study middle-class Black respondents displayed middle-class American values typically associated with whites to a greater degree than the whites in the sample (Ness and Stith 1984). In another study, Williams and Qualls (1989) found evidence that middle-class Blacks who have moved up the socioeconomic ladder are very similar to their Anglo counterparts at the same socioeconomic level, at least in terms of their responses to celebrity advertising.

This reminds me of the consumer response to a recently released movie, "To Sleep with Anger," which tells the story of a middle-class Black family. Yet to the dismay of all those who made the movie, it has typically been performing five times as well in white neighborhoods as in Black neighborhoods (Rohter 1990). Audiences attracted to the film were separated not by ethnicity but by class. The film is appealing mostly to the middle and upper class, both Black and white, not blue collar Blacks or whites. This indicates that at the upper socioeconomic levels there seems to be more similarity than differences in the values espoused by Blacks and whites.

Although I agree that middle-class Blacks and whites may have similar values, I disagree with Frazier's contention that middle-class Blacks have a weaker ethnic identity. In fact, I would say being middle-class and yet still experiencing prejudice and discrimination, despite the socioeconomic status one has achieved, makes one even more sensitive to his/her ethnic identity. For example, two recent news stories drive home this point. A study at Northwestern University on car dealerships found that salespeople who bargain with customers over the price of a new car make significantly lower final offers to white men than to Blacks (Schmidt 1990). Another story dealt with a department store which required its cashiers to note the race of the individual on the back of checks. When I read of such stories dealing with consumer interactions, it makes me more aware that being a member of the Black middle class still does not make me immune to inequalities faced by Black consumers in general. In my case this has led to an even stronger sense of pride and strength of ethnic affiliation. The end result is that I feel I am enjoying the best of two worlds -- 1.) espousing the values and enjoying the benefits of mainstream society as a middle-class consumer, and 2.) espousing the values of

my ethnic group as a Black consumer with strong ethnic affiliation.

This multicultural value system, a combination of mainstream and ethnic values, is exhibited in a number of ways by me and has a direct bearing on my behavior as a middle-class Black consumer. I will now elaborate on four issues related to Black consumer behavior and offer an introspective view which reflects this multicultural value system.

ISSUE #1: SHOULD THE BLACK ENGLISH DIALECT BE USED IN ADVERTISING?

There is a substantial difference in the form, content, and use of language by Blacks and whites (Haskins and Butts 1973). I have noted that one function of this difference is a mechanism for Blacks to signal solidarity with their group by selective use of in-group language, dialect, accent, and vocabulary, e.g. slang expressions, rapping, etc. This need for solidarity stems from the complex historic and sociocultural experience of growing up as members of a unique cultural group and experiencing elements of prejudice and discrimination (Wilcox 1971).

Emphasizing language as a means of solidarity should not be surprising, given the fact that many researchers consider language as the single most important component of ethnic identity (Giles et al. 1976, 1977; Leclezio et al. 1986; Taylor et al. 1973). In fact, research indicates that ethnic group members identify more closely with those who share their language than with those who share their cultural background (Giles, Taylor, and Bourhis 1973).

I have observed that many advertisers employ a strategy of trying to reach Black consumers through advertising language often referred to as the "right-on" school of advertising copy, i.e. injecting Black slang, "hip" expressions, and other elements of the Black English dialect into their ads. While some segments of Black consumers may respond favorably to this "slanguage" approach, I think advertisers should be cautious as they run the risk of turning off other segments (Sobers 1979; *Marketing News* 1984).

In particular, this may be true with middle-class Blacks who represent the most significant segment in terms of purchasing power in the Black community. Although it has been estimated that elements of the Black English dialect are used by 80% of Blacks in America (Dillard 1972), I would expect that there is significant variation in the extent of usage based on social class, gender, age, region, etc. (Payne 1986; Jenkins 1982). As noted by Kochman (1981), I would expect greater usage among Blacks at a lower socioeconomic level than among middle-class Blacks.

However, Smitherman (1984) points out that upscale, middle-class Blacks are also familiar with the language. I would agree since middle-class Blacks, even though they exhibit greater usage of the mainstream English dialect, have had to retain their ability to speak and understand Black English as it continues to be the lingua franca of the Black community and, as mentioned earlier, it is a means of maintaining community solidarity.

My being familiar with Black English and even using it as a common bond of expression with other Blacks does not necessarily mean that I favor its use in advertising copy. Although there are a number of arguments for legitimizing greater usage of Black English in all institutional contexts, including the school system and in advertising (Smitherman 1981; Smitherman and McGinnis 1977), I believe there also are some legitimate reasons to be cautious. For one, there is the danger of perpetuating stereotypes of Blacks and possibly the hindering of socioeconomic mobility by those who are not familiar with the richness and legitimacy of the dialect as a language. For example, Terrell and Terrell (1982) found that Black job hunters who spoke Black English got shorter interviews, fewer job offers, and offers at lower pay than Blacks who spoke standard English.

I am sure that Black English will continue to be used in advertising copy; I also am sure that certain segments of the Black community will find it very acceptable and appealing while others will not. This is further evidence of the diversity within the Black community with which advertisers will have to deal and which consumer researchers will need to study.

ISSUE #2: ARE BLACK MODELS THE ONLY WAY TO REACH BLACK CONSUMERS?

Another strategy used by advertisers to appeal to Black consumers is the use of Black models. This approach takes advantage of the Black cultural script characteristics of collectivism, group affinity, and identification with the collective in-group (Nobles 1980; Boykin 1983). In addition, it reflects in-group bias theory (Brewer 1979; Wilder 1981), which suggests that a member of any group should have a more favorable response to another member of the same group in an advertisement, i.e. whites should respond more favorably to ads with other whites, Asians should respond more favorably to ads with other Asians, etc.

To better understand how I respond to the source effects of other Black human models, I find the conceptual framework outlined by Kelman (1956) useful. Based on his work, credibility, attractiveness, and power are recognized as the three main source characteristics which affect consumers. These three characteristics lead to attitude change via three different psychological modes, namely, internalization, identification, and compliance.

I would consider ethnicity as a source effect falling mainly under the attractiveness domain. Although there are several dimensions of attractiveness (e.g. familiarity, similarity, liking, prestige, and physical attractiveness), I would view ethnicity primarily as falling within the similarity dimension. However, there are two ways in which I can respond to the source effect of a Black model in advertising based on similarity -- either demographic or ideological similarity. As a Black consumer I obviously will respond more favorably to ads with other Blacks (demographic similarity) compared to ads without Blacks. However, as a Black middle-class professional consumer, I also would respond more

favorably to ads with other Black middle-class professional consumers (ideological similarity) compared to ads with Blacks from other socioeconomic segments.

As McGuire (1969) points out, demographic versus ideological similarity poses some interesting issues. For example: Does a white segregationist like better a white integrationist (demographic similarity but ideological dissimilarity) or a Black segregationist (ideological similarity but demographic dissimilarity)? In my case: Do I respond more favorably to a white model in advertising representing ideological similarity (e.g. similar middle-class values) but demographic dissimilarity, or to a Black model representing demographic similarity but ideological dissimilarity (e.g. a young Black inner-city teen "rapping" in a commercial about a product)?

I would contend that in my case the cognitive processing of information contained in advertisements is not as simple as just favoring the ad with someone in it similar to my own ethnic group. Based on cognitive response theory, I should be processing other elements besides the model's ethnicity, e.g. the content of the message. Therefore, even though a particular advertisement may not contain Black human models, I may still view the advertisement positively due to the evaluation of the message or other factors, e.g. product attributes. Sometimes I may spend extensive amounts of time evaluating the message content via the central route to persuasion; at other times, I may give only superficial attention to the message and rely more on other cues via the peripheral route to persuasion (Petty, Cacioppo, and Schumann 1983). In either case, the ethnicity of the model is only one of the factors I use in processing information contained in an advertisement, and in many cases it may not be the most important.

This is not to deny that I respond favorably to advertisements containing Black models compared to advertisements without Black models, all other things being equal. However, there are many other mediating factors affecting my response. I believe this is also true with most other Black consumers; therefore advertisers and researchers should be interested in determining to what extent these other factors account for variation in the response of Black consumers to source effects. Based on my experience, source ethnicity should not be viewed as the all-powerful motivation behind reaching Black consumers, although the use of Black models can be effective in many situations.

ISSUE #3: IS IT "BLACK" OR "AFRICAN AMERICAN" CONSUMERS?

I have been asked on a number of occasions whether the term "Black" or "African American" is the preferred term of usage for this ethnic minority segment. Actually I can remember when I was asked a similar question about the terms "Black" and "Negro" in the 1960's. I suspect in earlier time periods, the question centered on the appropriateness of "Negro" and "Colored."

The easy answer is to call consumers what they feel most comfortable with. However, this approach presents a problem as once again we see evidence of diversity of opinion. For example, Jewell (1985) found that Black students provided eight different responses when asked to identify their race in an open-ended questionnaire. Concerning the most popular contemporary designation, many members of the Black community feel the term "Black" is inappropriate. They cite the common usage of land-based designations for other groups (e.g. Italians, Germans, Mexicans, etc.). Therefore, terms such as "Pan-African" or "African American" are perceived as preferred, more appropriate, and more acceptable to use when referring to members of this ethnic minority group. However, despite increasing use of these terms, most Black Americans still prefer to be called "Black," according to a recent survey by the Joint Center for Political and Economic Studies -- 72 percent preferred "Black" compared to 15 percent who preferred "African American" (Nelson 1991).

I believe that the reason for the continuing acceptance of the term "Black" is that a lot of people feel the same as I do -- the label is not as important as what the label stands for. For example, the most prestigious civil rights organization is called the National Association for the Advancement of "Colored" People (NAACP). Similarly, every year contributions pour in to support Historically Black Colleges as a result of the United "Negro" College Fund (UNCF) telethon. However, I also recognize that while certain terms may be acceptable for organizational labels, consumers may feel uncomfortable when those terms are applied to them individually. I greatly respect the NAACP and UNCF because I know what their organizational labels stand for, but I prefer to be referred to as a "Black" as opposed to a "Negro" consumer.

As noted by Cohen (1978), subjective self-labeling is the only valid measure of ethnicity, since it represents the internal beliefs of the individual and hence reflects the salience and reality of ethnic affiliation. For example, calling a consumer "Canadian" might be the marketer's or researcher's designation while the consumer may prefer the self-identified label of "French Canadian" or "English Canadian." Even subjective self-designation presents problems though. Some members of an ethnic group might define the label differently than the definition assumed by others. For example, the label "Hispanic" is not widely accepted by all persons classified under that umbrella category. Certain individuals may prefer other designations such as Chicano, Latino, Mexican, Cuban, Puerto Rican, Spanish American and Mexican-American, etc. From my experience of living in Colorado with a large Mexican American population and spending a great deal of time in New York with a large Puerto Rican population, I can attest that individuals within these two groups of Hispanics have varying understandings of the various labels. For example, "Chicano" has a more militant and activist connotation for certain "Hispanic" individuals compared to others.

Among Blacks, subjective self-designation of a particular label reflects different attitudes and actually may affect behavior. For example, Jackson and Kirschner (1973), in exploring the relationship between racial self-designation and preference for counselors, found that students who referred to themselves as "Black," or "Afro-American," preferred a Black counselor to a significantly greater degree than those who referred to themselves as "Negro."

I feel quite comfortable with the term "Black." I also realize that there is a sizeable segment which feels offended by the use of the term. What seems to be happening in the Black press is the use of both "Black" and "African American," recognizing the appeal of both terms to different segments of the Black community. (Sometimes both terms are used in the same sentence to refer to this ethnic minority segment; other times the terms are used alternately in sentences or paragraphs). I often attempt to get the best of both worlds by using the term "Black/African American." I would suggest that the most prudent choice for marketers and researchers is the adoption of both terms.

ISSUE #4: WHAT EFFECT DOES THE LACK OF BLACKS IN ADS HAVE ON SELF-ESTEEM?

A recent New York Department of Consumer Affairs study (Rothenberg 1991) charged that although Blacks constitute 11 percent of national magazine readership, only 3 percent of models used in national ads are Black. As a consequence, the study concluded that minorities suffer "psychic harm," i.e. minorities are hurt through damaged self-esteem, reinforcing a sense of segregation in the marketplace.

As a result of the study, New York's Human Rights Commission is investigating if it could sue recalcitrant advertisers under the Civil Rights Act for not including more minorities in advertising. Also, several law suits have been brought under the U.S. Fair Housing Act on the absence of Black models in real estate ads, and recently a federal appeals court ruled that newspapers can be held responsible for running ads which violate the Act (Lambert and Harlan 1991).

I agree there are a lot of societal reasons to see more Blacks in advertising, but I believe the low self-esteem theory is not one of them, or at least it has been overplayed. As noted by Cross (1991), many of the problems concerned with building Black self-esteem are misdirected. He takes on the somewhat sacred cow notion that Black self-hatred is the explanation for Black failure and finds the studies from the 1930's and 1940's severely flawed. (These studies dealt with photographs and line drawings of Black and white children, clowns, and chickens, or choices between Black and white dolls; most of the traditional work on Black self-esteem today can be traced back to these studies).

It seems to me that many today are making the same mistake of linking Black self-esteem to images in the media and assuming that the development of positive self-esteem is somehow dependent on seeing positive images in the media. If this theory were true, I would think that people in my generation who grew

up in an era when Amos 'N' Andy represented Black television, would have very low self-esteem. I don't find that to be the case.

I believe developing positive self-esteem is not as simple as just viewing an advertisement of another Black person or watching a television program which includes Blacks. While those types of exposures no doubt play a role in the development of self-esteem, I don't believe they play a major role. Viewing media images (such as advertisements and television programs) and decoding them to arrive at some meaning is a very complex process. There are multiple meanings I get when interpreting advertisements with other Blacks versus advertisements without Blacks. The ethnicity of the human model is only one media cue which affects my self-esteem, and as noted earlier regarding source effects, for me it is not necessarily a predominant one in many cases.

For example, I may be exposed to certain portrayals in the media which may highlight ethnic behavior which may be perceived as negative and stereotypical. However, I am also exposed to many other actual real-life situations in society, e.g. with my family, friends, co-workers, church members, neighbors, community members, etc. These real-life settings generally are quite different from unrealistic portrayals reflected in the media and hence act to discount those portrayals. A positive role model I encounter in real life, such as my father or other family members, has a much more powerful influence on my self-esteem than something I am exposed to or fail to get exposed to in the media. Therefore, while I am supportive of and applaud efforts to increase the number of minorities in the media, and more importantly to ensure that the portrayals are positive, I do not believe my self-esteem as a Black person hinges on that outcome.

CONCLUSION

I want to emphasize again that these thoughts represent my personal introspective analysis of issues related to Black consumer behavior. They are not meant to reflect the opinions of Blacks in general -- just the opinion of one Black middle-class consumer. But that is precisely the purpose of the introspection technique, to capture a more in-depth understanding by getting inside the mind of the researcher, and listening in, so to speak, as he reflects on his reaction to issues and concepts that affect consumers. As shown by Gould (1991), by using introspection, it becomes possible to make points about one's own consumer behavior experience that have not been otherwise dealt with in previous published studies, as well as to elaborate on other established concepts more deeply and richly.

Self-Fashioning Oneself Cross-Culturally: Consumption as the Determined and the Determining

Stephen J. Gould, Rutgers, The State University of New Jersey
Robert N. Stinerock, Fairleigh Dickinson University

What processes rather than essences are involved in present experiences of cultural identity? What does it mean to write as a Palestinian? As an American? As a Papua-New Guinean? As a European? From what discrete sets of cultural resources does any modern writer construct his or her discourse? To what world audience (and in what language) are these discourses most generally addressed? (Clifford 1988, p. 275-276).

Ethnographic self-fashioning (Clifford 1988) is a process which involves "increased self-consciousness about the fashioning of human identity as a manipulatable, artful process" (Greenblatt 1980, p. 2). In this process, an individual assumes the authority to control and purposely determine his/her own identity. This involves the linking of "cultural artifacts" drawn from discrepant worlds in ways that reflect the individual's own subjective experience (Clifford 1988). There are numerous well-known examples of such self-conscious bridging of cultures, especially in anthropology (e.g. Malinowski) and literature (e.g. Joseph Conrad). Such ethnographic self-fashioning also blends with today's postmodernist pastiche of emerging world cultural themes, made possible by both the mass and also the more segmented communications of the global village which have presented us with a montage of ever shifting and seemingly random images and their amalgams of ever new forms (e.g. world music). It also represents a process by which the self interacts with the extended self (Belk 1988) in the individual's self-determined psychodynamic development and also by which the self can adapt and integrate cross-cultural phenomena, such as occurs when one moves from one culture to another (Mehta and Belk 1991). Such a process situates the extended self in what one takes as one's given culture(s), defines its limits and range of activity, and helps to constitute what we might call one's personalized self-culture (cf. Obeyesekere 1981 on personal-private symbols versus public ones). In very practical or praxis terms (Gould 1991a), consumers can very much take an active role in designing their total consumption experience (akin to self-actualization) by deciding what cultural artifacts to take in or expose themselves to or avoid. They may have very definite goals in this regard (e.g. consumers who want to become more knowledgeable about classical music will attend concerts, read books toward that end, etc.) or they may have more 'goalless goals' defined in terms of 'experience and growth' though they are never certain where these will take them.

Against this backdrop, we as the Caucasian-American, middle class authors of this paper represent two colleagues who discovered that we have had parallel experiences in adapting Asian cultural beliefs and mores into our lives, while retaining our Western residences, livelihoods, and cultural roots. Our

consumption represents blends of the two cultures. We might characterize the process in the following terms: "When we're with Westerners, we feel Asian, but when we are with Asians, we feel Western." This pattern takes strange twists, however, in that many Asians have become so Westernized at least in our eyes that we feel more "Asian" in some respects than many 'real' Asians seem to be. Of course what it means to be Asian or Oriental is really problematic as a form of social construction and for further thought on this, see for example, Said (1978) and Clifford (1988). Here, we are concerned with our own phenomenological perceptions as individual consumers.

Consumption as an aspect of ethnographic self-fashioning plays a role in determining the directions we go as well as representing activities which are determined by the direction we have chosen. In the following, each of us gives an account of his personal self-fashioning experiences and at the end we draw some conclusions, based on these, for future developments in consumer research.

STEVE GOULD

When I was about seventeen, I made a kind of life-determining pledge to myself that I was going to realize as much about the world as possible in both a spiritual and intellectual sense. Needless to say, how I have framed that self-pledge over the last 27 years or so has changed enormously and continues to do so today. Perhaps most seminal in my ultimate life-course was the displacement and dislocation of the Sixties. For those of you who grew up about then, you will quite possibly have shared a similar displacement of our concepts of a 'normal existence' into wild, unknown, disorienting and sometimes frightening worlds involving a generally nomadic existence of disruption, disquiet, 'free love', drugs and self-exploration. My own self-explorations led me not only into these areas but also into such things as hypnosis, meditation and Eastern philosophy, and European film. In fact, I have as a practice tried things from just about anywhere if I felt something stimulating about it. I came to regard the ordinary culture in which I had been raised as somehow constituting a lack which could only be filled elsewhere. For instance, to this day, although I have fought with myself over it, I remain biased in favor of foreign movies, especially European and Japanese. I think I know what the American experience is like and therefore don't need to be told about it -- nonetheless I see more U.S. films anyway because I live here and some are of course good.

But it is my experience with Asian culture which has transformed me even more into something different than I could have ever conceived or different than most other people of my own culture even recognize. This long experience of over twenty years

has transformed the very nature of my consumption. On one level, I have explored products and services derived from Asia so that I have blended the use of Asian herbs and medicines, foods, books, ritual objects, etc. into my life. At this level, I have observed that people getting involved in Asian culture will often mark that involvement with the adoption of Asian customs of consumption -- a form of symbolic self-completion usually performed by someone less secure in a role than someone more secure in it (Wicklund and Gollwitzer 1982). This often marks an initial stage which later becomes more consonant with a combination of East and West. I must observe that I was combining from the beginning. For example, I have had no problem with being treated by traditional medical practitioners from India, Tibet or China nor do I have a problem being treated by modern Western allopathic doctors. It all depends on the circumstances but for some people, I have observed that such an openness extends beyond their belief system.

At a deeper level beyond the superficial parroting of Asian life style which I never really went too far with anyway, I have experienced a complete transformation of how I experience consumption and other aspects of life such as sex (Gould 1991b). Consumption has taken on a major role in my life praxis of self-fashioning a path of growth and balance. I have already recounted a portion of this in my paper on perceived vital energy in which I frame my consumption activities in terms of a general Asian approach to energy (Gould 1991a). Thus while some of my external forms of consumption activities have been visibly changed, much more important is how I consume in everyday circumstances some of the same things we all consume but with a different perspective. In this sense, I live in a visionary world in which all ordinary consumption activities help constitute and are inhabited by an extraordinary poetic beauty and grace. This vision I attribute to my internalization of various Asian views and my direct experience with 'high' practitioners of Asian methods and philosophies, especially Tibetan.

Thus, consumption for me is not a mundane matter of consuming to exist but instead is a revelatory activity in which my energy and consciousness are manifested as existence itself. This is not to glorify consumption since I regard other aspects of life to be more exalted but it is also to say that exaltation can emerge anytime, anywhere. At the same time, I make consumption choices with exaltation in my mind -- in others words, I both actively intend to create such exaltation out of my experience yet leave room for it to happen without any intended action on my part except to watch and experience it. For example, I may try a new food because I feel it has a certain power or appeal and I want to experience that. Yet, I might also have some passionate experience with something I eat everyday. This for me is the self-fashioning experience brought about by my continuing and insistent exposure to Asian culture which magnifies the ordinary. Indeed, it has been a major research project of mine to explore the dimensions of consumption experience in East-West terms (Gould 1991a,b,c) to enable us to emerge

from the "Occidental enclosure" which shields us not only from the East but much of the rest of the world (Barthes 1988). I might add that this might be construed as deconstructing and rephenomenologizing the 'modern/post-modern project' which disembowels traditional cultures and serves their sinews up as part of the hyperreality of Western culture (Baudrillard 1983). The real penetration of other cultures, if it is at all possible, and if it is also possible to speak of a culture as an existing thing at all, must be at much deeper level than hyperreal social construction will allow.

BOB STINEROCK

One particularly memorable and invigorating consumption experience -- an Asian trip during December 1989 to January 1990 -- led me to an entirely new pattern of subsequent consumption experiences. The decision to make such a trip was based on simple curiosity about the East as well as a life-long love of international travel. I had spent part of my life living overseas but never in the East -- several years in various parts of Europe, somewhat less time in parts of Canada, Latin America, and the Caribbean. I had also had many Asian friends and acquaintances during all periods of my life, most notably Chinese during my grade and secondary school years, and Chinese, Indians and Pakistanis during my college and graduate school years. Nonetheless, until I decided to make my initial foray into Asia, the West was all I knew directly; the East I only knew through friends, schoolmates, television, films, foods and a smattering of Eastern art, literature and music.

None of this prepared me for what I found in India. Indeed I learned that simply knowing a lot of Asians in New York City in no way prepared me for what I experienced. The impact was immediate, powerful and far-reaching. It occurred on at least three levels which can be seen in their effect on my consumption to this day: (1) physical, (2) mental and (3) spiritual.

Physically, I now practice hatha yoga which is characterized by exercise techniques with the goal of physical relaxation and mental calm. Also, my interest in Asian food has extended far beyond my having an occasional meal in Asian restaurants. For example, I regularly entertain groups of friends in my home by cooking Chinese, Indian, Indonesian, and Sri Lankan cuisines. This new interest culminated this year by my taking an extensive course in Indian cooking. Nearly half of all meals I prepare for myself include some type of Asian cuisine. Moreover, I returned to Asia the following year and I have plans for more extensive Asian travel (at this writing), including not only India where I concentrated before, but also Thailand, Malaysia and Hong Kong.

Mentally, my new consumption pattern is represented by my strong interests in Asian art, literature, and music. In addition, I have been watching television programs, seeing films and reading publications targeted to Asian-Americans. I also joined the Asia Society of New York and have taken a course in Hindi.

Finally, and most important to me in a personal sense, my new consumption pattern has manifested itself at a spiritual level as well. What started as merely an intellectual interest in Eastern philosophies and religions has inevitably evolved into something more deeply important in a spiritual sense. Indeed, I have been a struggling but enthusiastic student of meditation and raja yoga for nearly a year and a half.

Does all this mean that I have repudiated the more materialistic West of which I am a product. Certainly not. Even if I could do so, I have no desire to turn away from my formative culture. Even though I now see the West with a keener sense of perspective than I did before my travels to Asia and even though I now see my culture in a kind of "warts and all" light, I am, and always will be, essentially Western.

What all this does mean, however, is that I can now pick and choose my consumption experiences in a way I never could before and that I am now faced with choices which are the best of the West and the best of the East. For example, while the nature of and motivation behind many of my consumption experiences have changed, I still choose to live in the West (in Manhattan, where I have lived most of my life), work there (as a business school professor in New Jersey), and recreate there (spending part of each year in such places as Europe, Texas and Minnesota). Thus, I now have more choices and I make these choices in a more informed manner than I did before.

In the broadest sense, my consumption experience of traveling East turned out to be deeply and personally liberating and that I now have more interesting choices as a consumer represents only one change in my life. There are several others, not the least of which is my becoming aware of all the Western cultural biases I have been carrying all my life. Ironically, perhaps, I required a number of trips to the East to begin to learn what it even means to be Western. Happily, this awareness has resulted in a reduction in the initial tension I felt between my native Western side and my newly emerging Eastern persona. In fact, I feel no sense of dislocation but instead I feel more like a citizen of the world than merely a citizen of New York, the United States or even the West.

CONVERGENT/DIVERGENT PATHS OF TRANSFORMATION

While the two of us share many similarities in our approach to life and consumption, we have arrived there by different paths and continue on them as well. For example, one of us (Bob) took a trip to India and based on that intense experience underwent a psycho-spiritual transformation which led to his becoming involved in Indian spirituality upon returning to the states. On the other hand, the other of us (Steve) got involved in Tibetan spirituality in the U.S. and marked that some years after his initial involvement by a visit to India (where Tibetan refugees live). In Bob's case, the consumption experience served as a determinant of new unforeseen patterns of self-fashioning and led to a major and unexpected transformation which he has subsequently followed with continued self-fashioning.

In Steve's case, consumption experience in the form of an Indian trip was determined by his already ongoing pattern of self-fashioning.

Beyond these experiences, we two in common have engaged in a whole host of self-fashioning consumption 'growth' experiences such as eating and cooking macrobiotic food and also Indian food with hot spices, using Asian herbs such as Ginseng, collecting Asian art objects, reading Asian books, seeing Asian movies, listening to their music, and studying and practicing their psychotechnologies (Roberts 1989), such as yoga and meditation. Moreover, our own experience is not confined to one or two countries but extends to other East Asian countries, such as China, Korea and Japan as well as European. Beyond that, it seems to have made us open to other 'traditional' cultures such as Native American, Native Hawaiian, Balinese etc. in search of the 'primordial wisdom of the primitive. Yet again each of us has had our particular idiographic experiences which have made us differ widely in many aspects. In any case, our view of consumption in our own society has changed tremendously (cf. Gould 1991a). For example, an occasion of celebration, dancing and drinking etc. whether at a bar or a party now seems to take on shamanistic energies and informs and transforms the event semiotically into aspects and levels of meaning beyond what is ordinarily conceived. Thus, even our Western consumption has changed existentially, connotatively, and in purpose - a sort of Nietzschean transvaluation of our experience. While there may seem to be some conflicts and even some alienation between our Western and Eastern minds, our consumption necessarily will always be some amalgam of the values, beliefs and mores of the two cultures although the nature of the amalgam will always be evolving.

SUMMARY OF THEMES AND RESEARCH IMPLICATIONS

The following comprise the summary and interrelated themes of our experience in which cross-cultural consumption on the part of the individual plays a large self-fashioning role:

- (1) the enhancement of identity formation and enrichment, especially as that relates to one's cultural identity,
- (2) the formation of a transformed world-view which provides one with a radically different perspective than one had before,
- (3) the personalization of cross-cultural phenomena in relating and mixing various cultural symbols for oneself,
- (4) the marking of the encounter with otherness (i.e. foreign cultures) [Bar 1979], including many aspects of consumption from food to film,
- (5) the expansion of the construction of one's personalized self-culture.

Future research should aim at discovering the meanings of goods involved in self-fashioning and at penetrating the mysteries of consumers' overdetermined behavior which involves the nexus of cultural and psychodynamic phenomena (Devereux 1980) in the construction of their personalized self-cultures. This may involve cross-cultural aspects of consumer self-fashioning as we emphasized here but may involve many other aspects as well, among which are included: (1) sexual self-fashioning through the use of goods to enhance or fulfill sexual activities in defining one's sexual identity, (2) gender self-fashioning through taking on more or less qualities associated with a particular gender identity, (3) lifestyle self-fashioning in seeking to mold oneself as a representative of a particular lifestyle, and (4) self-actualizing self-fashioning in whatever way any particular consumer views it for him or herself. The idea of self-fashioning requires us to shift our focus to more holistic and phenomenological notions of consumption so that we can investigate at the deepest possible levels how consumers *actively* and *consciously personalize* their cultural environment, embody it, and transform it to suit themselves.

Implications of the Symbolic Interactionist Perspective for the Study of Environmentally-Responsible Consumption

Ed Petkus, Jr., University of Tennessee

ABSTRACT

Consumers can exhibit environmental responsibility by acquiring and using certain products, neglecting to acquire and use certain products, and conscientiously disposing of all products. This paper argues that environmentally-responsible consumption research can be enhanced by the application of the symbolic interactionist perspective. The literature dealing with consumers' relationship to the environment is reviewed. Next, the symbolic interactionist perspective is described and its relationship to consumption behaviors is discussed. Finally, the implications of the perspective for environmentally-responsible consumption research are discussed, and research issues are presented.

Consumers are currently professing environmental concern. Indeed, a recent survey revealed that people are not only concerned about environmental matters (76% of adults described themselves as "very concerned" about environmental issues), but that this concern is being manifested in altered consumer behaviors (ORC 1990). Another poll found that 4 out of 5 people agreed with the statement: "Protecting the environment is so important that requirements and standards cannot be too high, and continuing environmental improvements must be made regardless of cost" (Glazer 1990). Consumers have also indicated that they want to know how to select products that are environmentally safe, and that they desire accurate product labeling and advertising about environmental information (Chase 1991).

While such studies provide basic, general information on environmental attitudes and behaviors, there remains a need for research that provides a deeper understanding of environmentally-responsible consumer behavior. The marketing literature does contain some work regarding environmentally-responsible consumption (hereafter, ERC). Most of this research (to be reviewed later in this paper) occurred in the late 1970s and early 1980s. While many current environmental issues are undoubtedly similar to those that were studied then, there are important differences that make further study of ERC necessary. In general, consumers today are influenced by different political, cultural, and social atmospheres than they were ten and twenty years ago. Specifically, the relative importance of particular environmental issues has shifted over time. Issues such as the potential "greenhouse effect", ozone depletion, dolphins drowning in tuna nets, deforestation, and overflowing landfills are some of the current areas of concern. The fact that environmental issues and concerns are constantly changing (Hume 1991) implies that ongoing research into their influence on consumer behavior is essential.

"Environmentalism" can be viewed as a social phenomenon that influences, and is manifested in, individual behavior. Sociology provides researchers

with the theoretical perspective of symbolic interactionism (SI). The SI perspective holds that people act toward objects based on the meaning that those objects have for them (Blumer 1969; McCall and Simmons 1978). SI is an especially appropriate perspective for the study of ERC because (1) ERC is a specific type of consumer behavior that is directed toward and influenced by issues and concerns that can have a wide variety of meanings for different people, and (2) ERC involves individual responses to a socially-developed and socially-maintained concern.

The purpose of this paper is threefold. First, the literature regarding marketing and the environment will be examined, with an emphasis on ERC issues. Next, the SI perspective will be briefly described, along with a discussion of the links between SI and consumer behavior in the marketing literature. Finally, the implications of the symbolic interactionist perspective for ERC research will be presented, along with corresponding research issues.

MARKETING AND THE ENVIRONMENT:

A REVIEW OF THE LITERATURE

In the early 1970s, several authors addressed the broadening role of marketing in terms of the relationship of marketing to the environment. Kelley (1971) predicted that the environment would become the most important social issue to be considered by the business community. Feldman (1971) foresaw a developing social conscience in marketing, especially with respect to the restoration and preservation of the natural environment. Weiss (1971) anticipated that the "style" of our economy would shift away from one characterized by excessive production, consumption, and waste to one characterized by extensive recycling and more rational levels of production. Shuptrine and Osmanski (1975) discussed "clean-up" and "conservation" as aspects of the changing role of marketing.

The literature specifically addressing ERC issues can be segmented into three main areas. First, several researchers have studied socially responsible consumers, defined as consumers who tend to consider the effects of their purchases on society as a whole, or at least on certain aspects of the social world. Kassarijian (1971) found that people who were more concerned about air pollution had a greater awareness of and were more receptive to an advertising campaign introducing a low-polluting gasoline. Anderson and Cunningham (1972) profiled the high social-consciousness consumer as a pre-middle age adult with relatively high occupational and socio-economic status, who was more cosmopolitan, less dogmatic, less conservative, less status conscious, and less alienated than a consumer exhibiting low social consciousness. Kinnear, Taylor, and Ahmed (1974) identified *ecologically* concerned consumers as scoring high in perceived consumer effectiveness,

openness to new ideas, need to satisfy intellectual curiosity, and need to realize personal safety. Webster (1975) characterized the socially conscious consumer as a member of the upper-middle class "counterculture" that is willing to engage in purchase behaviors that are consistent with personal standards of responsibility, even though the behaviors may not be "popularly accepted." The socially conscious consumer was also characterized as "self-actualizing" (Brooker 1976). Finally, Antil (1984) found that perceived consumer effectiveness, willingness to undertake efforts to be socially responsible, knowledge of environmental issues, and environmental concern were positively related to a measure of socially responsible consumption tendency.

Second, a considerable amount of consumer research addressed the energy crisis of the late 1970s and early 1980s. Several authors researched the effects of energy conservation-related communications and information on consumers (e.g., Reizenstein and Barnaby 1976; Craig and McCann 1978; McNeill and Wilkie 1979; Hutton and Wilkie 1980; Walker 1980; Allen 1982). Consumer attitudes toward energy conservation topics have also been investigated (e.g., Reizenstein and Barnaby 1976; Heslop, Moran, and Cousineau 1981; Belk, Painter, and Semenik 1981; Bennett and Moore 1981; Tashchian, Slama, and Tashchian 1984; Haldeman, Peters, and Tripple 1987). Finally, consumer behaviors related to the energy crisis have been examined (e.g., Ritchie, McDougall, and Claxton 1981; Leonard-Barton 1981; Verhallen and van Raaij 1981; LaBay and Kinnear 1981; Hutton and McNeill 1981; Warriner 1981; Downs and Freiden 1983).

Third, research that specifically discusses ERC has been conducted, addressing the phenomenon from both an aggregate and an individual perspective. Taking an aggregate perspective, Fisk (1973, p. 24) defines responsible consumption as the "rational and efficient use of resources with respect to the global human population." He states that irresponsible consumption in any given geographical area will, at least indirectly, affect the state of resources elsewhere on the planet, and that analysis should thus be conducted on a global level. Uusitalo (1986) proposes a model of the ecological impacts of consumption style that relates demographics, institutional variables, and value variables to consumption style, which in turn has various ecological impacts (including post-consumption waste, energy use, and other pollution). In the applied arena, Henion (1972) found a relative loss of market share for detergent brands high in phosphate and a gain for brands low in phosphate when consumers were provided with phosphate-content information.

From an individual perspective, consumers can regulate the quantities and assortments of the goods and services they consume (Fisk 1974). Kinnear and Taylor (1973) found that (1) an ecological dimension was used by buyers in detergent brand perception; (2) the higher a buyer's ecological concern, the more important the ecological dimension in the buyer's perception of alternative brands; and (3) the higher a

buyer's ecological concern, the greater the perceived similarity of brands that are ecologically benign. Murphy (1975) showed that the importance rating of "harm to the environment" for paper towels and laundry detergents increased with the level of ecological information provided, and that the effectiveness of ecological information was inversely related to prior knowledge of environmental issues. Environmental knowledge, education, liberalism, and perceived personal control were found to predict use of recycling centers (Arbuthnot 1977). Allen (1982) found that perceived consumer effectiveness was linked to responsiveness to influence techniques and propensity for energy-conserving behavior (see also Awad et al. 1983). Olney and Bryce (1991) suggest that consumer researchers examine the ERC-information relationship with respect to two dimensions: (1) the consumption *process*, involving acquisition, use, and disposal stages; and (2) *focus* -- looking at the ERC-information relationship from an individual, interpersonal, and cultural or cross-cultural point of view.

In sum, previous academic treatment of ERC has provided descriptions of general relationships among relevant variables and has defended normative thought. However, a deeper understanding of ERC requires research that examines how, why, and under what circumstances the phenomenon occurs. This paper submits that the SI perspective can facilitate such research.

SYMBOLIC INTERACTIONISM AND CONSUMPTION

The basic principles of SI, as outlined by McCall and Simmons (1978), can be summarized as follows: People continuously construct plans of action. Plans of action are executed based on the meanings of objects (i.e., things, people, or ideas) encountered; therefore, people constantly identify and interpret the meanings of objects that are relevant to their plans. The meanings of these objects are the implications of those objects for the plans of action. For social plans of action, meanings of objects must be consensual to the extent that they are sufficiently common to allow mutual adjustment of lines of action. Finally, the most important object whose identity (and its meaning) must be consensually established in any situation is the person him/herself.

Fundamental to this conceptualization of SI is the concept of *role-identity*. McCall and Simmons (1978) define role-identities as people's imaginative views of themselves as they like to think of themselves being and acting as occupants of particular positions. A role-identity consists of (1) conventional elements (acquired through socialization and past social experiences) that are relatively stable and (2) idiosyncratic elements that arise from interpretations that are tied to specific situations, and are thus dynamic and mutable. Role-identities determine our interpretations of the meanings of situations, events, and people that we encounter in social interactions (McCall and Simmons 1978).

Role-identities are legitimated by role-performance, both internal (imaginative) and overt

(behavioral). Role performance in the form of overt behaviors is designed to elicit role-support, which is the implied confirmation by others of an individual's role performance (McCall and Simmons 1978). The elicitation of role-support can be facilitated by role-taking, which affords a person the ability to anticipate the actions or attitudes of others toward the self, and involves internalizing the attitudes, values, and anticipated actions of others associated with the relevant social context (Cuff and Payne 1979). In addition, role "self-support" can be used to maintain a role-identity through a process of self-interaction (McCall and Simmons 1978).

The role-identity model thus seeks to explain behavior based on the enactment of roles in the context of others' perceived reactions to the behavior:

The individual wants very much *to be and to do* as he imagines himself being and doing in a particular social position. As this congruence is seldom entirely possible, role support -- social testimony in support of his imaginings -- takes on considerable value to the person and may in fact become the major goal of a particular performance (McCall and Simmons 1978, p. 72-3, emphasis in original).

While the symbolic elements of consumption have been addressed by many authors (e.g., Holbrook 1978; Levy 1981; Belk, Bahn, and Mayer 1982; Holbrook and Hirschman 1982; Levy 1982; Holman 1983; Belk, Mayer, and Driscoll 1984; McCracken 1986; Mick 1986; Solomon 1988; Belk 1988), discussion of the SI perspective in consumer research has been limited. Kinch (1967) presents three postulates that relate SI to consumers:

1. A consumer's self-concept is based on perceptions of the responses of others.
2. A consumer's self-concept functions to direct behavior.
3. A consumer's perception of the responses of others to some degree reflects those responses.

Drawing on McCall and Simmons (1978), Schenk and Holman (1980) present a model in which comparison of brand image and situational self-image drives brand choice. When people select an image to project in a social situation, they find ways to express that self-image. One way this can be accomplished is through the purchase of products. Lee (1990) discusses the implications of symbolic interactionism for consumer self-concept and product symbolism research. Lee presents a model of brand choice that integrates: (1) the situational self with the actual self; (2) social risks with functional and performance risks; and (3) public consumption situations with private consumption situations.

Solomon (1983) discusses the role of products as social stimuli. Symbolic products "set the stage" for the various social roles that people assume, and the

consumption of such products is designed to indicate and clarify the meaning of role behavior. Products can thus help define the self, and can function as stimuli that cause behavior. In this capacity, product symbolism can facilitate role performance, self-attributions, and the establishment of situational self-images. The symbolic properties of products have meanings that are shared within a cultural context. People undergo a self-interactive, reflexive evaluation of the meanings assigned by others to products, and incorporate this interpreted appraisal by others into the self-concept.

IMPLICATIONS OF THE SYMBOLIC INTERACTIONIST PERSPECTIVE FOR ERC RESEARCH

Through news media coverage, advertising, and product labeling, the potential environmental impact of many products, whether positive or negative, can often be identified. Because of this, these products may function as symbols of "environmental responsibility" when associated with positive environmental effects, or as symbols of "environmental irresponsibility" when associated with negative effects. Similar environmentally-related symbolism may be associated with product use and disposal behaviors.

Application of Solomon's Symbolic Consumption Framework

Solomon's (1983) five propositions addressing the role of products as social stimuli can serve as a useful framework in which to study ERC issues:

1. The symbolism associated with many products is the primary reason for the purchase and use of those products (Solomon 1983).

The "environmental responsibility" symbolism associated with certain products (e.g., non-animal-tested cosmetics) and behaviors (e.g., recycling, choosing cloth vs. disposable diapers) may be the primary reason for the purchase of those products and the execution of those behaviors. Such purchases may serve to legitimate an "environmentally responsible" role-identity. This legitimation would be reinforced through role support by (1) direct support of others (e.g., comments about the responsibility of the purchase) and/or (2) a role-taking process where the reactions of others are anticipated. Also, the symbolism associated with environmentally-related use and disposal behaviors may stimulate their enactment.

2. Individuals can, to a significant degree, be evaluated and placed in a social nexus based on the products that surround them (Solomon 1983).

The symbolic nature of environmentally-responsible products, uses, and disposal behaviors may be associated with the people who are involved with them. The corresponding symbolism associated

with a person then serves to present to others an environmentally-related image of that person, and can facilitate others' evaluations of that person. For example, a person may be viewed by others as an "environmentalist" (e.g., carrying a cloth grocery bag filled with vegetarian foods walking toward an economical car with a Greenpeace sticker in the window), or a person may be identified as uncaring about the environment (e.g., carrying plastic grocery bags filled with beef, and pulling away in a gas-guzzling car exuding black exhaust smoke).

The possession of and use of environmentally-responsible products may affect how an individual is perceived by both significant and non-significant others. Whatever the image presented, others may evaluate it based on the meanings they themselves attach to the symbols upon which the image is grounded. Before individuals undertake an environmentally-responsible action, they may anticipate (through role-taking) the reactions and evaluations of others regarding the meaning of that action. Individuals' interpretations of the potential reactions of others can then serve to reinforce, modify, or negate the intended course of action.

3. Through reflexive evaluation, people can assign social identity to themselves based on the interpreted meanings of product symbolism (Solomon 1983).

Environmentally-responsible images perceived by others become self-images when individuals undergo a role-taking, interpretive, reflexive evaluation process in which they make indications to themselves as to the meanings of their outwardly-presented symbols. These indications can result in the formation of a role-identity in which a consumer desires to see him/herself as being and acting "environmentally-responsible," especially when positive feedback from others is perceived or anticipated. Role performance associated with such a role-identity may result in the development of corresponding attitudes (e.g., "Protecting the environment is the most important issue today") and lines of action (e.g., organizing neighborhood recycling projects). Interpretive self-interaction regarding the meaning of the symbolism associated with these attitudes and actions may also support the role-identity.

4. The process of self-definition will result in the development of scripts that guide behavior (Solomon 1983).

An environmentally-responsible role-identity would shape the interpretations of symbolism in consumption situations that have environmental implications. Subsequent behaviors will be directed toward further reinforcement of that self-image. The reinforcement of the self-image will be facilitated through further association with products and with use and disposal behaviors that embody symbolism that is commensurate with the developed self-image. For example, an individual who sees him/herself as

"environmentally-concerned" would tend to recognize the environmental implications of a wide variety of consumption behaviors, such as shopping for household supplies, heating a home, or deciding how to throw away things while cleaning the garage. Choices made with respect to these behaviors can symbolize environmental concern -- e.g., buying aerosol-free cleaning supplies, setting the thermostat low, and properly disposing of chemicals. By making such decisions, individuals reinforce their "environmentally-concerned" self-image.

5. Symbolic consumption can exert an a priori effect on role definition, especially in situations where scripts are weak (Solomon 1983).

The interpretive process whereby an environmentally-responsible self-image is developed may be more likely to occur in situations where alternative lines of action (perhaps based on alternative self-images) are absent or not adequately established to override an emergent "environmentalist" self-definition.

Application of Other SI Theoretical Considerations

Both the conventional and idiosyncratic elements of role-identities have implications for ERC. Conventional elements would involve the development of sustained behaviors and behavioral standards. These behaviors would be based in aspects of the role-identity that are developed through socialization and past social experiences. For example, environmentally-responsible habits may be learned from parents, school projects, etc. Idiosyncratic elements of role-identities would be involved in specific consumption situations that have implications for environmental responsibility. Decisions made in such situations would be tied to a situational self-image where the perception of others in the situation influences which self-image is evoked (Schenk and Holman 1980). For example, the decision of whether to toss a soft drink can into the trash or to save it for recycling might be affected by an individual's anticipation of the reactions of others nearby, with respect to the self-image that the individual desires to portray.

As Olney and Bryce (1991) suggest, ERC research can benefit from addressing the different stages of the consumption process -- acquisition, use, and disposal. As indicated above, all stages of the consumption process may be impacted by symbolic designation, role-taking, and self-interaction. Each of these stages can also have environmental implications (Olney and Bryce 1991). Purchase situations include those in which significant and/or non-significant others are present. For example, family members or friends could witness the purchase of an ozone-depleting aerosol, or consumers could be asked, "Paper or plastic?" at the grocery store with a crowd of strangers standing in line behind them. Use situations include driving a car that is emitting clouds of black smoke or using non-recyclable products when

recyclable alternatives are readily available. Disposal situations include throwing away recyclable materials.

Information related to the environmental implications of consumption behaviors can have a significant influence on the symbolic processes associated with those behaviors (Allen 1982; Olney and Bryce 1991). As mentioned earlier, media coverage of environmental issues, and the influence that consumers can have on these issues, has increased dramatically. Also, advertising and promotions are increasingly emphasizing the positive environmental effects of products. Consumers are therefore being exposed to a great deal of information that serves to develop and/or reinforce the symbolism associated with environmentally-related products and behaviors. Consumers can incorporate this information into the interpretive process by which meanings are attached to the symbols. However, research that simply examines the correlation between environmental information and ERC attitudes and behaviors, while perhaps necessary, is insufficient. An understanding of what that information *means* to the consumer and how it is incorporated into interpretive processes of self-image or role-identity formation is vastly more important for gaining an in-depth understanding of the phenomenon. Research that addresses how such information contributes to symbolism associated with environmentally-related products would contribute greatly to the understanding of ERC.

Another issue involving environmentally-related product information is the *accuracy* of that information. Conflicting reports of the environmental effects of various products and practices can be obtained across and even within sources. For example, despite the extensive reporting of the declining state of the environment, a recent editorial presents evidence that the air and water are getting cleaner, acid rain may prevent global warming, urban smog offers protection from ozone depletion, and family farmers dump more chemicals than toxic waste sites (Easterbrook 1990). Information that contradicts prior beliefs regarding the effects of products may play a different role in the interpretive process of role-identity formation -- perhaps catalyzing a modification of the role-identity.

Some ERC-related decisions, whether benign or detrimental, may involve habit or routine behavior. For example, a family may always use styrofoam rather than paper plates on their picnics, or a family may always purchase the same brand of non-biodegradable diapers, regardless of the amount of information to which they are exposed about the environmental impacts of such products. Conversely, some ERC decisions may involve a trade-off analysis. In this case, an evaluation of alternative courses of action occurs, and there are both positively- and negatively-perceived aspects of each alternative. Examples range from evaluating the higher price of an environmentally-responsible product to evaluating the relative effects of deforestation vs. overflowing landfills when making a "paper or plastic" grocery bag decision. Such alternatives may be evaluated based on the meanings that they are perceived to impart, especially with respect to the presentation of a self-

image. The relative attractiveness of alternatives may also be grounded in conflicting role-identities. For example, people may perceive themselves to be environmentally-responsible, but also as upscale and status-seeking. These role-identities could conflict, for example, in an automobile purchasing situation (energy-efficient and plain vs. gas-guzzling and prestigious).

ERC research would also benefit from examination at different levels of aggregation (from individuals, to segments, to society as a whole). SI holds that, at any level of aggregation, interlinkages of action are operating based on the meaning that these symbolic products have for people (Blumer 1969). An examination of the process by which the meanings of certain product symbols become consensual and widespread would enhance the understanding of ERC by bridging levels of aggregation. Such research could also improve the understanding of how ERC-related, societal-level "taboos" (such as "don't wear fur," "don't buy tuna", etc.) are established and maintained.

CONCLUSION AND RESEARCH ISSUES

This paper has attempted to show the potential for combining a current research area in marketing -- environmentally responsible consumption -- with a sociological perspective that has received limited attention in consumer research -- symbolic interactionism. ERC is a specific type of consumer behavior that is directed toward and influenced by issues and concerns that can have a wide variety of meanings for different people, and involves individual responses to a socially-developed and socially-maintained concern. ERC is a complex phenomenon; therefore, its investigation requires a research perspective that can facilitate and enhance the understanding of those complexities. This paper proposes and seeks to demonstrate that the conceptual implications of SI correspond compellingly to the conceptual issues involved in ERC, and that the application of the SI perspective can improve the level of understanding of ERC. By extension, the SI perspective may also be useful in understanding how the attitudes and behaviors associated with various lifestyles or values are established, maintained, and changed.

The above discussion of the implications of the SI perspective for ERC research suggests several research issues that can be organized around the main elements of the role-identity concept:

Role-Identity Issues

1. How are "environmentally-responsible" role-identities established, maintained, changed, and/or abandoned?
2. What do environmentally-symbolic consumption behaviors say about people to *themselves* in the course of self-interaction?

3. How do the reactions (both actual and anticipated or imagined) of others influence the establishment of ERC-related role-identities?
4. How are the conventional and idiosyncratic elements of an ERC-related role-identity related?
5. How is environmentally-related information incorporated into consumers' interpretive processes, and what is its function in the role-identity formation process? What are the implications of this process for modifying behavior?
6. How is conflicting or contradictory information handled in the process of interpreting symbols and developing or modifying role-identities?
7. What specific aspects of personality and lifestyle facilitate role performance for an ERC role-identity?
8. What are the differences between environmentally-responsible and -irresponsible consumers? How are ERC-related role-identities linked to other role-identities that are not related to environmental responsibility?
7. How do role-identities affect the reinforcement (or abandonment) of habits? How do they affect trade-off analyses?
8. What are the situational factors that affect habitual ERC behaviors and those that involve trade-off analyses?
9. What are the implications of ERC symbolism for behaviors at different levels of aggregation? How are societal-level, ERC-related "taboos" established, maintained, and/or abandoned?
10. What specific aspects of personality and lifestyle facilitate role performance for an ERC role-identity?

Role Performance Issues

1. How do the reactions (both actual and anticipated or imagined) of others influence role performance associated with an ERC-related role-identity?
2. What factors facilitate the link between the establishment of an "environmentally-responsible" role-identity and actual environmentally-responsible consumption behaviors?
3. How are lines of action modified as a function of the relationships among ERC-related role-identities and other role-identities?
4. How are ERC behaviors affected by the interaction of conventional and idiosyncratic elements of an ERC-related role-identity?
5. To what degree is environmentally-related symbolism a stimulus for acquisition, use, and disposal behaviors?
6. How do ERC behaviors differ across different stages of the consumption process?

Role Support Issues

1. How do ERC behaviors elicit role-support from others that reinforces the role-identity?
2. In what ways is role support for an ERC role-identity manifested?
3. What specific aspects of personality and lifestyle facilitate role support for an ERC role-identity?
4. What are the situational and temporal factors associated with the elicitation of role support?
5. Does environmentally-related information function as role support for an ERC role-identity?

McCall and Simmons (1978) offer a discussion of the research issues associated with role-identities. Role-identity sets (the assortment of role-identities associated with an individual) can be identified using a combination of unstructured instruments such as the Twenty Statements Test of Self-Attitudes (Kuhn and McPartland 1954) and structured questionnaires that allow subjects to select social roles from a comprehensive list. The relative prominence of the role-identities can be measured by having subjects rate the importance of various role-identities to themselves. Role-identities can also be rated in terms of their relative salience (as determinants of performance in specific situations), which will be influenced by prominence, current need for support, current need for intrinsic and extrinsic gratification, and perceived opportunity to enact the role-identity. To determine the role-identity "contents" (i.e., what an individual thinks about him/herself as an occupant of a role) of a role-identity of interest, attention should be paid to specific activities, style and manner, appearance, reference groups and significant others, and recurrent themes associated with the role prominence and salience hierarchies. This research scheme may thus be used to examine the existence,

prominence, salience, and contents of an "environmentally-responsible" role-identity.

In addition to role-identities, other individual and interpersonal constructs may be relevant to ERC research that is based on an SI perspective. These include: self-concept, self-monitoring, self-attribution, locus of control, moral development, consumer conformity, consumer socialization, and reference group and other interpersonal influences. An examination of these and other constructs in an ERC context would contribute to the body of knowledge about ERC.

Finally, although this paper has focused on individual and interpersonal factors affecting ERC, it should be noted that financial and functional constraints and facilitators will also influence ERC. Financial constraints on ERC could occur when environmentally-responsible consumption alternatives cost prohibitively more than other alternatives. Financial facilitators include incentives to stimulate energy conservation (Hutton and McNeill 1981; Hutton and Markley 1991). Functional constraints involve lack of availability of environmentally-responsible alternatives in some product categories, inadequate dissemination of information about the environmental consequences of consumption behaviors, and diminished performance of some environmentally-responsible products. Functional facilitators include proliferation of environmentally-responsible alternatives, increased amount and accuracy of information, better performance of some environmentally-responsible products, and community programs (such as those that provide recycling bins).

When all the social psychological, financial, and functional factors that influence ERC are considered, the complexity of the phenomenon becomes readily apparent. This complexity, combined with the current relevance of environmental issues, presents significant research opportunities. The investigation of ERC represents an important and timely challenge for consumer researchers, and such investigation would be significantly enhanced by a research program that applies the SI perspective.

Consumer Assessments of Responsibility for Product-Related Injuries: The Impact of Regulations, Warnings, and Promotional Policies

Mitch Griffin, Bradley University

Barry J. Babin, University of Southern Mississippi

William R. Darden, Louisiana State University

ABSTRACT

This paper examines the impact of regulations, warning labels and promotional policies on consumers' attributional processes. The results of an experiment manipulating these characteristics within a product-injury scenario show that the manner in which these managerial factors are treated can affect assignments of responsibility. In addition, the degree to which an injury is unanticipated is also shown to affect consumer attributions.

INTRODUCTION

A wide range of marketing decisions, including pricing policies, distribution systems, and advertising claims are governed by public policy regulations (Werner 1982). The area of consumer safety, however, may be the most heavily regulated aspect of the marketing discipline. Beginning with the Pure Food and Drug Act (1906), a steady stream of government agencies and legislation has been enacted in an effort to protect consumers from unsafe products. The marketing academic community has responded by investigating attitudes and opinions of various parties involved with public policy and by keeping abreast of developments in product safety legislation. As examples, Busch (1976) surveyed bicycle manufacturers to determine their evaluation of Consumer Product Safety Commission (CPSC) safety regulations. Later, Busch and Hair (1980) compared the attitudes of three different parties, manufacturing executives, insurance executives, and state insurance commissioners, regarding a variety of product safety issues. Taking a different approach, Morgan (1982; 1986; 1988; Morgan and Avrunin 1982) has extensively reviewed product liability legislation and court cases, discussing policy implications as they relate to consumers and policy makers. Each of these studies has provided valuable insight into a diversity of public policy issues.

The present study compliments previous research on product safety issues by offering perceptions and reactions from a consumer's perspective. More specifically, the objective of this research is to assess the effect of three dimensions of product safety policy on consumer attitudes and behavior: (1) product safety regulations; (2) warning labels; and (3) advertisements stressing product safety. To accomplish this goal, this study briefly reviews the present product liability situation, presents a theory-based model of consumer assessment of responsibility for a product-related injury, develops the intervening role of "unanticipated consequences" of product usage on consumer evaluations of these mishaps, and empirically tests relationships implied by the model utilizing experimental scenarios.

BACKGROUND

Unquestionably, the product safety arena is of great importance to consumers and decision makers. To illustrate this point, consider the plight of one industry, general aviation, hit particularly hard by escalating costs. The production of light aircraft has been sharply curtailed, from 17,811 units in 1978 to 2,438 in 1984 (North 1985) and continues to fall. This rapid decrease has been directly attributed to the reported \$60,000 to \$100,000 per unit liability insurance expense (Gatty 1987).

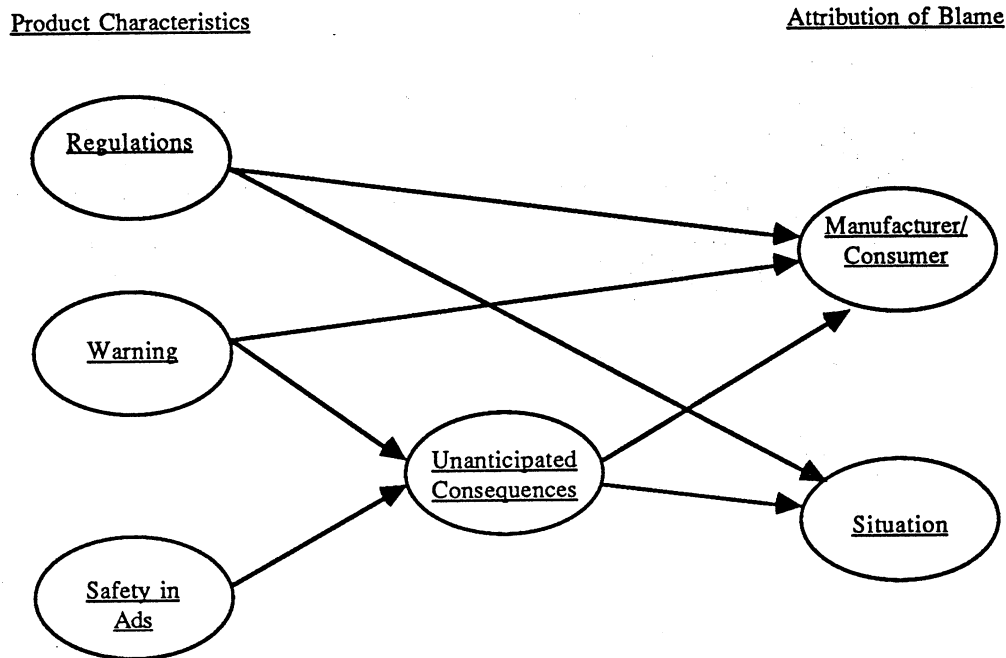

Likewise, many other industries, including pharmaceutical and cosmetic producers and distributors (Friend 1990), health care providers (consider the plight of OB/GYN physicians), and even volunteer coaches of children's sports teams (Mihoces 1990) have been hard hit by the potential of liability. For consumers, the liability crisis has greatly increased prices (*Private Pilot* 1990), limited the selection of products available in the market (Olsen 1989), and stifled technological innovation (Martin 1989). With few exceptions, those marketing consumer goods must be better aware of the costs and consequences of product liability, as well as consumer perceptions of product safety issues, to better serve their customers and secure a competitive position.

Three actions which may be taken by marketers which may affect consumer attitudes toward product safety concern (1) the application of available safety standards, (2) the use of appropriate warning labels on products, and (3) an increased emphasis of product safety in their promotional campaigns. While these three factors do not exhaust the possible actions which might impact consumer perceptions of product-related injuries, they are considered here for three main reasons. First, each is a variable which is highly controllable by policy makers and/or management. Second, under the legal doctrine of strict liability, these actions should not influence assignment of responsibility for a product-related injury. Third, these three factors were revealed as highly salient in qualitative research designed to explore consumers' product safety attitudes. The question of just how these factors might influence consumers' causal attributions of responsibility toward manufacturers, consumers, and situations for product-related injuries is explored by experimentally manipulating these three factors.

Theoretical Development

As consumers, individuals are frequently exposed to media sources reporting stories of people injured by products they themselves use. Further, when consumers become jurors, they are forced to ponder causes of injuries and determine precisely when and how much compensation should be awarded. In both roles, we feel that an individual pursues his/her

FIGURE 1
Hypothesized Relations Between Product Characterization and Attributions of Blame

natural motivation "to attain a cognitive mastery of the causal structure of his environment" (Kelley 1967, p. 109). The model shown in the Figure depicts a number of relationships proposed to represent the manner in which consumers ascribe responsibility for a product-related injury.

A central component of the model is a construct termed *unanticipated consequences* (UC) which intervenes between two of the manipulations and assignment of responsibility. Clearly, no consumer anticipates being injured or killed by a product they purchase. Other than those prone to suicide, no consumer would make such a purchase. Further, not only are product-related injuries unexpected events, but, they are *unexpected negative* events. In a recent study of unexpected favorable events (Howard and Barry 1990), the extent to which an event is unanticipated was shown to alter consumer product evaluations due to heightened affect. Considering the negative nature of product injuries, it could be argued that any effects due to the unexpectedness of an event would be even greater than for positive events (Tversky and Kahneman 1981) and be even more likely to evoke "spontaneous attributional activity" (Weiner 1985). Thus, the extent to which a product-related injury is unanticipated (UC) is presumed to alter consumers' attributions of responsibility for a mishap.

The unanticipated consequences (UC) variable shares similarities to the disconfirmation paradigm of product satisfaction (Olshavsky and Miller 1972; Tse and Wilton 1988). Using this paradigm, Churchill and Suprenant (1982, p. 493) define satisfaction as "an outcome of purchase and use resulting from the buyer's

comparison of the rewards and costs of the purchase in relation to the anticipated consequences." In this study however, the *consequences* are largely *unanticipated*; that is beyond the typical consumer's range of considered outcomes. Rather than merely experiencing a product performance worse than expected, UC may produce extreme levels of negative satisfaction and very strong levels of attribution of blame toward a product's producer. Consider a brief example as illustration. When purchasing a new lawn mower, a consumer has a set of expectations regarding the mower's ease of starting, durability, cutting ability, maintenance requirements and so forth. Negative disconfirmation would occur if the mower's performance on these attributes failed to meet prior expectations, or even if the mower failed to operate at all. However, if a largely unanticipated negative outcome (such as a product-related injury) were to occur, a traditional disconfirmation model may be insufficient to capture the consumer's reaction. More specific support for each of the relationships implied by the model follows.

Research Hypotheses

Indirect Effects. As can be seen in the figure, UC intervenes between two product characteristics and various attributions of blame. A number of hypotheses result. The hypothesized relationship between the experimental manipulations and UC is based on the above discussion as well as the concept of search, experience, and credence properties (Darby and Karni 1973; Nelson 1974). To make the consumer aware of the danger, the manipulations must represent search properties. In other words, we propose only

those factors which a consumer is made aware of prior to actually using a product would serve to affect the level of UC (Darby and Karni 1973; Nelson 1974). Therefore, how a product compares to governmental regulations, which is very difficult to determine prior to purchase, would have no affect on UC. On the other hand, proper warnings attached to the product should make the consumer aware of the dangers involved. Conversely, advertisements that stress the safe nature of the product (e.g., Michelin, Volvo, Mercedes Benz, etc.) may heighten UC. For instance, advertisements which depict a product as "totally safe" or "absolutely harmless" may create a latent sense of security regarding product safety. Thus we hypothesize:

- H1: Those products which include a safety warning are associated with lower levels of UC than are products without safety warnings.
- H2: Those products associated with advertisements stressing product safety are associated with higher levels of UC than products without such ads.

As mentioned above, strong casual attributions can be expected as an injury increases in UC, or is more unexpected. According to the "Just World Hypothesis" (Lerner and Miller 1978), the world is, in general, orderly and an individual's pursuit will not be blocked by environmental interference. Thus, unusual events "require for their occurrence a greater causal role by the victim or perpetrator" (Kelley and Michela 1980, p. 476). Therefore the respondents will be highly motivated to assign the responsibility for such an incident to someone or something. Furthermore, Weiner (1982) has posited that many negative events, such as a product injury, are likely to lead to external, rather than internal, attributions. In this case, higher levels of UC should increase attributions of blame toward the manufacturer (i.e., the manufacturer must have failed in their duty to provide a safe product or to make the consumer aware of the danger) and reduced attributions to the usage situation (i.e., a highly unexpected event would not occur by chance in a just world). We pose the following hypotheses:

- H3: A positive relationship exists between UC and assignment of blame to the manufacturer.
- H4: A negative relationship exists between UC and assignment of blame to the situation.

The result of this series of hypotheses is an indirect effect of both warnings and safety promotions on attributions of blame. The impact is felt through the intervening variable, UC.

Direct Effects. Aside from the indirect effects, a series of hypotheses represent direct effects of the experimental manipulations on attributions of responsibility. Is there a benefit from going beyond safety standards established by governmental

agencies? Under the doctrine of strict liability, simply meeting the required standards is all that is necessary and anything in addition (if an injury actually does result) is wasted. In making attributions, however, the "controllability" (Rosenbaum 1972; Weiner, Russell and Lerman 1979) of the causal factor is relevant information. In practice, safety standards are not under volitional control of a manufacturer, but a willingness to exceed these standards in an effort to make a safer product is. Assuming that government standards are in place to insure the safety of products, any goods exceeding these standards must be even "safer than necessary." Consequently, accidents resulting from one of these products may be perceived of as carelessness on the part of the consumer. Further, such actions by a manufacturer may create perceptions of a company which went out of its way to protect its product users and thus may be less likely to be blamed for a product mishap.

- H5: Products having safety standards which exceed government standards are associated with lower levels of attributional blame toward manufacturers than are products that simply meet those standards.
- H6: Products having safety standards which exceed government standards are associated with lower levels of attributional blame toward the product-use situation than are products that simply meet those standards.

A similar argument can be made regarding the presence of safety warnings. The manufacturer has fulfilled his responsibility by providing a warning concerning the danger of the product, reducing his blame for any ensuing mishap. While making a safer product (exceeding the safety standards) can reduce accidents due to chance, no amount of safety warnings can prevent a true accident from occurring. We anticipate:

- H7: Those products which include a safety warning are associated with lower levels of blame toward the manufacturer than are products without safety warnings.

RESEARCH APPROACH

Focus Groups

As mentioned earlier, the manipulations in the Figure represent three characteristics of product safety identified in a series of focus group interviews concerning attitudes toward product safety and the jurisprudence system. In total, six focus groups comprised of 61 participants were conducted. Focus group members were selected to represent a wide cross-section of demographic characteristics including sex, age, education, income, occupation, and knowledge and experience with the legal system. Throughout each focus group interview, the three factors (warnings, regulations, and advertisements stressing safety) consistently emerged as important factors to

consider in judging responsibility for product injuries. These three variables, therefore, were thought to be relevant for further analysis based on qualitative analysis, the level of managerial controllability and supposed courtroom irrelevance.

Experimental Design

Having determined three relevant managerial variables which might determine attributions of responsibility for product-related injuries, a 2 X 2 X 2 between-subjects design was employed to test the various research hypotheses. Each experimental variable was manipulated over two levels: (1) *warning labels* were positioned as either being present or not present, (2) the manufacturer was said to have either far exceeded or merely met all government *safety standards*, and (3) the *product ads* were described as either stressing safety or other product features. A product-related injury scenario was built around these manipulations which was patterned after an actual liability case involving an injury resulting from the use of a claw hammer. In *Chappuis v. Sears Roebuck & Co.* (1978), a young man lost the vision in his left eye when a chip flew off the head of a hammer and struck him in the eye. Aspects other than the manipulations (i.e., type of injury, plaintiff characteristics, and the defendant's reaction, etc.) were held constant across all subjects.

Data Collection

The data collection procedure follows the approach suggested by Abramson and Mosher (1975; Abramson, Goldberg, Abramson, and Gottesdiener 1975) and utilized in a psycholegal study by Feild (1978). Abramson and Mosher (1975) suggest using a large number of interviewers with varied demographic and personality traits in the data collection process in an effort to eliminate any interviewer bias. Feild (1978, p. 160) applied this procedure in a study of attitudes toward rape. In Feild's experiment, students were familiarized with the survey instrument and trained in the administration of its measures. The students were then used as field interviewers in questionnaire administration.

Following these procedures, students enrolled in marketing research courses at a large midwestern university were thoroughly familiarized with the survey instrument, and received training in its administration. Each student completed interviews with four members of the urban community, excluding students and university personnel, in exchange for course credit. Telephone surveys were conducted with a subsample of the respondents to control the quality of the survey. Following the telephone verification process and deleting questionnaires with incomplete responses, 91% of the questionnaires distributed were retained for analysis. The resulting sample consisted of 204 subjects. The demographic characteristics of the sample are representative of the community as a whole based on age distribution, male-female ratio, and ethnic origin, and slightly above average on education and income.

This procedure provides several benefits. First, interviewers of both sexes, a mixture of ethnic

backgrounds, and varied styles of interaction will be utilized to administer the survey instrument, thus avoiding the pitfall pointed out by Abramson et al. (1975). Second, the variance in characteristics of the interviewers is likely to be reflected in the respondents. Third, interviewers will be able to clarify any questions the respondents might have while completing the questionnaire. Finally, the nonresponse bias often associated with mail surveys can be avoided; Feild (1978) reported a usable response rate of 82%.

Manipulation/Confounding Checks

In experimental designs, subjects are exposed to various conditions and expected to react differently to those conditions. To insure the internal validity of this experiment, manipulations were tested and revised during pretesting as suggested by Aronson and Carlsmith (1968) and Wetzel (1977). The effectiveness of the experimental manipulations in the final scenarios was then assessed by asking the respondents if: (1) the product's warning labels were sufficient (warnings); (2) the manufacturer's advertisements stressed product safety (advertisements); and (3) the product exceeded government safety regulations (regulations).

To examine the manipulations the subjects were classified into high and low groups for each of the manipulations and then tested for a difference in the mean response on the three check questions. With this approach, both the effectiveness of the manipulations and any potential confounding effects between manipulations can be tested (Wetzel 1977). Or, as presented by Perdue and Summers (1986, p. 318), "the experimenter would like to be able to demonstrate that (1) the treatment manipulations are related to "direct" measures of the latent variables they were designed to alter and (2) the manipulations did not produce changes in measures of related but different constructs." In each case, a significant difference was found between mean scores on the appropriate measure, but not the others, suggesting that the manipulations were effective and independent. The results are presented in Table 1.

Measurement Results

Assignment of Blame/Responsibility. In measuring the assignment of blame/responsibility, two questions had to be answered. First, the appropriate bases for the causal attributions had to be identified. That is, *who* or *what* is the accident attributed to? Second, what was the suitable term(s) to use to capture *causality*?

In regard to the first question, Kelley's (1967, p. 194) principle of covariance (Kelley Cube) established three dimensions of causal inferences: (1) the stimulus object or *entities*; (2) the observer of the event or *person*; and (3) the context or *time* in which the effect occurs. In a frequently cited study of causal attribution, McArthur (1972, p. 175) operationalized these dimensions by asking respondents to assign the cause of an event to either (1) "something about *the person*," (2) "something about *Stimulus X*," (3) "something about the *particular circumstances*" or (4)

TABLE 1
Results of Manipulation Checks

Experimental Element	Warnings		Advertisements		Regulations	
	T Value	Prob.	T Value	Prob.	T Value	Prob.
1) Product Safety Warnings	4.21	.000	1.16	.253	0.14	.300
2) Safety Stressed in Advertisements	0.80	.430	3.17	.003	0.32	.280
3) Exceeded Safety Regulations	1.52	.138	0.12	.907	3.44	.002

TABLE 2
Factor Analysis of Blame and Responsibility Items

Scale	Scale Item	Factor Loading		Reliability
		1	2	
Assignment to the Manufacturer\Consumer				
	How RESPONSIBLE was Mike Johnson?	.9080	-.1278	.92
	How much do you BLAME Mike Johnson?	.8734	-.1472	
	How RESPONSIBLE was the MANUFACTURER?	-.9151	-.0347	
	How much do you BLAME the MANUFACTURE?	-.9000	-.0097	
Assignment to the Situation				
	How RESPONSIBLE was FATE or CIRCUMSTANCES?	.1056	.9190	.84
	How much do you BLAME FATE or CIRCUMSTANCES?	.1163	.9191	

a combination of these factors. Bettman (1979) has suggested that when applied to the study of consumer behavior, the corresponding causal agents would be the product, the person, and the situation. Folkes (1984) successfully utilized this categorization in her study of causal attributions of product failure. It is important to note, however, that Folkes (1984, p. 75) expanded the "product" category to include the retailer which sold the product (pants) as well as the manufacturer. Based on these studies, the consumer, the product/manufacturer, and the situation were determined to be the appropriate bases of causal attribution for the study.

The second question arises from the conceptual work of Shaver (1985), who argues persuasively that attributions of *blame* and *responsibility* are not identical and the different dimensions might relate more to one attribution than to another. Based on Shaver's supposition, pretests have been conducted using attributions of both blame and responsibility toward the person, product, and situation. The results revealed a high correlation between measures of blame and responsibility for each of the three bases of attribution. A similar finding has recently been

reported by McCaul, Veltum, Boyechko, and Crawford (1990) who employed measures of attributions of both *blame* and *responsibility* in a study of rape victims. Their results (McCaul et al. 1990, p. 13) also indicated a high correlation between the two measures (average correlation = .62), which they consequently summed for further analysis. Therefore, despite Shaver's arguments, empirical evidence suggests that respondents have a difficult time distinguishing between the concepts of blame and responsibility.

Furthermore, principal components analysis of the six items indicates that a two factor solution is appropriate. As can be seen in Table 2, the four items measuring attributions to the consumer and manufacturer loaded on a single factor (but with opposite loadings) and exhibit a high degree of internal consistency (Cronbach $\alpha = .92$). At the same time, the responsibility and blame items for the situation loaded on a separate factor. Thus, scales utilizing both terms are included in the survey instrument to provide a multi-item measure, but will be summed to create a measure of blame/responsibility toward (1) the manufacturer and (2) the situation.

TABLE 3
Model Statistics - Predicting Attributions of Blame for Product Mishaps

Variable	Dependent Variable:		
	Unanticipated Consequences (UC)	Attribution of Blame To:	
		Manufacturer/Consumer	Situation

Safety Promotion	.18 ^b	—	—
UC	—	.63 ^c	-.23 ^b
^a $p \leq .05$	^b $p \leq .01$	^c $p \leq .001$	

Unanticipated Consequences. UC is designed to measure the respondent's judgement of the plaintiff's expectations regarding product safety. In other words, does the respondent think the user of the product could or should have anticipated the danger associated with its use? Five items were devised to capture UC and refined and modified in pretesting. Three items were retained that both load highly on a single factor (.76 to .82) and display acceptable internal consistency ($\alpha = .76$), providing a parsimonious yet reliable scale. The items reflects the extent to which an incident should be (or should have been) expected given the nature of the product.

MODEL ANALYSIS AND RESULTS

The Figure depicts a three-equation path model employed to test each hypothesized relationship. Each hypothesis is illustrated by a single path in the proposed structure, and the strength and nature of each relationship can be represented by its standardized regression coefficient (β). Given that the model is recursive and overidentified, ordinary least squares can be used to estimate its parameters and assess the level of predictive validity associated with each endogenous construct (Blalock 1961; Asher 1976; Darden 1981). Consequently, Table 2 contains the results of estimating each equation using a series of OLS regressions, from which, a test of the previously discussed hypotheses can be inferred.

Overall Fit

Although our intent was not to provide a test of a fully specified model, an analysis of any regression model should begin by assessing its general level of significance. The overall fit of each equation comprising the path model, as indicated by its coefficient of determination (R^2) and corresponding F-

ratio, achieved an acceptable level of statistical significance. On closer inspection, the model was much more successful in predicting attributions of blame toward the manufacturer/consumer ($p \leq .001$), than it did attributions of blame toward a situation ($p \leq .02$) or UC ($p \leq .01$). However, given that a significant amount of variance in each dependent variable was explained by the proposed model, some general level of support is provided for its hypothesized relationships, and more specifically, justification is provided for interpreting each independent variable's predictive ability (Neter, Wasserman, and Kutner 1985). Specific results, by independent variable, for each hypothesis follow.

Hypothesis Testing

Safety Regulations. Two hypotheses (5-6) concerned attributional effects of a manufacturer meeting (coded 0) or exceeding (coded 1) government imposed safety regulations. Essentially, these hypotheses predict that manufacturers perceived as exceeding safety standards will experience (1) lower levels of blame directed toward themselves and higher levels directed at the product user (H5), as well as (2) lower levels of blame directed toward a situation in which an injury occurred (H6), than will firms merely meeting those standards. The first row of path coefficients shown in Table 3 supports H5 (-.27) but fails to support H6 (-.03). Thus, while exceeding safety standards may help alleviate some blame from manufacturers at the expense of consumers, it does not appear to influence attributions toward the usage situation.

Warning Labels. A second set of hypotheses involves the influence of warning labels. As predicted by H1 a negative relationship (-.21) is found between use of warning labels and unanticipated consequences

(UC). More simply, this relationship indicates that warning labels do provide consumers with information concerning potential results from misuse. In contrast, consumers may not consider these results when warning labels do not accompany a purchase. Additionally, as predicted by H7, a negative relationship (-.21) is observed between use of warning labels and attributions of blame toward a manufacturer. Thus, by employing warning labels, marketers may be perceived as somewhat less responsible for a product-related injury.

Promoting Safety. One hypothesis concerns the use of safety as an appeal in ads and promotions. Hypothesis 2 indicates that safety appeals may give consumers a sense of security making injuries more unforeseeable. The positive path coefficient (.18) between the safety manipulation and UC supports this hypothesis. In turn, safety as an appeal may affect attributions of blame through its ability to make an injury more unanticipated.

Unanticipated Consequences (UC). Two hypotheses concern the direct effect of UC on attributions of blame. Hypothesis 3 predicts higher levels of blame toward manufacturers when an injury is more unanticipated and is strongly supported in this analysis. A positive path coefficient of .63 is observed between UC and attributions of blame toward manufacturers indicating that when a product-related injury occurs, manufacturers (consumers) are more likely to be blamed under high (low) levels of UC. Further, this significant path accentuates the effects of warning labels on attributions toward a manufacturer/consumer. The indirect, or intervening, effect of UC on this relationship contributes an additional influence of -.13 or (-.21 X .64) to the effect of warning labels on attributions of blame toward a manufacturer/consumer yielding a total contribution of -.34 to the total zero order correlation between these two variables. Thus the theoretical relationship between warning labels and attributions of blame on the manufacturing/consumer construct is sensitive to the intervening presence of unanticipated consequences.

Additionally, H4 proposes lower levels of attribution of blame toward the situation when an injury is highly unanticipated. Consistent with this hypothesis, a significant negative relationship is found between UC and situational blame. That is, consumers tend to blame the situation less when a product-related injury is unanticipated. Further implications of these results follow.

DISCUSSION

This study demonstrates that managerial actions do affect consumers' assignment of responsibility for product mishaps. More interestingly, since the types of activities considered in the study should have little effect on due process in liability trials according to the doctrine of strict liability, it appears that the mental arithmetic of consumers when making personal causal attributions of blame does not resemble the legal process of strict liability. That is, the reasoning used by consumers does not coincide with the reasoning of the court. If

additional research were to prove consistent with this result, it may well spark a debate among policy makers over the reasonableness of recent product liability legislation.

A number of implications for corporate policy makers flow more directly from the experimental manipulations. For example, using warning labels to make consumers more aware of potential dangers appears one way to alleviate some of the negative results of product liability suits. The results of this study showed a marked reduction in blame attributed to manufacturers when a warning label was involved in the product-injury scenario. And while in some cases the use of warning labels is predicated upon previous court findings, the findings with regard to safety regulation indicate that going over and above legislative guidelines can reduce negative repercussions of product injuries. In the present study, firms portrayed as incorporating safety features above and beyond what is required legally experienced lower levels of causal attributions of blame than did firms simply meeting government standards. In addition, these findings may be indicative of how severe the impact of negative public publicity surrounding product injury situations will be (Griffin, Babin and Attaway 1991). Publicizing its use of warning labels and extra safety precautions may alleviate some of the fall out from these unfortunate situations.

Further, some evidence is presented which suggests that stressing safety as a feature of a product can create a sense of security among consumers and reduce consumer perceptions of unanticipated negative consequences from use of a product. Left for further study is the potential impact that steps taken to deal with product safety have on consumer purchase intentions and behavior. It is quite possible that tactics useful for dealing with the high costs of product liability (e.g., warnings) have a negative impact on sales. If so marketers are faced with trading off potential liability for potential sales.

Another interesting issue investigated in this paper deals with how an unanticipated event affects relationships between marketer actions and consumer attitudes. Evidence of this effect is demonstrated by the secondary influence of warnings on unanticipated consequences of product use, which in turn acts as an additional causal factor on attributions of blame toward the manufacturer. Practically speaking, further steps taken by marketers to increase consumer awareness of hazardous product uses can allay some attributions of blame toward the manufacturer. However a similar caveat as mentioned above, with respect to these actions impact on purchase intentions, holds here.

Additionally, the study of unanticipated negative events has some relevance for basic marketing research. The impact of UC demonstrates that like unexpected favorable events (Howard and Barry 1990), unexpected negative events also influence consumer decision processes. Further, although no direct comparisons are made in this study, an interesting issue related to this research concerns direct comparisons of the impact of unexpected positive versus unexpected negative events. As

discussed earlier, a substantial theoretical base (e.g., Tversky and Kahneman 1981) supports a more severe effect of losses compared to gains. Also, in terms of consumers' post-purchase product evaluations, unanticipated negative events may create consumer reactions which are beyond the scope of a traditional disconfirmation paradigm. Further studies are needed which directly compare the validity of the disconfirmation model to a model based on unanticipated rather than expected events.

CONCLUSIONS

The area of product safety clearly presents a heavy regulated operating environment for marketers and consumers. These regulations, the current legal doctrines guiding product liability suits, as well as the high cost of product liability, serve to limit alternatives for dealing with these issues. However, results presented in this paper indicate that marketer actions do have an impact on consumer attributions of responsibility. In addition to these results, some interesting theoretical issues are raised concerning the effect of unanticipated negative events. Clearly, unanticipated consequences do affect consumer decision processes, however, more work is needed to understand more closely the nature of this effect.

Extended Warranties: A Behavioral Perspective

Glenn B. Voss, Texas A&M University

Irfan Ahmed, Texas A&M University

ABSTRACT

Extended warranties have become a major revenue source for durable goods retailers, prompting some retailers to use questionable practices in an attempt to maximize their sales. This paper develops an integrated framework based on prospect theory and protection motivation within which to examine these practices. Propositions are presented with respect to: (1) individual consumer difference variables which contribute to a predisposition to the extended warranty offer; and (2) the impact of (a) the timing of the extended warranty offer and (b) the use of fear appeals in the offer on consumer perceptions of product quality and value. Implications for retailers are offered.

INTRODUCTION

Retailers in the past decade have increasingly offered extended warranties on durable consumer goods. These warranties provide retailers with an additional source of revenue in a market characterized by long repurchase cycles, with prices of extended warranties generally exceeding "...the average expected costs of repair by considerably more than what might be attributed to profit and overhead" (Fox and Day 1988, p. 337). They also offer dealers opportunities for repeat customer contact, with the goal of interesting customers in future purchases (*Advertising Age* 1985). Finally, the marketing of extended warranties offers retailers an opportunity to enhance the image of their store (Kelley et al 1988).

When effectively marketed and implemented, extended warranties offer a win/win situation for consumers and retailers alike. Extended warranties appeal to consumers by reducing perceived risk and assuring consistent and quality service (Bryant and Gerner 1982). Estimates of the number of eligible purchases which include extended warranties range from 30-50% (Koten 1984; Plotkin 1985). However, many retailers have exploited extended warranties as an opportunity for short-term profits, resorting to fear appeals to increase their sales, going so far as to overstate the likelihood of a product breakdown (*Sales & Marketing Management* 1985). In doing so, these retailers typically eschew marketing the extended warranty as an added service feature, opting instead to present this optional service after the purchase decision has been made.

How do consumers evaluate the extended warranty purchase decision? What consumer difference variables affect this decision? What impact does presentation timing have on the consumer's transaction utility? This paper seeks to provide answers to these questions by: (1) reviewing and integrating the relevant literature; (2) incorporating testable propositions into a sequential decision-making model based on protection motivation theory and prospect theory, and (3) exploring the impact of (a) the timing of the extended warranty offer, particularly in the context of cognitive dissonance and

the importance of post-purchase feedback in the consumer decision-making process, and (b) the use of fear appeals aimed at heightening the consumer's desire for risk reduction in the context of the consumer's overall retail experience. Finally, managerial policy implications are offered.

THEORETICAL BACKGROUND

Literature on the marketing of extended warranties and service contracts is limited. The Center for Policy Alternatives at the Massachusetts Institute of Technology conducted a major descriptive study on warranties and service contracts for consumer durables (Center for Policy Alternatives, 1978). Day and Fox (1985) offered a brief review of practices in the sales of service contracts, discussed issues raised in prior research and their own exploratory study, and offered some suggestions on the marketing of service contracts. Bryant and Gerner (1978) dealt with the economics of service contracts and developed an economic decision making model (1982) for the purchase of a service contract. Kelley and Conant studied the perceptions of consumers (1987) and the perceptions of retailers (1988) toward extended warranties, and followed up with a broad-based study (1991) of the perceptions of consumers and retailers. No attempt to date, however, has incorporated extant theory with the limited findings to produce a behavioral model of the extended warranty purchase decision.

Perceived Risk

Empirical evidence suggests that consumers view extended warranties as insurance to reduce perceived risk (Kelley and Conant 1987, 1991). Risk associated with consumer purchase includes dimensions of performance, financial, psychological, social, convenience loss, and physical risk (Kaplan, Szybillo and Jacoby 1974). An extended warranty specifically attenuates three of these dimensions: performance risk (Will it work properly?); financial risk (Will it cost too much to maintain it?); and convenience loss (How much time, convenience, and effort will be required if the product does fail?).

Perceived Quality

Perceived quality is a higher level abstraction that in some cases resembles attitude (Zeithaml 1988). Steenkamp (1990) proposes that quality beliefs can be formed through descriptive belief formation (by actually experiencing the product's experience attributes), informational belief formation (accepting information provided by outside sources), or inferential belief formation (based on prior knowledge of the product category), with consumers most often engaging in inferential belief formation. Brucks and Zeithaml (1987) have identified six abstract dimensions of product quality which can be generalized across categories of durable goods (the

domain for this paper): ease of use, functionality, performance, durability, serviceability, and prestige.

Protection Motivation Theory

Much of the research on insurance purchase behavior has focused on protection motivation. According to protection motivation theory (Rogers 1975), a fear appeal can be broken down into three components, each one initiating a cognitive appraisal process: (1) the magnitude of noxiousness of the depicted event, (2) the conditional probability that the event will occur in the absence of adaptive action, and (3) the effectiveness of a coping response that might avert the noxious event.

In the case of an extended warranty, the fear associated with a probabilistic product breakdown depends on the consequence of a breakdown, the probability of a breakdown occurring, and the perceived efficacy of the extended warranty in protecting against the loss incurred due to a breakdown. Slovic et al. (1977) found that people buy more insurance against events having a moderately high probability of inflicting a relatively small loss than against a low probability, high loss event. Slovic et al. (1978) found that protective behavior is influenced more by the probability of a hazard than by the magnitude of its consequences, and that people are not inclined to protect themselves voluntarily against very low probability threats. Accordingly, consumers who believe that there is a high likelihood that a product will break are more likely to purchase an extended warranty.

Prospect Theory

According to prospect theory, making a choice under risk involves a two-step process: (1) framing and editing and (2) evaluation. In the first phase, the decision-maker simplifies (edits) the problem into distinct prospects which are then framed according to: (1) the way the choice set has been externally framed during presentation (e.g., a fear appeal emphasizing the potential losses associated with a product breakdown would create a negative frame); and (2) how the decision-maker frames the decision internally based on an individual reference point (e.g., a risk-seeking decision-maker would frame a risky alternative more favorably than a risk averse decision-maker). In the evaluation phase, the framed prospects are evaluated and the most appealing prospect is chosen in one of two methods: (1) identifying the dominant prospect if dominance is apparent or (2) determining the prospect with the greatest value when dominance is ambiguous. The prospect of greatest value is determined by an S-shaped function that passes through the reference point, is concave for gains and convex for losses, and is steeper for losses than for gains (Tversky and Kahneman 1986). This implies that decision-makers in general are risk-averse when prospects have been framed as gains and risk-seeking when prospects have been framed as losses.

AN INTEGRATED MODEL

In the context of an extended warranty purchase decision, protection motivation theory and prospect

theory have comparable implications (see Figure 1). The risk associated with the decision in prospect theory parallels the noxiousness of the event in protection motivation theory. The perceived noxiousness of the event (product breakdown) can be viewed as the perceived consequences of a breakdown; that is, the risk associated with the financial and convenience loss in the event of a breakdown. The probability associated with the event occurring is consistent with both theories and is associated with the perceived performance risk. The efficacy of the coping response (extended warranty) would be incorporated into the framing and editing process in prospect theory.

The Quality-Risk Connection

Perceived risk and perceived quality also have many similarities: both are multidimensional constructs involving higher level abstractions; both are salient during the consumer decision-making process; and both share similar (at times identical) dimensions. Furthermore, we propose that perceived quality is a moderator variable that contributes to the determination of perceived risk (along with individual difference variables). For example, it is quite likely that a consumer considers quality cues that signal performance and durability quality to evaluate the perceived performance risk (Will it work properly now and in the future?) associated with a durable good purchase. Likewise, when evaluating financial risk, durability cues are used, and when evaluating convenience loss risk, serviceability cues are used. This connection leads to the following propositions on the role of quality dimensions as antecedent to assessment of perceived risk:

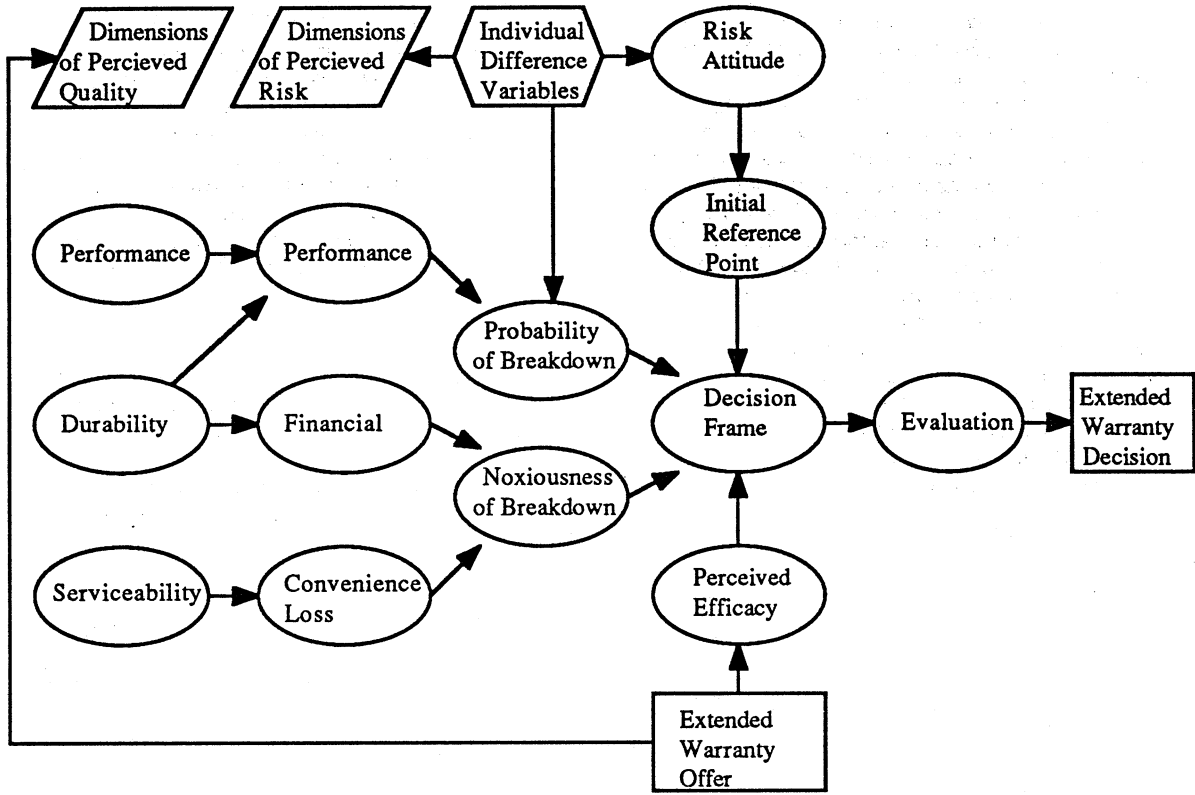

- PIA*: The perceived risk associated with a purchase decision is largely determined by the perceived quality of the product.
- PIB*: The perceived performance risk associated with a purchase decision is largely determined by the perceived performance quality and durability of the product.
- PIC*: The perceived financial risk associated with a purchase decision is largely determined by the perceived durability of the product.
- PID*: The perceived convenience loss risk associated with a purchase decision is largely determined by the perceived serviceability of the product.

In addition to perceived quality, individual difference variables (including risk attitude and initial reference point) and (the perceived efficacy of) the extended warranty offer determine the extended warranty decision.

Individual Difference Variables

Risk Attitude. Qualls and Puto (1989) noted that some consumers are immune to framing effects, concluding that, "These buyers appear to have a risk

FIGURE 1
An Integrated Extended Warranty Decision Model

attitude that remains invariant across decision contexts." (p. 190) Accordingly,

- P2A: Some number of very risk-averse consumers would purchase an extended warranty under any circumstances.
- P2B: Some very risk-seeking consumers would not buy an extended warranty under any circumstances.
- P2C: Most consumers would frame and evaluate the decision.

To frame and evaluate the extended warranty decision, it is first necessary to assign a probability to the likelihood that the product would break down in the time frame specified in the extended warranty. Since the exact likelihood that a product will break down is unknown, the consumer estimates the probability on the basis of experience and/or information available on the product class. Buyers differ in the extent of experience with the product class and the amount of information relating to product performance that they have acquired. Four types of consumers assigned to a 2 (high/low levels of experience) X 2 (high/low levels of search) matrix will be considered.

High Experience/Low Search. In the case of the extended warranty purchase decision, relevant information would be information regarding the

performance, durability and serviceability of the product. Prior ownership within the product class and/or of the brand would lead to prior beliefs for the product class, which in turn would be attributed to the brand currently under consideration through inferential belief formation (Steenkamp 1990). Positive experiences with the product class would have two effects: (1) the assignment of the probability of future breakdowns would be attenuated, as suggested by the availability heuristic (Tversky and Kahneman 1973) and (2) the perception of prior gains would lead to risk-taking behavior and rejection of the extended warranty (cf. Thaler and Johnson 1990).

High Experience/High Search. If prior experience and beliefs with the product class exist, external search is expected to be diminished (Beatty and Smith 1987) and to confirm rather than disconfirm prior beliefs (John et al., 1986; Snyder and Swann, 1978). Therefore, external search would be expected to have little impact on consumers with prior beliefs and consumers with high experience/high search should act similar to those with high experience/low search. Therefore,

- P3A: The single best predictor of quality and risk (i.e., product non-performance) is prior experience with the product class.
- P3B: The existence of prior gains (positive experiences with the product class)

would predict rejection of the extended warranty.

P3C: The existence of prior losses (negative experiences with the product class) would predict acceptance of the extended warranty.

Low Experience/Low Search. Consumers lacking prior experience who undertake little or no search would likely lack motivation (involvement) and ability. According to the Elaboration Likelihood Model (Petty and Caccioppo 1979), these consumers would have processed information mainly along the peripheral route and would likely rely on the salesperson to assign a probability of non-performance. In this case, the most important issue would be the credibility of the salesperson. Thus,

P4: In the absence of prior experience or search, the probability of the sale of an extended warranty will depend primarily on the source credibility of the salesperson.

Low Experience/High Search. In the absence of prior experience and beliefs, perceived quality would depend on either descriptive belief formation (if available) or informational belief formation. Since the salient dimensions for the extended warranty decision (especially durability and serviceability) depend primarily on credence attributes, in the absence of prior beliefs, informational belief formation is most likely (Steenkamp 1990). Secondary information could come from multiple sources: exposure to formal evaluative information (e.g., *Consumer Reports* repair and cost indices), informal evaluative information (from friends), advertising messages, an extensive search process, or the current salesperson. Since the current salesperson's input comes last (temporally), it is likely that by this time the consumer undertaking extensive search will have already existing beliefs regarding the purchase under consideration.

P5A: In the absence of prior gains or losses, the single best indicator of quality belief formation is extensive search or exposure to evaluative information.

Search Strategies. A consumer who has gone through extensive information search prior to making the product choice decision is likely to be highly involved with low product class knowledge (Beatty and Smith 1987); high involvement and the absence of prior experience are sufficient criteria to indicate that product quality information processing would be imperfect (Gotlieb & Swan 1990). Tellis and Gaeth (1990) propose that when information on product quality is not perfect, consumers follow one of three strategies: price-seeking, price aversion, and best value. A price-seeking strategy is based on a perceived price-quality correlation which implies a willingness to "pay for quality." Since quality information is imperfect, s/he is likely: (1) to

purchase a more expensive brand; (2) to use the brand name as a quality cue; (3) to frame the extended warranty as a potential gain (offering increased performance quality and diminished financial and convenience loss); and (4) according to prospect theory, choose to purchase the insurance.

P5B: In the absence of prior gains or losses, consumers who use a price-seeking strategy would be more likely to purchase an extended warranty.

A price aversion strategy, on the other hand, discounts the value of available quality information and uses (low) price as the sole choice criterion. Under this strategy, the consumer is likely: (1) to purchase the least expensive brand; (2) to frame the extended warranty as a loss (i.e., an additional cost); and (3) choose to reject the insurance.

P5C: In the absence of prior gains or losses, consumers who use a price aversion strategy would be more likely to reject an extended warranty.

Since price-seeking and price aversion strategies are unidimensional strategies, there is no reason to expect that the timing of the extended warranty offer would complicate the decision process. However, the timing of the extended warranty offer is likely to be salient to consumers using the more complex best-value strategy which seeks to maximize perceived value as determined by intrinsic and extrinsic attributes, perceived quality, and perceived sacrifice (Zeithaml 1988).

Timing of the Offer and Best Value

If the extended warranty is offered prior to or along with the product, the buyer is aware of the cost and terms of the extended warranty while determining the perceived quality and value of the product. The extended warranty offer represents an add-on bundle whereby the value (and sacrifice) of the warranty is added to the value of the product under consideration (cf. Guiltinan 1987). Since the extended warranty offer is made in general (with respect to the retailer's entire product line), the add-on bundle will not be perceived as being specific to the chosen product. The decision to purchase the bundle would depend on whether the perceived value of the bundle exceeded the perceived value of the unbundled product, and the extended warranty service would probably be viewed as an add-on service feature of this particular retailer (Kelley et al 1988). For the best value shopper encountering this optional service prior to or along with the product, the extended warranty decision is indeterminate.

On the other hand, if the subject of the extended warranty is broached after the purchase, the add-on bundle would be seen as being specific to the chosen product, thereby changing perceptions of the value of and sacrifice for the product. In this context, the following propositions are offered:

- P6A: An offer of extended warranty options prior to purchase of a product will not alter the perceived value of and perceived sacrifice for the product.
- P6B: Exposure to the extended warranty option after the commitment to purchase the product will alter the perceived value of and sacrifice for the product.

Post-Purchase Cognitive Dissonance.

Attempts to sell an extended warranty after the purchase decision has been made would form an extraneous input at the post-decision behavior stage, contributing to a post-purchase re-evaluation of the product. The introduction, at this stage, of new information regarding the possibility of non-performance and the need for the buyer to seek protection from this risk exposes a new, undesirable aspect of the product just purchased. The extended warranty would represent a new extrinsic attribute which would undermine the perceived quality and value of the product (Day and Fox 1985).

All three major models of consumer decision making (Nicosia; Engel, Kollat and Blackwell; Howard and Sheth) recognize the post-purchase experience as feedback into the consumer decision making process. According to Zaltman (1965), a buyer, after the purchase of a relatively specialized and infrequently purchased product, often experiences cognitive dissonance in spite of a careful pre-decision evaluation of competing products. The offer of an extended warranty to insure against failure of a product already purchased adds undesirability to that product.

P7: For the consumer using a best-value strategy:

- (A) Exposure to information on extended warranty options and attempts to sell these contracts after the purchase of a brand would cause a decrease in the perceived quality and value of the chosen brand.
- (B) The post-purchase offer of an extended warranty would introduce cognitions dissonant with the satisfaction derived from the purchase, creating or further aggravating post-purchase cognitive dissonance in the buyer.
- (C) The creation or further aggravation of post-purchase cognitive dissonance would add to the perceived non-monetary sacrifice associated with the product, further diminishing the perceived value of the product.

Fear Appeals & Psychological Reactance. In the post-purchase approach, retailers typically use hard sell tactics, including fear appeals emphasizing the risk of non-performance, the attendant financial loss that may occur during the life of the product, and how the extended warranty can insure against such losses. However, increasing the threat of negative

consequences increases persuasion only when source credibility is high; when the credibility of the source is relatively low, any level of fear arousal is non-persuasive (Sternthal and Craig 1974). Pressure to purchase often results in a boomerang effect (Clee and Wicklund 1980; Brehm and Brehm 1981), and hard sell messages foster an inverse relationship between perception of persuasive intent and favorability toward the consumer products being promoted (Robertson and Rossiter 1974).

The presence of cognitive dissonance (in the post-purchase scenario) would likely affect source credibility and acceptance of such fear arousing messages. Given the presence of cognitive dissonance and the tendency to perceive new information selectively, there could be an increase in confidence in the decision just made and consequent discounting of the negative information being presented by the seller. The seller's effort to induce a protection motivation response would lead to attribution of persuasive intent, thereby further reducing source credibility and chances of acceptance of the recommendations. Given the already existing need for assertion of confidence in the product purchase to reduce dissonance, persistence and pressure from the seller would be construed as an attempt to curtail choice and force a particular behavior, thereby fostering reactance behavior.

- P8: For the consumer using the best-value strategy, the creation (or aggravation) of cognitive dissonance by the post-purchase offer of an extended warranty would lead to rejection of the extended warranty offer.

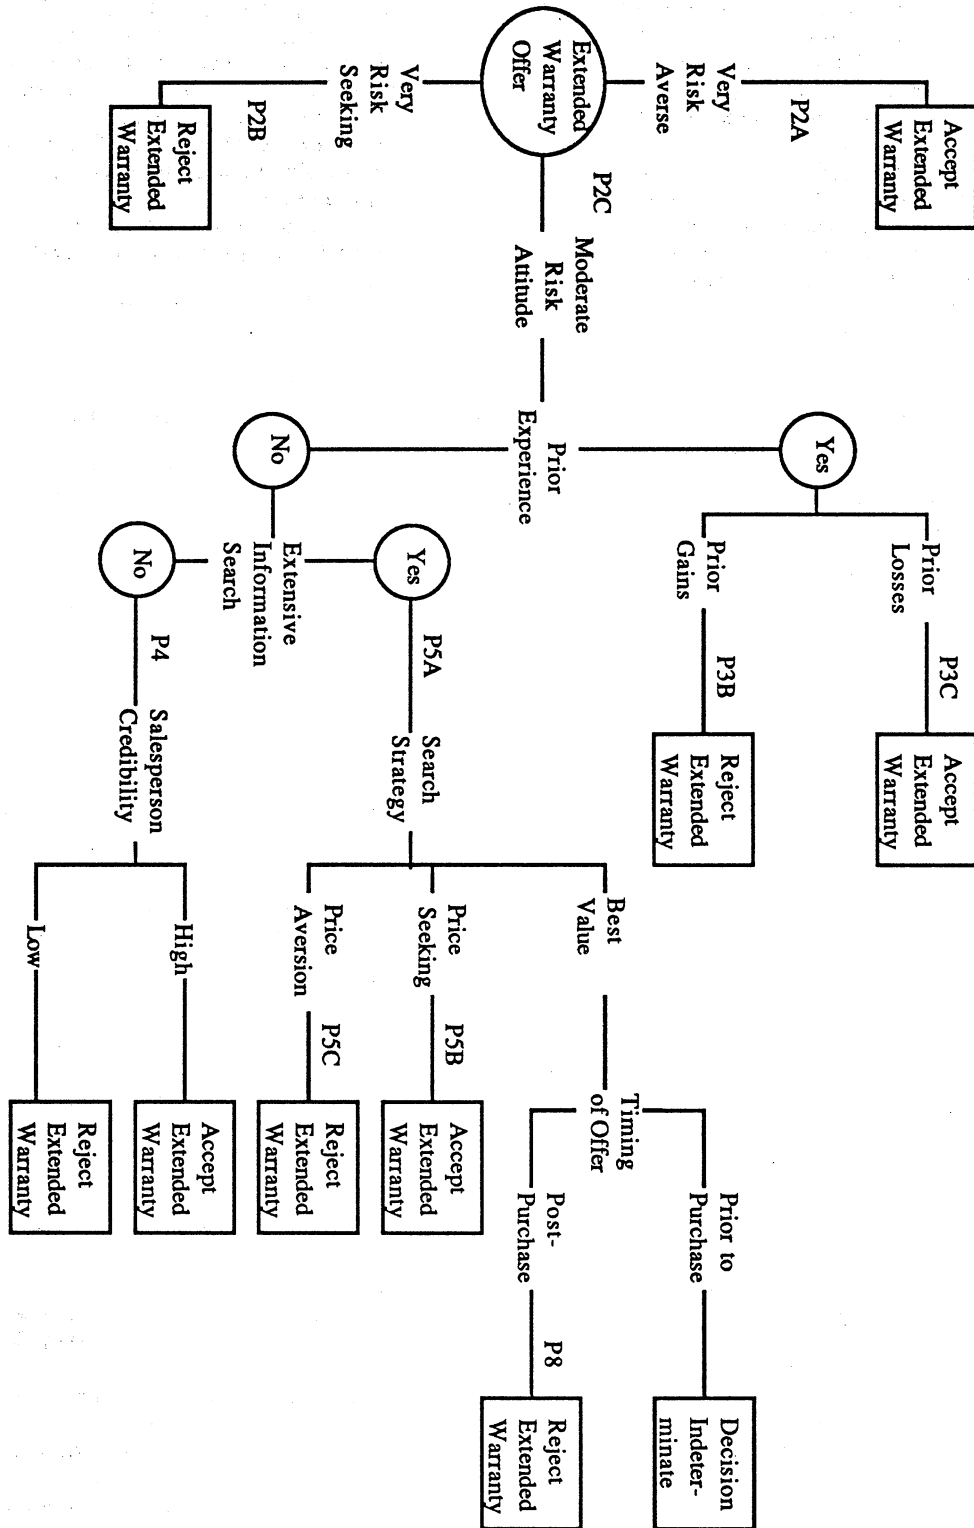

Figure 2 summarizes the propositions which have a direct impact on the extended warranty decision.

The Buyer's Experience

The preceding section discussed the possible outcomes of attempts to sell an extended warranty, and the influence of cognitive dissonance on the effectiveness of sales appeals. The appraisal of buyer characteristics and categorization of cues about the buyer have been proposed as determinants of selling effectiveness (Szymanski 1988), and depending on the accuracy of appraisal of buyer characteristics and suitable sales communication by the seller, a person may or may not buy the extended warranty. In either case, the buyer has been exposed to an additional element of risk, dissonance has been created immediately after the purchase, and s/he is likely to have been put through some emotional tension due to this exposure. This tension would cause a decrease in transaction utility and an increase in nonmonetary sacrifice leading to lower overall satisfaction with the purchase experience (Baker 1990).

- P9: The offer and rejection of an extended warranty after the purchase of a product would lead to lower overall satisfaction with the retail service experience.

FIGURE 2
A Sequential Decision Making Model

IMPLICATIONS AND CONCLUSIONS

Extended warranties offer durable goods retailers a source of profits to supplement their main activity of product sales. Some retailers resort to high pressure sales tactics to sell extended warranties to customers who have just purchased a product by arousing protection motivation against possible losses due to product breakdown. Retailers need to understand consumers' decision-making processes and the impact of their efforts to sell an extended warranty in this perspective. This paper explored some of the individual difference variables which mediate the extended warranty decision process as well as behavioral aspects relating to the timing of the extended warranty offer and the use of fear tactics in that offer. Subject to verification, the preceding discussion suggests that there are three types of consumers who are predisposed to purchase an extended warranty: those who are inherently very risk averse; those who have experienced prior losses in the product category; and those who use a price-seeking search strategy. Two categories of consumers -- one who has no previous experience and conducts little or no search and one who uses a best value search strategy -- may be susceptible to salesperson persuasion if source credibility is high.

Even though probability of non-performance remains the most important feature considered in making the decision, Rogers and Mewborn (1975) found the efficacy of the coping response to be the largest influencing variable for adoption of the communicator's recommendations. Therefore, the salesperson's message should focus on the benefits of the extended warranty rather than the deleterious effects of product non-performance. The use of fear appeals runs the risk of decreasing the perceived value of the purchase transaction and the overall retail experience. The overall dissatisfaction with the shopping experience could discourage future patronage since significant correlation exists between (a) satisfaction with a shopping experience and post-shopping attitudes; and (b) post-shopping attitudes and future shopping intentions (Swan 1977). At a time when retailers need to focus on service quality and customer loyalty (Berry 1986), the jeopardizing of customer goodwill by the creation of dissatisfaction should be avoided.

Three conclusions regarding the timing of the extended warranty offer are offered: (1) *at least* for the consumer using a best-value strategy, a post-purchase offer introduces or aggravates cognitive dissonance, increases non-monetary sacrifice and decreases the perceived quality and value of the product; (2) it is likely that this dissonance leads to source derogation diminishing the salesperson's efficacy; and (3) it is likely that this added aggravation is attributed to the retailer, thereby reducing the likelihood of future patronage. In the long term interest of continued patronage (especially relevant to retailers of products with quicker obsolescence), the practice of offering extended warranties, particularly in conjunction with fear appeals, is questionable.
