The standard theory in economics posits that an individual's consumption should not change in response to predictable income, like a salary paycheck (Carroll 1997; Deaton 1991; Hall 1978). However, researchers have continued to document a "payday effect" whereby they consistently find that individuals spend more immediately following receipt of predictable income (Olafsson and Pagel 2018; Parker 1999; Souleles 1999). While these studies provide evidence that there appears to be a consistent effect of income receipt on consumer spending, the findings regarding why this effect occurs are inconclusive. Some research suggests that this effect seems to be present for consumers who are financially illiquid (Kaplan and Violante

2014). However, others suggest that the payday effect occurs even for those with substantial liquid assets (Olafsson and Pagel 2018). A natural question emerges: Why are consumers deviating from standard economic theory (e.g. Hall 1978) and failing to smooth consumption on paydays?

To gain greater insight into the underlying mechanism of the payday effect, we used real income and spending data (N=67,360) provided by a popular financial application in the United Kingdom, Money Dashboard, to examine whether certain groups were more prone to this effect. The structure of the data allows us to observe the timing and amount of each user's paychecks and discretionary spending from January 2013 to December 2018 before individuals began using the budgeting application, as well as demographic information for each user. Our analysis follows the conventions set by Gelman et al. (2014) for investigating payday effects with big data. First, to measure the payday effect we perform panel regression analysis for which the econometric specification is:

$$Y_{ict} = \sum_{k=-7}^{7} \beta_{kc} I_i(Paid_{t-k}) + X'_{it} + \varepsilon_{it} \qquad \textbf{(Eq. 1)}$$

Where is the spending ratio of user i on day k in category c, *Paid* is a dummy equal to 1 if the user receives a pay cheque on day t, and is a vector of control variables. We compared the coefficients generated by Equation 1 using between-subject t-tests to determine if the size of the effect differs between groups (e.g., men and women). All consumers in our sample display significantly greater spending compared to their average spending across product types, however, we find that this effect is significantly larger amongst women (=0.15, =0.08; $p<$ .001), younger[1] consumers (=0.13, =0.08; $p<$ .001), and lower-income[2] consumers (=0.23, =0.05; $p<$ .001). This heterogeneity could be due to many potential sources. In particular, it could be argued that these groups experience greater financial constraint. However, past research has also indicated that anxiety is higher amongst these groups (Armstrong and Khawaja 2002; Misowsky and Ross 1999; Lindemann 1996). Therefore, could anxiety, above and beyond financial constraint, prior to payday lead individuals to be more prone to the payday effect?

In order to determine whether anxiety or financial constraint, as proposed by past research, could be driving the payday effect, we conducted three experiments. In Experiment 1 (N=246), to induce anxiety, we manipulated financial constraint, which is associated with experiencing anxiety (e.g. Hayhoe et al. 2012). This manipulation allowed us to determine if the payday effect is simply due to experiences of financial constraint or heightened anxious feelings. In a highly detailed hypothetical scenario, all participants read about events during a two-week period of their life where prior to their paycheck they experienced a sudden negative shock, a $50 parking ticket. Participants were randomly assigned to one of two experimental conditions that manipulated financial constraint. Participants in the constrained condition were told they had to cut back on their average daily spending prior to payday after a negative financial shock. Participants in the unconstrained condition were told they did not have to make any changes to their average daily spending prior to their payday after the negative financial shock. Following this, all participants were told they had received their paycheck. We tested payday spending by asking participants to order a meal, a drink and a main course at a restaurant, the day after receiving their paycheck. We found that though experiencing financial constraint increased anxiety ($M_{Constrained}$=4.61, $M_{Unconstrained}$=3.39; $p<$ .01), it did not produce significant differences in the total cost of participants meal choices ($p>$ .1). However, higher anxiety was significantly related to larger amounts spent at the restaurant ($\beta = 1.48, p=$ .02).

In Experiment 2 (N=701), we examined why anxiety might lead to increased spending. Past research has indicated that anxiety leads individuals to construe money differently, like overestimate the physical size of money (Zaleskiewicz et al. 2013). Similar to Experiment 1, we presented participants with a hypothetical scenario about a typical week in their life. To ensure that participants did not experience any undue financial constraint, all participants were told that they had $500 in their checking account a week prior to receiving their paycheck. To determine if anxiety leads to changes in the way individuals construe their income, consistent with past research, we asked participants to indicate their current level of anxiety and how much their paycheck feels like a "bonus" on a 7-point scale. To determine if individual's construe their income differently, we conducted a regression analysis controlling for participants average level of anxiety. We found that those with higher anxiety reported that their income felt more like a bonus ($\beta = 0.22, p<$ .001).

While the first two experiments provide initial support for our proposition that anxiety drives payday spending, in Experiment 3 (N=293), we test the full model. Specifically, we examined if construing income as a windfall explains the relationship between anxiety and increased spending on payday. Using the same manipulation as Experiment 1, in Experiment 3 we asked participants to indicate their preference for a cheap versus expensive restaurant following receipt of their income. Specifically, participants were asked to rate their preference between two restaurants; one where the average dinner was in the $10-30 price range versus one where the average was in the $25-45 range on a 7-point scale (Scale: 1=Definitely restaurant 1 to 7=Definitely restaurant 2). The restaurant choices were counterbalanced to ensure there were no order effects. We again find that experiencing financial constraint increased anxiety ($M_{Constrained}$=4.89,

---

[1] For age we use a median split to identify younger versus older consumers (Median age = 31)
[2] For income we use a median split to identify low income versus high income (Median income = £1,758)

$M_{\text{Unconstrained}}$=3.32; *p*< .01). However, experiencing financial constraint did not produce significant differences in restaurant preference (*p*> .1). Consistent with our anxiety account, we first find that experiencing higher anxiety is significantly associated with a preference for the more expensive restaurant (β = 0.21, *p*= .001) and construing income as a bonus mediated this effect (95% CI = [0.05, 0.17]). To examine the entire model, we conducted a path analysis. We found that the hypothesized model fit the data well (CFI=0.99; GIF=0.98; AGIF=0.94; RMSEA = 0.049; SRMR=.44). Specifically, we found that financial constraint lead to significantly higher levels of anxiety (*p*< .001), experiencing higher levels of anxiety was significantly related to construing income as a windfall (*p*< .001), and construing income as a windfall was significantly related to preferring the more expensive option (*p*< .05).

Collectively, our experiments shed light on the mechanism underlying previous findings regarding the payday effect. Mainly, we find that there is anxiety associated with financial constraint, which drives the payday effect for lower income individuals rather than financial constraint alone. Thus, if anxiety is driving the payday effect than we should expect to see a reduction in the payday spending for groups that typically experience greater anxiety when uncertainty is reduced.

To examine if a budgeting application could reduce an individual's uncertainty, we conducted a pilot study (*N*=99). Specifically, we wanted to understand what the purpose of a budgeting application is and why individuals used or would use a budgeting application. We asked participants to indicate their level of agreement with a number of statements regarding the purpose of a budgeting application (Scale: 1=Strongly disagree to 7=Strongly agree). We find that individuals believe that a budgeting application restores a sense of control (*M*=5.75), reduces uncertainty (*M*=5.54), and reduces anxiety (*M*=4.84). However, we also found that individuals did not believe that a budgeting application would make decisions for them (*M*=3.10). As such, using the same econometric specification in Equation 1 we examined the difference in payday spending prior to consumers using the Money Dashboard application and after they began using the application, conditional upon them logging into the application at least once. Consistent with our prediction, we find that those who are most likely to experience greater anxiety display the greatest proportional reduction in the payday effect after using the budgeting application.

In sum, these results demonstrate that experiencing anxiety prior to receiving a paycheck can lead individuals to increase the amount they are willing to spend. Further, we find that higher levels of anxiety lead individuals to think of their predictable income like a windfall, which facilitates spending. We also provide evidence that reducing uncertainty leads individuals, especially those who are most likely to experience anxiety, to reduce their payday spending consistent with our anxiety explanation. These results begin to provide some understanding for many individuals who are in a vicious cycle of living paycheck to paycheck, over and above just financial constraint alone. In addition, this work begins to provide some insight into practical interventions that can be used to curb overspending behaviors on payday.

Measuring Eco-Consumption Tendency as a Conjoint-Based Latent Variable

Karen Gorissen, Vrije Universiteit Amsterdam, The Netherlands
Bert Weijters, Ghent University, Belgium
Hans Baumgartner, Pennsylvania State University, USA

EXTENDED ABSTRACT

Scientists agree that human activities are the primary driver of climate change, and shifting consumer choices toward more sustainable options can significantly reduce greenhouse gas emissions (Beckage et al., 2018). Against this backdrop, marketing researchers often want to measure eco-consumption tendencies (ECT), defined as consumers' inclination to select eco-friendly options from a choice set. Lange, Steinke, and Dewitte (2018) point out that most ECT studies rely exclusively on self-report measures of behavior or proposed psychological antecedents (e.g., intentions or attitudes).

However, it is well-established in the methodological literature that responses to self-report items contain substantial individual variation that is not content-related but stylistic in nature (Baumgartner & Steenkamp, 2001). For instance, some respondents tend to agree with items irrespective of what is being measured, while others do not. Furthermore, self-report scales are susceptible to social desirability, especially if the content relates to morally charged issues (Steenkamp, De Jong, & Baumgartner, 2010). Finally, an essential limitation of self-report scales is the limited variation in the presented stimuli. That is, traditional self-report scales typically ask consumers to rate how likely they are to prefer one specific attribute, making the task very transparent and different from real life decisions.

Conjoint analysis is a procedure that can help avoid some of these issues (Green & Srinivasan, 1990). In rating-based conjoint studies, consumers rate stimuli consisting of several experimentally manipulated attribute levels. By quantifying the relation between the attribute levels of the stimuli and the profile ratings for each respondent, a respondent-specific weight (or part-worth utility) can be computed that captures the relative contribution of each attribute level to overall ratings. Although conjoint analysis is an extensively validated method, it has mostly been used to address applied issues (Green & Srinivasan, 1990). In the current paper, we propose that conjoint designs that experimentally vary the eco-friendliness of products can be used to measure consumers' ECT, and we show how this can be integrated into a nomological network of antecedents, mediators, and outcomes using Structural Equation Modeling for Within-Subject Experiments (SEMWISE), a novel approach for analyzing conjoint data (Weijters & Baumgartner, 2019) that so far has not been applied in consumer research.

Study 1

When identifying drivers of organic purchasing behavior, one difficulty is that many times the organic attribute is confounded with other attributes like taste and price (Nadricka, Millet, & Verlegh, 2019; van Doorn & Verhoef, 2011). In the first study, we illustrate how conjoint analysis can disentangle preferences for different attributes (and their potential interactions) by orthogonally manipulating them in a simple within-subject experiment. We then correlate the conjoint-based latent ECT variable with traditional self-report measures of ECT and related constructs in order to cross-validate the results, using the SEMWISE procedure. For a brief introduction to SEMWISE; for details, refer to Weijters and Baumgartner (2019).

Method

Participants (N = 560 coffee drinkers; M_{age} = 37.4 , SD = 8.6; 48.9% women) imagined ordering coffee and rated the attractiveness of eight coffee profiles using a continuous scale from 0 to 5 stars. The coffee profiles correspond to a full-profile complete conjoint design created by experimentally manipulating the (binary) attributes organic label (organic vs. regular), taste (consumer ratings of 3/5 'average taste' vs 5/5 'excellent taste'), and price (high €2.40 vs. low €2.00). Green consumption values were measured with an adapted translation (Weijters & Baumgartner, 2019) of the GREEN scale (Haws et al., 2013) consisting of six items, three are reverse-worded (e.g., 'I would describe myself as environmentally responsible', 'I'm not particularly bothered by worries about our environment' [reversed]). Health consciousness was measured with six items, half were reverse-worded (Chen, 2009) (e.g., 'I consider myself very health conscious,' 'I have the impression that other people pay more attention to their health than I do' [reversed]).

Results and discussion

First, we specify an unconditional SEMWISE model without environmentalism and health consciousness, and conduct a series of model comparisons. Throughout, indicator intercepts are fixed to zero, while indicator residual variances are freely estimated. For each set of effects (intercept, main effects, two-way interactions, three-way interaction), we consider three possibilities: (a) a model with freely estimated means and variances for the weight factors, implying that the average effect (part-worth utility) across respondents is non-zero and that there are individual differences in the strength of the effect; (b) a model with freely estimated means but zero variances for the weight factors, implying that the average effect is non-zero but the effect is the same for all respondents; and (c) a model in which the means and variances of the weight factors are zero, implying that there are no (significant) effects of the manipulated factors.

Setting the variance of the three-way interaction weight factor to zero results in a just-identified model, which is used as the starting point for the model comparisons. We gradually impose additional restrictions on this model and evaluate them based on model fit indices (preferring lower BIC values, RMSEA < .08 [preferably < .05], SRMR < .08 [< .05], CFI > .90 [> .95], and TLI > .90 [> .95]). The model that includes a random intercept factor and random main effect weight factors, as well as fixed weight factors for the two-way interactions results as the preferred model, as it is the most parsimonious model that meets all fit index cutoff criteria and has the lowest BIC value (χ^2(64.3) = 11555.4, p < .001, RMSEA = .065, CFI = .982, TLI = .973, SRMR = .044).

The parameter estimates based on this model are reported in Table 1. The findings show that, on average, people like better taste and dislike higher prices, hence the positive weight factor mean for good taste and the negative weight factor mean for high price. The relatively small variance estimates for these weight factors suggest that these preferences are rather consistent across individuals. The results also indicate that, on average, people prefer regular over organic coffee (controlling for price and taste). This may be related to the fact that, in vice products, consumers often associate organic claims with lower quality (van Doorn and Verhoef 2011) and that an organic label tends to increase perceived taste and attractiveness for healthy food (Nadricka et al., 2019). The organic weight factor has a much larger variance than the weight factors for price and taste,

indicating substantial heterogeneity in the part-worth utilities of organic claims.

In addition to the main effects, there are three two-way interaction effects. First, the small negative weight factor mean for high price x good taste (Table 1) implies that consumers are slightly less demanding about taste for higher priced coffees (Plassmann, O'Doherty, Shiv, & Rangel, 2008) regardless of the review information. Second, consumers are less price sensitive for organic coffee (i.e., high price has a negative mean, but the interaction of organic x high price has a positive mean; Table 1). Finally, for organic coffee, good taste is slightly less important on average (i.e., good taste has a positive mean, but the interaction of organic x good taste has a negative weight factor mean; Table 1).

Next, we add the covariates environmentalism and health consciousness, each modeled as a latent factor with six indicators. In addition, since for both scales half of the items are reverse-worded, we model a method factor on which all items have unit loadings (Maydeu-Olivares & Coffman, 2006) and is uncorrelated with the substantive factors in the model (note that items were not reverse-coded for analysis). The intercept and main effect weight factors are modeled as dependent variables with environmentalism and health consciousness as antecedents (the two-way interaction weight factors have zero variance and cannot be modeled as dependent variables). The resulting model shows acceptable fit to the data (χ^2(155) = 310.768, p < .001, RMSEA = .042, CFI = .971, TLI = .964, SRMR = .039). As expected, the organic label is valued more positively by consumers who score higher on environmentalism (B = .300, 95% CI = [.208, .392]) and (to a lesser extent) by consumers who score higher on health consciousness (B =.133, 95% CI = [.035, .230]). People higher in environmentalism also show a more positive attitude toward all the coffees (B = .145, 95% CI = [.049, .242]), possibly due to overlap in consumer segments visiting coffee bars and engaging in green consumption (Gilg, Barr, & Ford, 2005). No other regression weights were significant.

In sum, we analyzed conjoint data for coffee in which taste, price and organic label were varied experimentally, and found strong main effects of these attributes on preferences. The attribute weights (part-worth utilities) also showed significant individual variation. This was particularly true for the weight factor of organic labeling, and the variation in part-worth utilities was associated with individual differences in self-reported environmental concern and (to a lesser extent) health concern. We analyzed the data using the recently proposed SEMWISE approach, which enables the estimation of part-worth utilities as latent weight factors that can be integrated into a structural network consisting of antecedents, mediators, and outcomes.

Study 2

Consumers often rely on eco-information schemes (e.g., eco-labels) to assess products' environmental sustainability. A recent type of eco-information schemes are eco-ratings (Finnerty, Herther, & Stanley, 2011). Eco-ratings quantify the environmental (un)sustainability of products in a choice set in a standardized way, using a predefined score range. Generally, eco-ratings tend to be positively framed and express the extent to which an option is more or less ecological (vs. more or less damaging to the environment). However, there is no inherent reason why eco-ratings need to be positively framed. Even more, negatively framed eco-ratings may offer some advantages in promoting eco-behavior and is in line with how environmental campaigns are usually designed (they often induce negative emotions such as guilt to elicit reparative action). In the second study, we demonstrate the strengths of the SEMWISE approach by

testing the hypothesis that eco-ratings have a stronger influence on buying intentions when they are negatively framed, and that self-conscious emotions (anticipated pride vs guilt) mediate this effect.

Method

We collected data among students at a large American University (N = 267, M_{age} = 19.5, SD_{age} = .68; 36.3% women). We used a 2 (eco-rating framing: negative vs. positive; between-subjects) by 3 (eco-rating level: low, medium, high; within-subject) by 3 (price: low, medium, high; within-subject) mixed experimental design. We included the price manipulation to avoid confounding with eco-rating and to conceal the research objective. Participants were presented with nine fictitious product descriptions of washing liquids. Pictures of the products and fragrance type were filler attributes, and randomly sampled from a set of nine unbranded washing liquid bottle pack shots and a set of nine fragrances. Respondents rated each stimulus on two seven-point bipolar rating scales assessing anticipated pride vs. guilt ("I would feel guilty vs. proud buying this product") and buying intention ("I would definitely not buy this product" to "I would buy this product"). Eco-rating framing was experimentally manipulated between subjects by altering the labels. In the negative framing condition, 1 = *'very damaging for the environment'* and 5 = *'not damaging for the environment'*; in the positive framing condition, 1 = *'not environmentally friendly'* and 5 = *'very environmentally friendly'*.

Results and discussion

Based on preliminary exploratory analyses, we specified a SEMWISE model in which we estimated (a) an intercept factor, (b) two weight factors linking price to pride (vs. guilt) and intention, and (c) two weight factors linking eco-ratings to pride (vs. guilt) and intention to buy. For example, the eco-rating pride/guilt (intention) weight factor indicates how much pride vs. guilt improved eco-ratings elicit (i.e. how much improved eco-ratings increase buying intentions). Both eco-rating and price have three levels in this design, and we coded them by setting the factor loadings to -1 (low), 0 (mid) and 1 (high) (there was no evidence of a significant deviation from linearity). We also added a residual correlation for the pride and intention indicators pertaining to the same stimulus. As in study 1, the interaction weight factors had non-zero means but no significant variance, so we included them as fixed effects. The manipulation of eco-rating framing was modeled as a dummy variable, with 0 = positive framing and 1 = negative framing. We specified a model in which negative framing had a direct effect on both the pride (vs. guilt) and intention weight factors, and pride was hypothesized to mediate the effect of framing on intentions. This model showed acceptable fit to the data (χ_{MLR}^2(53) = 275.268, p < .001, RMSEA = .054, CFI = .914, TLI = .904, SRMR = .080).

Negative framing has a positive direct effect on both eco-rating pride (**B = .434, 95% CI = [.198, .670]**), and intentions (**B = .316, 95% CI = [.083, .548]**), but framing has no effect for the price attribute (**B = .324, 95% CI = [-.317, .965]**). Since eco-rating pride positively influences intentions, the indirect effect of negative framing of eco-ratings on intentions (via pride due to improved eco-ratings) is also significant (Est. = .184, SE = .060, p = .002). The indirect effect for the price weight factors is not significant (p = .367). In short, negatively framed eco-ratings lead to a higher intention to choose more eco-friendly products, and this effect is partially mediated by anticipated feelings of pride due to the use of more eco-friendly products.

In this study, we illustrated how the combination of conjoint analysis and SEM can be used in novel experimental paradigms in which (a) the stimuli used for the conjoint task are subject to experimental manipulations (e.g., positively vs. negatively framed

eco-ratings), (b) different dependent variables are used as response variable (affective vs. intentional responsiveness to eco-ratings) and/or (c) one responsiveness measure (affective responsiveness to eco-ratings) mediates the effect of an experimental manipulation on a downstream responsiveness variable (intentional responsiveness to eco-ratings).

Conclusion

Consumer researchers are often interested in measuring consumers' responsiveness to certain attributes and typically use self-report multi-item scales to do so. We believe that the suggested approach offers an interesting complement or alternative to traditional self-report scales. Previous research has shown that conjoint tasks are typically more engaging, have higher external validity, and are less prone to social desirability (Tomassetti, Dalal, & Kaplan, 2016; Weijters & Baumgartner, 2019). These advantages seem especially relevant in the context of pro-environmental consumer behavior. Furthermore, the proposed SEMWISE method provides an analytical framework in which individually varying response functions to experimentally manipulated stimulus attributes (or part-worth utilities) are modeled as latent variables, meaning that they can be easily integrated into broader nomological networks of antecedents, mediators and consequences. Moreover, all the general advantages of SEM apply, including the availability of detailed model fit information and the possibility to model measurement error and method effects. We briefly illustrated the SEMWISE approach for measuring ECT in two studies. In study 1, we found that the conjoint-based latent ECT variable correlated strongly with a traditional self-report measure of ECT. In study 2, we showed that negatively framed eco-information boosts ECT using a conjoint-based latent ECT variable in combination with a between-subjects framing manipulation.

EXTENDED ABSTRACT

Daring to offer someone a second-hand gift, not buying anything during a day's shopping with friends, and so on. To what extent do individuals manage to assert themselves in relation to others when the practices at the heart of the interaction are based on anti-consumption (Cherrier, Black, and Lee 2011)? Individuals, even if activist, can be subject to the tension between constraining social structures and their own creativity (Cherrier, Szuba, and Özçağlar-Toulouse 2012; Cherrier and Gurrieri 2014). Some authors believe that breaking free is, if not impossible, at least difficult, since the determining factors are too strong, while others propose the paradigm of identity in its relational dimension in response to that of determinism (Mead 1963).

Much debated in the field of anti-consumption, the question of identity change has been addressed through the study of its various phases (Cherrier and Murray 2007). However, the way of dealing with adversity, the positions adopted, and the meaning of the relationship with others during interaction in these contexts have been little conceptualized. Yet these interactions contribute to the construction of identity.

The aim of this paper is not to understand the meaning of anti-consumption for individuals, but rather the meaning of interactions within their social sphere in a context of anti-consumption. More precisely, it is a question of uncovering the relational strategies that individuals mobilize to socially engage in their consumption reduction practices. For this purpose, the theoretical framework of symbolic interactionism is used (Mead 1963; Blumer 1969). This framework makes it possible to understand the extent to which individuals become actors by adjusting to norms, thus freeing up spaces for creativity. The individuals concerned interpret the reactions of others, make sense of them within the interaction and adjust to them by implementing relational strategies, which helps to build their identity.

To understand the meaning of interaction with others, a particular context was studied, that of commitment to the Rien de Neuf (Nothing New) challenge, launched in 2018 by the association Zero Waste France. This challenge, extended in 2019, aimed to encourage consumers to reduce their consumption of new objects. Twenty-four long interviews were conducted by telephone. They were asked several questions: the reasons for committing themselves to such a challenge, difficulties in sticking to it, and the progress made. A phenomenological analysis of the data was carried out (Pollio, Tracy, and Thompson 1997), which brought out the respondents' sense of relationship with others through describing their experience, in other words, through speaking about what took place. Communicating functions via two dimensions: doing, that is, the practices engaged in, and saying (or talking about them), which bring out four ways of being in relation to others.

Not doing and not saying: hiding and submitting to determining factors. One way of being towards one's entourage is to remain secret, defined in its interactive forms as the "limitation of reciprocal knowledge" (Simmel 1991, p.24) and more particularly in its passive form, as the unspoken. Fearing social judgment, consumed by the dread of not being understood and of causing offence, these consumers are unable to free themselves from social constraints. For example, they give new products to other people in general and second-hand items within their immediate circle.

Hiding can also be fuelled by social determinism. This is particularly the case for transclass individuals (Jaquet 2014), in other words, people who live in a social environment that is different from their original environment. These people imagine that those who have remained in that environment (socially constructed as "inferior") would interpret a gift of a second-hand item as contempt on the part of those who "have managed to get out of it".

Doing and not saying: camouflaging oneself in order to remain true to oneself. One of the ways to adopt a position in relation to others is to buy second-hand rather than new products without saying so, in order not to "betray" one's approach. Lying (an active form of secrecy, Simmel 1991) out of self-interest engenders a division of the self, a mode of defense that helps to protect one's self-image (Freud 1938). Lying is the manifestation of two opposing desires: self-presentation and privacy (Tisseron 2011). Such concealment, however, may be exposed, leading to mistrust or even aggressiveness on the part of one's circle, which in turn alters the relationship and can undermine identity.

Not doing, but saying: raising awareness and taking the risk of being oneself. Some people explain what they do in order to make other people think about their real needs, but without imposing their views. In return, their objective is to nourish their existential needs by gaining recognition. This relational strategy allows them to confront constraining social structures, which in turn sometimes generate ridicule, experienced as a form of rejection that may be embodied in the phrase "You are not what you want me to believe you are" (Laing 1961).

Doing and saying: asserting oneself in order remain who one is. Some individuals, often activists, refuse to buy new products for anyone and explain why. The source of their self-affirmation is their accumulated experience of different environmental practices (waste reduction, etc.). This approach allows them to confront constraining social structures by engaging in discourse as to their value, a real exercise in self-presentation (Goffman 1988).

The aim of the present study is to understand how individuals who choose anti-consumption relate to constraining social structures (Cherrier, Szuba, and Özçağlar-Toulouse 2012). Drawing on the theoretical framework of symbolic interactionism (Mead 1963; Blumer 1969), the findings reveal the meaning of the relationship with others within an anti-consumption perspective through four types of relationship: hiding (secrecy); camouflage (lying); awareness raising (need for recognition); assertiveness (self-affirmation). These findings provide a finer degree of granularity for understanding how identity is constructed through the meaning of the relationship with others (Cherrier and Murray 2007). Discourse analysis (lexical analysis) could help identify people's discursive identity (Zéhenne 2010) in order to understand how the legitimacy of individuals in anti-consumption is formed, in other words, what justifies their right to speak out.

Consumer Attributions of Profit- and Customer Need-Driven Firm Motives in Coproduction Contexts

EXTENDED ABSTRACT

In the last two decades, technological advancements have stimulated many firms to employ a coproduction concept, in which customers play a more active role in the creation of goods and services (Stadler and Bolton 2019; Vargo and Lusch 2016). Today, many firms engage their customers in the creation of the final offering using self-production kits (e.g., Ikea, Hello Fresh), self-service technologies (e.g., American Airlines, Walmart), or offer toolkits for product customization (e.g., Nike, Dell) (Atakan, Bagozzi, and Yoon 2014).

Academics and practitioners have often praised coproduction as a win-win concept that enables firms to 1) realize cost-efficiencies and 2) better satisfy customer needs at the same time (Prahalad and Ramaswamy 2000). However, recent studies and business cases reveal that coproduction does not always lead to favorable outcomes, thus indicating that the underlying mechanisms that explain when and why coproduction yields positive or negative outcomes for customer relationships are not fully understood yet (Dong and Sivakumar 2017).

The present research integrates theoretical notions of the multiple inference model (Reeder et al. 2004) and the negativity bias (Baumeister et al. 2001) to suggest that customer beliefs about a firm's coproduction motives (cost/profit and customer-need motive) offer a psychological mechanism that helps to explain when and why coproduction has positive/ negative short- and long-term consequences for customer relationships. Two qualitative studies provide initial support for the notion that these two motives are highly prevalent among customers in different countries and coproduction contexts. Using a longitudinal field study and a randomized experiment, we then examine the key notion that the negative effects of attributions of profit-driven firm motives are temporally more persistent than the positive effects of attributions of customer-need driven firm motives. We further investigate how customers infer these motives based on managerial decisions related to the extent of labor customers have to contribute in the process, the degree to which they can customize the outcome, and the extent to which they can realize savings through their active engagement.

Study 1 builds on a large-scale multi-wave longitudinal data set in which the subjects were customers of a multinational retailer that sells ready-to-assemble furniture. We employ a latent growth modeling approach to analyze longitudinal data at the individual customer level (Bollen and Curran 2006). The results of Study 1 show that customers can hold perceptions of both profit- and customer need-driven firm motives for offering coproduction simultaneously and that these motive attributions have substantial short- and long-term influences on relevant marketing outcomes. Specifically, the results confirm our predictions that the positive effects of attributions of customer need-driven motives on customers' satisfaction and willingness to pay decrease over time whereas customers' perceptions of profit-driven motives have detrimental effects on both outcomes, which are highly persistent over time.

The field study further shows how motive attributions vary with the nature of a firm's coproduction offer. Specifically, the results show that greater coproduction effort and time investments reduce attributions of customer-need driven motives but fuel attributions of profit-driven motives, while greater customization possibilities amplify attributions of customer-need driven motives.

Study 2 is a large experimental study in which we offer additional evidence for the causality of the proposed relationships and provide insights into the role of perceived monetary savings through engaging in coproduction processes. The study was administered online and builds on a 2 (degree of customization: low vs. high) × 2 (degree of effort: low vs. high) × 2 (degree of savings: low vs. high) between-subjects design. We kept the study context constant to offer a better comparison to the results of the field study.

Results of Study 2 replicate the results of the field study and thereby provide further support for the robustness of the proposed relationships. Due to the manipulation of the factors that characterize a firm's coproduction concept (coproduction effort, customization, and savings), the study offers further insights into the generalizability of the relationships.

This research makes three major contributions to marketing theory and practice. First, it extends the coproduction literature by providing first insights into the differential roles of customer attributions of mixed coproduction motives. We show that profit- and customer-need driven motive attributions serve as independent mechanisms that guide customers' impression of a firm's coproduction concept and exert differential influence on customers' satisfaction and willingness to pay. The study thereby answers calls for research on the psychological mechanisms that link coproduction with outcomes and helps to explain controversial findings regarding the success of a coproduction concept in research and practice (Dong and Sivakumar 2017). From a practical perspective, it significantly advances managers understanding of how decisions related to the configuration of a coproduction concept interact to affect customer attitudes and behaviors.

Second, the study advances both research on coproduction and motive attribution by offering first insights into longitudinal dynamics of the effects of mixed motive attributions on marketing outcomes. A novel and intriguing finding that adds to both literature streams is that the effects of self- and other-centered motive attributions follow different temporal patterns. Whereas the positive effects of customer-centered motive attributions decrease over time, the negative effects of self-centered motive attributions remain persistent over time. The shift from a static to a dynamic perspective thus offers a deeper understanding of the differential short- and long-term effects of managerial decisions related to coproduction concept on customer satisfaction and willingness to pay.

Third, we advance current coproduction literature by identifying three managerial decisions that are central to the configuration of a coproduction concept influence customer attributions of firm motives. Specifically, we show that customers draw inferences of coproduction motives based on the extent to which customers participate in coproduction (intensity), the degree to which they gain autonomy to influence the configuration and design of the outcome (customization), and the degree to which they can realize financial benefits for their engagement in coproduction (savings). We thereby contribute to a better understanding of the joint effects of customer participation in design and production stage (Atakan, Bagozzi, and Yoon 2014;

Buechel and Janisczewski 2014) on the development of favorable customer relationships over time.

Happy to Have and Happy to Do: The Role of Self-Expression (A)symmetry in Material and Experiential Purchases

Georgios Halkias, University of Vienna, Austria
Sofia Kousi, NOVA SBE, Portugal
Hans Baumgartner, Pennsylvania State University, USA

EXTENDED ABSTRACT

Empirical research on the relative contribution of material possessions to happiness suggests that material purchases are inferior to experiential purchases (Van Boven & Gilovich, 2003) and recommends prioritizing the latter to enhance consumer happiness – a notion dubbed the *experience recommendation* (Nicolao et al., 2009). However, recent evidence has cast doubt on the alleged happiness dominance of experiential purchases, suggesting that it is not the type of purchase *per se*, but the specific properties of a purchase that drive happiness (Guevarra & Howell, 2015; Caprariello & Reis, 2013).

In this context, we argue that the experience recommendation may be largely attributed to an asymmetry between experiential and material purchases that studies relying on past recollections have neglected to consider: individuals tend to intuitively recall more self-expressive experiential, as opposed to material, purchases. Given that the expression of our identity has long been associated with increased happiness (Kifer et al., 2013), such an asymmetry raises questions about whether experiential purchases naturally outperform material purchases in eliciting happiness. What if self-expression asymmetries across the two types of purchases were eliminated? Would equally self-expressive material purchases still have a happiness disadvantage compared to experiential purchases? The present paper tries to answer these questions empirically through three experiments. Our findings challenge the dichotomy between experiential and material purchases and suggest that people should not dismiss material purchases altogether. Instead, they should opt for purchases that are instrumental in expressing their true selves.

Hypothesis 1:   *Compared to material purchases, experiential purchases generate higher levels of self-expression which, in turn, is positively related to happiness.*

Hypothesis 2:   *Compared to self-expressive material purchases, self-expressive experiential purchases are more readily accessible in memory.*

Hypothesis 3:(a) *Compared to low self-expressive purchases, high self-expressive purchases lead to higher happiness irrespective of purchase type, and (b) purchase type (experiential vs. material) does not influence happiness when purchases are equally self-expressive.*

Study 1 replicated extant studies' procedures by testing whether asking participants to recall an experiential vs. material past purchase results in more self-expressive experiences than self-expressive material purchases, which in turn is positively related to perceived happiness (H_1). A total of 119 respondents (M_{age} = 38.16, 58% female) participated in a single-factor, between-subjects experiment in which participants were asked to report a past purchase (experiential vs. material) and to rate it on happiness and self-expression (Van Boven & Gilovich, 2003).

Consistent with the experience recommendation, experiential purchases generated greater happiness than material purchases ($M_{experiences}$ = 7.35 vs. $M_{objects}$ = 6.00, $F(1, 116)$ = 24.04, $p < .001$, d

= 0.86), controlling for the cost of the purchase. Also as predicted, participants reported more self-expressive experiential than material purchases ($M_{experiences}$ = 6.72 vs. $M_{objects}$ = 4.22, $t(117)$ = 6.87, $p < .001$, d = 1.26). A mediation model revealed a significant indirect effect of purchase type on happiness through self-expression (b = 0.84, 95% BCI [.482 – 1.245]). The total effect of purchase type on happiness ($\beta_{type \to happy}$ = 1.45, $p < .001$) becomes non-significant in the presence of self-expression, which seems to be a direct consequence of the manipulation.

Study 2 sought to provide additional evidence for the notion that self-expressive experiential purchases are naturally more accessible in memory than self-expressive material purchases (H_2). A 2 (experiential vs. material purchases) × 2 (control vs. forced high self-expression recall task) between-subjects design with 140 participants (M_{age} = 29.85, 41% female) was conducted. We forced memory to high self-expression and compared responses to unprompted recalls of past purchases similar to Study 1.

In line with Study 1, participants in the control condition reported more self-expressive experiential (vs. material) purchases ($t(68)$ = 5.99, $p < .001$, d = 1.31), which were not significantly different from those in the forced high self-expression conditions. Corroborating the idea that self-expressive experiential purchases are more accessible in memory, the results showed that ease of retrieval for experiential purchases did not vary between control and high self-expression recall condition. In contrast, it took more time ($t(68)$ = 2.64, $p < .01$, d = 0.63) and it was more difficult to report highly self-expressive, as opposed to any, material purchases ($t(68)$ = 2.38, $p < .01$, d = 0.57).

Study 3 manipulated rather than simply measured low and high self-expression, directly testing the causal link between self-expression and happiness, and examining the experience recommendation in the absence of self-expression asymmetries (H_3). A 2 (material vs. experiential purchases) × 2 (low vs. high self-expression) between-subjects design with 101 participants (M_{age} = 39.85, 40% female) was conducted.

An ANCOVA analysis revealed a significant main effect for self-expression ($F(1, 96)$ = 130.35, $p < .001$, = 0.576), and non-significant effects for purchase type and the interaction between the two factors (purchase type: $F(1, 96)$ = 1.58, $p = .212$; self-expression × purchase type: $F(1, 96)$ = 1.23, $p = .271$). Consistent with H_3, the findings indicate that highly self-expressive purchases generate greater happiness, regardless of the purchase type.

The present paper offers a more nuanced understanding of the consumption–happiness relationship. By disentangling the roles of purchasing type and self-expression, it reveals that material goods do not have an inherent disadvantage and can meaningfully contribute to well-being. Our findings challenge the dichotomous thinking of the experience recommendation, suggesting a causal relationship between self-expression and happiness, and showing that experiential purchases increase happiness only when they are more self-expressive than material purchases. The results indicate that a high level of self-expression afforded by a purchase promises *higher* happiness levels than simply distinguishing between material and experiential purchases. For consumers, this helps guide discretionary spending decisions to increase well-being: our findings suggest that people should not dismiss material purchases. Instead, they should be more

deliberate when making purchase decisions and opt for goods and services that are instrumental in expressing their self. For managers, it corrects the presumed happiness disadvantage of material goods inherent in the experience recommendation, and offers different options for marketing communication and new product design. Consumers and researchers alike should shift from prioritizing one purchase type over the other and focus instead on identifying the ingredients that can promote happiness from all purchases.

Are You Paying Attention? Consumption-Related Antecedents and Consequences of the Spotlight Effect

Matthew J. Hall, Oregon State University, USA

EXTENDED ABSTRACT

The spotlight effect is a well-established bias in which consumers perceive that others pay more attention to them than is actually the case (Gilovich et al. 2000). While individual differences and artificial manipulations can enhance or attenuate the spotlight effect, research has yet to examined how this bias is influenced by day-to-day consumption behaviors. The spotlight effect occurs because consumers anchor on the attention they pay to their own behaviors and fail to adequately adjust away from this egocentric perspective when considering others' attention allocation. Thus, this bias should be enhanced when consumers encounter signals that increase egocentrism because such signals should lead to a decreased adjustment relative to one's egocentric perspective (Fenigstein and Abrams 1993). One such signal is feedback consumers receive after sharing content online (views, likes, etc.)—a signal that indicates others are paying attention to one's behaviors (Skågeby 2009). Therefore, I propose that the level of attention consumers receive online will influence their spotlight effect bias in subsequent offline settings.

Research has not explicitly considered the consumption consequences of the spotlight bias. However, because it stems from egocentrism and the awareness of the self in relation to others, theory suggests it may influence conspicuous consumption. While some research suggests an *enhanced* spotlight effect should increase conspicuous consumption (Xu et al. 2019), other findings suggest an *attenuated* spotlight bias might increase conspicuous consumption (Lee and Shrum 2012). I propose these differing responses may depend on consumers' regulatory focus (Higgins 1997). With conspicuous consumption, the desired end state is to enhance status by attracting attention and facilitating positive social impressions. Consumers with conspicuous motives should therefore be dissatisfied if others are not paying attention, suggesting an attenuated spotlight bias should increase conspicuous consumption, regardless of regulatory focus (compensatory consumption when feeling ignored; Lee and Shrum 2012). Alternatively, if others are already paying attention (enhanced spotlight bias), consumers are already partially in a desired end state. Thus, those with a promotion focus—who actively pursue ideal end states—should leveraging this perceived "spotlight" to demonstrate their taste and wealth through conspicuous consumption. Alternatively, prevention-focused consumers should be less likely to consume conspicuously when they are the focus of attention because conspicuous consumption sometimes leads to negative evaluations (Truong 2010; Wong 1997).

In study 1, undergraduate students (n=203) completed a 2-condition (received attention: high/low) lab study. Participants read about posting a restaurant experience on social media. Stimuli were presented as mock Instagram posts, which indicated that participants received either 150 (high attention) or 15 (low attention) views. After this attention manipulation, participants participated in a brief activity to measure the spotlight effect (from Pfattheicher and Keller 2015). Participants affixed a pink sticky-note to their shirt and left the lab to walk through a nearby atrium where other students often study. Upon returning to the lab, participants reported how many other students were in the atrium ($M=24.94$, SD=15.98; no difference between conditions) and how many of those students they thought noticed the sticky-note on their shirt. As expected, those who received more attention after sharing online reported an enhanced spotlight bias offline ($M_{High}=31.96\%$, SD=25.37%; $M_{Low}=16.44\%$, SD=16.50%; $F(1,201)=26.75$, $p<.001$).

Study 2 examines how received attention influences the spotlight bias relative to when no attention information is available. Undergraduates (n=229) were assigned to one of three conditions (received attention: high/low/control). After viewing the same attention manipulation from study 1—control condition participants saw the post with no attention information—participants completed a spotlight effect measure. They imagined spilling sauce on their shirt while eating in a restaurant, and that while walking to the bathroom in the restaurant, they passed 30 people—participants reported how many they thought would notice the stain. As expected, those receiving high attention ($M=9.05$, SD=3.42) reported that more people would notice the stain, relative to the low attention ($M=5.46$, SD=2.93; $F(1,226)=50.71$, $p<.001$) and control ($M=6.79$, SD=3.37; $F(1,226)=20.10$, $p<.001$) conditions. The low attention condition also reported a lower spotlight bias than the control condition ($F(1,226)=7.23$, $p=.008$).

In study 3, undergraduates (n=299) completed a 2(attention: high/low) x 2(regulatory focus: promotion/prevention) study. After completing a regulatory focus manipulation (writing task from Freitas and Higgins 2002), high and low received attention were manipulated as in study 1. Next, participants completed the same spotlight measure from study 2 and finished by making a hypothetical choice between two Nike t-shirts—a more conspicuous option (large logo) and a less conspicuous option (small logo; Lee and Shrum 2012). In the high attention condition, participants again reported an enhanced spotlight bias ($M_{High}=10.70$, SD=3.39; $M_{Low}=4.86$, SD=2.71; $F(1,297)=267.74$, $p<.001$). Further, a logistic regression revealed that regulatory focus moderated the effect of the spotlight bias on conspicuous choice ($B_{Interaction}=.111$, $\chi^2_{Wald}=11.84$, $p<.001$; no main effects). In the promotion condition, an enhanced spotlight effect bias led to increased conspicuous choice ($B=.086$, $\chi^2_{Wald}=4.04$, $p=.044$), while the opposite effect was observed in the prevention condition ($B=-.135$, $\chi^2_{Wald}=7.94$, $p=.005$). The full theoretical model was confirmed using Hayes' PROCESS macro model 14 ($CI_{95}=[.563, 2.131]$), as there was a positive indirect effect of received attention on conspicuous choice, through an increase in the spotlight effect, within the promotion condition ($CI_{95}=[.127, 1.378]$), and a negative indirect effect within the prevention condition ($CI_{95}=[-1.227, -.030]$). Notably, this was the only model that resulted in a significant index of moderated mediation (b-path moderation only).

By considering a context in which consumers have actual feedback regarding the attention others pay to them, I demonstrate that consumers use their discrete online interactions to influence the anchoring and adjusting process that results in the spotlight bias. Thus, consumers' spotlight biases are not static, especially in an environment in which social media provides consumers with constant feedback about the attention they receive. I also contribute to literature on conspicuous consumption by demonstrating that the effect of attention biases on conspicuous consumption is dependent on consumers' regulatory focus. To my knowledge, this research is the first to demonstrate the effect of regulatory focus on consumers' preferences for conspicuous products.

How Public Recognition Promotes Donations to Out-groups

Eunjoo Han, Penn State Behrend, USA
Saerom Lee, University of Guelph, Canada
Karen Page Winterich, Pennsylvania State University, USA

EXTENDED ABSTRACT

In 2018, American consumers donated more than $290 billion to charitable organizations (Giving USA 2019). However, most donations by individual donors have been made to support domestic causes, with only 3% of the funds donated to international causes (Giving USA 2006). Although this pattern of behavior is not surprising given prior research suggesting that consumers are generally far more willing to help victims belonging to their in-group compared to an out-group (Cuddy, Rock, and Norton 2007; James and Zagefka 2017; Levine, Prosser, Evans, and Reicher 2005), this is not ideal in that donations are increasingly needed for international causes. According to the United Nations, 168 million people in 53 countries will need emergency relief in 2020 and the relief efforts are expected

to cost $28.8 billion (OCHA 2019). Thus, it is critical to find ways to encourage consumers to engage in charitable giving toward victims beyond their in-group boundaries. To this end, we investigate how public recognition of charitable contributions can encourage consumers to donate more to out-group victims. Specifically, we propose that public recognition enhances charitable giving for out-groups due to the benefits of public out-group giving in elevating consumers' moral self-regard.

Prior work has explored the role of public recognition (e.g., displaying donors' names on an organization's website, printed medium, or a physical object, or donating in a public setting) in charitable contributions. One stream of research has highlighted the positive effect of public recognition on donations. Public recognition often increases donations in a wide range of contexts (e.g., Basil et al. 2009, Harbaugh 1998) by fulfilling consumers' desire to present a positive social image (Karlan and McConnell 2014) or conform to the expectations of others (Fisher and Ackerman 1998). Another stream of research, however, suggested public recognition does not always increase charitable giving. For example, public recognition decreases donations by consumers with an independent self-construal who are willing to make decisions based on their own freewill without being influenced by social pressure (Simpson et al. 2018). Public recognition can also dampen charitable giving if donors are suspected of being motivated by ulterior, self-presentational motives (Benabou and Tirole 2006). Extending the prior research, we suggest the effect of public recognition on charitable giving will depend on the group membership of victims: Whether donation recipients belong to the same group as potential donors (in-group victims) or not (out-group victims). More specifically, the current research suggests public recognition will primarily have a positive effect on donations toward out-group victims; however, it would not necessarily increase donations toward in-group victims (the latter is consistent with conflicting results on the role of public recognition in charitable giving).

Individuals tend to categorize themselves into social groups, positively differentiating their group from other groups (Abrams and Hogg 2010; Tajfel and Turner 1979). This accounts for why individuals prefer to help victims of their own group over those of other groups (Bear and Rand 2016; Mullen, Brown, and Smith 1992). Indeed, people find it more challenging to empathize with others' suffering when victims belong to out-groups (Batson and Ahmad 2009). According to Reed and Aquino (2003), out-group helping requires expanding circle of moral regard toward out-groups, and because of that, donating to out-group victims tends to be observed among individuals who consider being moral is important and essential to their self-identity. This finding, in turn, may suggest that out-group (vs. in-group) helping can be more diagnostic of the helper's altruistic characters since it is a behavior associated with high moral identity. Thus, helping victims of an out-group (vs. in-group), when publicly recognized, may engender more positive reactions from others. Prior work on self-identity has shown that if observers of a helping behavior are expected to perceive the helper altruistic, the expected positive social evaluations should elevate the helper's self-view on his altruistic identity, leading to a more prosocial follow-on behavior (e.g., Barnes, Mason, and Leary 1988; Luhtanen and Crocker 1992). Building on this research, we propose that donating to out-group victims is a form of behavior that will improve consumers' moral self-regard particularly when it is publicly recognizable.

Consumers will consider that donating to out-groups, when publicly recognized, will generate positive social evaluations on their moral identity and elevate their moral self-regard. As such, consumers will be more likely to donate to out-groups under public recognition, driven by elevated perceptions of moral self-regard (e.g., Zlatev et al. 2020).

Taken together, we suggest that public recognition will promote donations to out-groups by improving their moral self-regard (not simply by raising self-presentation motives as typically demonstrated in the literature). In contrast, we do not expect that public recognition will promote donations toward in-group victims, because in-group helping is typically regarded as a social default (Insko et al. 2001) and taken more for granted as a normatively expected behavior (DiDonato, Ullrich, and Krueger 2011; Sierksma and Thijs 2017; Van Bavel, Packer, and Cunningham 2008).

Study 1

Study 1 aims to provide an initial test of our basic prediction. We examine participants' choice of a charity between charities supporting in-group versus out-group victims as a function of public recognition.

Method and Procedure

The study was a two-group (Public recognition: Present vs. Absent) between-subjects design. Sixty-seven undergraduate students (63.2% females) participated in this study in exchange for course credit. Most of the participants (78%) were U.S. nationals.

Participants first read about how global food banking systems work and how two specific foodbanks – Feeding America (supporting in-group victims in the U.S.) and Somali Foodbank (supporting out-group victims in Somalia, Africa) – work to end hunger crises.

After that, participants were asked to choose a foodbank they would like to donate between the two organizations. To minimize any differences in the perceived impact of helping, we informed that every dollar (USD) would help foodbanks distribute 5 meals in both countries. In the public recognition condition, participants were instructed that donors' names would be posted on the official Facebook pages of the university and the chosen foodbank. In the control condition, participants did not receive any information on public exposure.

Results and Discussion

A logistic regression analysis was conducted to examine the effect of public recognition (recognition = 1, control = -1) on participants' choice of charity (Feeding America = 1, Somali Foodbank = 2). Public recognition was found to increase willingness to help an out-group (β = .59, *SE* = .26, χ^2 = 4.96, *p* = .03): Somali foodbank was chosen by 27.6% of the participants in the control condition, but its choice share increased to 55.3% in the public recognition condition. As expected, this finding suggests that individuals are more likely to help an out-group when their contribution is publicly recognizable (vs. not).

Study 2

Study 2 aims to demonstrate the robustness of the effect of public recognition on out-group versus in-group helping using an actual donation measure in a real context of disaster relief. To this end, the study was conducted a few weeks after a large earthquake struck Indonesia (September 28, 2018) and Hurricane Michael hit the East coast of the U.S. (October 10, 2018).

Method and Procedure

The study was a 2 (Victim: In-group vs. out-group) X 2 (Public recognition: Present vs. Absent) between-subjects design. Three hundred and fifteen U.S. citizens recruited from Prolific (43.5% females) participated in this study in return for monetary compensation.

Participants were first reminded of a recent natural disaster and read further information about victims affected by the natural disaster in Indonesia (Sulawesi earthquake and tsunami) or in the U.S. (Hurricane Michael) depending on the victim condition.

Participants were also told that they would be able to help affected families in America or Indonesia by donating to the Save the Children's emergency response team.

Following that, all participants were instructed that they would be entered into a random draw to receive a bonus payment of $20 and that they can choose to donate any portion of the bonus to Save the Children. When public recognition was present, participants were told that donors' names would be listed in the official website of Save the Children.

When public recognition was absent, participants learned that their decision would be confidential. Participants indicated how much of $20 bonus they would donate to Save the Children.

Results and Discussion

An ANOVA with victim and recognition as independent variables and participants' log-transformed donation amount as the dependent variable revealed a significant two-way interaction on the amount of donation ($F(1, 311)$ = 7.05, *p* < .01). Public recognition (vs. no recognition) increased donations to out-group victims ($F(1, 311)$ = 3.61, *p* = .058). In contrast, public recognition slightly decreased donations to in-group victims ($F(1, 311)$ = 3.44, *p* = .065). Looking at another direction, the amount of donation was significantly higher for out-group (vs. in-group) victims when public recognition was present ($F(1, 311)$ = 4.69, *p* = .03). When public recognition was absent, however, donations to out-group versus in-group victims did not differ ($F(1, 311)$ = 2.52, *p* = .11). These results again provide support for our basic theorizing that public recognition promotes donations to out-group (vs. in-group) victims. Importantly, these effects were demonstrated with actual donations.

Study 3

The purpose of study 3 is to offer evidence for the mediating role of moral self-regard. Recall we argued that public recognition would lead individuals to anticipate elevated moral self-regard from donating, particularly when donation recipients are out-group (vs. in-group) victims. Thus, we measured participants' moral self-regard (i.e., how moral they would feel; Monin and Jordan 2009) and tested its mediating role in the proposed relationship. We also explore alternative accounts including personal happiness (e.g., Duclos and Barasch 2014), impression management motives, and the perceived impact of helping.

Method and Procedure

The study was a 2 (Victim: In-group vs. out-group) X 2 (Public recognition: Present vs. Absent) between-subjects design. One hundred and eighty-four U.S. citizens recruited from Amazon Mturk (46.20% females) participated in this study in return for monetary compensation.

Participants were first exposed to a hunger crisis appeal by Save the Children either in the U.S. or South Sudan depending on the victim condition. Participants then learned they had an opportunity to support the organization's food security programs and indicated how willing they were to donate to the organization (*a* = .95). In the public recognition condition, participants were informed that their contribution would be publicly recognized via the Facebook page of Save the Children. When public recognition was absent, participants were told that their contribution would be confidential.

Next, participants reported (1) how much donating would lead them to feel like a moral person (*a* = .90), (2) how much donating would make them happy (*a* = .90), (3) their desire to make a positive impression toward others (*a* = .94), and (4) the perceived impact of helping (*a* = .90).

Results and Discussion

Donation intention. An ANOVA with victim and recognition as independent variables and charitable intention as the dependent variable revealed a significant interaction on charitable intent ($F(1, 180)$ = 6.51, *p* = .01). Public recognition (vs. no recognition) increased participants' willingness to donate to the charity when it addressed the crisis in South Sudan (i.e., out-group victims) ($F(1, 180)$ = 4.03, *p* = .046). However, there was no difference in charitable intent between the two recognition conditions when the cause involved in-group victims ($F(1, 180)$ =2.53, *p* = .11). Looking from a different perspective, when the contribution was publicly recognizable, participants exhibited greater willingness to donate to victims in South Sudan (vs. the U.S.) ($F(1, 180)$ = 4.91, *p* = .03). When public recognition was absent, charitable intent did not differ between the victim conditions ($F(1, 180)$ = 1.91, *p* = .17).

Mediation analyses. A bootstrapping analysis for moderated mediation (Hayes 2013; Process Model 8; N of iterations = 5,000) revealed a significant index of moderated mediation (-.37, 95% CI = -.66 to -.07). Specifically, the indirect effect of public recognition on charitable intent via moral self-regard was significant when the cause was involved out-group victims (.30, 95% CI = .09 to .52). In contrast, the indirect effect was NS for in-group victims (-.07, 95% CI = -.28 to .14). These findings support our prediction that public recognition promotes charitable giving for out-group victims by elevating moral self-regard. We also explored the mediating roles of personal happiness, impression management motives, and the perceived impact of helping. When the four mediators were entered the model simultaneously, the indirect effect via moral self-regard

remained significant (-.27, 95% CI = -.50 to -.06). None of the other accounts mediated the observed findings.

These findings provide support for the role of moral self-regard as an underlying mechanism of the effects of public recognition on charitable giving to out-groups versus in- groups. Public recognition of charitable contributions enhanced consumers' perceptions of their moral self, which, in turn, increased intentions to donate to out-groups.

Conclusion

Across three studies, we demonstrate that public recognition of charitable contributions can be an effective tool to promote out-group helping but is not effective in promoting in-group helping. We further show that public recognition facilitates out-group helping by elevating a donor's moral self-regard.

This research contributes to the literature on charitable giving in two important ways. First, we add to the literature on intergroup helping by delineating conditions under which charitable giving can be increased depending on recipients' group membership. Second, we enhance the understanding of factors increasing effectiveness of public recognition as a tool to promote charitable giving. Our work suggests public recognition improves the effectiveness of donation appeals when out-group victims are involved. Further, our theorizing may be extended

to suggest public recognition may promote other forms of pro-social behavior which are not normatively taken for granted. Future studies can investigate this possibility.

Importantly, our results deliver substantial practical implications to charitable marketing: Publicly recognizing donors' charitable contributions can encourage donations for foreign aids supporting victims who belong to potential donors' out-groups. If funds are raised for domestic causes supporting victims who belong to potential donors' in-group, public recognition will not have much benefits in promoting charitable giving. In such a case, to best utilize public recognition as a promotion tool, organizations need to try to make target victims perceived as more socially distant from potential donors.

Political Ideology Driven Differences in Consumers' Switching Behavior for Differentially Involving Products

Hyerin Han, University of Minnesota, USA
Hyun Euh, University of Minnesota, USA
Hyesung Yoo, Washington University in St. Louis, USA
Akshay R. Rao, University of Minnesota, USA

EXTENDED ABSTRACT

Consumer switching indicates a consumer's voluntary movement from a current option to another option (Su et al. 2017). The present study adds to extant research which has identified psychological factors that lead consumers to deviate from buying the same product or brand repeatedly by identifying the role that political ideology might have on consumers' switching behavior. We predict that conservatives, due to their tendency to maximize, search for information about and switch products or brands more so than liberals do. However, this result is reversed for product classes which carry a high risk to consumers if they fail due to their high self-relevance.

Individuals with a high maximizing tendency seek out information about available options and compare them extensively with the goal of making the best choice (Schwartz et al. 2002). Consumers with a high maximizing tendency are less likely to settle for the current option and more likely to search every time they buy something even if a similar search process has been undertaken in the past, thus increasing the chance of switching (Carrillat, Ladik, and Legoux 2011).

We expect that political conservatism ought to be associated with higher levels of the tendency to maximize based on extant findings regarding the association between political conservatism and a Social Dominance Orientation (SDO). Conservatives tend to display a higher SDO defined as a motivational tendency that assures the high status of the in-group (Pratto 1994). This tendency to seek dominance and be the best in a hierarchy ought to result in high SDO individuals pursuing a goal of selecting the best option. Thus, we predict that as political conservatism increases, the tendency to maximize increases too due to high SDO which are traits associated with political conservatism. This tendency ought to yield higher switching following the search for the best option.

This effect should be observed, unless the adverse consequences associated with performance failure of the option to which they switch, are relatively high. In many cases, products which are highly relevant to the self (i.e., high involvement products), by being central to the person's identity or by providing solutions or benefits that are personally important, are more likely to carry a high risk to consumers if they fail compared to products that are low in self-relevance (i.e., low involvement products). When exposed to a high risk, people experience a diminished motivation to search for information and a lack of certainty. As a result, they are likely to stay with the status quo because they don't need to engage in information search if they stay with a current option, and also a known option offers a high sense of certainty (Thórisdóttir and Jost 2011). For the same reason, consumers are likely to not switch from an incumbent option for high involvement products. We predict that this inertia to cling to an incumbent option for high involvement products will be stronger among conservative consumers due to conservatives' higher threat sensitivity compared with liberals (Jost et al. 2017).

Hypothesis 1: *Conservatives will display greater switching behavior than liberals, but this effect will be reversed for high involvement products.*

Hypothesis 2: *Differences in switching behavior between conservatives and liberals will be mediated by their tendency to maximize, which will be reflected in their search behavior.*

We first examined the association between political conservatism and maximizing tendency through a pilot study. Two components of maximization – the goal of choosing the best option and the strategy of increased search among alternatives – were measured separately. The results of a regression on political conservatism showed that participants with right-wing (vs. left-wing) ideology reported higher scores on both components of maximization.

The goal of Study 1 was to test H1 by using a longitudinal panel data of U.S. households that provided their grocery shopping information. Five high involvement products (beer, coffee, cold medicine, female sanitary protection, and male contraceptive products) and five low involvement products (household cleaners, shampoo, air freshener, laundry detergent, and soap) were selected through a pretest. Switching rate was measured by the number of times a household switched from one brand to another as a percentage of its total number of purchases in a given product class. Each county's average Republican vote share for the 2012 and 2016 US Presidential elections was used as a county-level measure of political conservatism. We regressed the switching rates for high and low involvement products on county-level conservatism and control variables (e.g., household-specific demographics such as age, gender, race, income level). The results revealed that households in conservative counties were more (less) likely to switch brands for low (high) involvement products compared to those in liberal counties (Low: $\beta = 2.90$, $p < .001$; High: $\beta = -1.71$, $p < .001$).

In Study 2, we tested H2 by examining the mediational role of alternative search and the moderating role of product involvement on switching behavior. Participants read a passage ostensibly written to help them choose headphones. In the high involvement condition, headphones were depicted as highly self-relevant (e.g., a noise-canceling function helps you prevent hearing loss and enjoy music better), whereas the same features were described in a neutral way in the low involvement condition (e.g., noise-cancelling functions require a power source). After that, participants were asked to choose among five headphones. They could access the information of each headphone by clicking on its picture. After making their choice, they read that they had been generally satisfied with the headphone, but one day they had lost it and needed to buy a new one. They could select a headphone among five new headphones (coded as switching) or they could choose the headphone that they had originally selected (coded as non-switching). Alternative search was measured by the number of different headphones the participants examined before they made their second purchase decision. Supporting H2, the results of a moderated mediation analysis revealed the significant indirect effect of the interaction between political conservatism and product involvement on switching decision through alternative search (b = .23, SE = .10, 95% CI = [.05 to .46]).

Can Money Buy International Migrants Happiness? It Depends on How You Spend It

Haiming Hang, University of Bath, UK
Jing Yang Zhong, Birmingham City University, UK

EXTENDED ABSTRACT

Subjective well-being (SWB) reflects people's own evaluations of and feelings toward the quality of their lives (Diener 1984). High levels of SWB can confer a variety of benefits, such as longevity (Chida and Steptoe 2008) and better health (Lamers et al. 2012). However, whether moving to another country can make international migrants happier remains unclear. A lack of a sense of belonging in host country has become the most common challenge facing international migrants (Hendriks 2015). This has raised wide concerns about their SWB. However, international migrants' material welfare still dominates current focus among policymakers. This is surprising because Diener and his colleagues have repeatedly argued that happiness is not determined by money but by fulfillment (or lack thereof) of basic psychological needs (Diener, Oishi, and Tay 2018).

In this paper, we first argue that international migrants prefer spending money on material purchases (acquiring a tangible object to keep in possession ,Van Boven and Gilovich 2003) to cope with their lack of a sense of belonging in host country. This, in turn, has a negative impact on their SWB. Building on the literature regarding whether money can buy happiness (Aknin, Wiwad, and Hanniball 2018), we suggest that both experiential purchases (acquiring a life experience to live through) (Van Boven and Gilovich 2003) and prosocial purchases (spending money on others rather than oneself) (Dunn, Aknin, and Norton 2008) can enhance international migrants' SWB, with prosocial purchases more effective than experiential purchases. We further argue that this is mainly because while both experiential purchases and prosocial purchases can satisfy relatedness need, the satisfaction from beneficence associated with prosocial purchases can independently contribute to SWB (Martela and Ryan 2016).

Study 1 (n = 151,602) used 10-year data from the BHPS to compare the consumption patterns and SWB levels of international migrants and locals in the U.K. The BHPS collected the panel's actual spending on material purchases such as personal properties. Experiential consumption was collected via the panel's monthly expenditures on leisure activities, entertainment and hobbies via an ordinal scale. Our model suggests the coefficients of migrant status was positive and statistically significant ($b = .17, p < .01$), suggesting the locals were happier than international migrants. Our results further suggest that compared to locals, international migrants spend more on materials but less on experiential purchases. The coefficient of material purchases was negative and statistically significant on SWB ($b = –.02, p < .05$) while experiential purchases were positive and statistically significant ($b = .03, p < .001$). That is to say, material purchases had a negative impact on SWB, experiential purchases had a positive impact. This may contribute to the lower SWB of the international migrants. A parallel mediation analysis (PROCESS Model 4) support this, with the indirect effects on material purchases ($b = –.0285, 95\% \, CI = –.0361, –.0211$) and experiential purchases ($b = .0245, 95\% \, CI = .0176, .0315$) both significant.

Study 2 (n = 400) was a one-factor (sense of belonging: low vs. high) between-subject design. Participants were randomly asked to recall a memorable event after moving to the USA that made them feel they belong/did not belong to the country. For each migrant, we measured their basic psychological needs as in Chen et al. (2015) and their preferences for experiential purchases as in Kumar and Gilovich (2016). We also measured participants' preferences between material and prosocial purchases. Results suggest low sense of belonging were less likely to prefer prosocial purchases ($M_{low} = –.16, M_{high} = 1.71, F (1, 280) = 35.17, p < .001$), and less likely to prefer experiential purchases ($M_{low} = .22, M_{high} = 1.58, F (1, 280) = 16.56, p < .001$). They also had lower life satisfaction ($M_{low} = 6.45, M_{high} = 7.29, F (1, 280) = 11.60, p < .01$).

Study 3 (n = 598) was a 2 (sense of belonging: high vs. low) × 3 (purchase type: material vs. experiential vs. prosocial) between-subject design. Purchase type was manipulated in the same way as in Van Boven and Gilovich (2003). In order to gather participants' beneficence satisfaction, we used the four-item scale from Martela and Ryan (2016). Results suggest for participants in the low sense of belonging condition, their SWB differed across purchase type: $F (2, 293) = 14.28, p < .001$, with prosocial purchase leading to highest SWB. However, purchase type did not influence participants' SWB in the high sense of belonging condition. Following Martela and Ryan (2016), we used a hierarchical regression analysis to test the independent contribution of beneficence satisfaction to SWB. We found when beneficence was incorporated in the model, R-squared change was statistically significant: $F (1, 593) = 44.34, p < .001$. Thus, the impact of beneficence satisfaction on SWB is different from the impact of psychological need satisfaction.

Study 4 (n = 306) was a one-factor (purchase type: experiential vs. prosocial with high beneficence satisfaction vs. prosocial with low beneficence satisfaction) between-subject design. Results indicated that SWB differed across conditions ($F (2, 299) = 3.29, p < .05$), with prosocial purchases with high beneficence satisfaction leading to highest SWB while the other two conditions did not differ. The same pattern was evident for participants' relatedness need satisfaction ($F (1, 299) = 4.05, p < .05$). Thus, prosocial purchases with high beneficence satisfaction can more effectively satisfy relatedness need than experiential purchases.

Together, our studies demonstrate that coping with psychological threats such as the lack of a sense of belonging in host country makes international migrants spend money suboptimally. Study 1 shows that compared to locals, international migrants spend more on material purchases but less on experiential purchases, which in turn leads to their lower SWB. More importantly, our Studies 2, 3 and 4 suggest that prosocial purchases are more effective than experiential purchases in increasing international migrants' SWB. The results of Studies 3 and 4 suggest that this is because prosocial purchases can lead to both relatedness needs satisfaction and beneficence satisfaction, with each of them independently contributing to international migrant workers' SWB.

The Social Power of Narcissists in Mass Customization

Johanna Hasenmaile-Aspin, University of St. Gallen, Switzerland
Emanuel de Bellis, University of St. Gallen, Switzerland
Andreas Herrmann, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

Consumers are increasingly flooded with information, not only from firms but also from peers. Providing information online through electronic word of mouth (eWOM) enables consumers to communicate about products, services, and brands (Rosario et al. 2016). Whereas much is known about the consequences of eWOM and its underlying processes (Berger 2014; Chevalier and Mayzlin 2006; Hennig-Thurau et al. 2004), less attention has been paid to which communication by which consumers has which influence. Exploring this issue, we propose that narcissism is key to understanding the effectiveness of eWOM.

We conceptualize narcissism as unjustified conceit, which implies excessive motivation to self-enhance (Lee et al. 2013). Narcissists are highly self-centered, persistently seek attention, and often consider themselves the epicenter of their social world (Sedikides et al. 2002). Their social interactions are shaped by the need to boast about their achievements (Sedikides et al. 2007). Narcissists communicate to convey "heroic I" messages; this self-centered "configuration of selfhood" means that narcissists strive to be the heroes of their own stories (Goodman, Dueck, and Langdal 2010, 667). The prevailing opinion is that narcissistic communication is I-centered as narcissists tend to use more first-person singular ("I" and "me") than plural ("we" and "us") pronouns compared to non-narcissists (Chatterjee and Hambrick 2007; Raskin and Shaw 1988). However, this relationship has been examined with contradictory results. Some studies have not found a significant correlation between I-centered communication and narcissism (Carey et al. 2015; DeWall et al. 2011; Fast and Funder 2010). It remains unclear how narcissists communicate—especially in specific settings such as mass customization (MC) systems.

Our research integrates insights from eWOM and narcissistic communication into the MC domain. Integrating social elements into MC systems is attracting increasing attention across industries as consumers can share and discuss their customized products (e.g., cars or sneakers) directly with their peers via social product configurators. Thus far, little is known about the consequences of integrating elements of social interaction into MC systems. The few existing systematic studies have examined how feedback impacts the uniqueness of product designs, the role of social distance in product modifications, and satisfaction with self-designed products (D'Angelo, Diehl, and Cavanaugh 2019; Hildebrand et al. 2013; Schlager et al. 2018). However, none has investigated whether and how communication styles in consumer feedback messages affect peers when customizing products.

We propose that narcissistic consumers employ self-promoting interaction patterns in social product configurators. When narcissistic consumers share their customized products, their underlying motivation is to highlight their greatness (Goodman et al. 2010). They are hence likely to use more first-person singular pronouns compared to non-narcissists.

Hypothesis 1: *The greater consumers' narcissistic tendencies, the more they use I-centered (vs. product-centered) communication in social product configurators.*

How does such narcissistic (i.e., I-centered) communication, beside a shared configuration, affect others? We expect this type of message to tell peers that the product designer identifies with the customized product. Its use of "I" makes such communication seem more authentic and competent, and thus more influential (Brunell et al. 2008). Therefore, when consumers can repeat their configuration, we suspect that they are influenced by a narcissist's sample configuration, resulting in an adjustment of their original configuration.

Hypothesis 2: *Consumers adjust their own customized product to their peers' sample configuration if its presentation is I-centered (vs. product-centered).*

Peer input on evaluating preliminary design solutions can have positive effects (Franke, Keinz, and Schreier 2008). However, social comparisons and deviating from initial preferences can devalue self-designed products (Hildebrand et al. 2013). Thus, while consumers likely adjust their customized product more to a narcissist's sample configuration, we expect them to be less satisfied with their own customized product because they perceive narcissists' configurations as more competently customized.

Hypothesis 3: *Consumers perceive their own customized products less favorably after seeing an I-centered (vs. product-centered) sample configuration.*

Our pilot study (field study; N=64) explored how social networks impact a recent car purchase and how consumer communication depends on narcissistic tendencies. We found that narcissists more frequently use social networks and that narcissistic tendencies predict the use of first-person singular pronouns. Therefore, narcissists can be described as opinion leaders heavily using first-person singular pronouns when communicating via social networks.

Study 1 (online study, N=146) examined how narcissists' messages impact peer product customization. We employed a 2 (perspective: I-centered vs. product-centered) × 2 (appraisal: appraising vs. non-appraising) between-subjects design. Having measured narcissistic tendencies, participants configured a car with a mock-up configurator. Next, they were randomly assigned to a sample configuration along with an experimentally manipulated message. We created four sample configurations (to be used with one of four messages) that varied in terms of perspective (I-centered vs. product-centered), appraisal, and whether attribute options were made explicit. Finally, participants configured their car a second time. Using the adjustment index, we computed the difference between customizations 1 and 2. Overall, consumers receiving an I-centered (vs. product-centered) message were significantly more likely to adjust their customized product to a sample configuration.

Study 2 (lab study, N=169) explored whether consumers were satisfied with their customized product after receiving a narcissistic sample configuration. Participants configured a car and evaluated their customized product. Next, they were randomly assigned to one of four experimentally manipulated messages and shown one of four fully configured cars supposedly posted on a social network. Finally, they reevaluated their customized product by responding to diverse variables. Overall, consumers consistently evaluated their customized product more negatively (e.g., decreased choice satisfaction,

pride of authorship, fit of configured features) after seeing a narcissistically communicated sample configuration while expressing a greater desire to reconfigure their customized product.

Our research highlights the social power of narcissists in MC systems. Narcissistic communication seems critical to understanding the effectiveness of eWOM and to determining what cuts through the noise and influences consumers in social product configurators. We contribute to three literature streams—eWOM, narcissism, and MC—by demonstrating that narcissistic (vs. non-narcissistic) communication in social product configurators is more influential while decreasing consumers' satisfaction with their customized products.

When Brands Speak: The Effects of Personified Content on Word of Mouth

Daniel He, National University of Singapore, Singapore
Jin Miao, Columbia University, USA

EXTENDED ABSTRACT

Pepsi thought it had all the right ingredients: a winsome celebrity, stirring music and imageries, and a timely commentary on social activism. However, when the Kendall Jenner "Live for Now" ad debuted in 2017, outrage over the perception that Pepsi was trivializing social justice spread so quickly on social media that the beverage brand immediately issued an apology and removed the advertisement just a day after its release (Victor 2017). Pepsi is not alone in releasing well-intended marketing campaigns that unwittingly elicited consumer backlash.

Numerous brands both before and after the Live for Now misstep have experienced the same fundamental challenge facing all digital marketers: losing control of word of mouth on social media.

Although social media has given brands the ability to reach more consumers with greater precision at a lower cost (Berger and Milkman 2011; Berger and Schwartz 2011; Moe and Schwedel 2012; Lamberton and Stephen 2016), the benefits come at the expense of forgoing control over what consumers say about the brand. In the past, brands have relied on a combination of social influence and review management to better manage word of mouth. For example, recognizing the benefit of information cascade (Muchnik, Aral, and Taylor 2013), hotels manage their online reputation by actively responding to customer reviews on travel forums (Proserpio and Zervas, 2017). Other businesses rely on more insidious methods by manipulating online reviews (Mayzlin, Dover, and Chevalier 2014) or by soliciting fake positive reviews with monetary incentives (Luka and Zervas 2016).

However, existing methods of word of mouth management are reactive in nature and focus on improving product reviews instead of improving word of mouth of the brand. In this research, we document a proactive approach that can inoculate the brand itself from negative word of mouth. We find that brands can improve word of mouth by incorporating distinctly human characteristics into their online content, which we call personified content, to help anthropomorphize the brand. Unlike the more formal messages that firms typically send, personified content expresses distinctly human attributes, including the ability to think and feel, the capacity for creativity, and the presence of a personality. Using 5 years of Twitter data from National Basketball Association (NBA) teams, we find that we find that personified brands not only have more positive word of mouth compared to non-personified brands, but that when the need to defend the brand arises (*i.e.,* losing games), the benefit of personified brands on word of mouth is further increased.

Literature Review

Before social media, brands lacked the means to speak directly to consumers; instead, they relied on intermediaries like spokespersons, mascots, or their executives to communicate on behalf of the brand. For example, although the brand Disney could not literally speak on TV or the radio, Mickey could lend his voice to speak on behalf of the brand.

On social media, brands can not only transmit information to their followers, but they can also express their voice and personality based on how they communicate. Brands like Wendy's Burgers have taken advantage of this opportunity to cultivate a vibrant and sassy personality by tweeting jokes, picking fights with rival brands, and referencing cultural trends (Jargon 2017).

Instead of merely using social media as an additional channel to answer questions, promote products, and collect feedback, brands like Wendy's now transmit content that incorporate distinctly human characteristics to anthropomorphize the brand, a phenomenon we call personified content.

The extensive literature on anthropomorphism show that ascribing humanlike qualities to products can improve perception of those goods (Aggarwal and McGill 2007; Aggarwal and McGill 2011; Kim, Chen, and Zhang 2016). This occurs in part because greater relatability can cultivate stronger relationships with the products. For example, Epley et al. (2007) document a relationship between the tendency to anthropomorphize and the desire for relationship by showing that individuals with a higher need to belong are more likely to anthropomorphize objects and nonhuman agents. Similarly, people who are chronically lonely or primed to feel lonely anthropomorphize to a greater extent than those who are not (Epley et al. 2008), and satisfying people's need to belong by reminding them of their social connections attenuates the tendency to anthropomorphize (Bartz, Tchalova, and Fenerci 2016).

Whereas past work have manipulated anthropomorphism by assigning humanlike features, such as adding a face, a smile, a gender, or a name to a product (Epley, Waytz, and Cacioppo 2007; Zhou, Kim, and Wang 2018), we examine incorporating distinctively humanlike traits through language expressed through digital content. Specifically, we focus on humanlike qualities, including thinking, feeling (Epley et al. 2008), and personality (Aaker 1997), as determinants of personified content and investigate how word of mouth is influenced by brands that frequently shares personified content.

We predict and find that the brands that use personified content not only has more positive word of mouth compared to non-personified brands, but that these benefits further increase at times when a brand relationship is tested. Specifically, when the brand is attacked due to poor performance, personified brands experience even more positive word of mouth compared to non-personified brands.

Archival Study

Because personified content is a recent phenomenon, it is important to study how real brands are actually personifying their digital content. Thus, we collected 5 years of twitter data of every team in the National Basketball Association (NBA), which includes every tweet that each of the 30 teams had shared (*i.e.,* parent tweet) as well as every user tweet that were posted in response to the teams' tweet (*i.e.,* child tweet).

We chose to examine NBA tweets for three key reasons. First, NBA teams are some of the most well-known and beloved brands in the world, which made them suitable to study how word of mouth differs between personified and non-personified brands. Second, compared to brands in other industries, numerous NBA teams have begun to personify their content within the 5 year period of collected data, which shed light on how the transition from non-personified to personified content affects word of mouth. Lastly, given that the 30 teams in the NBA are in the same industry and share the same seasonal schedule, idiosyncratic differences between the brands are minimized to make for more meaningful comparisons.

What is Personified Content?

Using posts on Twitter and ratings provided by human raters, we first analyzed how personified tweets differ from non-personified tweets across distinctively humanlike dimensions. We recruited 15 research assistants who collectively coded over 27,000 unique parent tweets that were randomly selected from the complete data set of Twitter posts from every team in the National Basketball Association. Each tweet was rated by different combinations of 3 human coders along 10 dimensions, including personification and 9 other measures that were predicted to be determinants of personification. Specifically, five of these other categories measured humanlike characteristics, including expressing emotion, humor, cognition, creativity, and popular culture awareness. Four of the other measures were adapted from the dimensions of brand personality (Aaker 1997), including sincerity, maturity, sassiness, and social. We find that other than maturity, personification significantly correlates with all measures ($p < 0.01$).

How do Personified Content Affect Word of Mouth?

We build regression models to test the hypothesis that personified brands will not only have better word of mouth than non-personified brands, but that this difference will also increase when the brand is under attack (i.e., negative shocks). Using the personification scores rated by the human coders, we classified the 30 NBA teams into three categories – *High Personified Teams, Medium Personified Teams, Low Personified Teams* – ($M_{High} = 2.02$, $M_{Medium} = 1.79$, $M_{Low} = 1.62$, $F(2, 94197) = 856.5$, $p < 0.001$). We collected all 1.4 million replies in response to all the NBA tweets during the period of October 2014 to April 2019 and measured the corresponding word of mouth using two separate text analysis software: LIWC and the Stanford Natural Language Processing (NLP) parser. A composite and standardized measure of reply sentiment was constructed with the optimal weights determined by Principal Component Analysis.

As evidenced in figure 1, on average word of mouth is positive at the beginning of the season and becomes negative by week 4. Regression analysis shows that tweets from highly personified teams generated significantly more positive word of mouth than those from lowly personified teams. All else being equal, with one point higher in personification score, word of mouth valence would increase by 0.047 points, which translated to 0.04 standard deviation.

In the context of NBA teams, the brand is often attacked when they perform poorly.

Thus, we operationalized attacks on the brand as losses in games. The results reveal that although on average, all brands experience more negative word of mouth following a loss, this effect was attenuated for highly personified teams. More specifically, following a loss, the impact of negative word of mouth was reduced by as much as 69.2% for highly personified teams compared non-personified teams.

Interestingly, the relationship between personification and word of mouth only held during the regular season. During the playoffs, both the main effect of personification and the interaction between personification and losses were no longer significant. One probable mechanism is that consumers were more results-oriented during the playoffs, in which each loss could be season ending. Thus, the playoffs may represent a boundary condition for the effect of personification on word of mouth.

Fixed Effects Model

A potential weakness in the previous analysis is that highly personified teams and lowly personified teams are not comparable due to differences other than the level of personification in their digital content. To control for differences that might arise from differences in performance, reputation, or market size across teams, we built fixed effect regression models to tease out idiosyncratic differences between each team. Specifically, to take advantage of the time series aspect of the data, we first constructed more precise classification of personified teams by identifying the year in which a team adopted personified content. For example, a team that was highly personified in the 2018 season could have been lowly personified three years prior. Thus, we classified each season for each team into one of three more refined categories – *High Personification Team-Year, Medium Personification Team-Year, Low Personification Team-Year*. The results show that tweet-level personification score are significantly different across the three groups ($M_{High} = 1.85$, $M_{Medium} = 1.70$, $M_{Low} = 1.53$, $F(2, 94197) = 965.9$, $p < 0.001$).

The fixed effect regression replicates our main finding, showing that personification reduced negative word of mouth. All else being equal, with one point higher in personification score, word of mouth valence would increase by 0.069 points, which translated to 0.058 standard deviation. Similar to our previous analysis, the effect size of personification on word of mouth valence is much smaller during playoffs and more than double during off-seasons. Moreover, the effect of losing one game on word of mouth valence is quite consistent before and after controlling team-related factors. All else being equal, word of mouth valence after a loss was 0.176 points lower than that after a win, which translated to 0.144 standard deviation. We found supporting evidence for that attacks on the brand, represented by losses, have less of an effect on the word of mouth of personified brands than non-personified brands. More specifically, when brands were under attack, highly personified content, compared with highly non-personified content, reduced the impact of loss on word of mouth valence by as much as 49.3%.

In addition, we found a small but significant effect of expectation on word of mouth.

Compared to a normal loss, losing a game in which a team is favored to win should arouse more intense negative word of mouth. To test the impact of expectation, we collected Las Vegas betting lines for each of the games that was played during the period of our word of mouth data. Whereas a positive betting line represents an underdog status, a negative betting line means that a team that is favored in a match. The results show that on average, consumers express more positive word of mouth for underdog teams that lose than for favored teams that lose. Moreover, this effect was accentuated for personified teams, in which highly personified underdog teams experienced more favorable word of mouth compared to lowly personified underdog teams.

Discussion

One of the greatest challenges digital marketers face is the loss of control on social media. Although social media has enabled firms to reach more consumers at lower costs, marketers cannot control what consumers say to one another. In this research, we propose and find that word of mouth can be improved by personifying a brand's social media content.

Compared to the lowly personified NBA teams, highly personified teams not only have more positive word of mouth throughout the season, but this difference is further strengthened following losses. This suggest that personified content can be used as a proactive measure to inoculate brands against future attacks that normally arouse intense negative word of mouth.

Travelling Thoughts: The Downstream Effect of Prospective Experiential Materials on the Purchase Intentions of Experiences

Kimberley van der Heijden, Maastricht University, The Netherlands
Caroline Goukens, Maastricht University, The Netherlands
Anouk Festjens, Maastricht University, The Netherlands
David Gal, University of Illinois at Chicago (UIC), USA

EXTENDED ABSTRACT

Consumers typically consider dozens of prospective experiential materials (e.g., pictures of a vacation resort) prior to purchasing experiences (e.g., a vacation) — allowing their mind to latch on to good times ahead. For experiences in particular, this pre-factual savoring can stretch the enjoyment and pleasure derived from them beyond the actual experiential event (Kumar, Killingsworth and Gilovich 2014). Even more, the joy sparkling from anticipating an experience can subsequently even enhance the *actual* experience (Chun, Diehl and MacInnes 2017).

Thus, existing research advises practitioners to turn to tactics inducing savoring, and thus to increase the amount of prospective experiential materials that consumers are exposed to. Nevertheless, we add caution to this recommendation. Most of the experiential materials that are being offered (brochures, trailers, etc.) are meant to cater consumers early in their decision process. While it might be the case that pre-factual imagination enhances the actual experience, we propose that it might equally well be the case that it prompts consumers to decide to forego the experience, as he or she pre-factually already lived the experience, and thus feels satiated on his or her need to engage in the actual experience.

Prior research—mainly in the food domain—lends supports to the possibly satiating qualities of stimulus exposure: With extensive exposure to a stimulus, a decrease in motivational and hedonic response can be observed (e.g., Groves and Thompson 1970; McSweeney and Swindell 1999). In line with this thought, both behavioral (Morewedge, Huh and Vosgerau 2010, Larson, Redden and Elder 2013, Kappes and Morewedge 2016) and brain imaging research (e.g. Jeannerod 1994, 2001) suggest that mental simulations (e.g., elicited by exposure to certain stimuli) elicit similar—satiating—responses as actual experiences, and thus potentially reduce the desire for experiences.

At first sight, our hypothesis seems to contradict prior research stressing the positive consequences of savoring prospective information on subsequent purchase intentions (e.g. Petrova and Cialdini 2005). However, a methodological characteristic of all existing studies is that the amount of experiential information presented was highly limited. As such, prior research corroborates findings in consumption research showing the sensitizing effects of imagery (e.g. Dadds et al.,1997) and is highly analogous to the "whet-the-appetite" effect of initial stimulus exposure (e.g. McSweeney and Swindell 1999). Real-world situations, on the contrary, often provide a wealth of experiential information, sometimes even an overwhelming amount.

Five studies test our hypotheses. First, we propose that exposure to an extensive (vs. limited) set of experiential materials will make consumers less willing to further engage in the experience (studies 1 N=152 MTurk and studies 2 – 4). In this study, participants were asked to imagine that they were planning a vacation at the Maldives and were considering booking a particular resort. They were then given a brief written description of the resort and a series of pictures (limited condition: 4 pictures of different scenes of the resort; extensive condition: 12 pictures zooming in on the scenes depicted in the limited condition). After inspecting the pictures, participants were asked to indicate their inclination to book a room at that particular resort and filled out the dispositional imagery vividness scale (Marks 1972), the latter of which was used in the analyses as a covariate. In our second study, we additionally manipulated the consumption goal in a 2(set size: limited vs. extensive set) x 2(hedonic vs. utilitarian) between-subjects design (study 2 N=205 MTurk). We propose that our effect only holds in the context of experiential purchases (i.e. booking a vacation) and not for utilitarian purchases (i.e., buying an accommodation as an investment), where the experiential materials are rather inspected to obtain practical benefits (Pham 1998). Furthermore, in two subsequent studies we tested whether feelings of satiation mediate our effect (cf. methods by Haws, McFerran and Redden 2017; Redden and Haws 2013) (study 3 N=110 students, study 4 N=209 online pool). In study 4 we also test whether salience of repetitiveness in particular is driving our effect. In a single factor between subjects design we exposed participants to either a limited set of experiential materials, an extensive set with similar experiential materials (like previous studies, zooming in on scenes depicted in the limited set) or an extensive set with dissimilar experiential materials (i.e. showing different pictures of the different scenes). Additionally, we measured attractiveness of the pictures. Finally, in our last study we exposed participants to multiple resorts (i.e., providing a more realistic scenario) and employed a 2(set size: limited vs. extensive set) x 2(replication set: resort A depicted through extensive set (B through limited set) vs. resort A depicted through limited set (B through extensive set)) mixed-design.

Across five studies, we demonstrate that exposure to an extensive (vs. limited) set of experiential materials will satiate consumers from the experience as they enable consumers to live the experiential event to such an extent that they are less willing to further engage in the experience (studies 1-4). We only find this effect in the context of experiential and not for utilitarian purchases (study 2). Furthermore, we provide explicit process evidence by showing a mediation effect of satiation (study 3 and 4). Moreover, we demonstrate that particular salience of the repetitiveness of the experiential materials is most detrimental to consumers' willingness to engage further in the experience. We also demonstrate that our findings are not due to a difference in attractiveness between the conditions. Finally, when given the choice between two similar travel options, consumers also prefer to further engage in the option that was presented with a limited (vs. extensive) set of pictures (study 5).

This paper thus challenges conventional wisdom that more is always better. Overall, existing research thus advises practitioners to turn to tactics inducing imagination (e.g., Chun et al. 2017), and thus to increase the amount of prospective experiential materials that consumers are exposed to. We add cautious to this recommendation as it might equally well be that it prompts consumers to forego the experience as it might also already satiate consumers from the experience. Furthermore, we contribute to the literature on the satiating effects of simulated consumption (Morewedge et al. 2010; Larsson et al. 2014) by testing satiation in the domain of experiences (which are purely psychological (Nicolao, Irwin and Goodman 2009; Redden 2015)), and thus demonstrate that—in our case—satiation is merely a psychological effect.

A Token As A Ticket To Smarter Financial Decision-Making

Kimberley van der Heijden, Maastricht University, The Netherlands
Anouk Festjens, Maastricht University, The Netherlands
Caroline Goukens, Maastricht University, The Netherlands
Tom Meyvis, NYU Stern, USA

EXTENDED ABSTRACT

Current theories largely suggest that financial constraint leads to short-sighted decision-making: constrained individuals typically favor smaller immediate payoffs ($50 now) to larger delayed ones ($100 later) in traditional intertemporal choice paradigms (e.g., Bickel et al. 2016; Haushofer & Fehr 2019; Liu et al. 2012; Mellis et al. 2018; Ong, Theseira & Ng 2019; Pender 1996; Tanaka, Carmerer & Nguyen 2010). It thus seems that financially constrained individuals prioritize immediate concerns, showing little concern for long-term outcomes.

However, another stream of research demonstrates that financially constrained consumers *are* concerned about the long-term benefits of their decisions. For example, scarcity has been shown to lead to greater concern for enjoying one's resources for a longer period of time (Fernbach, Kan, & Lynch 2015, Tully, Hershfield & Meyvis 2015) and greater consideration of future needs (Spiller 2011; study 3). Thus, there is evidence supporting the view that scarcity does not inherently reduce one's ability to think or care about the future.

In sum, the feeling of financial constraint seems to bring about two (instead of one)—seemingly competing—motivations: Not only does it bring along an ultimate concern to satisfy one's pressing needs and immediate shortfall (Shah et al. 2012; Mani et al. 2013), but also a concern to spend one's scarce resources in a wise and future-oriented fashion. Important to note is that this increased concern for future needs does not manifest itself in the current scarcity-myopia paradigm.

In investigating how constraint affects myopic behavior, existing research studies typically rely on individual's preferences for either an immediate, smaller reward versus a later, larger reward (Bickel et al. 2016; Griskevicius et al. 2011; Haushofer & Fehr 2019; Liu et al. 2012; Mellis et al. 2018; Ong et al. 2019; Pender 1996; Tanaka et al. 2010). All studies have in common that they allow individuals to experience consumption utility at only one point in time, either now or later. We argue that this constraint—which is an artifact of the particular design of these tasks—could potentially shift attention to the immediate—at first sight myopic—choice alternative. This could lead to the premature conclusion that financially constrained individuals are short-sighted decision makers that have no concern for the future.

To illustrate, consider the following two choice scenarios: Scenario 1 involves a choice between an immediate $100 versus a delayed $200. Scenario 2 involves a choice between an immediate $150 versus a delayed $200, plus an immediate $50. Note that the second scenario represents a shifted case of the first one where an immediate $50 is added to both alternatives. Hence, utility is consumed at multiple consumption episodes.

In the first scenario, prior literature (e.g., Haushofer & Fehr 2019) would predict that feelings of constraint (vs. non-constraint) will lead to a higher preference for the smaller immediate alternative. From an evolutionary perspective, this prediction makes sense: constraints bring about a concern for—hierarchically higher—pressing needs (e.g., paying for basic groceries, rent, basic utilities; Maslow 1943; Shah et al. 2012), which makes the smaller, sooner alternative loom larger than the delayed alternative.

Conversely, when the choice situation allows individuals to satisfy both immediate needs *and* long-term concerns—as is the case in the second choice scenario—we propose that financially constrained individuals will make less myopic decisions. When both choice alternatives guarantee an accommodation of pressing needs, the conflict between short-term versus long-term needs is mitigated, enabling financially constrained individuals to carefully think about how to invest their scarce and precious resources. Put differently, if all choice alternatives within a choice scenario accommodate pressing needs (versus not), financial constraint consumers might thus *not* make short-sighted decisions.

Three studies support our hypotheses. In study 1 (N = 200, online pool of volunteers), participants were randomly assigned to one of the conditions in a 2(constraint level: constrained vs. not constrained) x 2(immediate token present: yes vs. no) between-subjects design. We manipulated financial constraint by asking participants to recall and write about a situation where they felt financially worse off (i.e., constrained condition) or better off (i.e., unconstrained condition) in comparison to their peers (Sharma & Alter 2012). Subsequently, participants in the "token absent" condition were presented with three hypothetical choice scenarios between a smaller immediate payoff versus a larger later one. The choice scenarios differed in the magnitudes involved and the length of the delay. In the "token present" condition, a small immediate sum (which varied across choices) was added to both the smaller immediate and larger later payoffs (see Table 1 for the stimuli). For each of the choice scenarios, participants indicated their preference among the alternatives on an 11-point scale (1 = I very much prefer alternative A to alternative B, 11= I very much prefer alternative B to alternative A). We also recorded participants' income and SES (Griskevicius et al. 2011). In study 2 (N = 251, Mturk workers), we measured financial constraint by asking participants to indicate when they received their last paycheck. It was expected that participants who received their paycheck a longer (shorter) time ago would feel more (less) constrained. Study 3 (N = 161) tested our hypotheses in a field setting. Specifically, we conducted our experiment either at a location where mainly constrained participants were present (i.e., the foodbank) or at a location where mainly non-constrained participants were present (i.e., golf club).

The results of the three studies demonstrate that consumers who feel financially constrained (vs. non-constrained) show more short-sightedness (i.e., higher preference for the immediate option) when faced with a classical intertemporal choice task (i.e., token absent condition), which is consistent with previous research. In contrast, financially constrained consumers show less short-sightedness when faced with an intertemporal choice task where an immediate sum was added to both alternatives (i.e., token present condition), as opposed to a classical intertemporal choice task. There is no difference in behaviour among financially non-constrained consumers in the token absent (vs. token present) condition.

The findings of this current research provide important implications, theoretically and practically. First, we contribute to previous research on resource scarcity and intertemporal decision making by calling for using a wider variety of tasks when studying the effects of financial constraint on intertemporal choice making. Furthermore,

from a more societal point of view, we advocate that financial services (e.g., saving plans) apply a choice architecture similar to the one we present in our studies. For example, giving participants a small bonus when opening a savings account would enable financially constrained individuals to carefully think about how to invest their scarce and precious resources and thus increase savings.

Effect Sizes in Experimental Consumer Psychology Are Underestimated: Introducing a Simple Correction

Walter Herzog, WHU, Germany
Christopher Beisecker, WHU, Germany

EXTENDED ABSTRACT

The present research suggests that effect sizes in experimental consumer psychology are systematically underestimated because the dominant estimation strategy ignores the "reliability" of the experimental manipulation (i.e., the squared correlation between the manipulation and the independent variable, which is usually assessed via manipulation checks; Bollen 1989; Perdue and Summers 1986; Wilson, Aronson, and Carlsmith 2010). It is shown how to correct for this bias in published articles even when raw data are not available.

Corrected Effect Sizes

Experimental researchers report effect sizes to quantify the magnitude of a postulated effect. To do so, they typically compute a measure of statistical association between their experimental manipulation T (e.g., $T=1$ for the treatment condition; $T=0$ for the control condition) and the dependent variable Y. For example, Rosenthal, Rosnow, and Rubin (2000) argue that behavioral researchers should report the correlation between T and Y as an effect size measure because this statistic has a straightforward interpretation and can easily be transformed to other popular effect size measures (e.g., *eta-squared*, *Cohen's d*).

However, the standard method of computing such effect sizes does not take into account that in many psychological studies, the manipulation T is not a perfect proxy of the independent variable of interest X. For instance, consider a study aimed at investigating the impact of perceived product anthropomorphism (X) on product evaluations (Y). To create exogenous variance in X, a researcher might apply an experimental manipulation T, where the product is either described in humanlike terms ($T=1$; anthropomorphism condition) or in neutral terms ($T=0$; control condition). A formal manipulation check is typically conducted where the researcher quantifies the relationship between T and X (X is measured by manipulation check items; Perdue and Summers 1986). Such manipulation checks will almost certainly reveal that T and X are not perfectly correlated. For example, in a study by Huang, Wong, and Wan (2020, study 2), the correlation between T (a manipulation of perceived anthropomorphism) and X (perceived anthropomorphism) is .45. In other words, only .45²=20% of the variance in T corresponds to variation in the conceptual independent variable X. The latter quantity—that is, the *squared correlation between T and X*—is known as the *reliability* of the experimental manipulation Rel*(T)* (Bollen 1989; Perdue and Summers 1986).

Overall, the preceding discussion suggests that the currently used measures for quantifying the size of the effect of X on Y, such as the correlation between T and Y, are biased because T is an imperfect proxy for X. Furthermore, it is not possible to compute effect size measures based on the correlation between X and Y because X is not a randomized variable and hence, the correlation between X and Y does not correspond to a causal effect (Angrist, Imbens, and Rubin 1996; Rubin 2005). However, we argue that it is possible to "purge" the correlation between T and Y of the effects of unreliability in T, thereby creating an unbiased effect size measure with a causal interpretation (note that T is a randomized variable).

Specifically, it is well-known that a correlation-based effect size can be corrected for unreliability in the independent variable measure by dividing the correlation-based effect size by the square root of the reliability of the independent variable measure (Bollen 1989). This procedure is commonly referred to as "disattenuation" of a correlation coefficient (McDonald 1999) and it is frequently applied by behavioral scientists working with observational data to correct for measurement unreliability in an independent variable (Schmidt and Hunter 1996). Yet, the derivation of the underlying formula holds independent of the way in which a proxy for the independent variable is generated (Greene 2003; McDonald 1999). Hence, it can be applied in the context of observational studies (to correct for unreliability in measurement items of the independent variable) as well as for experiments (to correct for unreliability of manipulations of the independent variable). Overall, the disattenuation procedure can be used to "purge" the correlation between T and Y of the effects of unreliability in T:

$$C = \frac{Cor(T,Y)}{\sqrt{Rel(T)}} = \frac{Cor(T,Y)}{Cor(T,X)}$$

In this equation, C denotes the corrected effect size correlation. $Cor(T, X)$ can be estimated based on the data from the main study if measures of X were included in this study. Alternatively, it can be computed based on the data from a pre-study that was designed to test the effectiveness of the manipulation T. $Cor(T, Y)$ is estimated based on the data from the main study.

As can be seen from this equation, the standard effect size measure $Cor(T, Y)$ *underestimates* the true effect size C whenever T is an imperfect proxy for X (i.e., for Rel(T)<1). This is the case because only the reliable variance part in T (i.e., the variance in T which reflects variance in X) affects variance in Y. Hence, unreliability in T dilutes the traditional effect size measure $Cor(T, Y)$.

Example

Huang et al. (2020) hypothesized that perceived product anthropomorphism (X) leads to "increased preference for the [product] option with a more favorable overall evaluation over the [product] option with a greater number of superior dimensions" (p. 936) (Y). In study 2, the authors manipulated X by describing products in first-person language ($T=1$) versus third-person language ($T=0$) and measured X as well as Y. As predicted, T increased Y ($F(1, 99)=5.04$, $p=.027$, $\eta^2=.05$ and hence, $Cor(T, Y)=\eta==.22$). Furthermore, the manipulation check was successful, that is, T increased X ($F(1, 99)=24.95$, $p<.001$, $\eta^2=.20$ and hence, $Cor(T, X)=\eta==.45$). Thus, the corrected effect size correlation is

$$C = \frac{Cor(T,Y)}{Cor(T,X)} = \frac{.22}{.45} = .49$$

C is 123% larger than the uncorrected effect size correlation (.22). Furthermore, the corrected *eta-squared* coefficient is .49²=.24 and thus 380% larger than the uncorrected coefficient (.05).

Discussion

Overall, the present research suggests that experimental psychologists are currently underselling the importance of their empirical findings for consumers, policy makers, and managers. We provide a simple method to improve the current research practice and

correct already published effect sizes. Extensions of the proposed method (e.g., simultaneous correction for unreliability in T, X, and Y and applications in settings with more than two experimental groups) will be made available.

De-Democratizing Search: When Financial Resources Scarcity Decreases Opportunity Cost Consideration

Diogo Hildebrand, Baruch College, CUNY, USA
Daniel Fernandes, Catholic University of Portugal, Portugal
Jannine Lasaleta, Sy Syms School of Business, Yeshiva University, USA
Leandro Malloy-Diniz, Federal University of Minas Gerais, Brazil

EXTENDED ABSTRACT

People making purchase decisions are likely to consider alternative ways to spend their resources (Spiller 2011; Shah et al., 2015). Although all individuals should benefit from a broader, careful evaluation of the alternatives available, such opportunity cost consideration should be especially beneficial to people living under a momentary or chronic scarcity of financial resources (Shah et al., 2015). Unsurprisingly, prior research shows that people under permanent or temporary financial resource scarcity are most likely to consider the opportunity cost of their decisions (Spiller 2011).

Implicit to the argument behind the positive effect of financial resource scarcity on opportunity cost consideration is the notion that search incurs in time and effort costs. Interestingly, however, although technological advancements have made such costs negligible, the impact of such reduction in informational cost on the consideration of alternative options among individuals with abundance and scarcity of financial resources is still unknown. We offer the counterintuitive prediction that reducing the informational cost disproportionally benefits those with abundance rather than scarcity in financial resources.

Choosing from a wide set of products can be detrimental to an individual's well-being because assortment size, or greater consideration of opportunity costs, have decreasing gains in utility when deciding across the different alternatives is difficult (Chernev, 2006; Schwartz, 2004). Scarcity increases the perceived importance of an individual's choices (Shah et al., 2015), which increases the perceived difficulty of the decision (Krijnen et al., 2015). Further, since scarcity impedes cognitive function (Mani et al., 2013), it should also increase the difficulty of making decisions. Taken together, these findings suggest that resource scarcity should increase perceptions of decision difficulty which has been shown to result in lower motivation to consider alternative options. In sum, while scarcity should make consumers less sensitive to the costs of considering opportunity costs, it should also decrease their baseline willingness to consider opportunity costs, such that when informational costs are sufficiently high (low), scarcity will result in greater (lower) willingness to consider opportunity costs. We tested this general framework over the course of four studies, reported next.

In study 1, fifty-nine undergraduate students first engaged in a perceived financial resources manipulation (Shah et al. 2015) and then were asked to perform an unrelated typing task rewarding them with additional options of candies they could choose from. Before, choosing a chocolate from a set of 8, participants described their thoughts during the choice task and indicated their perceived worth of the task and perceived effort they put on the task. After choosing the chocolate, they described their thoughts during the choice task, indicated their satisfaction with their choices, and decision difficulty. Results revealed that participants in the low (vs high) perceived resources condition typed more, had greater perceived worth of and effort put on the typing task, marginally significant lower satisfaction with the choice made, spent more time and were more redundant in justifying the choice. These findings indicate not only a greater motivation to consider the opportunity cost of the decisions, but a concomitant decision difficulty among those assigned to the financial scarcity condition. Given the nature of these countervailing forces, we theorize and test in the next studies that varying the cost of obtaining alternative options should moderate the effect of perceived financial resources on willingness to consider opportunity costs.

In study 2, participants recruited using Prolific Academic (N=194) received a financial allocation and had to use it to buy products in seventeen rounds. Each round, participants were also given the opportunity to obtain information about products that would be available on future rounds by clicking with the mouse (10 or 30 times per product, depending on information cost condition). We manipulated the participants' perceived financial resources by telling them that they would be randomly selected to receive either $50 or *$10* ($100) in the *high* (low) perceived financial resources condition; all participants received, in fact, $50. Results revealed a predicted a significant interaction as well as a significant main effect of information cost, with a positive significant effect of perceived financial resources on opportunity consideration when information cost was low and a negative significant effect when information cost was high. We provided robustness to these findings by replicating these findings in an additional study (study 3) where we manipulated actual (as opposed to perceived) financial resources by allocating either $10 or $100 dollars to participants.

In study 4 we analyzed data from a PEW Research Center survey (N = 2,864) on search behavior prior to purchasing products. We used income as a proxy for resource scarcity and information source (store visit vs. internet) as a proxy for informational cost. Results revealed a significant main effect of income and, importantly, a significant income by cost of search interaction, such that when the information was more costly to obtain, income decreased motivation to search, but increased motivation to search when the information was less costly to obtain.

This work makes several contributions to research on scarcity and opportunity cost consideration. Primarily, we are the first to propose and demonstrate that resource scarcity may be detrimental to consumers' opportunity cost consideration. Further, we propose a moderator that both explains parsimoniously findings from previous research and identifies conditions under which resource scarcity will reduce rather than increase information search. Finally, in providing evidence that resource scarcity increases decision difficulty, we add to a long list of factors that hinder the decision ability of individuals under resource scarcity.

"Yes You Can" – How to Reduce the Collective Action Problem For Sustainable Consumer Behavior

Tobias Hinze, University of Cologne, Germany
Magdalena Bekk, University of Cologne, Germany; Seeburg Castle University, Austria

EXTENDED ABSTRACT

Consumers in today's world are confronted with the alarming consequences of unsustainable behavior (van der Wal, van Horen, and Grinstein 2018). To reduce the problems, a large group of consumers must undertake sustainable (pro-social and pro-environmental) behaviors for the benefits to be fully realized (White, Habib, and Hardisty 2019). Sustainable consumer behavior, such as donating for a good cause or recycling requires collective as opposed to individual action (Bamberg, Rees, and Seebauer 2015). But, there appears to be little motivation to participate in a collective action when individuals believe that the collective outcome will occur without their costly individual contributions ("collective action problem"; John and Klein 2003). Despite the increasing importance of sustainable consumer behavior for businesses and society, it remains unclear whether and how to reduce the collective action problem for sustainable consumer behavior.

Across three experiments, we show that collective (versus individual) action framing discourages sustainable consumer behavior, indicating that individual action framing serves as the more promising strategy. Further, we address recent calls in the literature to investigate the collective action problem from a marketing perspective (White, Habib, and Hardisty 2019) by examining how and why the collective action framing influences sustainable behavior looking at the moderating role of goal concreteness as well as the mediating role of perceived lack of self-efficacy.

Study 1 establishes the negative effect of a collective action framing on sustainable consumer behavior with a prosocial behavior in a fundraising field experiment in collaboration with Action Against Hunger. In a two group (framing: collective vs. individual action) between-subjects experiment, 145 participants (56.6% female) took part. A standardized verbal script, a poster (A1) and handout (A3) were used to approach participants and to ask them to donate, emphasizing the collective (individual) action of the donation. Two research assistants, blind to the hypotheses, went on campus on four days to collect donations as our dependent variable. We counterbalanced the order of experimental groups per day using an ABBA design (Otterbring et al. 2018). We conducted an ANCOVA to compare the amount of donation across the two groups (i.e., collective vs. individual action framing) whilst controlling for other factors potentially driving the amount of donation (e.g., gender). The analysis revealed a significant difference in the amount of donation ($F(1, 137) = 4.710$, $p = .032$), suggesting that the collective ($M = 2.623$, $SD = 3.116$) compared to individual ($M = 3.184$, $SD = 3.541$) action framing decreases the amount of donation and, thus, sustainable consumer behavior.

Study 2 replicates the finding from Study 1 and examines goal concreteness as moderator (Lee and Ariely 2006). In total, 242 participants ($M_{age} = 31.6$, 58.3% female) took part in the 2(framing: collective vs. individual action) × 2(type of goal: concrete vs. abstract) between-subjects experiment. Participants viewed a website screenshot of an actual online-petition of Action Against Hunger. We manipulated framing, as in all other studies, by communicating the collective (individual) action of the behavior: "If at least 30,000 people (you) sign the petition hunger in Yemen can be ended." The petition was open during the entire data collection period of Study 2. After showing the stimuli, participants indicated whether they will sign the petition. From Action Against Hunger, we obtained information on actual signatures on a daily basis, which we used to build a variable measuring the likelihood to sign the petition as an indicator of sustainable behavior. The results from the ANOVA replicate the main effect of framing ($F(1, 238) = 5.609$, $p = .019$) but no main effect of goal type ($F(1, 238) = 1.867$, $p = .173$) on sustainable behavior. The analysis revealed a significant interaction between framing and goal type, $F(1, 238) = 4.749$, $p = .030$. Simple main effects showed that sustainable behavior was significantly higher for participants with a concrete goal ($M = .314$, $SD = .192$) compared to an abstract goal ($M = .254$, $SD = .115$) in the individual action framing situation, $F(1, 238) = 6.29$, $p = .013$. Goal concreteness did not matter in the collective action framing situation.

Study 3 extends the negative effect from Studies 1 and 2 to a pro-environmental behavior and identifies the mediating role of perceived lack of self-efficacy. A sample of 101 participants ($M_{age} = 33.9$, 50.5% female) took part in a two group (framing: collective vs. individual action) between-subjects experiment. Participants viewed a recycling campaign poster and were asked to indicate their motivation to obtain recycling information (adapted from Acquisti, John, and Loewenstein 2012) and perceived lack of self-efficacy (Hanss and Böhm 2010). The results from the ANOVA replicate the main effect of framing for motivation to obtain recycling information, $F(1, 99) = 4.93$, $p = .029$. This result indicates that collective action framing reduces the willingness to behave sustainably. To examine whether perceived lack of self-efficacy mediates the effect, we run mediation analyses using the PROCESS macro (coding of framing: individual = 0, collective = 1, 10,000 bootstraps, Model 4; Hayes 2013). We included control variables to account for other factors driving sustainable behavior. Results revealed that framing positively affected perceived lack of self-efficacy, $b = .88$, $SE = .43$, $p = .043$. Perceived lack of self-efficacy affected participants' motivation to obtain recycling information negatively, $b = −.35$, $SE = .15$, $p = .018$. The indirect effect of framing on participants' motivation to obtain recycling information via perceived lack of self-efficacy was significant (a×b = −.31, 95% CI = [−1.059; −0.002[).

This research is the first to provide empirical evidence on how to reduce the collective action problem for sustainable consumer behavior from a marketing perspective. Specifically, it suggests that an individual action framing would be the more promising strategy compared to a collective action framing. We show that particularly for an individual action framing, marketers can increase sustainable behavior by providing a concrete goal to consumers. Lastly, to reduce the collective action problem, managers should shift consumers' focus to their personal abilities and to the impact their abilities can have (i.e., increase self-efficacy).

Bundling Products Worldwide: How Self-Construal Influences Product Bundle Evaluation

Jennifer Seokhwa Hong, Seattle University, USA
Andrea Bonezzi, New York University, USA

EXTENDED ABSTRACT

Product bundling is a widely observed marketing practice, as it is known to be an effective strategy to increase sales of companies' offerings across various product categories. Despite its preexisting ubiquity, product bundles are still growing in number, because it has become easier for online-retailers to offer various forms of bundles to a wide range of customers across the globe (Venkatesh and Mahajan, 2009). Given that the same bundle offerings are being exposed to consumers with different cultural and individual characteristics, it is important to investigate what type of bundles appeals to which segment of consumers. The current research answers this question by examining the impact of the interplay between the bundle type and self-construal on consumers' bundle evaluation.

A bulk of research has shown that consumers prefer bundles of complementary products to bundles of substitute (Gaeth, 1990; Telsler, 1970) or unrelated products (Harlam et al., 1995; Popkowski-Leszczyc and Haubl, 2010). Together, these studies indicate that consumers extract an additional value from the perceived degree of complementarity between bundled items when evaluating product bundles. Building on this, we propose that the amount of value that a consumer extracts from complementarity differs depending on which self-construal consumers adhere to. It has been well documented that individuals with interdependent self-construal have a more pronounced ability to detect relationships between objects and/or concepts, compared to individuals with independent self-construal (Ahluwalaia, 2008; Lalwani and Shavitt, 2013; Monga and John, 2007). Accordingly, we predict that interdependents may be superior not only at uncovering the relationship between bundled products, but also at discerning the types of relationships between bundled products relative to independents. Thus, when bundles include complementary products, interdependents would evaluate bundles more favorably relative to independents because they would extract greater value from the complementarity. We test our hypotheses across one study using secondary sales data and three laboratory studies.

Study 1 provides an initial demonstration of the effect of self-construal on bundle evaluation using global cosmetics company's sales data from South Korea and U.S. We employed culture as an operationalization for self-construal, as interdependence is more prevalent in Korea, whereas independence is more prevalent in the U.S. Controlling for price, product categories, and fixed-time effects, sales of product bundles was greater in Korea than in the U.S. ($p = .002$). In contrast, sales of standalone single products did not differ across countries ($p = .23$). Furthermore, sales of bundles of complements was greater than that of bundles of non-complements in Korea ($p < .001$). This difference, however, was not evident in the U.S. ($p = .52$). Also, the market share of complement bundles was greater in Korea than in the U.S. ($p = .001$), supporting our prediction.

It is possible that the differences we found between these countries may be due to differences in other unobservable factors like distribution channels and market size. To address this issue, in Study 2 (n = 237 from U.S. online-panel), we directly measured participants' chronic level of self-construal and examined how that correlated with their evaluation of product bundles using a homogenous sample. Participants first filled out Oyersman's self-construal scales (1993) and then evaluated either a bundle of complements (La Roche-Posay's facial cleanser and moisturizer) or a bundle of substitutes (La Roche-Posay's two different facial cleansers). An OLS regression on bundle evaluation revealed that overall, participants favored the complement bundle more than the substitute bundle ($p = .003$). More importantly, this main effect was qualified by a significant bundle-type x interdependence interaction ($p = .04$), but not by bundle-type x independence interaction ($p = .64$). Interdependence was positively associated with bundle evaluation ($p < .001$) when it consisted of complements. When the bundle included substitutes, however, interdependence did not predict bundle evaluation ($p = .21$).

In Studies 3 (n = 343) and 4 (n = 247), we directly tested the causal effect of self-construal on bundle evaluation by manipulating self-construal. In addition, we examined the moderating role of a contextual factor (i.e., brand composition) on the relationship between self-construal and bundle evaluation. Consumers find multiple products to be more complementary to each other when the product are labeled with the same brand (vs. different brands, Rahinel and Redden, 2014). Thus, because interdependents are more susceptible to contextual cues like brand labels than independents, interdependents would extract greater value from the complementary between bundled products when they are from the same brand versus different brands. As a result, interdependents would favor a bundle of complements from the same brand. However, because independents are less concerned about relationship associated cues, a variation in brand composition would not affect their bundle evaluation.

We first primed self-construal by having participants write about who they are using a first-person singular vs. plural pronouns (S3) and what makes them similar to vs. different from their family and friends (S4). Subsequently, approximately half of participants saw a bundle of complements from the same brand (S3: MUJI notebook, pencil, and eraser; S4: Pantene shampoo, conditioner, and hairmasque). The other half saw the comparable products from different brands. We then measured participants' willingness-to-pay (S3) and purchase intention (S4) for the bundles. A significant self-construal x brand-composition interaction ($p_{S3} = .01$, $p_{S4} = .02$) revealed that interdependents indicated greater WTP and purchase intention for the same-branded (vs. differently-branded) bundles ($p_{S3} = .001$, $p_{S4} = .01$). These differences were not evident among independents ($p_{S3} = .94$, $p_{S4} = .50$). Furthermore, in Study 4, we measured perceived degree of complementarity among bundled items to test its moderated mediating impact. Primed interdependence increased the purchase likelihood of the bundle through enhanced perceived complementarity (C.I. [.04, .28]). There was no corresponding indirect effect among participants who evaluated the bundle of complements from different brands (C.I. [-.39, .08]).

In summary, we identify a key individual- and cultural-level difference in bundle evaluation that previous research has overlooked. In doing so, the current research suggests a novel marketing strategy to segment product bundles in both global and domestic markets, as certain regions are known to possess collectivist than individualistic culture.

The Effect of Mere Physical Distance on Wishful Thinking:
How Proximity and Valence Interactively Affect Probability Judgment

Jennifer Seokhwa Hong, Seattle University, USA
Chiara Longoni, Boston University, USA
Vicki G. Morwitz, Columbia University, USA

EXTENDED ABSTRACT

Probability judgments are ubiquitous—from estimating the chance of landing a job, to predicting the movements of the stock market—and typically plagued by numerous errors and biases (Kahneman and Tversky 1973). We add to this stream of research by identifying a novel *proximity bias* in probability judgments, whereby event valence and event nearness systematically interact in determining probability estimates.

When it comes to the relationship between event valence and probability estimates, a robust finding is people's tendency to predict that they are less likely than others to experience negative events, and more likely than others to experience positive events (Perloff and Fetzer 1986). This optimistic bias is so pervasive that some consider it an adaptive regulatory function for protecting the self (Taylor and Brown 1988).

We extend this research by uncovering a novel bias: That proximity of an event moderates people's optimistic bias in probability judgments. Specifically, we theorize that the physical nearness of an event accentuates self-enhancing tendencies when predicting positive events, and self-protective tendencies when predicting negative events. Across five studies we manipulate (a) the valence of an event (i.e., whether the outcome of an event is positive or negative) and (b) the physical proximity of this event (i.e., whether the event takes place in a location that is nearby or far away), and then measure people's probability estimates. We consistently find interactive effects of event valence and nearness, such that near, positive events are predicted to be more likely than near, distant events. On the contrary, near, negative events are predicted to be less likely than distant, negative events. Boundary conditions underscore the motivational underpinnings of this bias.

In study 1 (n = 284), participants read a lottery scenario. Participants in the positive condition were told there was a 60% chance of winning a lottery for a laptop. In the negative condition, we told them there was a 60% chance of losing the lottery and the $20 they had paid to participate. We manipulated proximity by describing the lottery draw taking place in a location that was nearby or far away. We measured probability estimates as the likelihood of winning (positive condition) or losing (negative condition) the lottery. Significant valence vs. proximity interaction ($p < .01$) revealed that winning the lottery seemed more probable when the draw took place nearby than far ($p = .03$). Conversely, losing the lottery seemed less probable when the draw occurred nearby than far ($p = .05$). In study 2 (n = 295), we replicated the same findings with two different events where positive event is not the opposite of negative event.

In study 3 (n = 485), we directly examined the hypothesized motivational nature of this bias. We hypothesized that the proximity bias is due to a tendency to be self-enhancing with respect to positive outcomes and self-protecting with respect to negative outcomes. If this is indeed the case, it follows that this bias should emerge for probability estimates made for a self-relevant outcome, but not for a self-irrelevant outcome. In a job-offer scenario, participants read that a hiring decision would take place in either a close or far location. Participants estimated the probability of either getting an offer (positive-condition) or not getting an offer (negative-condition), for either themselves (self-relevant-outcome) or another similarly quali-

fied candidate (self-irrelevant-outcome). Results revealed significant three-way valence x proximity x relevance ($p = .01$) and two-way valence x proximity interactions for the self ($p < .01$) but not for other ($p = .43$). As predicted, participants estimated they were more likely to get an offer when the event was close than far ($p = .04$), and less likely to lose an offer when the event was close than far ($p = .04$), but this effect did not emerge when estimating likelihood for another individual.

Providing converging evidence for the motivational account, in, the next two studies, we manipulated (un)desirability of an outcome while keeping outcome valence constant. We expected to replicate our previous results in case of a highly (un)desirable outcome. However, we expected an attenuation of the proximity bias in case of a less (un)desirable outcome. In study 4A (n = 607), participants estimated the likelihood of highly undesirable and moderately undesirable outcomes. Participants read that they were experiencing symptoms that could indicate either a severe disease or a mildly severe disease. They were further told that their blood sample was being tested at a hospital located 2 miles or 200 miles from where they were. Participants then estimated the likelihood of testing positive for the disease. When considering a highly undesirable outcome, participants predicted that they were less likely to contract the severe disease when the hospital was located nearby (M = 37.78%) than far (M = 45.62%; p = .006). When estimating the likelihood of contracting the mild disease, however, that difference disappeared (M_{close} = 46.34%, M_{far} = 45.90%; p = .88)

In study 4B (n = 385), we used positive outcomes only. Using a simulation of an online-dating app, participants viewed the profiles of two potential dates who were either nearby or far away (between-subjects), and whose attractiveness varied (within-subjects). Participants estimated their probability of getting successfully matched with both dates. As expected, when considering a highly desirable date, participants predicted that they were more likely to be successfully matched if the potential date was nearby (M = 58.69%) than far-away (M = 50.91%; p < .001). However, the difference was weaker when considering a moderately desirable date (M_{close} = 48.97%, M_{far} = 46.37%; p = .34).

In summary, we extend prior research on biases in probability judgments by documenting a novel proximity bias. Importantly, by corroborating the motivated nature of the effect, we demonstrate our findings cannot be accounted for by existing theories explaining how people make probability judgments, such as construal level theory (Wakslak and Trope 2009; Wakslak 2012), which is agnostic to motivated reasoning effects on predictions. In so doing, this research extends prior work on biases in judgments and decision making.

The Appeal of Copycats When the Horizon is Wide: How Broad Versus Narrow Mindset Influences Evaluation of Product Imitations

Femke van Horen, Vrije Universiteit Amsterdam, The Netherlands
Zachary Estes, Bocconi University, Italy

EXTENDED ABSTRACT

Copycat brands imitate the name, logo, and/or package design of a national brand to capitalize on the latter's positive associations and marketing efforts (Van Horen and Pieters 2012a; Zaichkowsky 2006). Past research investigating the success of copycat brands has focused on *product* characteristics, such as degree of similarity (Aribarg, Arora, Henderson, and Kim 2014; Loken, Ross, and Hinkle 1986), type of similarity (Van Horen and Pieters 2012b), price (Warlop and Alba 2004), and positioning (Sayman, Hoch, and Raju 2001; Van Horen and Pieters 2017). Although those prior studies have provided many insights about copycatting, notably, none of those studies has examined how *consumer* characteristics influence copycat evaluation.

In the present studies we focus on the role of mindset in copycat evaluation and predict that a broad (inclusive and holistic information processing) as compared to a narrow mindset (exclusive and differentiating information processing) will positively affect copycat evaluation, independent of perceptions of similarity. When consumers process more inclusively, attending to the entire package, a transfer of positive associations is likely to occur, resulting in positive copycat evaluation (Van Horen and Pieters 2012a). When, on the other hand, a narrow mindset is activated, consumers will focus on the disparate imitated features and become more aware of the imitation practices used, causing reactance (Campbell and Kirmani 2000; Friestad and Wright 1994; Van Horen and Pieters 2012b). We test this rationale in four studies.

Study 1 (N = 385, students) tested whether holistic thinking was positively correlated with copycat evaluation. After completion of the holistic thinking scale (10-items, Choi, Dalal, Kim-Prieto, and Park 2003), participants evaluated the high similarity copycat "Bellamia"– an imitation of "Bertolli" spreadable butter – and indicated their willingness to buy, all on 7-point scales (4 items collapsed, α = .88). The results showed that participants who are more inclined to think holistically evaluated the copycat more positively (β = .14, t = 2.84, p = .01). Inclusion of the three control variables (familiarity with, evaluation, and purchase frequency of the imitated brand) did not change the pattern of results.

Study 2 (N = 148, students) tested whether a direct perceptual measure of processing mindset, the Framed Line Task (Kitayama, Duffy, Kawamura, and Larsen 2003), predicts copycat evaluation. The FLT measures the extent to which people are attuned to contextual information, by calculating the difference between the length of an original line presented in a frame and the line participants draw in a new frame that is either larger or smaller than the original frame, with larger error indicating a broader mindset. After completing six trials of the FLT, participants were asked to evaluate the high similarity copycat "Lecha" (imitation of "Milka" chocolate) and to indicate their willingness to buy (collapsed, α = .92). Results showed that the broader and more inclusive participants' processing mindset (higher error), the more positively participants evaluated the copycat (β = .17, t = 2.06, p = .04).

Study 3 (N = 93, students, 2-group between-subjects design) tested the effect more directly by experimentally activating a broad versus narrow mindset using the why/how task (Freitas, Gollwitzer, and Trope 2004). After thinking in an increasingly broad (narrow) way *why* (*how*) one would maintain good personal friendships, participants were asked to evaluate the Milka copycat, using the same stimuli and measures as in Study 2 (collapsed, α = .87). In addition to the control variables of Study 1, perceived similarity with the imitated brand and appropriateness of such similarity were assessed. As predicted, participants evaluated the copycat significantly more positively in the broad (M = 3.80, SD = 1.07) than in the narrow mindset (M = 3.08, SD = 0.98), $F(1, 91)$ = 11.41, p = .001, η_p^2 = .11. Furthermore, the effect of mindset on copycat evaluation remained significant after accounting for perceived similarity and appropriateness of similarity ($F(1, 90)$ = 8.83, p = .004 η_p^2 = .09). None of the control variables accounted for any of the variance (all ps > .10).

Study 4 (N = 556, Amazon Mechanical Turk) tested whether the effect of broad mindset is specific to *copycat* products, or improves evaluations of *any* product. Participants were randomly assigned to a 2 (mindset: broad, narrow; between-subjects) × 2 (product similarity: high, no; within-subject) mixed design. Participants in the narrow mindset condition generated examples of a given item, whereas those in the broad mindset condition generated superordinate categories of the same item (Fujita, Liberman, and Levin-Sagi 2006). All participants then evaluated, in random order, a "no" and "high" similarity brand of hazelnut spread (mimicking "Nutella"), and indicated their willingness to buy (collapsed, αs > .92). A two-way mixed ANOVA yielded a significant main effect of mindset ($F(1, 554)$ = 6.01, p = .02, η_p^2 = .01), with evaluations more positive in the broad (M = 4.87, SD = 1.31) than in the narrow mindset (M = 4.59, SD = 1.38), and a significant similarity×mindset interaction ($F(1, 554)$ = 4.68, p = .03, η_p^2 = .008). The high-similarity copycat was evaluated more positively in the broad (M = 4.96, SD = 1.44) than in the narrow mindset (M = 4.56, SD = 1.59; $F(1, 554)$ = 9.75, p = .002, η_p^2 = .02), whereas there was no such difference for the no-similarity brand (p = .21). Including perceived similarity, or any of the control variables, did not affect the product similarity×mindset interaction ($F(1, 554)$ = 5.18, p = .02, η_p^2 = .009).

Four studies demonstrate that copycats are evaluated more positively when people have a broad mindset – processing information more inclusively and holistic – than when they have a narrow mindset. These effects could not be explained by differences in similarity perception. We demonstrate the effects across different measures (traits) and manipulations (states), and across product categories, copycat stimuli, and samples, attesting the generalizability and robustness of the effect. This research demonstrates that consumer characteristics in general, and information processing more specific, critically affect copycat evaluation, demonstrating the appeal of copycats when the horizon is wide.

EXTENDED ABSTRACT

Using a payment method is an indispensable part of any transaction in the marketplace. While traditional payment methods (such as credit cards or cash) are still responsible for the majority of transactions in the marketplace (84%, Kumar, Maktabi, and O'Brien 2018), new Peer-to-Peer (P2P) payment methods (such as Venmo and Zelle) have rapidly grown in the last decade, with an adoption rate of 52.1% in 2017 (Green and Stavins 2018). Notably, while originally P2P payments were offered exclusively for interpersonal transactions, the use of P2P payment methods in business transactions is expected to reach $74 billion dollars in 2021 (Kharif 2018). Yet, little is known about how these new payment methods impact consumer perceptions and willingness to transact.

We propose that the adoption of P2P payment methods by business providers can have unanticipated consequences. Specifically, we propose that when service providers offer P2P payment methods, consumers will perceive such providers as less competent and will be less likely to complete the transaction. We further propose that such perceptions would be enduring and have downstream consequences for firms and consumers over time: consumers would only change their evaluations after repeated positive experiences with the providers highlighting the competence dimension of their business. We discuss our theoretical development below.

First, P2P payment methods, such as Venmo, were introduced as an easy way to carry out social transactions with acquaintances, friends, and family, such as paying back friends for dinner (Zhang et al. 2017). P2P payment companies also promote these payment methods as platforms to foster social relationships, merging financial transactions with social life (Bary 2017). Pairing of two stimuli strengthens the mental association between them (Rudman 2004; Smith and Queller 2001; Van Osselaer 2008). Thus, P2P payment methods should be more likely to evoke social (vs. business) transactions.

Second, the mental association between P2P payment methods and social transactions will affect consumers' perception of service providers and their decisions to transact with them. In the marketplace, consumers often lack direct information about the competence or quality of a service provider and rely on other available cues to make these inferences. For example, consumers infer higher quality of product and service from a higher price (Baumgartner 1995) and availability of warranties (Boulding and Kirmani 1993). We suggest that the payment method offered would also affect consumers' perceptions of the service provider.

Third, consumers often form perceptions of others based on two dimensions: warmth and competence (Cuddy, Fiske, and Glick 2008). Warmth judgments relate to evaluations of kindness, friendliness, trustworthiness, and helpfulness (Aaker, Vohs, and Mogilner 2010), and competence judgments relate to the evaluation of effectiveness, intelligence, power, and skillfulness (Hoegg and Lewis 2011). Social interactions typically make the warmth dimension salient (Cuddy, Fiske, and Glick 2008). Because P2P payment methods are often used for social transactions, they are more likely to be associated with the warmth dimension. However, consumers often view warmth and competence as opposites: when forming judgments about people

or companies, an increase in perceived warmth decreases perceptions of competence (Aaker, Garbinsky, and Vohs 2012; Aaker et al. 2010). Thus, we expect that consumers will perceive business service providers offering P2P payment methods as less competent, when no other direct competence cues are available (H1).

Inference about the competence of service providers is an important evaluative dimension when consumers decide whether to transact with providers (Kirmani and Campbell 2004). This happens because consumers hire such providers to help them accomplish a goal. Therefore, consumers should focus more on provider's ability to help achieve that goal (competence) than on other dimensions of the provider, such as provider's perceived warmth (Kirmani and Campbell 2004; Kirmani et al. 2017). As a consequence, consumers should be less willing to buy from companies perceived as less competent (Aaker et al. 2010). Thus, we expect that the lower perceptions of service providers' competence should negatively affect the likelihood of consumers hiring them (H2).

We further propose that consumers' perceptions of a business service provider offering P2P payment methods can change over time. Perceived service quality is jointly determined by consumers' beliefs and the actual quality of the delivered service, and consumers update their perceptions of service providers based on their interactions with them (Boulding et al. 1993). When there is evidence that the service provider can deliver unambiguous and consistently competent service, consumers' evaluation of the service provider should improve over time. However, when the service provider demonstrates variance in service quality, such improvement in evaluation is less likely to take place. This happens because consumers attend more to negative (vs. positive) information when making judgments (Baumeister et al. 2001; Ito et al. 1998; Rozin and Royzman 2001). And they tend to encode new information in a way that is consistent with their prior knowledge, especially when the evidence is ambiguous (Higgins, Rholes, and Jones 1977; Srull and Wyer 1979, 1980). Thus, when a service experience contains mixed positive and negative information, consumers, who hold the prior belief that a business service provider who offers P2P payment methods is less competent, are less likely to update their perceptions than when their experienced service quality is consistently high. Thus, the negative impact of P2P payment methods on perceptions of a business service provider should attenuate over time when repeated interactions with the provider are consistently positive but not when they are ambiguous (H3).

Finally, we expect that a positive change in consumer judgments over multiple transactions with the service provider depends on positive performances being demonstrated in the domain of competence but not warmth. Consumers view warmth of a service provider as "extra-role aspect of the service encounter" (Grandey et al. 2005, 47). Displaying extra warmth in service does not improve consumers' satisfaction and expected service quality perceptions, when the core characteristic of a service provider, competence, is not secured (Grandey et al. 2005). For instance, consumers are less willing to purchase from non-profit companies when there is doubt about their competence, even when perceived warmth of these companies is high (Asker et al. 2010). Thus, the negative impact of P2P (vs. non-

P2P) payment methods on perceptions of a business service provider should attenuate over time only when repeated positive interactions with the provider highlight the competence dimension of the service but not when they highlight the warmth dimension (H4).

We test our hypotheses in three studies.

Study 1 (N = 264) tests whether consumers perceive a business service provider offering P2P payment methods to be less competent and subsequently are less likely to hire them (H1 and H2). We test the effect in two service domains (based on pretest) that require either a high level of competence or warmth, i.e. computer repairing and dog walking, with a 2 service type (computer repair vs. dog walk) x 2 payment method (P2P: Venmo vs. non-P2P: credit card) between-subjects design. Participants were asked to imagine either looking to hire a computer repairman or a dog walker. Then, participants in the P2P (non-P2P) payment condition read that the service provider requests to pay with Venmo (credit card). Participants indicated their likelihood to hire the service provider and rated competence (competent, experienced, and professional, α=.93) and warmth (kind, warm, and social, α = .85) of the service provider.

Hiring Likelihood. A 2-way ANOVA revealed a significant interaction ($F(1, 260)=40.29, p<.001$). Specifically, P2P payment led to a significantly lower hiring likelihood (M_{P2P}=3.42, SD=1.84 vs. M_{nonP2P}=4.31, SD=1.61; $F(1, 260)=9.53, p=.002$) in the computer repair condition, but a higher hiring likelihood (M_{P2P}=5.18, SD=1.59 vs. M_{nonP2P}=3.49, SD=1.57; $F(1, 260)=34.68, p<.001$) in the dog walker condition.

Competence and warmth ratings. In the computer repairman condition, the results revealed a significant interaction of payment type by rating type ($F(1,130)=90.50, p <.001$). Importantly, consumers perceived computer repairman as less competent, when the provider asked for P2P (vs. non-P2P; $M_{P2P=3.20, SD=1.17}$ vs. $M_{nonP2P=4.76, SD=1.23}$; $F(1,130)=55.40, p<.001$). There was a marginal increase in warmth ratings ($M_{P2P=4.39, SD=.90}$ vs. $M_{nonP2P=4.08, SD=.98}$; $F(1,130)=3.62, p=.06$). Further, the perceived competence of the service provider mediated the effect of payment methods on hiring (indirect effect: $\beta = 1.22$, 95% CI [.78, 1.75], while the perceived warmth did not (indirect effect: $\beta = -.08$, 95% CI [-.34, .02]).

In the dog walker condition, the results also revealed a significant interaction of payment type by rating type ($F(1,130)=27.22, p<.001$). Consumers perceived the dog walker as warmer when the provider asked for P2P (vs. non-P2P) ($M_{P2P=4.84, SD=1.17}$ vs. $M_{nonP2P=3.89, SD=1.23}$; $F(1,130)=27.22, p<.001$). No comparable effects were observed for competence ratings ($p > .80$). Opposite to the results in the computer repair condition, the perceived warmth of the dog walker mediated the effect of payment methods on hiring (indirect effect: $\beta = -.28$, 95% CI [-.57, -.02]), but the perceived competence did not (indirect effect: $\beta = .02$, 95% CI [-.17, .21]).

Study 2 (N = 226) tests the effect of P2P payment methods on consumers' expected service quality by a service provider over time (H3). In this study, we use service quality expectations as our main dependent variable because they reflect consumers' perceived competence of the service provider (Swartz and Brown 1989) and often predict consumer hiring decisions (Boulding et al. 1993). Study 2 employed a 2 payment method (P2P: Venmo vs. non-P2P: credit card; between) x 2 experienced service quality (consistently positive vs. ambiguous; between) x Time (within) mixed design. Participants were told that they were looking to hire a pest control service for a monthly visit and found a provider that accepted Venmo (credit card) in addition to cash. Then, participants rated the expected service quality in the first month prior to having any interaction with the pest control provider (T_0). Next, in the consistent positive condition, participants first read that the service for the first month was effective

and indicated the expected pest control service quality in the second month (T_1). Next, participants read again that the service was effective and reported the expected service quality in the third month (T_2). By contrast, in the ambiguous condition, participants first read that pest control was effective and rated the expected service quality in the second month (T_1). Next, participants read that the service was not effective and reported the expected service quality in the third month (T_2). To make the last service experience more comparable in the two conditions, in the ambiguous condition only, participants received third feedback. They read that the service was effective and rated the expected service quality in the fourth month (T_3).

Consistent positive experience condition. A mixed ANOVA with payment method (between-subjects) and time (within-subject) revealed a main effect of payment method ($F(1,116)=5.94, p=.016$), such that the adoption of P2P (vs. non-P2P) payment methods lowered expected quality of the business service provider (M_{P2P}=5.21, SD=1.25; $M_{nonP2Pp}$=5.72, SD=1.00), consistent with study 1. Importantly, there was a significant payment method by time interaction ($F(1,116)=12.28, p=.001$). Offering P2P (vs. non-P2P) payment methods led to lower expected service quality at T_0 (M_{P2P}=4.19, SD=1.51; M_{nonP2P}=5.20, SD=1.32; $F(1,116)=15.09, p<.001$). However, the contrasts were not significantly different at T_1 and T_2 ($Fs < 2.32$), indicating that consistent positive experience over time attenuated the negative effect of offering P2P payment methods on the perceptions of service quality.

Ambiguous experience condition. A mixed ANOVA again revealed a significant main effect of payment method ($F(1,106)=10.03, p=.002$), such that offering P2P (vs. non-P2P) payment methods lowered expected service quality (M_{P2P}=4.36, SD=1.21; M_{nonP2P}=5.07, SD=1.14). The was also a quadratic main effect of time ($F(1,106)=6.50, p=.012$), such that experiencing effective service increased expected service quality and experiencing ineffective service decreased expected service quality. There was no interaction between payment methods and time (quadratic effect: $F < 1$), suggesting that the negative effect of payment methods persists over time when experienced service quality is more ambiguous, supporting H3.

Study 3 (N = 267) tests the impact of repeated positive interactions with the provider that highlight the competence vs. the warmth dimension of the service (H4). The study employed a 2 payment method (P2P: Venmo vs. non-P2P: credit card; between) x 2 experienced service (warmth vs. competence; between) x Time (within) mixed design. Participants were told that they needed to hire a pest control provider for a monthly service and found one that, besides cash, started to accept either Venmo or credit card. Participants rate the expected service quality at T_0, T_1, and T_2 as in study 2. In the competent service experience condition, participants read that the pest control agency acted in a very professional and efficient way. While participants, in the warm service experience condition, read that the service provider acted in a very warm and friendly way (e.g. after T_0 and T_1).

Competent service experience condition. Replicating study 2, the results revealed a significant interaction of payment method by time ($F(2,247)=11.34, p < .001$). Specifically, offering P2P (vs. non-P2P) payment method led to lower expected service quality at T_0, (M_{P2P}=4.18, SD=1.41; M_{nonP2P}=4.86, SD=1.42; $F(1,137)=8.08, p=.005$). However, the contrasts between were not significantly different at T_1 and T_2 ($Fs<.95$), indicating that providing competent service over time attenuated the negative effect of payment methods.

Warm service experience over condition. The analysis revealed a significant main effect of payment method ($F(1,126)=11.31, p=.001$), such that the use of P2P (vs. non-P2P) payment methods

led to lower expected service quality. However, there was no interaction between payment methods and time ($F < .20$): the expected service quality when P2P (vs. non-P2P) payment method was used was lower for all time periods, supporting H4.

In three studies, we address the consequences of service providers adopting new P2P payment methods for consumer perceptions and willingness to transact. We argue that consumers associate P2P payment methods more with social transactions than with business transactions, which leads them to rate service providers as warmer and thus less competent, and decreases the likelihood of transactions. This effect has long-term consequences: perceptions of service providers improve only when their competence is demonstrated over multiple service encounters. However, the negative impact of P2P payment methods on perceptions of business service providers persists when experiences are mixed (both positive and negative) or highlight only warmth aspects of business.

Our work has both theoretical and managerial contributions. Prior work on payment methods has almost exclusively focused on the differences in experienced pain of payment between the payment methods and its consequences for amount and type of product purchased (Prelec and Simester 2001; Raghubir and Srivastava 2008; Soman 2004; Thomas, Desai, and Seenivasan 2011). The paper extends the literature by showing that payment methods can have a broader impact on evaluations of business, specifically judgments of competence of service providers. Furthermore, we demonstrate that this happens via a different mechanism (mental associations with warmth and competence) than pain of payment. Our work also contributes to the growing literature that shows that benefits of innovations adoption are context-dependent (Longoni et al. 2019; Van Ittersum et al. 2013). While keeping up with technological innovations is often seen as critical for businesses to survive in the marketplace, our findings suggest that service providers should be cautious when adopting novel payment methods, which might be associated with unexpected characteristics of transactions (e.g., warmth vs. competence).

Presence of Meaning in Life Improves Response to Others' Self-Promotion

Young Eun Huh, Korea Advanced Institute of Science and Technology (KAIST), South Korea
Irene Scopelliti, City University of London, UK
Seo Young Myaeng, Northwestern University, USA

EXTENDED ABSTRACT

It is not uncommon to be exposed to others' self-promotional attempts, especially in the digital age. People use social media platforms to convey a positive self-image by sharing positive moments, consumption experiences, and the best aspects of their lives (Kross et al., 2013). They may believe their audiences would receive their achievements and fortunes favorably, yet recipients often perceive self-promotion as bragging and respond negatively to it (Packard, Gershoff, & Wooten, 2016; Scopelliti, Loewenstein, & Vosgerau, 2015; Sezer, Gino, & Norton, 2018). Frequent exposure to this type of messages may in part explain why the consumption of social media has been linked to declines in subjective well-being (Kross et al., 2013; Orben & Przybylski, 2019; Verduyn et al., 2015).

Previous research has shown that the lack of a sense of meaning underlies some negative emotional consequences of social media use (Sagioglou & Greitemeyer, 2014), and that the effect of social feedback on post authors' self-esteem is moderated by individual differences in one's sense of purpose in life (Burrow & Rainone, 2016). Yet, little is known about whether individual differences can mitigate the perceived aversiveness of others' self-promotion. The present research addresses this gap by proposing that the *search for* vs. *presence of meaning in life* (MIL; Steger, Kashdan, Sullivan, & Lorentz, 2008; King & Napa, 1998) influences recipients' well-being by changing their emotional responses to others' self-promotion.

MIL, defined as "the extent to which people comprehend, make sense of, or see significance in their lives, accompanied by the degree to which they perceive themselves to have a purpose, mission, or overarching aim in life (Steger, 2009, p. 682)," has a multitude of beneficial and salubrious effects, including higher life satisfaction, better social relationships, and more skillful adjustment to stressful life events (Park & Baumeister, 2017; Steger et al., 2008). Presence of MIL is associated with psychological stability, healthy self-acceptance, strong social relationships, higher satisfaction with oneself and others, and better ability to recover emotionally from exposure to negative stimuli (Steger et al., 2008; Schaefer et al., 2013). Thus, we predict presence of MIL to be related to less negative emotional responses to others' self-promotion—perhaps the act being viewed as a form of celebration rather than bragging. We tested this prediction in two pre-registered studies, the second of which shows that a simple intervention to increase one's sense of presence of MIL can improve responses to others' self-promotion.

In study 1 (N = 202), we the relationship between MIL and emotional responses to others' acts of self-promotion. Participants imagined following many of their former high school classmates on Instagram, and seeing that a former classmate posted a photo of a luxurious spa with a caption about having a wonderful holiday. They indicated the extent to which the post made them experience positive emotions and negative emotions (1 = not at all; 7 = very much), and completed the Meaning in Life Questionnaire (MLQ; Steger et al. 2006).

As predicted, the presence of MIL was positively correlated with the experience of positive emotions ($r = .196$, $p = .005$) and negatively correlated with the experience of negative emotions ($r = -.157$, $p = .026$).

Study 2 tested whether an intervention to foster one's perceptions of presence MIL would reduce negative responses to self-promotion. At Time 1, participants (N = 1,808) completed the MLQ questionnaire. One week later (Time 2), all participants were invited to take part in a second survey, which was open to 400 participants (401 actually completed it). These participants were randomly assigned to an intervention or control condition. Participants in the intervention condition were asked to reflect upon and write a few sentences about the meaning in their lives. They were instructed to focus on anything that gives meaning to their lives and makes their lives significant. Participants in the control condition did not complete this writing task. Afterwards, all participants imagined accessing their Facebook account and seeing a post by a former classmates mentioning a promotion to a higher rank position. Participants indicated the extent to which the post caused them to experience positive and negative emotions, annoyance, envy, and irritation (1 = not at all; 7 = very much). Finally, participants completed the MLQ a second time and reported their demographic information.

The intervention increased presence of MIL at Time 2, $F(1, 255) = 30.21$, $p < .001$. Participants in the control group showed no change in their MIL scores between Time 1 and Time 2. Replicating the results of Study 1, the presence of MIL was positively correlated with the experience of positive feelings ($r = .280$, $p < .001$) and negatively correlated with the experience of negative feelings ($r = -.269$, $p < .001$) and other specific negative emotions ($rs < -.186$, $ps < .001$) when reading the post.

Most importantly, participants in the intervention condition experienced less negative emotions, $F(1, 396) = 6.93$, $p = .009$, and felt less annoyed, envious, and irritated, than participants in the control condition. As a more rigorous test of whether the intervention changed emotional responses to self-promotion by increasing presence of MIL, we observed a significant mediation of presence of MIL on all emotions measured. These results demonstrate that an intervention as simple as writing a few sentences about what makes one's life meaningful significantly increased participants' sense of presence of MIL and improved their experience when exposed to a self-promotional social media post.

Social media has become an integral part of people's lives. Although a beneficial means of instant communication and connection, these platforms are also commonly used for self-promotional purposes, which may be received adversely (Pew Research Center, 2018), decreasing one's sense of well-being (Kross et al., 2013; Orben & Przybylski, 2019; Verduyn, et al., 2015). The present research is one of the first to suggest simple ways to reduce negative interpretations of acts of self-promotion. Our findings suggest that briefly contemplating the significance and meaning of one's life can help mitigate negative responses to others' acts of self-promotion.

When Curiosity Helps to Make Sense of It: How Ad-Evoked Curiosity Affects the Evaluation of Low-Fit Brand Extensions

Verena Hüttl-Maack, University of Hohenheim, Germany
Tara Madleen Sedghi, University of Hohenheim, Germany

EXTENDED ABSTRACT

While it is a promising strategy to introduce high-fit brand extensions (e.g., Aaker and Keller 1990), for some brands, it might be necessary to extend into more distant categories to exploit growth and ensure long-term success. However, consumers confronted with low-fit brand extensions face the challenge of resolving the perceived incongruity between the brand and the new extension category. The effortful process of understanding and cognitively classifying new low-fit extensions is challenging, and thus their evaluation tends to be negative. However, if they can be integrated into the cognitive structure, an affectively intense and positive reaction follows (Mandler 1982). An important factor in this process is the perceived ease of resolution, defined as the facility by which an incongruent situation is resolved. A higher ease of resolution typically leads to positive evaluations (Alden, Mukherjee, and Hoyer 2000). We argue that the process of incongruity resolution can be facilitated by inducing curiosity with an advertisement. Curiosity is a motivating force that triggers exploratory behavior and an active search for information (Berlyne 1960; Loewenstein 1994). Therefore, it urges individuals to make sense of an unclear situation (Litman and Jimerson 2004). Moreover, resolving curiosity causes positive affect (Ruan, Hsee, and Lu 2018).

Our research aims to investigate whether and how ad-evoked situational curiosity influences the processing and evaluation of brand extensions and, more generally, how it affects incongruity resolution. We assume that curiosity can ease incongruity resolution, resulting in a more favorable evaluation, and we expect the effect to be stronger for low-fit compared to high-fit brand extensions. In three studies following a 2 (curiosity: low vs. high) x 2 (category fit: low vs. high fit) between-subjects design, we investigated these assumptions.

Study 1 examined the effect of curiosity on the attitude toward brand extensions and the moderating role of fit. In a paper-and-pencil study, university students ($N = 280$) were randomly assigned to one of the four conditions and were shown fictious ads for a new brand extension. We chose two well-known and equally liked brands and combined them with the product category chewing gum to create high- and low-fit brand extensions. To manipulate curiosity, a stepwise procedure of information disclosure was applied, with an information gap being created and subsequently resolved (Menon and Soman 2002). To avoid any perceptual differences induced by the manner in which the information is disclosed, we used the stepwise procedure in both the high- and low-curiosity conditions. In the high-curiosity condition, the ad showed only a brand logo, a hint about the new product, and a request: "Find out more!" It neither showed the product nor provided any further information. However, in the low-curiosity condition, the respondents were shown a product picture and some basic product information. After measuring situational curiosity (Lee and Qiu 2009), a follow-up ad revealed details about the brand extension. Participants then reported their perceived fit (Boush et al. 1987; Keller and Aaker 1992) and their attitude toward the brand extension. A two-way ANOVA revealed a positive effect of curiosity on the attitude toward the brand extension ($p < .001$) and the expected interaction ($p < .05$), indicating that curiosity led to a more favorable attitude toward the low-fit brand extension but did not affect the attitude toward the high-fit brand extension.

Study 2 investigated the mediating role of ease of resolution by again surveying university students ($N = 182$) in a paper-and-pencil study. The test product category consisted of potato chips. Combining this category with a well-known crackers brand created a high-fit brand extension, and with a sausage-brand, a low-fit brand extension. The procedure, curiosity manipulation, and measures were similar to Study 1. Additionally, the ease of resolution (Alden et al. 2000; Jhang, Grant, and Campbell 2012) was assessed after the second ad. A moderated mediation model (PROCESS, Hayes 2018) provided evidence for the indirect effect. For the low-fit brand extension, curiosity increased the ease of resolution, which led to a more positive attitude (.34; CI: [.14; .56]). The indirect effect was not significant for the high-fit brand extension (.02; CI: [−.19; .20]).

Study 3 additionally examined the role of curiosity's affective consequences (Ruan et al. 2018) with a consumer sample ($N = 152$) in an online shopping context. Again, two different brands were used to create the perception of a high-fit and a low-fit extension for the category of e-book readers. A moderated multiple mediation model confirmed the ease of resolution as a mediator only for the low-fit extension. In addition, we found a parallel sequential mediation indicating that an increased ease of resolution led to positive feelings, which consequently resulted in a more positive attitude (.13; CI: [.02; .29]). Unlike for the effect on ease of resolution, there was no significant interaction of curiosity and fit on positive feelings.

Our results show that ad-evoked curiosity improved brand extension evaluation, driven by an increased ease of resolution and positive feelings. This is especially relevant for low-fit brand extensions, which are challenging to process. An interesting aspect is that perceived fit was not directly affected by curiosity, although this also would have been plausible. Examining this in more depth is an avenue for future research. For marketers, curiosity-evoking advertisements may provide a good possibility for increasing the acceptance of incongruent products, be they brand extensions or innovations.

Consumer Response to Nutrition Claims: Focus on Adding Good or Removing Bad

Iina Ikonen, University of Bath, UK
Aylin Aydinli, Vrije Universiteit Amsterdam, The Netherlands
Peeter Verlegh, Vrije Universiteit Amsterdam, The Netherlands

EXTENDED ABSTRACT

Nutrition claims are one way to highlight the healthiness of a food. While there is regulation surrounding the way manufacturers may use such claims, freedom to decide whether or not to carry such claims, and which specific ones, remains. For example, a product may be low in fat, but high in fiber: does it matter which claim a manufacturer decides to place on their product? While recent work has established that consumers react differently to various types of nutrition claims (André et al., 2019), current regulation and previous academic research seems to ignore such differences. Furthermore, though a framework of claim types has been established (André et al., 2019), understanding of what is driving the different consumer reactions and which claim types may be preferred is still missing.

Furthermore, research has found mixed results for consumer reactions to nutrition claims – some find that consumers eat more healthy as a result, others find even negative results (Seymour et al., 2004; Wansink & Chandon, 2006). To understand this, and to further study consumer reactions to nutrition claims, the purpose of this paper is to understand how consumers differentiate between two specific types of nutrition claims, namely those focusing on adding positive nutrients (from now on "addition claims" vs. highlighting the removal of negative nutrients, "removal claims"). While previous work has differentiated different broad categories of food claims, such as nutrition claims, health claims and health risk reduction claims (e.g. Aschemann & Hamm, 2008; Paek et al., 2011), the specific focus on the content of these claims has been very limited in previous academic research. In fact, there is limited understanding of how consumers react to the variety of nutrition claims, while the importance of such knowledge is increasingly important as concerns for consumer health as well as the usage of nutrition claims on product packaging are both increasing (André et al., 2019).

Research has found that positively framed messages are typically more effective in influencing consumer perceptions and behaviors as they increase consumers' positive associations towards the product (Levin et al., 1998; Newman et al., 2012), though the opposite has also been argued (Amatulli et al., 2019; Block & Keller, 1995). Previous work specifically on nutrition claims has also found consumers to like removal claims less, possibly as the removal process is seen as hurting the naturalness of the product (Rozin, 2006; Rozin et al., 2009).

However, adding a nutrient may also be perceived as receiving something additional with the product. As long as consumers perceive the addition as a wanted "bonus", consumers should react positively to addition claims as they do towards for example bonus pack or multiple item promotions even when the unit price remains the same (Cohen & Babey, 2012). Following the idea of André, Chandon and Haws (2019), who suggested consumers may perceive addition claims as higher effort from the manufacturer, we argue that consumers react positively towards addition claims as they perceive products carrying such claims to bring more value through this added nutrient. In other words, the addition of positive nutrients offers consumers something more than a regular product, or one where nutrients have been removed.

Based on this, we formulate the following hypotheses:

Hypothesis 1	*Consumers will evaluate a food product carrying an addition claim more positively than one carrying a removal claim.*
Hypothesis 2	*The positive effect of addition claims (vs. removal claims) is driven by a higher perceived value offered by the product with the claim.*

We first conduct a meta-analysis of previous work on nutrition claims to find initial evidence for our proposal that consumers differentiate between these two claim types. To shed more light on the mechanism behind the effect, we follow up with two experiments, which support the idea that consumers react more positively to addition claims (vs. removal claims) and that this effect is driven by the increased perception of value for money of the product. We further exclude some potential alternative explanations, such as a removal claim hurting tastiness perceptions.

The contribution of our work is threefold. Firstly, the findings offer an explanation to the inconsistencies in existing research and can function as a starting point for future research on nutrition labeling and claims. Secondly, we offer guidance to marketers looking to improve consumer reactions to healthier food products by offering insight into the types of claims that consumers react more positively towards. Finally, we highlight the importance of taking these differences in claim types into account in creating new regulation on nutrition claims. Policy makers need to be aware that consumers differentiate between addition and removal claims, and to look further into avoiding the claims being used in a misleading way by food manufacturers.

Meta-analysis of main effect

To gather initial evidence to our general proposal that consumers differentiate between the two types of nutrition claims, namely addition and removal focused ones, we conducted a meta-analysis of existing work focusing on front-of-package nutrition claims. To this end, we searched databases of EbscoHost, Web of Science and Pro-Quest for peer-reviewed articles written in English using the search terms ((packag* AND food*) AND ((health* OR nutrition*) AND (claim*))) in the fall of 2018. After going through the initial set and checking them for matching the inclusion criteria, such as comparing a claim present condition to a no claim control condition as well as focusing on food products and nutrition claims, the final article set included 30 academic papers from various fields of research, including for example Marketing and Nutrition Science.

Nearly all of the identified articles reported multiple effect sizes, resulting in a total set of 419 effect sizes. For each effect size, the relevant coded variables for the analyses presented here include type of claim (addition or removal claim), sample size and dependent variable. Our analysis here focuses on purchase intentions and healthiness perceptions given the limited number of observations for other types of dependent variables – for example for tastiness perceptions all research has focused on removal claims and a comparison between the claims types was therefore not possible. Thus, our final analyses include 58 effect sizes for healthiness perceptions and 41 for purchase intentions. The effect size was calculated as a correlation coefficient r and standardized using Fisher's Z_r transformation (Hedges & Olkin, 1985). We used a standard meta-analytical

approach by investigating the mean effect sizes with a random effects Hedges-Olkin meta-analysis (HOMA) and meta-regression weighing each effect with the inverse of its variance (N–3) (Lipsey & Wilson, 2001).

For purchase intentions, the results show that the addition of a nutrition claim focusing on the addition of positive nutrients increases consumers' intention to purchase the product (M_r = .095, SE = .027, p < .001). For claims focusing on the removal of negative nutrients, the effect is in fact negative with consumers reporting lower intentions to purchase the product than without the claim being present (M_r = -.071, SE = .034, p = .040). A random-effects meta-regression shows that this difference in significant (β = .083, SE = .022, p < .001).

Looking at the weighted average effect size for healthiness perceptions shows that both types of nutrition claims have a positive effect on consumers' perceptions about the product's healthiness ($M_{r\_removal\_claim}$ = .100, SE = .024, p < .001; $M_{r\_addition\_claim}$ = .137, SE = .049, p = .005). The random effects meta-regression analysis shows that this difference in effect sizes is not significant (β = .018, SE = .027, p = .501).

All in all, the meta-analysis shows that while consumers on average perceive products carrying nutrition claims more healthy than versions without a claim, they do prefer purchasing products with an addition claim. This difference does not seem to be explained by an addition claim being more trustworthy as this should be reflected in the healthiness evaluations. Another possible explanation, which we could not exclude based on the meta-analysis due to the limited number of previous studies, to the effect could be that removing nutrients from food products signals a lower level of tastiness to consumers. We followed the meta-analysis with two experiments to understand what is driving the different reactions to these two types of nutrition claims. Specifically, we look for evidence for our proposal that suggests the addition of positive nutrients adds additional value to the product, while showing that the tastiness explanation does not account for the effect.

Experiment 1

Experiment 1 focused on the main effect of nutrition claim type on product attitude, and tested the proposed mechanism by moderation. 236 undergraduate students (M_{age} = 19.69, 28.4 % female) took part in a 2 (addition vs. removal claim)* 2 (naturalness highlighted vs. not) experiment in a research lab, and were exposed to a cornflakes package with one of four claims (non-natural removal: "low fat", non-natural addition: "high fiber", natural removal: "no artificial sweeteners", natural addition: "only natural sugar").

We follow the approach by André, Chandon and Haws (2019) in assuming that unless naturalness is specifically mentioned, consumers expect a "high" or "low" claim to imply modifications to the product. If the effect is driven by the added value from the addition of the positive nutrient, it's natural presence should not show a similar positive effect as the natural form of the product has not changed. The respondents reported their attitude towards the product on a 7-point 3-item scale (bad–good, unfavorable–favorable, negative–positive). We also measured perceived tastiness to exclude the alternative explanation that removing ingredients would hurt the taste. Some additional control measures are not reported here for space reasons.

A two-way ANCOVA with gender as a covariate (controlling for uneven distribution of genders in the sample) shows no main effect of either naturalness (p = .145) or claim type (p = .116). However, there is a marginally significant interaction of the factors (F(1, 231) = 3.527, p = .062). Specifically, the simple effects show that in

the non-natural condition, respondents report more positive attitudes towards the addition claim (M_{high_fiber} = 3.94) than the removal claim (M_{low_fat} = 3.45, F(1, 231) = 5.95, p = .015). In the natural condition the two claims ($M_{no\_artificial\_sweeteners}$ = 3.50; $M_{only\_natural\_sugar}$ = 3.46; p = .763) do not differ. A similar pattern emerges for purchase intention. For tastiness, no such interaction emerges (p = .555).

These results show that consumers indeed show more positive attitudes towards products with addition claims, but only when the positive nutrient is indeed added and not simply naturally present in the product. This supports our premise that the positive reaction may be driven by the added value consumers derive from the addition of the positive nutrient. Importantly, there is no interaction of the two independent variables on tastiness perceptions – the product with the removal claim is not expected to taste worse than the one with added nutrients. Therefore, our effect cannot be explained by the idea that removing ingredients would lower tastiness perceptions.

Experiment 2

The goal of experiment 2 was to investigate the proposed underlying process through mediation by measuring perceived value for money. We also addressed a key shortcoming of experiment 1, where one possible explanation for the effect could have been the differences between the nutrients (fat and fiber) highlighted in the claims. The positive reaction towards the high fiber claim could have signaled a generally more positive attitude of the respondents towards fiber. We designed a single-factor between-subjects experiment with three levels (addition claim, removal claim and a no claim -control; N = 172; M_{age} = 19.12; 49.4% female). Participants were undergraduate students taking part in a number of unrelated studies in one session in the research lab of the university. We used a claim with an unknown nutrient, alanine (approach similar to Wänke & Leutner (2009), and gave respondents fictional information about it being either a positive (in the "high" condition) or a negative nutrient (in the "low" condition). After reading this information, respondents saw a pack of cornflakes with one of the claims or no claim. They then reported their attitude towards the product, perceived tastiness, willingness to pay as well as perceived value for money (for a price of 2.50).

A one-way ANOVA shows a main effect of experimental group on product attitude (F(1, 169) = 17.50, p < .01). Importantly, post-hoc comparisons show that this effect is driven by a positive reaction towards the "now with added alanine" claim (M = 4.34) compared to the "now reduced in alanine" (M = 3.14, p < .001) as well as the no claim control condition (M = 3.29, p < .001). The reduction claim and the control do not differ (p = .764). Similar results appear for WTP and purchase intention. A mediation analysis (PROCESS Model 4; Hayes, 2013) shows that a higher perceived value for the addition claim mediates the effect (b = .243, 95% CI [.082; .470]). Importantly, even though the addition claim is perceived as tastier than the other products (p's < .01), the reduction claim is not less tasty than the control condition (p = .993). Thus, the reduction claim does not hurt tastiness perceptions compared to the regular product.

General discussion, limitations and implications

These results support our premise that consumers perceive the 'positive nutrients added' claim to signal a higher value for money due to additional ingredients being present in the product. If the positive claim highlights that the positive nutrient is present naturally, such a perception of receiving "something extra" will not take place. These results help explain the mixed findings of previous research on nutrition claims, and offer more insights into nudging consumers towards healthier consumption. For example, promoting healthier

products in terms of added benefits may be more impactful in driving consumers towards healthier choices.

Similarly to the work of André, Chandon and Haws (2019), our results highlight that it is important for policy makers to understand that these two nutrition claim types are not perceived as the same by consumers, and regulation should take these differences into account. Given consumers' more positive reactions towards addition claims, they may be more easily misled by such claims compared to removal claims. This, however, remains to be confirmed in future research. Given that many food products may qualify for multiple claims, and often do carry more than just one claim and even a mix of the various types (Holtrop et al., 2019), further work should also aim to understand how the two claim types interact when presented simultaneously.

Finally, previous work suggests that consumers react to nutrition claims differently depending on the healthiness of the carrier product (Steinhauser et al., 2019). Future research should look to understand whether this preference for addition claims is general or dependent on the product category. As more research on nutrition claims, and especially addition claims, is conducted, expanding on this current meta-analysis would provide a useful tool for such a category comparison allowing for a broad range of categories and settings.

The Perfection Premium

Mathew S. Isaac, Seattle University, USA
Katie Spangenberg, University of Washington, USA

EXTENDED ABSTRACT

Media reports suggest that people disproportionately value perfection. For example, Walnut Hills High School was featured in national newspapers after seventeen students earned a perfect score of 36 on the American College Test (ACT).[1] However, individuals also seem to value near-perfection. For example, Tesla's Model S received accolades after earning a near-flawless road test score of 99 (out of 100) from *Consumer Reports*.[2] We find that even when the objective numerical gap between two values is identical, people perceive the difference between items to be greater if one item has attained a perfect attribute value or rating. Our work suggests, for example, that the perceived difference between products of 100%- and 99%-effectiveness is greater than the perceived gap between products of 99%- and 98%-effectiveness. In addition to documenting this *perfection premium*, we show that it occurs at least in part because of a categorization bias.

Relevant to our proposed perfection premium is prior research documenting discontinuities in judgments at endpoints of a scale. This work has shown that a change in probability near 0% or 100% is weighted more heavily than an identically-sized change in the middle of a distribution (Li & Chapman, 2009; Tversky & Kahneman, 1992; Wu & Gonzalez, 1996). However, given that most research examining whether people perceive meaningful differences near maximum scale values has focused on risk perceptions, it is unclear whether differences will emerge when comparing the performance of individuals or items that do not vary in terms of riskiness.

In addition to documenting a perfection premium in performance perceptions, we aim to implicate a new psychological mechanism: categorization. Individuals are prone to categorize numbers (e.g., odd/even; Laski & Siegler, 2007). For example, people spontaneously create mental categories at "round number" (e.g., zero- or five-ending) boundaries, thus expanding the perceived distance between adjacent numbers in different categories (Isaac and Schindler, 2014). We posit that when individuals encounter high attribute values, a natural basis for categorization is whether an item is perfect. If an item with a perfect attribute is categorized separately, the evaluative distance between it and a near-perfect item will be exaggerated.

In Experiment 1 (N=450), participants were assigned to one of three conditions. Those in the perfect condition read that Baking Bar A (B) contained 99% (100%) pure ingredients. In the two near-perfect conditions, Baking Bar A (B) contained 98% (99%) and 97% (98%) pure ingredients. Consistent with the perfection premium, Bar B was chosen by 67.5% of participants in the perfect condition, as compared to 51.0% of participants in the higher near-perfect condition ($\chi^2(1) = 8.44$; $p = .004$) and 59.2% of participants in the lower near-perfect condition ($\chi^2(1) = 2.27$; $p = .13$). Responses to a relative preference measure also revealed a similar pattern.

Next, we tested the perfection premium in a different context (i.e., social cognition) and used points on a test rather than percentages. In Experiment 2 (N=252), participants learned that 20 high school students had taken the ACT, which was partially correlated with IQ scores. Participants then rated the intelligence of two students on ten separate occasions. Each time, we randomly varied the numerical in-formation that participants encountered such that the higher-scoring student in each pair was between 32 and 36 (i.e., a perfect score) and the lower-scoring student's score was one or two points less. A 2 (perfection: perfect, near-perfect) x 2 (score difference: 1 point, 2 points) repeated-measures ANOVA on relative intelligence ratings revealed a significant main effect of perfection, ($F(1, 251 = 22.32$, $p < .001$). When paired students' ACT scores were one point apart, relative intelligence ratings were more disparate when the higher-scoring student achieved a perfect score ($M_{36/35} = 74.27$) as compared to a near-perfect score ($M_{other} = 70.64$; $F(1, 251) = 23.81$, $p < .001$). We observed the same pattern when the scores were two points apart, and the interaction between perfection and score difference was non-significant.

Based on our theorizing, if we place near-perfect and perfect numerical values in the same evaluative category, the perfection premium should be attenuated. In Experiment 3 (N=322), participants were told the wool content of two pairs of socks: 100% versus 98% (perfect superior option) or 96% versus 94% (near-perfect superior option). Participants in the categorization cue absent [present] condition were not given any further information [told that both pairs of socks had received perfect 5-star ratings on Amazon from the same number of reviewers]. A 2 x 2 ANOVA on relative sock preference revealed a significant interaction between perfection condition and categorization cue condition ($F(1, 318) = 4.56$, $p = .033$). When the categorization cue was absent, we replicated the perfection premium ($F(1, 318) = 11.54$, $p = .001$). However, when the categorization cue was present, the relative preference of participants in the perfect and near-perfect conditions did not differ.

Finally, Experiment 4 provided direct evidence for our mechanism by using categorization as a dependent variable. Participants (N=338) learned that three students (Q, R, and S) had taken a test in which a perfect score was either 100 points [round perfect value] or 88 points [non-round perfect value]. Those in the perfect (near-perfect) condition learned that the three students had earned 98, 99, and 100 (97, 98, and 99) points out of 100, or 86, 87, and 88 (85, 86, and 87) points out of 88. Subsequently, participants assigned the students to Group A or Group B based on their performance, with at least one student in each group. In line with our prediction, a binary logistic regression showed a significant main effect of the superior option condition ($B = 1.32$, $SE = .32$, Wald = 16.58, $p < .001$) on participants' likelihood of placing the highest-scoring student into its own category.

This research shows that individuals disproportionately value items or individuals that are perfect on certain attributes as compared to those that are near-perfect on those same attributes. Further, we find this perfection premium occurs because individuals spontaneously categorize perfect items separately from other items.

The Half-Robin Hood Effect: How Corporate Political
Activism Leads Consumers to Cheat Corporations

Pradeep Jacob, Arizona State University, USA
Naomi Mandel, Arizona State University, USA

EXTENDED ABSTRACT

In recent years, corporations have increasingly taken widely publicized stances on divisive political issues, often offending and alienating consumers who do not share similar views. Prominent recent examples include Delta Airlines' elimination of discounts for NRA members, Hobby Lobby's opposition to insurance coverage for birth control, Nike's use of Colin Kaepernick as a brand ambassador, and Chick-fil-A's stance against gay marriage. In this research, we examine how and why a consumer's political ideology influences reactions to corporations' public opinions on divisive political issues.

Corporations frequently engage in political activism, either advocating for liberal or conservative issues. While consumers' political ideology plays a pivotal role in shaping their attitudes, very little is known about their marketplace behavior in response to corporate political activism. The current research examines the impact of consumers' political ideology on their likelihood to dishonestly retaliate against corporations that take a liberal or conservative stance on a divisive political issue. More precisely, we examine whether liberals or conservatives are more willing to dishonestly retaliate (i.e., the willingness to unethically retaliate against a corporation due to an active desire to harm the corporation) against corporations that take a conservative (vs. liberal) stance. We predict and find that liberals are more likely than conservatives to dishonestly retaliate against corporations that take conservative stances, because they are more likely to perceive that the corporation's actions have caused harm to vulnerable others. In contrast, liberals and conservatives are equally unlikely to dishonestly retaliate when the corporation takes a liberal activist stance because both liberals and conservatives perceive that a corporation's liberal stance is less harmful to vulnerable individuals and groups than a corporation's conservative stance. Like Robin Hood, liberals desire to punish the rich (i.e., corporations that take a conservative stance) to indirectly benefit the weak (i.e., marginalized others perceived to be harmed by corporate activism). However, we use the term "Half-Robin Hood" because the participants in our studies take from the "rich" (corporations) but keep the money for themselves, rather than giving it to the poor.

Prior research at the intersection of political orientation and consumer behavior has typically examined the impact of ideology on purchase behavior (e.g., Fernandes and Mandel 2013; Ordabayeva and Fernandes 2018), or customer complaints (Jung et al. 2017). Our research differs from prior research that examines how ideology influences one's likelihood of seeking reparations from firms with whom one has had a service interaction (e.g., Jung et al. 2017), as we examine the impact of political ideology on individuals seeking retribution against activist firms, even when the corporation's actions do not impact them directly. The construct of dishonest retaliation is conceptually distinct from previously examined constructs such as relationship exit (e.g., boycott) and demands for reparation (e.g., complaining behavior) because consumers do not engage in such acts to retaliate against firms (Grégoire and Fisher 2008). We contribute to the literature on political psychology and consumer retaliation by expanding the range of phenomena explored to politically motivated retaliation via fraud against corporate political activism.

Theoretical Background

Conservatives are typically more threat-sensitive than liberals (Hibbing, Smith, and Alford 2014), and are thus more motivated to accept inequality and preserve the status quo to help manage threat and uncertainty (Jost, Glaser, et al. 2003). Thus, conservatives (vs. liberals) value traditional social institutions that bind people and maintain the social order (Graham, Nosek, et al. 2011). Conservative corporations therefore take activist stances that protect traditional social structures that bind people and maintain the social order, whereas liberal corporations take activist stances that protect vulnerable individuals from harm and promote social justice. Corporations' conservative stances, thus, tend to favor dominant groups while preventing vulnerable groups from achieving social equality (Sidanius and Pratto 1999, Wilson 1973, Billig 1982). In contrast, corporations' liberal stances tend to challenge the legitimacy of traditional institutions that endorse a dominance-based social hierarchy (Diekman and Goodfriend 2007). Given that conservative corporate activism advocates preserving relatively abstract traditional social values, the victims of such activism are often relatively identifiable marginalized individuals and groups that do not conform to traditional societal norms. In contrast, given that liberal activism challenges the dominance-based hierarchy (Hydock, Paharia, and Weber 2019), the victims of such activism are often relatively abstract traditional institutions and social conventions.

Individuals across the political spectrum perceive moral violations such as the repudiation of traditional institutions and social conventions to be less harmful compared to the harm inflicted on vulnerable victims, because such violations typically harm institutions that possess high levels of power and agency, and are thus less capable of experiencing suffering (Gray, Jenkins, et al. 2011, Rai and Diermeier 2015). Consumers develop stronger emotional reactions towards identifiable victims than abstract victims (Small and Loewenstein 2003) and thus, perceive the severity of the harm experienced by identifiable victims to be greater than the harm experienced by abstract victims (Nordgren and McDonnell 2011), like a social convention or traditional institution. Thus, consumers across the political spectrum perceive conservative corporate activism as more harmful to vulnerable individuals and groups than liberal corporate activism, because the victims of conservative corporate activism are more identifiable than those of liberal corporate activism.

However, liberals (vs. conservatives) place the prevention of harm to vulnerable individuals and groups to be more morally relevant to their judgment (Graham, Haidt, and Nosek 2009) and feel greater empathy towards vulnerable populations (Skitka and Tetlock 1993). Thus, while liberals and conservatives perceive a conservative (vs. liberal) activist firm to be more harmful, liberals do so to a significantly greater extent.

Consumers seek to retaliate against harmful corporations because they assign a higher standard of responsibility to corporations (vs. individual perpetrators), as they possess greater resources and greater ability to anticipate the consequences of their actions (Hans and Ermann 1989). Furthermore, corporations have a social contract or obligation with society to not harm others for selfish reasons (Sousa and Piazza 2014), and thus, consumers are more likely to punish harmful corporations for violating their social contract with society (Rotman, Khamitov and Connors 2017). Moreover, consumers will

also be able to justify punishing corporations, even through unethical means, because they find it easier to rationalize their dishonest actions when such behavior benefits other individuals, apart from themselves (Wiltermuth 2011). Thus, given that liberals perceive that a corporation's conservative stance is more harmful than conservatives do, and given that consumers are more likely to seek retaliation against harmful corporations, we propose that liberals, but not conservatives, will be motivated to dishonestly retaliate against such corporations.

Experiments

Across three studies, we examined whether liberals would be more likely than conservatives to dishonestly retaliate against a corporation that takes a conservative (vs. liberal) stance. First, to determine the extent to which political positions were considered conservative or liberal, we conducted a pre-test with undergraduates (N = 557, female = 55.5%). Participants assessed whether the support or opposition to various social issues, such as universal healthcare, gun rights, abortion rights, transgender bathroom access rights, etc., was conservative or liberal. Based on the responses we received, we created vignettes depicting institutions taking either a very conservative or a very liberal position on healthcare access (study 1), and transgender bathroom access (studies 2 and 3). Also, across the following studies, we controlled for socioeconomic status and perceptions of large firms, to ensure that the need for money, and negative perceptions of large corporations respectively, did not influence likelihood of dishonest retaliation against corporations that took a conservative (vs. liberal) stance.

Study 1 examines the likelihood of an individual returning $100 that was accidentally credited into his or her credit card by a restaurant. We randomly assigned undergraduate business students (N=694, 56.7% female) to one of two conditions (liberal restaurant vs. conservative restaurant). Participants viewed a short description of a restaurant chain, which either took a liberal position on healthcare (i.e., advocating Medicare For All), or a conservative position on healthcare (i.e., opposing any expansions to Medicare and Medicaid). Finally, we measured each participant's conservatism on a 7-point scale ranging from 1=extremely liberal to 7=extremely conservative ($M = 3.88, SD = 1.376$). This resulted in a 2 (restaurant's ideology: liberal vs. conservative; manipulated) X participant's conservatism (continuous; measured) experimental design.

A regression analysis with individuals' conservatism and restaurant's ideology on cheating revealed a marginally significant main effect of political ideology on dishonest retaliation ($b = -.159, t (684) = -1.875, p = 0.06$) indicating that liberals were marginally more likely to dishonestly retaliate than conservatives. The main effect of the firm's ideology was significant ($b = -0.956, t(684) = -1.953, p = .05$), indicating that participants who viewed the conservative firm were marginally more likely to dishonestly retaliate than those who viewed the liberal firm. The interaction of political ideology and firm ideology condition was directionally significant ($b = .195, t(684) = -1.634, p = .10$). Simple slopes analysis (Aiken and West 1991) revealed that the slope of political ideology was marginally significant for the conservative firm ($b = -.159, t(684) = -1.875, p = .06$) and nonsignificant in the liberal firm ($b = .036, t(684) = 0.425, p > .67$) indicating that liberals were marginally more likely to dishonestly retaliate than conservatives among those who viewed the conservative firm, while liberals and conservatives were equally unlikely to dishonestly retaliate in the liberal firm condition.

In study 2, we examined the likelihood of an individual returning $25 that was accidentally credited into his or her credit card account by a restaurant. We randomly assigned undergraduate business

students (N=306, 49.6% female) to one of two conditions (liberal restaurant vs. conservative restaurant). Participants also provided their political ideology on a nine-point Likert scale (Jost 2006; 1 = Very liberal, 9 = Very conservative; $M = 4.88, SD = 1.671$) in a presurvey several weeks before the main study. Participants viewed a short description of a restaurant chain, which either took a liberal or a conservative stance on transgender bathroom access rights. We measured participants' perceptions of whether the restaurant chain's actions caused harm to other vulnerable groups on a 7-point scale (1 = Not at all, 7 = A great deal), because we hypothesized that both liberals and conservatives will perceive a conservative activist firm to be more harmful than a liberal activist firm, while liberals will perceive that conservative activist firms cause greater harm to vulnerable individuals and groups than conservatives do. A regression analysis revealed a main effect of firm ideology, indicating that participants across the political spectrum perceived the conservative firm to be more harmful than the liberal firm ($b = -6.314, t(303) = -9.708, p < .001$). Spotlight analyses also revealed that conservatives also perceived the conservative firm as more harmful than the liberal firm ($b = -1.173, t(303) = -4.194, p < .001$). Moreover, a simple slopes analysis revealed that liberals found the conservative firm to be more harmful to vulnerable others than conservatives did ($b = -.376, t(303) = -4.010, p < .001$).

A regression analysis with individuals' conservatism and restaurant's ideology on dishonest retaliation revealed a significant main effect of the restaurant's ideology ($b = -2.211, t(303) = -2.933, p < .01$), indicating that participants were more likely to dishonestly retaliate when the restaurant took a conservative (vs. liberal) stance. We also found a marginally significant interaction between conservatism and the firm's ideology ($b = .275, t(303) = 1.888, p = .060$). The simple slopes of individuals' political ideology for each firm ideology condition (Aiken and West 1991) revealed that slope of political ideology was significant in the conservative firm condition ($b = -.233, t(303) = -2.135, p < .05$) and nonsignificant in the liberal firm condition ($p = .66$), thus indicating that liberals were more likely to dishonestly retaliate against the conservative firm than conservatives, while liberals and conservatives were equally unlikely to dishonestly retaliate against the liberal firm. We also tested the proposed moderated mediation path where perceptions of harm to vulnerable others and desire for retaliation serve as serial mediators: firm's ideology -> perceived harm to vulnerable others -> desire for retaliation -> dishonest retaliation. The index of moderated mediation was significant ($95\% \ CI \ [-.1071, -.0035]$), indicating that individuals' political ideology moderated mediation through perceived harm to vulnerable others and desire for retaliation. Importantly, pairwise contrasts indicate that the process is stronger for liberals than for conservatives ($95\% \ CI \ [.013, .350]$).

Finally, in study 3, we replicated the results of study 2 by examining the likelihood of an individual returning $25 that was accidentally credited into his or her credit card account by a restaurant. In contrast with study 3, undergraduate business students (N=657, 59.2% female) were instead assigned to one of three (vs. two) scenarios, where a restaurant chain took a liberal conservative, or apolitical stance on transgender bathroom access. Participants provided their political ideology on a nine-point Likert scale (1 = Very liberal, 9 = Very conservative: $M = 4.72, SD = 1.973$).

The main effect of political ideology was significant ($b = -.261, t (647) = -3.747, p < .001$), indicating that liberals were more likely to dishonestly retaliate than conservatives. The main effect of the firm's ideology (liberal vs. conservative firm) was significant ($b = -1.813, t (647) = -3.621, p < 0.001$) indicating that participants who viewed the conservative firm were more likely to dishonestly retali-

ate than those who viewed the liberal firm. The main effect of the firm's ideology (apolitical vs. conservative firm) was also significant *(b = -1.064, t (647) = -2.011, p < 0.05)* indicating that participants who viewed the conservative firm were more likely to dishonestly retaliate than those who viewed the apolitical firm. More importantly, the interaction of political ideology with the liberal firm significantly predicted dishonest retaliation *(b = 0.268, t (647) = 2.753, p < 0.01)* while the interaction of political ideology with the apolitical firm was not significant *(p > 0.12)*. Simple slopes analyses revealed that the slope was significant in the conservative firm condition *(b = -.261, t (647) = -3.747, p < .001)*, but nonsignificant in the liberal and apolitical firm conditions *(all p's > .2)*. Again, moderated serial mediation analysis (Hayes 2018) supported our hypothesized process. The conditional indirect effect for the hypothesized process was significant in the conservative (vs. liberal) firm condition *(95% CI [.050, .127])* and in the conservative (vs. apolitical) firm condition *(95% CI [.031, .086])*.

In this research, we demonstrated that liberals are more likely than dishonestly retaliate against harmful corporations. Our findings may help managers and executives assess the implications of taking a broad politically motivated stances on their business. Customers may defraud a business in a variety of ways, including returning items not purchased or filing a false claim for an injury or accident. Corporations will be well advised to better understand the political ideology and sentiments of their target customers before taking an activist stance on political issues, as consumers are willing to go beyond boycotts and complaining behavior to actively retaliate against corporations that they perceive to be harmful to vulnerable others.

Increasing Donations for Multiple Victims

Hyunkyu Jang, Governors State University, USA

EXTENDED ABSTRACT

People are less willing to help multiple unidentified victims than a single identified victim, which previous studies have referred to as the identifiable victim effect (Jenni & Loewenstein, 1997; Slovic, 2007; Small, Loewenstein, & Slovic, 2007). Singularity has been suggested to be a driver for the identifiable victim effect, which results in people donating more to a single identified victim than to multiple identified victims (Kogut & Ritov, 2005; Västfjäll, Slovic, Mayorga, & Peters, 2014).

Kogut and Ritov (2005) mentioned the lack of perspective-taking as a possible reason for why singularity matters, stating that people may be more likely to adopt a victim's perspective when a single victim is involved than when there are multiple victims. The current research suggests that after people have taken the perspective of a single victim, if they see other victims whose situations are similar to that of the single victim, they will be more likely to help the other victims. Some research on intergroup relations has shown that taking the perspective of an out-group member or a stigmatized group member leads to more positive evaluations and attitudes about the out-group or the stigmatized group as a whole (Batson, Polycarpou, et al., 1997; Dovidio et al., 2004; Finlay & Stephan, 2000; Galinsky & Moskowitz, 2000; Todd, Bodenhausen, & Galinsky, 2012; Vescio, Sechrist, & Paolucci, 2003). These findings imply that prior perspective-taking of a single victim may lead to more favorable attitudes towards other victims who are in a similar situation to that of the single victim, which, in turn, may lead people to help other victims more.

Hypothesis 1:   When multiple victims are potential beneficiaries of donations, prior perspective-taking of a single victim who is in a similar situation to that of the multiple victims will increase donations.

Some research has shown the positive effect of prior perspective-taking of an out-group member on attitudes toward the out-group as a whole and has demonstrated that the positive effect is mediated by self-other overlap with the out-group member (Todd et al., 2012; Todd & Burgmer, 2013). Similarly, the positive effect of prior perspective-taking of a single victim on donations for multiple victims, predicted in H1, may be mediated by self-other overlap with the single victim. As perspective-taking of another person increases self-other overlap with that person (Davis et al., 1996; Galinsky & Moskowitz, 2000; Goldstein & Cialdini, 2007; Laurent & Myers, 2011; Myers et al., 2014), perspective-taking of multiple victims may increase self-other overlap with those victims. If prior perspective-taking of a single victim leads to perspective-taking of multiple victims who are in a similar situation as the single victim, perspective-taking of a single victim should result in not only increased self-other overlap with the single victim, but also increased self-other overlap with the multiple other victims. Increased self-other overlap with multiple other victims should then lead to greater helping behavior toward the multiple victims. Taken together, the positive effect of prior perspective-taking of a single victim on donations for multiple victims may be sequentially mediated by self-other overlap with a single victim and self-other overlap with multiple other victims. Therefore, it is expected:

Hypothesis 2   Self-other overlap with a single victim whose perspective was taken and self-other overlap

with multiple victims serve as serial mediators of the effect of prior perspective-taking of a single victim on donations to multiple beneficiaries.

One pre-study and Studies 1 and 2 were conducted to examine Hypotheses 1 and 2. Pre-study ($N = 300$) used a 4 (prior perspective-taking: imagine-other, imagine-self, imagine-both, objective) between-subjects design. The goal of the pre-study was to examine whether donations increase with a potential donor's prior experience of adopting the perspective of a single victim who is in a similar situation to that of the multiple victims and whether there would be a difference between different perspective approaches.

Participants received an instruction about one of the four prior perspective-taking approaches. The pre-study also adopted perspective-taking approaches from past research (Batson, Early, & Salvarani, 1997; Davis, Conklin, Smith, & Luce, 1996). After reading the instructions about a perspective-taking approach, participants in all conditions read the story about a single victim and took the perspective of a single victim (i.e., prior perspective-taking). The pre-study adopted and revised the stimulus stories about multiple victims and a single victim from past research (Kogut & Ritov, 2005a, 2005b). Next, participants in all conditions then read the story about multiple victims who were described as being in a similar situation to that of the single victim. Participants then indicated their donations amounts to the multiple victims.

The results of the pre-study showed that participants in the three prior perspective-taking conditions donated more ($M = \$7.26$) than participants in the objective condition ($M = \$6.00$, $p < .05$). This indicate that prior perspective-taking increases donations to multiple victims. There was no significant difference between the three difference perspective-taking approaches (ps = n.s.).

In Study 1 ($N = 400$), the design was a 2 (singularity of victim: single-victim, multiple-victim) x 2 (perspective-taking: prior perspective-taking, no prior perspective-taking) between-subjects. The results showed there was no main effect of singularity ($p > .60$) or perspective-taking ($p > .20$). However, there was a significant interaction effect ($p < .05$): donations in the single-victim condition did not differ between the prior perspective-taking condition ($M = \$5.79$) and the no prior perspective-taking condition ($M = \$6.16$, $p > .40$), whereas in the multiple-victim condition, donations in the prior perspective-taking condition ($M = \$6.69$) were significantly greater than those in the no prior perspective-taking condition ($M = \$5.28$; $p < .05$).

Study 2 (N = 450) used a 2 (prior perspective-taking: prior perspective-taking, no prior perspective-taking) between-subjects design. Study 2 showed that donations in the prior perspective-taking condition ($M = \$5.70$) were significantly greater than those in the no prior perspective-taking condition ($M = \$4.82$, $p < .05$). In Study 2, a serial mediation analysis with 10,000 bootstrap samples (model 6 in PROCESS; Hayes, 2017) demonstrated that prior perspective-taking of a single victim increased donations to multiple victims through two serial mediators, self-other overlap with a single victim and self-other overlap with multiple victims (95% bootstrap CI: 0.0187, 0.5055).

The current research contributes to the literature on the identifiable victim effect by adding a new strategy to increase donations to multiple victims. Charities can collect as many donations for multiple victims as for a single victim by leading potential donors to

engage in perspective-taking of a single victim prior to requesting donations for multiple victims in order to enable them to take the perspectives of multiple victims who are in a similar situation to that of the single victim. This will lead to greater self-other overlap between donors and multiple victims and to greater donations for those multiple victims.

Experiential Disadvantage For the Lonely Consumer

Eunyoung Jang, Oklahoma State University, USA
Pramit Banerjee, Oklahoma State University, USA

EXTENDED ABSTRACT

Previous research has shown that experiential purchases elicit greater happiness than material purchases, and this is referred to as the 'experiential advantage' (Carter and Gilovich 2012, Howell and Hill 2009, Van Boven and Gilovich 2003). However, does this hold true for every consumer? In this research, we propose that this experiential advantage may not hold true for lonely people, and they may in fact derive lower happiness from their experiential purchases compared to material purchases. This is because experiences reside in people's memories, but lonely people's impaired memory tends to inhibit the recall of the positive feelings they experienced at the time of the consumption, eventually weakening the evoked happiness from their experiential purchases.

Loneliness has many negative effects on cognition. For example, Cacioppo and Hawkley (2009) suggest that loneliness impairs cognitive function. Loneliness increases the levels of stress hormones like cortisol (Fratiglioni, Paillard-Borg and Winblad 2004) or other inflammatory markers (Jaremka et al. 2013) which impair cognitive function. Due to the memory disadvantage, lonely people would need more memory aids to maintain the positive feelings of their experiences. However, while the tangible and permanent nature of material goods offers a better connection between the feelings experienced in the past and the present, the intangible and ephemeral nature of experiential goods makes the evoked feelings from the experiences inconsistent and likelier to decay across time (Goodman, Malkoc and Stephenson 2016; Shu and Gneezy 2010). This makes experiential purchases more difficult to recall than material purchases. Thus, we predict a negative association between loneliness and the happiness evoked from past experiential purchases. However, we expect that the effects of material purchases on happiness would be constant regardless of the levels of loneliness. Lonely people's lower happiness from their experiential purchases would be mediated by the memory associated with consumption. In order to test these hypotheses, we ran two studies.

Study 1. The purpose of this experiment was to find out whether lonely people derive greater happiness from material purchases rather than experiential purchases. Participants (N=116, M_{age} =37, female 48%) were recruited from Amazon TurkPrime.com (Litman, Robinson and Abbercock 2017) and randomly assigned to one of two conditions (experiential vs. material) of a between-subject design. Participants were instructed to think of the last time they spent their money on a purely experiential or material purchase, then they completed three items of happiness (Guevarra and Howell 2015) on a nine-point scale. We then measured their loneliness using the SELSA-S scale (Ditommaso, Brannen, and Best 2004) which has three dimensions (Social Loneliness, Family Loneliness and Romantic Loneliness), each measured on a seven-point scale with five items each.

Results revealed a significant interaction between loneliness and purchase type on happiness (β = .75, SE = 0.30, t (112) = 2.54, p = .012). Specifically, in the experiential purchase condition, there was a significantly negative association between loneliness and the levels of happiness (β = -.74, SE = .22; t(112) = -3.41, p < .001). On the other hand, in the material purchase condition, there was no association between loneliness and the levels of happiness (β = -.03, SE = .20; t(112) = -0.12, p = .90). To probe this interaction, we used the Johnson-Neyman floodlight analysis technique (Spiller et al. 2013) and found that levels of happiness from experiential (vs. material) purchases was higher at the value of loneliness below 2.09 (β = -.91, SE = .46; t(112) = -1.98, p = .05) supporting the existing finding of experiential advantage. However, the levels of happiness from experiential (vs. material) purchase was lower at the value of loneliness above 5.86 (β = 1.92, SE = .97; t(112) = 1.98, p = .05). Overall, study 1 shows that the level of happiness of experiential purchase decreased as loneliness increased.

Study 2. The purpose of study 2 is to explore the possible underlying mechanism behind this finding. Participants (N=201, M_{age} = 37.23, female = 54.5%) were randomly assigned to one of the conditions of a 2 (purchase types: experiential vs. material) x continuous (loneliness) between-subject design. The procedures were identical to study 1, except that participants were asked to rate on two-items of memory (Goodman, et al. 2016) and ten-items of UCLA loneliness (Pieters 2013). Participants also rated other variables related to purchase such as price, time of purchase and time of last use so as to control those factors.

We regressed the loneliness and purchase types on happiness by using Process model 1 (Hayes 2018) including several control variables. Replicating study 1, in the experiential purchase condition, there was a negative association between loneliness and the levels of happiness (β = -.87, *SE* = .22; t(190) = -4.01, *p* < .001), while in the material purchase condition, there was no association between loneliness and the level of happiness (β = -.24, *SE* = .21; t(190) = -1.14, *p* = .26). To test the mediating role of memory, we conducted a moderated mediation analysis by using Process model 8 (Hayes 2018). We used loneliness as a predictor variable, purchase type (0=experiential, 1=material) as a moderator, memory as a mediator, and happiness as a dependent variable. The results showed a significant indirect effect of memory (β = .12, SE = .07, 95%, CI [.01, .28]). For experiential purchase, the relationship between loneliness and happiness was negatively mediated by the memory (β = -.15, SE = .08, 95%, CI [-.33, -.02]). On the other hand, for material purchase, there was no significant mediating effect of memory (β = -.03, SE = .05, 95%, CI [-.14, .04]).

In conclusion, the present research suggests a boundary condition for the experiential advantage. Previous research found that experiential purchases lead to higher happiness than material purchases. However, when consumers feel lonelier, the positive effect of experiential purchases on happiness disappears, possibly due to memory impairment. This research has important contributions for consumers well-being. Also, as a managerial implication, we suggest that to increase lonely consumers' happiness, companies involved in experiential goods (e.g., vacation, music, etc.) should provide some memory aid such as souvenirs.

Are Lonely Consumers Loyal Consumers?

Eunyoung Jang, Oklahoma State University, USA
Zachary Arens, Oklahoma State University, USA

EXTENDED ABSTRACT

Loneliness has widespread effects on consumer behavior. Lonely consumers are more materialistic (Pieters 2013), are more likely to go shopping (Kim, Kang and Kim 2005), and prefer humanlike products (Orth et al. 2017). But the implications of loneliness on brand loyalty are contradictory. Prior studies suggest inconsistent findings. Some suggest that loneliness strengthens brand loyalty (MacInnis and Folkes 2017) while others suggest that it weakens it (Long et al. 2015).

The present research proposes that loneliness can strengthen and weaken brand loyalty, depending on the loneliness dimension. Although most consumer research treats loneliness as a unidimensional construct, evidence suggests two dimensions – emotional and social. Emotional loneliness is due to inadequate relationship quality (i.e., a desire for greater relationship intimacy) whereas social loneliness is due to inadequate relationship quantity (i.e., a desire for more relationships). Since these dimensions of loneliness are not completely compensatory (Weiss 1983), emotional loneliness are resolved by developing intimate relationships with one individual, while social loneliness are resolved by developing new relationships with many individuals.

Just like human relationships, consumers' brand relationships are multidimensional, varying in quality and quantity (Fournier 1998; 2014). Brand loyalty reflects the quality of a consumer's relationship with brands, whereas brand assortment reflects the quantity of brands with which the consumer has a relationship. Thus, a multidimensional conceptualization of loneliness suggests distinct effects on consumer preferences for brand loyalty and brand assortment. Specifically, consumers experiencing emotional loneliness will prefer loyal brand relationships. However, consumers experiencing social loneliness will prefer a large assortment of brands rather than any single brand. Three experiments were conducted.

Experiment 1 used a 2 (loneliness level:high vs. low) x 2 (loneliness dimension:emotional vs. social) between-subject design. Loneliness was manipulated by asking participants to write about a time when they felt lonely (or not) due to lacking (vs. having) close relationships (emotional loneliness) or social networks (social loneliness). Next, they chose a bottled-water brand to drink each day over the next five days, and rated their brand loyalty towards them on a nine-point scale ($\alpha = .91$). Regarding brand loyalty, there was a significant interaction ($F(1, 426) = 5.35, p < .05$). Specifically, participants in the high (vs. low) emotional loneliness condition showed a stronger brand loyalty ($M_{High\text{-}emotionalL} = 6.04, SE = .20$ vs. $M_{Low\text{-}emotionalL} = 5.24, SE = .20; F(1, 426) = 8.00, p < .05$). However, social loneliness had no significant impact on brand loyalty ($M_{High\text{-}SocialL} = 5.48, SE = .19$ vs. $M_{Low\text{-}SocialL} = 5.58, SE = .19; p = .71$). Regarding the brand assortment, there was a significant interaction ($F(1, 426) = 7.44, p = .01$). Participants in the high (vs. low) social loneliness condition chose more brands ($M_{High\text{-}socialL} = 1.99, SE = .11$ vs. $M_{Low\text{-}socialL} = 1.59, SE = .11; F(1, 426) = 6.41, p < .05$), whereas emotional loneliness had no effect on assortment ($M_{High\text{-}emotionalL} = 1.55, SE = .12$ vs. $M_{Low\text{-}emotionalL} = 1.78, SE = .12; p = .18$). Overall, the experiment 1 provides initial evidence that different loneliness dimensions have different outcomes for brand loyalty and brand assortment, corresponding relational deficits.

Experiment 2a aims to show further evidence by using an advertisement setting, with a 3 (loneliness:emotional vs. social loneliness vs. control) x 2 (ad emphasis:brand loyalty vs. brand assortment) between-subjects design. Loneliness was manipulated by asking participants to read a scenario in which their friendships changed—a best friendship grows emotionally distant (emotional loneliness), a number of casual friendships end (social loneliness), or a scenario unrelated to loneliness (control). Next participants viewed an advertisement for a fictional socks-of-the-month delivery service, which emphasized either loyal devotion to customers or a large brand assortment. Then, participants indicated a willingness to purchase. Results revealed a significant interaction ($F(2, 424) = 4.68, p < .05$). Participants in the emotional loneliness condition showed greater willingness to purchase when the ad emphasized loyalty ($M = 5.64, SE = .28$) than brand assortment ($M = 4.82, SE = .27; F(1, 424) = 4.61, p < .05$). However, participants in the social loneliness condition were more willing to purchase when the ad emphasized brand assortment ($M = 5.82, SE = .26$) than loyalty ($M = 5.00, SE = .27; F(1, 424) = 4.69, p < .05$). Participants in the control condition showed no differences ($p = .74$).

Experiment 2b proposes that these findings are due to consumers' lay belief about brand and human relationships. The method was identical to experiment 2a except for the addition of an ostensible reading comprehension task. In the non-substitute condition, the reading task article argued that brand relationships cannot substitute for human relationships. In the baseline condition, the article discussed a neutral topic unrelated to loneliness. As in experiment 2a the dependent measure was willingness to purchase a brand after viewing an ad that emphasized loyalty or brand assortment. We predict that the baseline condition will replicate the prior experiment, whereas the non-substitute condition will eliminate the effect of loneliness. As expected, it revealed a significant three-way interaction ($F(1, 598) = 10.94, p < .01$). The baseline condition successfully replicated the prior result: a significant interaction between loneliness dimension and ad emphasis ($F(1, 598) = 12.07, p < .01$). However, in the non-substitute condition, this effect disappeared ($p = .21$). When participants were led to believe that brand relationships cannot substitute for human relationships, loneliness dimensions had no effect on brand relationships.

In conclusion, we demonstrate the consequences of multidimensional loneliness on brand loyalty and assortment. We find that emotionally lonely consumers prefer loyal brand relationships. This is consistent with prior work linking loneliness with stronger brand loyalty (MacInnis and Folkes 2017; Tsai 2014). We also find that socially lonely consumers prefer a greater number of brand relationships, weakening their connection to any single brand. This is consistent with prior work suggesting that loneliness weakens brand loyalty (Long et al. 2015). Our findings suggest a potential resolution to this inconsistency. Practically, we also provide implications on relationship marketing strategies such that brands can provide intimate relationships for emotionally lonely consumers and multiple brands experiences for socially lonely consumers.

Humanizing the Family Business: When is Communicating Family-ownership Beneficial?

Philipp Jaufenthaler, University of Innsbruck, Austria
Roland Schroll, University of Innsbruck, Austria

EXTENDED ABSTRACT

The vast majority of businesses are family businesses. For example, family businesses account for approximately 90% of all U.S. companies, employ around 60% of the total U.S. workforce, and are responsible for 30-60% of the domestic GDP (Astrachan and Shanker 2003). Moreover, some of the largest and most successful companies such as Wal-Mart, Nike, and Ford are family-owned businesses.

Despite their omnipresence, relatively little is known about how consumers respond to the communication of family ownership. Initial research in that domain indicates that family-owned companies can leverage their family ownership to positively influence consumer responses (Beck and Prügl 2018; Binz Astrachan et al. 2019). However, it is unlikely that communicating family-ownserhihp univocially enhances consumer responses. Thus, it is important to understand, from a theoretical and managerial perspective, under what conditions communicating family-ownership enhances versus deteriorates consumer response.

Drawing from knowledge activation theory (Epley, Waytz, and Cacioppo 2007; Higgins 1996), we argue that consumers humanize a company that communicates family-ownership. Specifically, the cue "family" activates existing knowledge about families (e.g., warmth and caring), which lead to a more human perception of the company. In turn, we predict that a more human perception of the company should lead to more favorable consumer responses due to greater perceived benevolence. Benevolence refers to "the extent to which a trustee is believed to want to do good to the trustor, aside from an egocentric profit motive" (Mayer, Davis, and Schoorman 1995, 718). Accordingly, because warmth and caring are uniquely human characteristics, we predict that a humanized (vs. non-humanized) company is perceived to be more attentive to consumer needs and to take special care of their interests. More formally:

Hypothesis 1: *Communicating family-ownership humanizes the company and, in turn, enhances consumer response because of greater perceived benevolence.*

Knowledge activation theory further states that incongruity between activated knowledge and a stimulus often leads to negative responses. For example, Van Horen and Pieters (2012) demonstrate that consumers react negatively to copycat strategies that imitate a leading brand's perceptual features. Thus, we expect that antisocial corporate behavior will be perceived as incongruent with the activated human schema as it contradicts the expected caring and concern for others. Consequently, consumers will punish a family-owned company more for negative corporate behavior so that the positive effect of communicating family-ownership vanishes in the presence of information about negative corporate behavior. More formally:

Hypothesis 2: *The effect of communicating family-ownership depends on the congruence of corporate behavior. That is, communicating family-ownership enhances consumer responses only when corporate behavior is congruent with the activated human schema.*

In a pilot study, 80 U.S. consumers from MTurk were exposed to a company logo that either contained or was lacking the information "family-owned" below the company name (between-subjects design). We measured perceived humanness adapting Aggarwal and McGill (2007)'s anthropomorphism measure. As predicted, the results show that consumers humanized the family-owned company significantly more than the company with no ownership information ($p = .010$).

Study 1 (N = 142) used the same procedure as the pilot study, with two differences. First, study 1 used a different ownership manipulation (i.e., company description) and provided ownership information also in the control condition (i.e. publicly owned). Second, in addition to humanization, we also measured benevolence (Mayer and Davis 1999) and purchase intention. The results show that consumers humanized the family company significantly more versus the publicly-owned company ($p = .003$), attributed significantly greater benevolence to the family-owned versus the publicly-owned company ($p = .004$), and were significantly more likely to purchase from a family-owned versus the publicly-owned company ($p < .001$). Importantly, we found a significant indirect effect (CI_{95}: [.03, .38]) via our proposed pathway (ownership communication → humanization → benevolence → purchase intention).

Study 2 (N = 212) used a 2 (ownership: no ownership cue vs. family-owned) × 2 (corporate behavior: no information vs. negative) between-subjects design. A company description referred to the company as either "family-owned," or just "company". While the negative corporate behavior condition showed a newspaper article about an environmental scandal involving the company, no such article was provided in the control condition. The results show a significant ownership × corporate behavior interaction ($p = .016$). When no corporate behavior information was provided, participants reported more favorable attitudes towards the company when the company was described as family-owned (vs. no ownership cue) ($p = .001$). However, as proposed, this positive effect vanished in the presence of negative corporate behavior ($p = .977$).

Study 3 (N = 204) used a 2 × 2 mixed factorial design with ownership (publicly-owned vs. family-owned) as a between-subjects factor and corporate behavior (no information vs. negative) as a within-subjects factor. We used the same company descriptions as in study 1. To manipulate corporate behavior, we again created a fictitious newspaper article informing about contaminated beer possibly related to the company described. First, participants read a company description containing our ownership manipulation and reported purchase intention. Second, participants read a fictional newspaper article containing our corporate behavior manipulation and again reported purchase intention.

The results show that, before knowing about negative corporate behavior, consumers were significantly more likely to purchase from a family-owned versus publicly-owned company ($p < .001$). This positive effect vanished after consumers learned about negative corporate behavior ($p = .214$).

In sum, the current research makes the following contributions. First, this work extends research on consumer's tendency to humanize family businesses (Beck and Prügl 2018) by using a more established measure of humanization (i.e., anthropomorphism). Results show that consumers attribute greater benevolence to a humanized company, which, in turn, positively influences purchase intention and attitude toward the company. Second, we identify a relevant boundary condition to this positive effect. Our results suggest that commu-

nicating family ownership enhances consumer responses only when corporate behavior is in-line with the activated human schema.

Speed Up, Size Down: How Animated Movement Speed in Product Videos Influences Size Assessment and Product Evaluation

He (Michael) Jia, University of Hong Kong, China
B. Kyu Kim, Yonsei University, Korea
Lin Ge, Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Fueled by advances in telecommunication technologies, video advertising has penetrated various digital channels and plays an increasingly crucial role in marketing communications (Teixeira, Wedel, and Pieters 2012). Video advertising often involves dynamic presentations of products that are displayed to move spontaneously but not able to move freely in reality (i.e., immobile products). Products in video ads cannot be shown as their actual physical sizes. When no explicit size information is provided in video ads, consumers may have different assessments of the product's physical size, which is an important attribute in consumer decision-making (Deng and Kahn 2009; Hagtvedt and Brasel 2017; Ordabayeva and Chandon 2013).

Given the potential ambiguity regarding product size in video ads and the importance of size assessment in consumer preference formation, it is beneficial for marketers to be aware of what dynamic visual cues consumers might draw on to infer the physical size of a product. To shed light on this issue, we examine whether and how the *movement speed* of a product (e.g., the speed at which a product rotates, vibrates, or bounces as a whole, moves its parts, or transforms its shape) displayed in video ads can influence consumers' size assessment as well as their willingness-to-pay for the product.

Developing a cross-domain knowledge transfer model (Goode, Dahl, and Moreau 2010; Gregan-Paxton and John 1997; Moreau, Markman, and Lehmann 2001), we propose that consumers overgeneralize the negative size–speed association learned from the base domain of free-moving, animate agents (e.g., animals and humans) to the target domain of immobile, inanimate products (e.g., consumer goods) that are animated to move in video ads. Specifically, we propose a *speed-based scaling effect*, such that consumers estimate the size of a product to be smaller when the product is displayed to move faster in video ads.

Study 1 ($N = 352$) adopted a single-factor between-subjects design with five product-animation conditions varying in movement speed (50%, 100%, 150%, 200%, vs. 250% of the original speed) and two static-image conditions (slide mode and image combination). The results show that an incremental increase in movement speed leads to a proportional decrease in size assessment ($B = -2.12$, $t(248) = -2.86$, $p = .005$), and the speed-based scaling effect seems to result from fast movement speed decreasing product size assessment, compared to the slide-mode condition ($B = -5.02$, $t(297) = -3.04$, $p = .003$) and the image-combination condition ($B = -3.89$, $t(293) = -2.35$, $p = .02$).

Study 2 ($N = 403$) used a 2 (movement speed: fast vs. slow) × 2 (perceived movement similarity: control vs. low) between-subjects design. Participants watched a video, in which a Swiss Army knife is animated to unfold its various tools (e.g., blades) and spin spontaneously at either a fast or a slow speed. After watching the product animation, participants completed a choice task. In the low-similarity (vs. control) condition, participants were shown three pictures of objects, including a gear, a tire, and a fan (vs. animate agents, including a fish, a dog, and a bird) and indicated which of the three objects (vs. animals) was relatively the most similar to the knife they viewed earlier in the way they are moving. A movement speed × perceived movement similarity interaction emerged ($F(1, 399) = 6.12$, $p = .01$). In the control condition, participants estimated the knife to have a smaller size in the fast-movement condition than in the slow-movement condition ($M_{fast} = 5.27$, vs. $M_{slow} = 6.07$; $F(1, 399) = 4.58$, $p = .03$). In the low-similarity condition, this effect was attenuated ($M_{fast} = 5.79$, vs. $M_{slow} = 5.27$; $F(1, 399) = 1.86$, $p = .17$).

Study 3 ($N = 163$) used a 2 (movement speed: fast vs. slow) × 2 (learned association: default/negative vs. reversed/positive) between-subjects design. We sequentially presented three video clips. The first two video clips manipulated the accessibility of the relationship between physical size and movement speed. In the default-association cells, participants watched a video of a small, fast-moving animal (a hummingbird) and another video of a large, slow-moving animal (an elephant). In the reversed-association cells, participants watched a video of a small, slow-moving animal (a snail) and one of a large, fast-moving animal (a cheetah). The third video clip was the target video for size assessment, in which a mobile WiFi device performs various lively movements, such as spinning and zooming out. There was a movement speed × learned association interaction ($F(1, 159) = 7.04$, $p = .009$). In the default-association cells, participants estimated the mobile WiFi device to be marginally smaller when it moved faster ($M_{fast} = 5.99$ vs. $M_{slow} = 6.85$; $F(1, 159) = 2.95$, $p = .09$). In the reversed-association cells, the effect of movement speed was reversed, such that participants estimated the size of the mobile WiFi device to be larger when it moved faster ($M_{fast} = 6.73$ vs. $M_{slow} = 5.68$; $F(1, 159) = 4.13$, $p = .04$).

Study 4 ($N = 200$) further demonstrates that the speed-based scaling effect was moderated by participants' target-domain knowledge ($B = 1.21$, $t(196) = 2.16$, $p = .03$). Fast speed decreased size assessment only for participants who had low target-domain knowledge ($M_{fast} = 19.60$ vs. $M_{slow} = 25.03$; $B = -2.71$, $t(196) = -3.03$, $p = .003$). In contrast, for those who had high target-domain knowledge, movement speed did not influence size assessment ($M_{fast} = 24.44$ vs. $M_{slow} = 24.38$; $B = .03$, $t(196) = .03$, $p = .98$).

Two final studies show the downstream consequences of the speed-based scaling effect, such that faster animated movement speed leads to higher willingness-to-pay when a small product size is desirable (e.g., mobile WiFi device, Study 5), but it results in lower willingness-to-pay when a large product size is preferable (e.g., bottled beverage, Study 6). Moreover, size perception mediates the effect of animated movement speed on willingness-to-pay.

We demonstrate a speed-based scaling effect across various product categories (e.g., consumer electronics, hand tools, home appliances, consumer packaged goods). The findings provide new theoretical insights into digital video advertising and offer important managerial implications.

Low-Power State Promotes Variety-Seeking

Fei Jin, Sichuan University, China
Xiaodan zhang, Peking University, China

EXTENDED ABSTRACT

We propose that low-power state promotes variety-seeking. This effect occurs because consumers in low-power state desire sense of control and variety-seeking is a way to restore it. Furthermore, the effect is reduced when consumer knowledge in a certain consumption domain is high and when the low power state is stable.

Variety plays a critical role in consumer choice, and companies often stimulate purchase by constructing an assortment. Previous research examines factors influencing consumers' variety-seeking tendency from multiple perspectives, such as personality traits (Ariely and Levav 2000; Berlyne 1970), product characteristics (Gourville and Soman, 2005), and environmental factors (Levav and Zhu, 2009). However, how consumers' internal psychological factors affect variety-seeking remains an open question worthy of further exploration.

Contributing new insights to existing work on the topic, the current research tackles this question by examining how power states, one of the key psychological states of consumers, impact variety-seeking. We propose that low-power states promote consumers' variety-seeking tendency which is rooted in the compensatory value of variety-seeking. As an important basis of social hierarchy, power refers to asymmetrical control over valuable resources (Magee & Galinsky, 2008) which can affect consumers' thinking, feeling, perception, and behavior (Guinote, 2017). Low power is an aversive state. Consumers in low-power state often feel out of control in relation to their own or others' behaviors (Rucker & Galinsky, 2008). Previous research suggests that loss of control leads to many negative consequences. When people are in low-power states, they are motivated to change this aversive condition. Previous studies have shown that offering multiple choices can enhance consumers' sense of autonomy and happiness, and even the mere exercise of making choices can improve consumers' sense of control (Iyengar & Lepper, 1999). Similarly, the behavior of seeking variety can make consumers think that they are independent and autonomous (Kim & Drolet, 2003), and such autonomy serves as an important component of sense of control. Therefore, we argue that if consumers have the motivation to fulfill a need for control, they will choose variety. Our hypothesis is supported to an extent by Inesi et al. (2011), who note that when consumers are deprived of control, they prefer a large choice set to small one, as a large choice set (vs. a small choice set) contains more various items. We hypothesize that need for control mediates the effect of low power state on variety-seeking.

However, if consumers have an alternative means to increase their power state, they will not seek variety. We probe the moderating role of consumer knowledge. For consumers in low-power state, knowledge, as a source of power states (French and Raven, 1959), can compensate for a lack of sense of control. When choosing knowledge as an alternative means to enhance sense of control, they would therefore be less likely to choose variety. In contrast, consumers in high-power state make decisions based more on their own preferences than on their level of consumer knowledge, hence, the level of knowledge will not affect their variety-seeking tendency. We hypothesize that consumer knowledge moderates the effect of power state on variety-seeking, such that when consumer knowledge is high (vs. low), consumers in low-power state show a lower variety-seeking tendency.

Furthermore, stability is an important factor that has been shown to influence the extent to which consumers strive to change or maintain their power state (Maner and Mead 2010). If consumers in low-power state choose variety to restore sense of control, we predict that they would seek variety only when the current state is unstable, because they think that they can struggle out from the aversive state. However, consumers would less likely to choose variety when they find it is hard to change the current state. Hence, the effect of low-power on variety-seeking will be moderated by whether one's sense of power is stable. That is, they choose variety when the low-power state is unstable.

Study 1

This pilot study gave a correlational evidence for the relationship between power and variety-seeking. We analyzed transaction data from jd.com, a popular online ecommerce platform in China. We use consumers' level of membership as a proxy variable to measure power states (Magee and Galinsky, 2008). 1702 reviews concerning ten products, including transaction information and consumers' level of membership from jd.com were captured through R software during late January, 2018. Membership level, from registered member to diamond VIP member, was coded from 1 to 5 (1 = lowest membership level, 5 = highest membership level). Results indicated that membership level was negatively correlated with variety-seeking (r (1702) = -0.34, $p < 0.001$, Fisher's Z = 0.35). However, from a correlational analysis we could not claim there was a causal relation between power state and variety-seeking. There might be a number of alternative explanations for this correlation. For example, high membership level may represent an experienced consumer for whom a tendency toward variety-seeking might be reduced, or it may represent consumers with a strong internal tendency toward variety-seeking. Therefore, we conducted four experiments to test for a causal relationship between power states and variety-seeking by manipulating power states directly.

Study 2

Study 2 aimed to provide direct evidence that consumers in low-power state (vs. high-power state) were more likely to seek variety, by manipulating participants' power state. Following Garbinsky, Klesse, and Aaker (2014), 100 students were assigned into high-power (vs. low-power) condition by manipulating power states through role play. We measured variety-seeking by counting the number of different colors participants chose. A general linear model analysis was performed with power states (high-power state = 2, low-power state = 1) as the independent variable and variety-seeking as the dependent variable. Results demonstrated that the main effect of power state was significant ($F(1,96) = 7.21$, $p = 0.009$, $\eta^2 = 0.07$), and participants in the low-power state were more likely to choose variety than those in the high-power state ($M_{\text{low-power state}}$ = 4.33, SD = 0.99 vs. $M_{\text{high-power state}}$ = 3.61, SD = 1.58). The results held when we added appealing and liking as covariates.

Study 3

Study 3 aimed to provide convergent evidence for the main effect by using different experimental context, and probe the underlying mechanism of need for control. 180 participants were first asked to complete an episodic priming manipulation of power (Galinsky et al., 2003), and then were asked to complete a chocolate shopping

decision task. We directly measured need for control (Burger and Cooper, 1979; Consiglio et al., 2018). Two research assistants majoring in English rated the participants' recall tasks ("To what extent, did the participants' recall task reflect his/her power states?" 1 = not at all, 7 = very much). A one-way ANOVA was performed on the average of the two RAs' scores. The results showed that the power state of participants in the high-power group was significantly higher than that of participants in the low-power group ($M_{\text{high-power state}}$ = 4.61, SD = 1.60; $M_{\text{low-power state}}$ = 2.29, SD = 0.57; $F(1,174)$ = 164.19, $p < 0.001$, Cohen's d = 2.73). A general linear model analysis indicated that the main effect of power state was significant and participants in low-power state were more likely to choose variety than those in high-power state ($M_{\text{low-power state}}$ = 4.23, SD = 1.40; $M_{\text{high-power state}}$ = 3.56, SD = 1.52; $F(1,174)$ = 9.27, p = 0.003, η^2 = 0.05). Furthermore, the indirect effect of need for control was significant (95% CI = [-0.40, -0.03]), indicating that the mediating effect of need for control was significant (see Fig. 1).

Study 4

Study 4 examined whether consumer knowledge moderates the effect of low-power state on variety-seeking. 120 university students were randomly assigned to two groups (low power state vs. high power state), with measuring consumer knowledge (Clarkson, Janiszewski, and Cinelli, 2013). The scenarios and measurement of variety-seeking were consistent with those in Study 3. The results indicated that the interaction of power states and consumer knowledge was significant (B = 0.20, t = 2.41, p = 0.02, Cohen's d = 0.41), the main effect of consumer knowledge was significant (B = -0.33, t = -3.87, $p < 0.001$, Cohen's d = 0.70), but the main effect of power state was not significant ($p > 0.1$). Further spotlight analysis illustrated that in the condition of low consumer knowledge (vs. high consumer knowledge), consumers in low-power state showed a higher variety-seeking tendency (B = -1.04, t = -4.53, $p < 0.001$, [-1.50, -0.59]), but consumer knowledge did not affect the variety-seeking tendency of participants in high-power state (B = -0.23, t = -0.04, p = 0.37, [-0.72, 0.27], *ns*). Furthermore, in the condition of low consumer knowledge, participants in low-power state showed higher variety-seeking tendency than those in high-power state (B = -0.57, t = -2.875, p = 0.01, [-0.97, -0.17]). However, in the condition of high consumer knowledge, there was no significant difference between consumers in high or low-power states in variety-seeking tendency (B = 0.11, t = 0.56, p = 0.58, [-0.28, 0.51], *ns*).

Study 5

Study 5 examined the moderating role of stability. 201 university students were randomly assigned to 2 (power: low vs. high) × 2 (stability: stable vs. unstable) between-subjects design. We manipulated power and stability using workplace contract. After that, participants saw a list of six activities and were asked to choose six activities they would like to do over the next week (adapted from Etkin, 2016). Participants could choose six different activities or the same one(s) many times. the results of MANOVA showed that there was a significant interaction of power and stability ($F(1, 197)$ = 6.23, p = 0.01, η^2 = 0.03), but no main effect of power ($F(1, 197)$ = 0.19, *ns*) or stability ($F(1, 197)$ = 0.40, *ns*). Planned contrast revealed that for low-power participants, when they were in unstable condition, they showed higher variety-seeking tendency (M = 4.39, SD = 1.62) than they were in stable condition (M = 3.63, SD = 1.69, F = 4.89, p = 0.03, η^2 = 0.02). But there were no significant differences between stable (M = 4.34, SD = 1.69) and unstable condition (M = 3.89, SD = 1.88, F = 0.19, p = 0.03) for those in high-power states. The results

still held if we put marital status as a covariate ($F(1, 197)$ = 6.55, p = 0.01, η^2 = 0.03).

General Discussion

Variety-seeking is an important characteristic in contemporary society and it is influenced by numerous factors. The current research explores whether, why, and when power state affects variety-seeking. Five studies, including secondary data from jd.com and experiments using different contexts, provide convergent evidence that variety-seeking can be used to compensate for lacking sense of control.

Our research extends the literature on power states, variety-seeking, and consumer knowledge in several ways. First, we enrich the related research on compensatory consumption (Rucker & Galinsky, 2008). Previous literature on compensation consumption has focused mainly on symbolic or status products (Rucker & Galinsky, 2008; Rucker, Hu, & Galinsky, 2014), but our research demonstrates that consumers also perform strategic compensation for ordinary products through variety-seeking. Second, we contribute to the power states literature by showing that a lower-power state promotes variety-seeking behavior. Third, we demonstrate that consumer knowledge moderates the effect of power state on variety-seeking, providing a more nuanced understanding of how power state affects variety-seeking and how consumer knowledge influences decision making.

Our results also have managerial implications for businesses and marketing managers. First, in market segmentation, companies can consider the strategy of increasing the variety of products if consumers have the characteristics of low-power states (such as low income and low social status). Companies can enhance consumer knowledge of target groups if they do not want consumers to switch to competitors due to variety-seeking. Second, although many sellers always emphasize variety in their promotion activities, our results suggest that such advertising strategies may not be effective for consumers with rich knowledge in a certain domain. For those in high-power state and with rich consumer knowledge, a single and deep strategy is better than one of variety.

Matching Rewards with Backers: The Differential Impact
of Rewards Types on Contributions in Crowdfunding

Anna Bernard, UCP - Católica Lisbon School of Business & Economics, Portugal
Rita Coelho do Vale, UCP - Católica Lisbon School of Business & Economics, Portugal

EXTENDED ABSTRACT

Crowdfunding has been constantly growing since its first development in 2008 (Beck et al. 2016) and is likely to raise more than $300 billion by 2025 (Massolution, 2015). The reward-based model, used by popular websites like Kickstarter.com or Indiegogo.com, has become commonly adopted throughout time, especially in the case of creative projects (Boeuf, Darveau, and Legoux 2014). In reward-based crowdfunding, entrepreneurs bypass the traditional fundraising by collecting funds among a large number of individuals. Instead of providing monetary returns, project owners frequently offer rewards in return of consumer contributions, which can be of various types, from highly tangible and material (e.g., a copy of an album, a t-shirt) to pure tokens of gratitude (e.g., thank-you note) (Thürridl and Kamleitner 2016). Practitioners and researchers seem to believe that these rewards play a vital role in crowdfunding behaviors (Gerber, Hui, and Kuo 2012; Thürridl and Kamleitner 2016).

Crowdfunding campaigns' success relies on a composite pool of backers, who are often heterogeneous regarding their motivation or their experience with the platforms. Some contributors are driven by early access to novel products (Belleflamme, Lambert, and Schwienbacher 2013) while others may be driven by altruistic motivations (Gerber et al. 2012). The different tiers of rewards enable endogeneous price discrimination (Hu, Li, and Shi 2015) and backers self-select in the type of rewards they are interested into. Most of the research in crowdfunding has focused on categorizing backers according to their motivation (Ryu and Kim 2016) or on building a typology of rewards (Thürridl and Kamleitner 2016).

In the present research, we aim to study the role of rewards on participants' likelihood of contributing and on amount given to projects. Specifically, we aim to understand which type of rewards (from pre-orders to tokens of gratitude) attracts different types of backers (non-users, unique backers, serial backers).

In Study 1, ninety undergraduate students from a South European University (females = 53%, M_{age} = 24.01, SD = 1.20), who declared they never participated in crowdfunding, were exposed to a fictional crowdfunding campaign to produce a music album. In exchange of their monetary contribution, participants were either not rewarded (*No Reward* condition, N = 30), rewarded with a copy of the album (*Product-type Reward* condition, N = 30) or with a thank-you note (*Grateful Reward* condition, N = 30). We further assessed their contribution likelihood and contributed amount. We found a statistically and marginally significant difference in average contributed amount according to reward type (F(2,87) = 2.78, p =.068) but not on the contribution likelihood (F(2,87) = 0.63, p = .536). Post hoc comparisons (Tukey) of the three groups indicate that participants in the *Grateful Reward* condition (M_{SR}=18.50, SD_{SR}=18.62) were willing to contribute more on average than those in the *Product-type Reward* condition (M_{TR}=1 1.00, SD_{TR}=9.16, p_{TRvsSR} = .087), while no statistical difference were found for the other comparisons with the *No Reward* condition (M_{NR} = 11.77, SD_{NR} = 10.98, p_{TRvsNR} = .138 and p_{SRvsNR} = .973).

Study 2 used the same scenario as Study 1, yet we modified the manipulation of the rewards. This study followed a 2(reward tangibility: digital, physical) x 2(reward gratitude: low, high) between-subjects design. Tangibility included two levels (low and high: digital album or physical album) and gratitude included 2 levels (low

and high: thank-you note, thank-you note + special song). We obtain a sample composed of participants who already participated in crowdfunding (the "users") and other who did not (the "non-users") using Amazon MTurk. MTurkers (206 US citizens, 47.57% women) were asked to report how likely they would contribute as well as by how much. For the "users" (N = 112), an ANOVA with contribution amount as the dependent variable revealed a significant effect of high tangibility (F(1, 100) = 3.44, p = .066). Participants expressed a lower contribution amount when the reward was in a digital version than when it was in a physical version ($M_{digital}$ = 34.48, $SD_{digital}$ = 29.20 vs $M_{physical}$ = 42.68, $SD_{physical}$ = 34.90). There was no significant simple effect of gratitude or significant interaction between the effects of tangibility and gratitude level on contribution amount. The same ANOVA ran on contribution likelihood revealed no significant main or interaction effects. A two-way ANOVA ran on the sample of 94 "non-users" to examine the effect of tangibility and gratitude levels on contribution amounts and on contribution likelihood revealed no significant main or interaction effects. A Probit regression on the likelihood of giving strictly more than 10€ (i.e. the reward value) revealed that non-users are more likely to overcontribute if the reward yields a high level of gratitude (52.92% vs. 47.58%, p = .084).

In a third study, we study this phenomenon using real contribution behavior for project observed on a French crowdfunding platform specialized in creative projects. When a contribution reaches a given threshold, it gives access to a reward composed of one or more items. Data was coded by two French-speaking coders who evaluated each item (N = 1029) composing the rewards (N = 761) selected by 746 contributors. For each item, coders had to state whether they agree with the following statements (1 = Definitely disagree; 7 = Definitely agree): "If I was receiving the reward, I would have the impression that the project owner express his/her gratitude towards me" (GRATITUDE); "The reward corresponds to the end product the project owner wishes to realize" (PRODUCT-RELATED). We regress the average scores over the items composing the reward with a dummy variable "Serial backer" (= 1 when a contributor support at least two projects), controlling for the number of items and the reward value and using clustered standard errors at the individual level. Results show that the expected average score for "PRODUCT RELATED" is significantly higher for serial backers (,). We do not find statistically significant effect of serial backers "GRATITUDE".

In sum, the present research contributes to a better understanding of the role of reward type on crowdfunding. We show that while rewards type does not impact the likelihood of contribution, it has an impact on the contribution amount. More specifically, non-users and occasional contributors tend to be attracted by grateful rewards, while serial backers wish to be rewarded with product-related items.

Cultural Differences in Consumer Responses to Celebrities Acting Immorally

In-Hye Kang, University of North Carolina at Greensboro, USA
Taehoon Park, Florida Gulf Coast University, USA

EXTENDED ABSTRACT

Scandals involving celebrities' moral misconduct are common in both Western and Eastern cultures. Prior literature examined consumer responses to these scandals in Western countries (e.g., Bhattacharjee et al., 2013; Lee & Kwak, 2016) while paying little attention to Eastern countries. We examine the cross-cultural differences in consumers' responses to celebrities engaged in moral transgressions and the brands they endorse.

We propose that Eastern (vs. Western) consumers show lower support for celebrities who have acted immorally. Different cultures promote different styles of thinking (e.g., Nisbett et al., 2001), such that Westerners tend to view the world as consisting of independent, isolated objects (analytic thinking), whereas Easterners tend to view the world as composed of interconnected objects and events (holistic thinking). Building on this prior work, we argue that Eastern (vs. Western) consumers would have a stronger belief that different traits within an individual (i.e., competence and morality in our context) are inherently connected. Because of this belief in the association, we expect that Eastern (vs. Western) consumers will engage in less moral decoupling—separating the judgments about celebrities' morality from judgments about their competence in the professional domain (Bhattacharjee et al., 2013). This difference in moral decoupling will, in turn, lead to lower consumer support for celebrity transgressors in Eastern (vs. Western) culture.

Building on the proposed process, we identify a moderating variable: transgression relevance. When a transgression is relevant (vs. not relevant) to the domain of competence, consumers in the U.S. find it more difficult to engage in moral decoupling (Bhattacharjee et al., 2013). However, if Eastern consumers have a belief that one's competence and morality are interconnected as we propose, they should not engage in moral decoupling regardless of high versus low transgression relevance. Hence, we expect that the high (vs. low) transgression relevance would reduce moral decoupling and consumer support for Western consumers, not for Eastern consumers. Looking at the other way, we expect that the effect of Eastern (vs. Western) cultures on lowering moral decoupling and consumer support will be attenuated when transgression relevance is high.

In the studies, we examined two countries, the U.S. and South Korea, to represent cultures with high analytic versus holistic thinking styles, respectively (Choi et al., 2007). We first ran a pretest to identify moral transgressions that were perceived as equally immoral in the two countries to use in the main studies (extramarital affair, intoxicated driving, and taking steroids).

In Study 1, participants read a scenario about a popular actress who had been confirmed to engage in an extramarital affair. As predicted, Korean (vs. U.S.) participants showed lower support for the actress ($p < .001$) and less moral decoupling ($p < .001$). Moral decoupling significantly mediated the effect of culture on consumer support.

Study 2 tested the multi-step mechanism that the cultural effect on consumer support is mediated by consumers' belief in the association between morality and competence and subsequent moral decoupling. Participants read a scenario in which a famous baseball player was confirmed to drive while intoxicated. Korean (vs. U.S.) participants showed lower support for the baseball player ($p < .001$) and less moral decoupling ($p < .001$). Korean (vs. U.S.) participants reported a greater belief in the association between morality and competence ($p < .001$). A proposed serial mediation path was significant.

Study 3 tested the moderating role of transgression relevance. The procedure was identical to Study 2 except for the transgression relevance manipulation. In the [low / high] relevance condition, participants read that a baseball player [drove while intoxicated / took steroids]. We found a significant interaction between culture and transgression relevance on consumer support ($p = .015$). In the low relevance condition, Korean (vs. American) participants showed lower support for the baseball player ($p < .001$). In the high relevance condition, although still significant, the effect of culture on consumer support was significantly reduced ($p < .001$). Moreover, as expected, U.S. participants showed lower support when the transgression relevance was low (vs. high; $p = .006$). Korean participants did not show any difference in their support based on the transgression relevance ($p = .57$). The same pattern of results emerged for moral decoupling. A moderated mediation analysis revealed a significant higher-order interaction, suggesting that the indirect effect of moral decoupling was significantly attenuated in the high (vs. low) relevance condition.

Study 4 examined whether the cultural effect on celebrity support would extend to consumer support for the endorsed brand. We predicted that if an endorsed brand decides to retain the celebrity endorser, Eastern (vs. Western) consumers would indicate a lower brand attitude. In contrast, we predicted that if an endorsed brand dismisses the celebrity endorser, the negative effect of Eastern (vs. Western) cultures on brand attitude would be attenuated.

Participants read a scenario that a competent basketball player, who had been an active brand endorser of a sports drink brand, engaged in an extramarital affair. In the [retain / dismiss] condition, the company decided to [keep / end] its brand endorsement contract with the basketball player. As predicted, there was a significant interaction between culture and the brand's decision on brand attitude ($p < .001$). Korean (vs. American) participants showed a less favorable brand attitude in the retain condition ($p < .001$), but not in the dismiss condition ($p = .18$). With regards to support for the basketball player, as expected, only the main effect of culture was significant ($p < .001$), such that Korean (vs. U.S.) participants showed lower support. A moderated mediation analysis revealed that celebrity support significantly mediated the cultural effect on brand attitude when the company retained the celebrity, but not when the company dismissed the celebrity.

Across the studies, we ruled out several alternative explanations, including moral rationalization, deontology, consequentialism, perceived importance of morality over other traits, and perceived responsibility of celebrities. Theoretically, our findings contribute to the literature on consumer moral judgment and styles of thinking. Managerially, our findings provide brand managers with practical guidance regarding culturally specific risk management strategies in the use of celebrity endorsers.

Kawaii Women: Empowered, or, Entrapped?

Aparna Kansal, Indian Institute of Management Calcutta, India
Krishanu Rakshit, Indian Institute of Management Calcutta, India

EXTENDED ABSTRACT

Marxist philosopher Gramsci pointed out that societies are, in general, realm of consent, and Althusser (1970) extended this understanding by defining basic institutions of society as sites of control and power. As subcultures attempt to forge resistances to these established power structures, they ironically seem to reinstate the power structures. This paper focuses on the *Kawaii* subculture in Japan and how it impacts its main participants, Japanese women who attempted to break the power hierarchy in society. The paper also attempts to draw common grounds with the teenybopper subculture.

It is impossible to escape the intense cuteness that embodies the Japanese society. The prevalent soft objectification of young women; known as '*Kawaii*'; is frequently equated to 'cute' in the western world. However, *Kawaii* is a much more multilayered and gendered concept. "*Kawaii* means childlike; it celebrates sweet, adorable, innocent, pure, simple, genuine, gentle, vulnerable, weak, and inexperienced social behavior and physical appearances" (Kinsella,1995). In a way, *Kawaii* has saturated Japanese culture to make it a "standard aesthetic of everyday life" (McVeigh, 2000) but it is more readily applicable to women. The ideals of Japanese femininity are associated with the notion of *Kawaii* and it is a quality that is a prerequisite for a woman to have a place in the society (Mcveigh,1996). The official meaning of *Kawaii* from the 2000 edition of *Nihon Kokugo Daijiten* (Nittono, 2016):

"…. Kawaii (adjective) (1) looks miserable and raises sympathy. pitiable. pathetic. piteous. (2) attractive. Cannot be neglected. cherished. beloved. (3) has a sweet nature. lovely. (a) (of faces and figures of young women and children) adorable. attractive. (b) (like children) innocent. obedient. touching. (4) (of things and shapes) attractively small. small and beautiful. (5) trivial. pitiful. (used with slight disdain)."

Nittono (2016) points out, these "somewhat contradictory meanings" reflect the word's subjectivity, context-dependency, and situation-specificity, with which Japanese people today use and understand *Kawaii*. Nittono (2016) in his two-layered model of *Kawaii* argues that the basis of *Kawaii* stems from a protective nature towards babies, however, suggests that the understanding has a much broader psychological space- not just connected to babies. The other view presents a more darker aspect. It suggests that *Kawaii* draws people in through the pitiable nature (Ngai, 2012). Ngai asserts that cuteness has a sadistic element, crude aestheticization of powerlessness ("what we love because it submits to us").

Kawaii symbolizes the rebellion of of young teenage girls against the patriarchy and their expected role in the society. Japan's post-war success in reconstruction had been attributed to the dedication and the hard work of workforce; men picturized as hard-working salarymen and women as homemakers and child bearers. Women were expected to work only till marriage; leading young girls to adopt cuteness as an antithesis to adulthood (Hinton,2014). Kinsella (1995) highlights the craze of "fake child writing" using rounded/stylized characters gaining ground among young adults out the craze for cute. It was followed by the rise of infantile slang words, as when "sex" was referred to as *nyan nyan suru (*"to meow meow"). This led to the invention of other cute commodities in the market such as the Hello Kitty by Sanrio, which, incidentally, has no mouth and therefore appears non-threatening and vulnerable.

However, this very attempt to challenge the patriarchy through *Kawaii* did not succeed. Rather, it reinstated it further- leading to Japanese women having to embrace *Kawaii* to the very thing that started out to counter patriarchy has reinstated it even more, so much so, that today women in Japan have to be *Kawaii* to be accepted easily. This demonstrates the negative effect and unforeseen impact of *Kawaii* on the power hierarchy in the existing patriarchy. To illustrate the negative nature of *Kawaii*, this paper focuses on the portrayal of women in *Manga* and their acceptability among women readers to demonstrate how 'aestheticization of powerlessness' and its portrayal in media once again re-established the very power structure that women had tried to subvert by engaging in the *Kawaii* culture. Young girls displaying *Kawaii* characteristics are extremely common objects of sexual fantasies in a whole gamut of mainstream *animes* and *Mangas*. Pornography has also acquired many of aspects of the *Kawaii* aesthetic: "wholesome and innocent schoolgirls in sailor suits…have appeared in novels, erotic *Manga*, illustrations, photo magazines, and videos, and on internet sites" (Kinsella, 2002). The male onlooker gained authority through the position of experience. Women became "sexy" without being overtly sexualized, as if her sexuality was but imposed upon her by the male onlooker. *Kawaii* was so pervasive in Japan that it became a feminine ideal (Walker, 1995)- a new normal for the women to internalize. A subculture, which began as a "free choice" soon became a symbol of subordination to their male counterpart.

The teenybopper subculture rose to prominence in the mainstream media in the seventies and has become a mainstay ever since. On the surface, these two subcultures do not have much in common, but they are in fact, quite similar. Firstly, both are highly gendered and are ascribed mostly to female. Secondly, they provided a means for the female population to set themselves apart from their adult counterparts Whiteley (2000). The teenybopper culture gained popularity among the young females because it gave them an entity, which were the teen idols, whom they could fantasize about from the comfort of their room and engage in a "quasi-sexual ritual" (Hall & Jefferson,1976) and as resistance to the contemporary, strict sexual boundaries placed on the female gender. Both these subcultures started out resisting existing power hierarchy but in the end at best furthered the disparity across genders. Once again, the youth subculture that was started by the female as a resistance to the patriarchy re-established the existing normative. Similarly, *Kawaii* strips its object of any power and places the control in the hands of the subject. The effect of *Kawaii* is so damaging that the object, that is the woman, began to shift its identity to mold to the desires of the subject to continue to hold relevance.

Online Reviewers: Approaches to Online Reviewing, Narrative Voices And Emergent Market Interactions

Gwarlann de Kerviler, IESEG School of Management and LEM-CNRS 9221, France
Catherine Demangeot, IESEG School of Management and LEM-CNRS 9221, France

EXTENDED ABSTRACT

Having just finished reading a book, one might want to write an online review of it. The 'voice' may lean towards a personal, experiential perspective, such as: *"Having Type 1 diabetes, I felt different, as no family member has every had* [sic] *it in history. It helped me not feel alone, and that something so heartbreaking makes you stronger"*; a more descriptive and evaluative angle as in: *"This is a story of a young boy who is left with his undesirous extended family after his father and mother die. This book was full of adventure, mystery, and entertainment that pulls the reader into the story"*; or a more authoritative, contextualized viewpoint, as in *"If your children are in an 'Accelerated Reader' program at school and looking for books to keep them interested while improving their AR level ... look no more. The Harry Potter series is exactly what you'll need".* The above are extracts from actual reviews of the same book ("Harry Potter and the Sorcerer's Stone"), collected online (Amazon.com 2020), which all have the same star rating. Such variety in the texts reporting an experience is intriguing, yet limited attention has been given to what shapes reviewing. What might account for these widely different voices found in reviews about the same experience? What do the different voices say about the perspective of the authors of these reviews? Answers to these questions are of theoretical and practical importance, and the current research addresses them both. The vast literature around online reviewing acknowledges that reviews can be written differently but focuses on the effects on readers as opposed to explaining this heterogeneity.

Our research connects reviewing voice with the perceptions that reviewers form of the online reviewing activity. We draw from relational models theory (Fiske 1991, 1992), which stipulates that individuals develop mental models of social systems within which they interact in order to answer the questions: *"Who am I in relation to the other(s)"?* and *"What is appropriate behavior for myself and the other in this social interaction?"*, and further articulates that individuals draw from forms of sociality to function in all social systems. Our findings indicate that reviewers construct mental models of the online reviewing activity to develop representations of the online reviewing system (ORS) and know what role they have, as reviewers, in relation to other actors within that system. In turn, these mental models inform their reviewing voice. We conceptualize four interconnected dimensions of consumer participation to online reviewing systems, that we label 'the 4Rs': **R**epresentation of ORS, perceived **R**ole within ORS, **R**eviewing voice, and evolving **R**apport with market actors. These four Rs then serve to characterize three different reviewer profiles that have emerged from the analysis; they mirror Fiske's (1991) relational models (communal sharing, equality matching and market pricing) and have corresponding writing behaviors and interactions with market actors.

This research contributes to research on consumer-centric systems by uncovering mental models shaping their participation in ORSs. It adds to knowledge on consumers' participation in consumer-centric systems by identifying three distinct reviewer profiles (*communal sharers, conscientious contributors, and aspiring experts),* which co-exist within the same platforms. Third, it complements research on eWOM/online reviews by showing how a reviewing voice manifests its author's mental model of online reviewing.

Our data consists of 50 depth interviews conducted with online reviewers who also shared some of their reviews with us (610 reviews in total, 12.2 reviews per participant); 409 reviews collected on TripAdvisor about three regional tourist attractions; and 480 reviews collected on Amazon and authored by 96 reviewers (5 reviews per reviewer). The interviews covered participants' reviewing activity, perception of their role, stance towards other market actors in ORS and approach to review writing. We sought variance among participants in terms of age, gender, occupation, and reviewing experience; and among reviews collected in various platforms about different types of consumption experiences.

Data analysis proceeded in two stages. First, we used structural narrative analysis (e.g., Riessman 2005) to code 409 TripAdvisor reviews and 480 Amazon reviews authored by 96 reviewers, proceeding from an intra-review, to an intra-reviewer, then a cross-reviewer perspective, to ascertain that narrative voices remain consistent across platforms and across reviews authored by the same reviewer. Second, we analyzed the 50 interview transcripts using the constant comparative method. Three approaches to reviewing emerged from interviews. We then, independently, categorized the 610 reviews provided by participants into one of the three narrative voices identified in the first stage. Finally, we triangulated participants' approach to reviewing and their reviews' narrative voices.

Our rigorous process across two steps and the triangulation of respondents' own perspective gathered through interviews with their actual reviews enabled the emergence and validation of three distinct approaches to reviewing:

1) *The Communal sharing* views the ORS audience as an 'in-group' of other consumers, sharing similar pursuit of making the most from their consumption choices. They provide like-minded people with access to great consumption options, and protection from unfair or low-value options.

2) *The Equality matching* approach to reviewing views the ORS audience as connected by a mutual interest in improving market offers and experiences. Equality matching underlines a sense of obligation: by contributing versus just reading reviews, reviewers satisfy their need for equality.

3) *The Market pricing* approach views the ORS as a system offering a rewarding new market role. They gain status through their intensifying contributions, satisfying a need for achievement. They define themselves at the personal level as independent entities.

Using Fiske's (1991; 1992) relational models theory, we delineate three distinct stances towards reviewing, manifested in different reviewing voices, and in emergent forms of interaction with market actors. The communal sharing approach shows similarities with sharing (Belk 2010); the equality matching approach shows similarities with reciprocal gift giving (Giesler 2006); and the market pricing approach shows similarities with emergent social media influence activities (Kozinets et al. 2010; Scaraboto and Fischer 2013). Using relational models theory enables a consolidated comprehensive view of the nature of reviewers' participation.

Findings suggest that reviewers tend to consistently adopt one approach, across reviews and platforms, with market pricing as more emergent. Our results provide practitioners with insights on how ob-

servable reviews' narrative voice informs how reviewers perceive their role and the other market actors, enabling marketers to decide how best to respond online, adjust their offer, or communicate offline.

Managing Customer Response to Service Failure Through Exposure to Order

Jamel Khenfer, Zayed University, UAE
Olivier Trendel, Grenoble Ecole de Management, France

EXTENDED ABSTRACT

Although service organizations often aspire to deliver outstanding customer service, most—if not all—of them have had moments where they find themselves unable to meet a customer's expectations. These discrepancies constitute service failures (McCollough et al., 2000). When such failures are non-customer related, customers can react quite negatively, going as far as questioning their loyalty to the brand (McCollough et al., 2000; Vaerenberg et al., 2014).

According to attribution theory (Folkes, 1984), customers cope with the discrepancy between actual performance and expected performance by engaging in a process of causal reasoning whereby they attempt to determine why the service failed, and in doing so, attribute responsibility for the negative outcome. Customers do so by considering three factors: locus (i.e., whether the cause is customer- or firm-related), stability (i.e., whether the cause is temporary or fairly permanent), and controllability (i.e., whether the cause is under volitional control or constrained).

Prior works have investigated a wide range of post hoc solutions on how companies may deal with service failures such as recovery efforts (e.g., prompt handling, compensation) (McCollough et al., 2000; Vaerenberg et al., 2014). But dealing with service failure in hindsight means waiting for customers to develop negativity toward the brand. How then could service organizations influence the attribution process, before customers formulate attribution judgments, to keep brand approach at levels similar to the absence of service failure?

In this research, we propose that introducing order and predictability in the customer's environment as the service experience occurs may boost brand approach in contexts of service failure because exposure to order lowers people's willingness to attribute responsibility. When customers experience a service failure, causal reasoning is triggered not by the episode per se, but by the episode as a deviation from the expected (McGill, 1989). In other words, they start the process of attributing responsibility because their social and physical environments no longer appear orderly and predictable, but chaotic and unpredictable.

Supporting studies shows that activating sources of order boosts feelings of control, and as such, promotes willingness to invest effort in the pursuit of outcomes associated with important personal goals. For example, people exposed to subtle reminders of orderly patterns in the natural environment reported a greater willingness to take actions (Kay et al., 2014). Likewise, portraying corporations as interventionist agents that bring order in people's lives reversed the loss of motivation that normally occurs when the path toward the desired outcome seems overly confusing (Khenfer et al., 2017). In support of the unique power of orderly patterns, this effect disappeared when corporations were portrayed as merely benevolent.

Thus, we expected that exposure to order would lower attribution of responsibility following a service failure because it would elicit a sense that the world is an orderly, clear place where everything is predictable and understandable. In doing so, exposure to order should help keep brand approach to levels similar to situations where customers did not experience a service failure. Put differently, we hypothesized that exposure to order (vs. baseline or disorder) would increase brand approach in contexts of service failure.

We ran four online and lab experiments to test this hypothesis and examine boundary conditions.

Study 1 (N=424) used a 2-condition (service failure: no failure vs. failure) between-subjects design and established a relationship between people's chronic preference for orderly environments and brand approach in contexts of service failure. Specifically, the more individuals had a need to perceive the world as orderly and predictable, the less they were likely to purchase again a brand involved in a service failure.

Study 2 (N=238) used a 2 (service failure: no failure vs. failure) × 2 (exposure to order: baseline vs. order) × 2 (brand's involvement in failure: involved vs. non-involved) mixed design. While we found support for our hypothesis, we also identified locus of the cause of failure as a boundary condition. Following a service failure, exposure to order increased brand approach for the provider but not for third parties. We argued that, under such circumstances, consumers considered brands not ostensibly involved in service failure as disconnected from the chain of events that introduced chaos into their lives and therefore irrelevant in the attribution process.

Study 3 (N=403) used a 3 (service failure: no failure vs. unstable failure vs. stable failure) × 2 (exposure to order: disorder vs. order) between-subjects design. We sought to test our hypothesis and another boundary condition, that is, stability of the cause of failure. We predicted that our effect should disappear when failure appeared to have been predictable all along, that is, stable over time. While we found that exposure to order increased willingness to pay withdrawal charges despite an unexpected failure from the credit card company, we found no difference between participants who were exposed to order and those who were not when said failure was presented as a repeating event.

Study 4 (N=484) used a 4 (service failure: no failure vs. failure under constrained causes vs. failure under confounded causes vs. failure under volitional causes) × 2 (exposure to order: baseline vs. order) between-subjects design. Study 4 explored mechanism and tested a third boundary condition, that is, the perceived controllability of the cause of service failure. Specifically, we found that exposure to order lost its effect on brand approach following a service failure when the provider appeared in controlled of the causes that led to said failure.

This research demonstrates that reminders of orderly patterns can facilitate brand approach in contexts of service failure because exposure to order lowers customers' willingness to attribute responsibility. Yet, exposure to order should not be viewed as a magic wand. Its effect on brand approach is contingent on three factors: the locus, stability, and controllability of the causes of service failure. Overall, our work suggests that putting forth orderly patterns using the service environment can be a cost-effective method to help firms optimize damage control in contexts of non-customer-related failure.

A Relational Account of Powerlessness: The Role of the Attachment System in Consumer Inaction

Junha Kim, The Ohio State University, USA

EXTENDED ABSTRACT

Power is the basis of hierarchical differentiation and inherently relational (Magee and Galinsky 2008; Rucker, Galinsky, and Dubois 2012). Given the pyramid-shaped nature of hierarchies, most consumers will report to someone who has power over them, thus putting them in the position of low-power. The experience of low power can create challenges for consumers by inhibiting self-initiated exploratory actions (Anderson and Galinsky 2006; Galinsky, Gruenfeld, and Magee 2003). With the lion's share of people less prone to act, the impact of negative downstream consequences from powerlessness is substantial.

A recent review (Schaerer et al. 2018) suggests that unique phenomena come into play only during the experience of low power. Investigating the experience of low-power individuals provides a relational perspective through which to interpret and predict their behaviors. In the current work, we propose and test relational mechanism of powerlessness and inaction link. We propose that consumers are less likely to act (e.g., risk-taking and counter-offer in negotiations) because of the activation of anxious attachment and that this link would be weaken or even eliminated with the presence of secure attachment figures.

While attachment anxiety may not be the sole driver of inaction among low-power individuals, one way to illustrate that attachment anxiety is indeed an important factor in the powerlessness-inaction link is to examine whether how-power consumers also increase inaction when they experience state attachment anxiety. Making unpredictable and variable others temporarily salient will activate state attachment anxiety and put consumers to state attachment anxiety, deactivating their exploration system and inhibiting the powerful from taking exploratory action.

We present three studies that provide evidence that experiencing low power activates attachment anxiety which in turn decrease exploratory behaviors. We also demonstrate that activating attachment anxiety reduce the exploratory behaviors of the powerful consumers.

Study 1 (N = 102 Mturkers) was a one-factor (power: high vs. low) between-subject design. We instructed participants in the high-power (low-power) condition to recall and write about an experience in which they had power over others (in which someone else had power over them; Galinsky et al., 2003). After completing the power recall task, participants reported their state attachment anxiety and state attachment avoidance (Wei et al. 2007) with regard to how they felt "at the moment". Low-power participants reported greater state attachment anxiety ($M = 3.72$) than did high-power participants ($M = 3.17$, $p = .028$). There was no significant difference in state attachment avoidance between low-power participants ($M = 2.56$) and high-power participants ($M = 2.28$, $p = .198$). These results support that consumers with low power experience greater state attachment anxiety than those with high power.

Study 2 (N = 75 Mturkers) tested the consequences of heightened state attachment anxiety, using a blackjack game to measure inaction (Galinsky et al. 2003). We used the same recall task as in Study 1, then measured their state attachment anxiety and avoidance using State Adult Attachment Measure (SAAM; Gillath et al. 2009) on a 7-point scale. Finally, they decided whether to take a card or not in a game of blackjack. Participants in the low-power condition had greater state attachment anxiety ($M = 5.04$) than did those in the high-power condition ($M = 4.22$, $p = .013$). The effect of power on state attachment avoidance was not significant ($M = 2.91$ vs. $M = 2.52$, $p = .135$). Further, there was a significant indirect effect of low power on inaction via attachment anxiety, 95% CI = [.04, .91].

Study 3 (N = 97 Mturkers) examined the attachment anxiety mechanism by process of moderation approach (Spencer, Zanna, and Fong 2005). We used the propensity to negotiate as a measure of inhibited action (Magee, Galinsky, and Gruenfeld 2007). The study was a 2 (power: high vs. low) x 2 (attachment: anxiety vs. control). We used the same recall task to manipulate power. Participants in the attachment anxiety condition were asked to recall a situation in which they were anxious because they believed that focal person was reluctant to be as close as they would have wanted, but the participant still felt uncomfortable being without a close relationship and worried that the partner did not value them as much as they valued the partner (Baldwin et al. 1996; Mikulincer, Gillath, and Shaver 2002). We used a simple buyer-seller negotiation scenario as an indirect measure of approach/inhibition (Magee et al. 2007). Participants rated their likelihood to negotiate for a specific item ("You are buying a new car. How likely would you be to negotiate the price?") on a 7-point scale, where a lower likelihood indicates greater inhibition. The interaction between power and attachment on propensity to negotiation was significant, $p = .042$. Without attachment manipulation, participants in the low-power condition showed lower propensity to negotiate ($M = 5.42$) than those in the high-power condition ($M = 6.32$, $p = .045$). However, with attachment anxiety manipulation, both high- and low-power participants showed low level of negotiation propensity ($M_{\text{high-power}} = 5.04$ vs. $M_{\text{low-power}} = 5.42$, $p = .385$). These results further provide evidence that the direction of the effect is based on low power's increase in attachment anxiety, rather than high power's reduction in attachment anxiety.

In three studies we demonstrate that consumers who experience low power are less likely to take risk and show exploratory behaviors because of the activation of attachment anxiety. Our research contributes to the literature on consumer power. Prior research on consumer power has predominantly theorized based on control and compensatory motivation (see Rucker et al. 2012 for a review). However, the current research highlights a new consequence of powerlessness: attachment anxiety. Power is a relational construct existing only within social relationships (Emerson 1962; Fiske 1993; Salancik and Pfeffer 1974; Thibaut and Kelley 1959). In spite of its grounding in interpersonal connections, there has been a lack of systematic examination of how power, especially low power, is interlaced with mental representations of relationships.

The Influence of Store Spaciousness on Salience of Product Quality Versus Price During Product Evaluations

Yenee Kim, EDHEC Business School, France
Richard G. McFarland, ESSEC Business School, France

EXTENDED ABSTRACT

This research examines the complex structure of retail spaciousness and customer purchase behavior. Specifically, we examine how store layouts influence customers' product evaluations through feeling of confinement. How does the feeling of confinement induced through the retail environment impact the salience of product quality versus product price when consumers are evaluating products? We explore this question across five studies operationalizing feeling of confinement in diverse ways. The findings of this research reveal that feeling of confinement can lead to higher purchase intentions for products salient in quality compared to price. This shift can be explained by compensatory consumption theory as feeling of confinement can be perceived as a self-threat (Levav and Zhu 2008) and consumers are motivated to react to eliminate this threat through consumption (e.g., Rucker and Glinsky 2008; Cutright and Samper 2014). Specifically, product quality can be associated with self-worth (Truong and McColl 2011), whereas lower product price can be associated with lower self-worth and the inability to purchase higher quality products which can reinforce lack of freedom and lower self-worth.

Further, this research shows that perceived control which is the belief that one is in control of his/her outcomes in life and environment (White 1959) mediates the relationship between feeling of confinement and salience on product quality. In detail, feeling of confinement can decrease an individual's perceived control of the environment (Hui and Bateson 1991; Xu, Shen and Wyer 2011) which leads to higher purchase intentions on high quality products compared to low priced products in order to restore perceived control by creating a sense of power.

Across five studies, we examine the impact of feeling of confinement on purchase intentions and actual behavioral choices for products salient on quality vs. price. In Study 1, participants wrote about an experience when they felt confined or unconfined and then indicated purchase intentions for chocolate with a "Best Quality" or "Best Price" sign. Results revealed a significant interaction between feeling of confinement and product salience (p <.001). Specifically, consistent with our prediction, confined participants had higher purchase intentions for chocolate salient in quality than chocolate salient in price (p <.001). By contrast, unconfined participants did not differ in purchase intentions for chocolate salient in quality and price (p =.720).

Study 2 used articles and pictures of actual retail settings to prime feeling of confinement. Participants read a short article on retail stores with small vs. large layouts with photoshopped pictures and imagined their shopping experience in the store. Afterwards, participants indicated purchase intentions for a portable charger with a "Best Price" sign or "Best Quality". Results showed a significant interaction between feeling of confinement and product salience (p <.05). Further, confined participants had higher purchase intentions for portable chargers salient in quality than price (p =.052). On the other hand, non-confined participants did not have differences in purchase intentions between the two portable chargers (p =.37).

Study 3 replicated the results of the previous studies and ruled out mood as a potential alternative explanation. Participants saw a photo of an electronics store with wide vs. narrow aisles that were photoshopped and imagined their shopping experience in the store.

After, they indicated purchase intentions for a radio with a "Best Price" sign or "Best Quality". Then, they completed the PANAS (Watson, Clark, and Tellegen 1988) to measure current mood. Results revealed a significant interaction between feeling of confinement and product salience (p <.001). In detail, confined participants had higher purchase intentions for radios salient in quality than radios salient in price (p =.001). Whereas, there were no differences for purchase intentions between ratios salient in quality and price for non-confined participants (p =3.03). Further, there were no differences in positive and negative mood across the two conditions of confinement and non-confinement (p_{PA}=.216; p_{NA}=.713).

The objectives of Study 4a and Study 4b were to test the mediation of perceived control through an experimental-causal-chain design. Accordingly, we expect Study 4a to show that feeling of confinement leads to lower perceived control and Study 4b to show that lower perceived control leads to higher preference for products salient on quality versus products salient on price.

In Study 4a, participants wrote about a situation when they felt confined or unconfined and then rated their perceptions of perceived control (Lachman and Weaver 1998). As predicted, participants in the confinement condition reported lower levels of perceived control compared to participants in the non-confinement condition (p < .05).

In Study 4b, participants wrote about a personal experience on when they felt a heightened sense of control or loss of control and then indicated purchase intentions for a doormat with a "Best Quality" or "Best Price" sign. Results revealed a significant interaction between feeling of confinement and product salience (p< .05). Specifically, participants in the low perceived control condition had higher purchase intentions for doormats salient in quality than price (p< .05) whereas, there were no differences for purchase intentions between doormats salient in quality and price for participants in the high perceived control condition (p= .596).

The objective of Study 5 was to replicate the results of previous studies with behavioral choices using wide vs. narrow aisles. Participants walked through a narrow or wide aisle (narrow: 3 feet wide by 15 feet long; wide: 7 feet wide by 15 feet long) and either chose a chocolate package with a "Best Price" sign or "Best Quality" at the end of the aisle. Analyses revealed that participants in the narrow aisle condition significantly chose the "Best Quality" chocolate more than the participants in the wide aisle condition (p= .063).

Overall, this research contributes to theory as we develop a theoretical framework that integrates feeling of confinement and purchase intentions for product quality versus product price to advance our understanding of compensatory consumption. Further, we add to research examining how store atmospherics (Kotler 1973) and environmental psychology such as feeling of confinement affect decision making in the retail setting.

Mere Exposure to Unhealthy Smell Demotivates Health Behavior

Kyeongheui Kim, Sungkyunkwan University, South Korea
Suyeon Jung, University of Wisconsin-Madison, USA

EXTENDED ABSTRACT

Obesity has become a public health crisis. More than 1.9 billion adults are overweight and over 650 million of these are obese (WHO 2018). Past research on the effect of scent on food consumption has shown that prolonged exposure to an indulgent food-related scent (e.g., popcorn) led to decreased consumption of the food cued and other similar indulgent foods (Biswas and Szocs 2019; Biswas et al. 2014; Inman 2001; Rolls and Rolls 1997). These findings imply that smelling the scent of unhealthy foods can be helpful for a healthy consumption. However, no research has explored how the scent of unhealthy foods affects healthy behavior in *nonfood* context such as exercising.

In the present research, we propose that the scent of unhealthy foods (i.e., unhealthy scent), which motivates people to eat healthier foods, actually demotivates people from engaging in healthy behavior in nonfood context. Specifically, we argue that people who are exposed to an unhealthy scent are less motivated to exercise, more tempted to engage in hedonic behavior, and less satisfied with health-related behavior than those exposed to a relatively healthy scent or no scent.

Prior research has shown that smelling a scent can activate semantic associations of the scent (Holland, Hendriks and Aarts 2005) and an exposure to an appetitive odor or temptation prompts people to seek anything rewarding and pleasing, activating heightened hedonic thoughts and goals (Van Dillen, Papies, and Hofmann 2013; Wadhwa, Shiv and Nowlis 2008). The activated hedonic goal further can be used as an input for a subsequent behavior in an assimilative way, suppressing a competing health goal (Laran and Janiszewski 2009; Van Osselaer and Janiszewski 2012). Building on this literature, we hypothesize that unhealthy scent can demotivate people's engaging in healthy behavior, which is driven by the activation of a hedonic goal.

In **Study 1**, 120 participants smelled either a caramel scent or a peppermint scent before entering a gym to exercise. We recorded the time when participants entered the gym and the time when they finished exercising to measure the duration of exercise. We also measured their average exercise time at a gym. As predicted, participants who smelled the caramel scent ($M = 69.40$ minutes, $SD = 29.16$) took less time for exercising than those who smelled the peppermint scent ($M = 77.22$ minutes, $SD = 30.85$, $F(1,117) = 4.562$, $p = .035$, $\eta^2 = .04$). In addition, participants who smelled the caramel scent exercised much less than their average exercise time ($M = -10.27$ minutes, $SD = 30.75$), whereas those exposed to the peppermint scent exercised as usual ($M = 1.47$ minutes, $SD = 24.45$, $F(1,118) = 5.352$, $p = .022$, $\eta^2 = .04$).

In **Study 2,** we tested whether an unhealthy (vs. healthy) scent demotivates people's healthy behavior by measuring their exercise intensity given the same time duration. 130 undergraduates wearing a pedometer freely walked in a caramel- or a peppermint-scented room for four minutes. As predicted, participants exposed to the caramel scent ($M = 410$ steps, $SD = 134.46$) walked fewer steps than those exposed to the peppermint scent ($M = 489$ steps, $SD = 142.25$; $t(128) = 3.259$, $p = .001$, $d = .57$).

Study 3 used a 3 (scent: unhealthy vs. healthy vs. control) between-subjects design. 154 undergraduates were exposed to a caramel scent, a peppermint scent or no scent. Then, they indicated their preference between one-time coupon of a free personal training and a movie ticket and chose which one they would like to receive. Participants in the caramel scent condition less preferred the coupon for PT ($M = 1.04$, $SD = 1.65$) than those in the peppermint scent condition ($M = 2.23$, $SD = 2.20$, $F(1,102) = 9.650$, $p = .002$, $\eta^2 = .09$) or those in the control condition ($M = 2.30$, $SD = 2.60$, $F(1,99) = 8.482$, $p = .004$, $\eta^2 = .08$). In addition, fewer participants in the caramel scent condition (7 out of 51; 13.7%) chose the coupon for PT than those in the peppermint condition (18 out of 53; 34.0%, $\chi^2(1) = 5.829$, $p = .016$) or those in the control condition (20 out of 50; 40.0%, $\chi^2(1) = 8.899$, $p = .003$).

In **Study 4**, we tested whether the activation of a hedonic goal mediated the effect. 98 undergraduates smelled either a caramel scent or a peppermint scent and played a word search puzzle. After that, they watched a workout tutorial video and indicated how they evaluated the video. As predicted, the number of hedonic goal-related words found mediated the demotivating effect of the unhealthy scent on the evaluation of the workout video (indirect effect =.086, $SE = .055$, $CI_{95\%} = [.0089, .2342]$).

In **Study 5**, we predicted that when hedonic behavior is *nonfood-related*, unhealthy scent tempts people to engage in unhealthy behavior (i.e., demotivates healthy behavior) and thus increases their satisfaction with such behavior. On the other hand, as Biswas and Szocs (2019) suggested, when hedonic behavior is *food-related* (i.e., eating), unhealthy scent should demotivate people's engaging in unhealthy behavior and thus decrease their satisfaction with such behavior. This study employed a 2 (scent: unhealthy vs. healthy) x 2 (hedonic behavior: nonfood vs. food) between-subjects design. 208 undergraduates smelled either a caramel scent or a peppermint scent and played game (in the nonfood condition) or ate cookies (in the food condition). After that, they indicated satisfaction and perceived temptation to continue the activity. As predicted, there was a two-way interaction between scent and behavior on temptation ($F(1, 204) = 7.452$, $p = .007$, $\eta^2 = .04$) and on satisfaction ($F(1, 204) = 7.750$, $p = .006$, $\eta^2 = .04$). Participants who smelled the caramel (vs. peppermint) scent were *more* tempted to play game and more satisfied with it, whereas they were *less* tempted to eat cookies and less satisfied with cookies.

In sum, the current research provides novel findings that unlike in the context of food-related hedonic behavior, in nonfood-related behavioral context, unhealthy (vs. healthy) scent demotivates consumers' engaging in healthy behavior.

The "Achilles Heel" of Established Brands: The Effect of Brand Age on Consumers' Brand Choices

Yaeeun Kim, Temple University, USA
Joydeep Srivastava, Temple University, USA

EXTENDED ABSTRACT

Firms often focus on extrinsic attributes to create and shape brand associations that make up brand image (Keller 1993, 2003). One extrinsic attribute that firms often advertise is their age or year of establishment (YOE). Examples include both relatively established brands like Lindt ("Master Chocolatier Since 1845") and younger ones like Honey and Babies ("Est. 2014").

Although there is a large literature on the effects of extrinsic cues (Jiang et al. 2016), little research has been done on the effects of brand age on consumers (Desai, Kalra, and Murthi 2008). We examine the link between brand age and impressions of brand personality (Aaker 1997; Aggarwal and McGill 2007) to identify the conditions under which a more established or a younger brand is preferred. We hypothesize that there is a positive relationship between perception of product category innovativeness and preference for a younger brand (hypothesis 1); that this relationship is mediated by impressions of brand personality based on age stereotypes (hypothesis 2); and that it is attenuated when brands provide information that is inconsistent with age stereotypes (hypothesis 3).

In Study 1, participants (n = 211) were asked to choose between two brands in each of thirteen product categories; for example, "If you were shopping for a box of chocolates, which brand would you choose to purchase? Brand A, Since 1942, or Brand B, Since 2011?" The orders of product categories and brands were randomized. For each category, participants' perceptions of product category innovativeness were measured by averaging their responses to three seven-point items ($\alpha = .94$) adapted from Lee and O'Connor (2003).

A repeated-measures logistic regression revealed a significant effect of perceptions of product category innovativeness (= 0.37, SE = .07, Wald χ^2 = 32.12, Exp (= 1.45, $p < .001$) with no effects of order or two-way interaction (all p's > .159). Perceptions of product category innovativeness varied from 3.9 (table runner) to 5.9 (home security camera). Preferences for the established brand dropped from almost 74% (table runner) to 29% (home security camera) as perceptions of innovativeness increased. These findings support hypothesis 1.

In Study 2, participants (n = 325) were randomly assigned to one of four conditions in a 2 (product category: virtual reality headset and chocolates) × 2 (presentation order: Brand A established and Brand A young) between-subjects design. We generated a set of 90 potentially age-relevant traits (Aaker 1997; Rosen and Jerdee 1976) and asked participants to rate the extent on seven-point scales.

A logistic regression revealed a significant effect of product category (= 1.05, SE = .33, Wald χ^2 = 10.30, Exp (= 2.86, $p = .001$). No other effects were significant (all p's > .250). Principal component factor analyses (40 traits were retained) revealed a three-factor structure accounting for 66% of the total variance. The three factors were labeled "stableness" (22 traits, $\alpha = .97$), "dynamism" (14 traits, $\alpha = .96$), and "irrelevant" (4 traits, $\alpha = .90$).

Hayes' (2017) parallel multiple mediator test (PROCESS 4) showed that the indirect effect of product category innovativeness on brand choice was significant through stableness (indirect effect: = 0.86, SE = .27, CI 95% = [.444, 1.484]) and dynamism (indirect effect: = –0.35, SE = .16, CI 95% = [–.708, –.099]), but not the irrelevant dimension (indirect effect: = 0.10, SE = .09, CI 95% = [–.056, .309]). These findings support hypotheses 1 and 2.

Study 3 tested hypothesis 3 and explored the extent to which implicit theories of the self, or consumers' beliefs about the malleability of personality traits, affected the use of age stereotypes in the formation of brand personality impressions. Participants (n = 664) were randomly assigned to one condition in a 2 (product category: dried tea leaves and home security camera) × 2 (implicit theory salience: entity and incremental) × 2 (brand tagline: none and stereotype inconsistent) × 2 (presentation order: Brand A established first and Brand A young first) between-subjects design.

After reading a paragraph of a research article supporting either entity theory (i.e., personality traits are fixed) or incremental theory (i.e., traits can be changed; Chiu, Hong, and Dweck 1997), participants chose between an established brand and a young brand. We also measured participants' impressions of brand personality dimensions.

A logistic regression revealed a significant effect of product category as preference for the younger (vs. established) brand was significantly higher in the home security camera category (45.5%) than in the dried tea leaves category (16.8%; = 1.73, SE = .34, Wald χ^2 = 26.17, Exp (= 5.61, $p < .001$). Although no other effects were significant (all p's > .159), a two-way interaction between product category and brand tagline was significant (= –1.20, SE = .52, Wald χ^2 = 5.47, Exp (= 0.30, $p = .019$). Preferences for the younger brand in both the home security camera (60.1%) and dried tea leaves (16.4%) categories were more polarized when there was no tagline relative to the preferences for the younger brand (30.9% for home security cameras, 17.3% for dried tea leaves) when the tagline was stereotype inconsistent.

Hayes' (2017) parallel multiple moderated mediation test (PROCESS 7) showed that the indirect effect of product category on brand choice was significant through the stableness dimension when there was no brand tagline (= 1.02, SE = .28, CI 95% = [.540, 1.659]), but not when the brand tagline was stereotype inconsistent (CI 95% = [−.573, .326]). The indirect effect of product category on brand choice through the irrelevant dimension showed a similar pattern.

This research contributes to our understanding of how brand attributes shape brand impressions and thereby influence brand preferences. First, we demonstrate that consumer preferences for a relatively young brand increase with their perceptions of product category innovativeness. Second, we shed insight into the underlying process. Third, we highlight the malleability of brand impressions using stereotype inconsistent information. From a managerial perspective, our research identifies conditions under which an established brand or a younger brand will be preferred.

Positioning High- and Low-Status Brands in Social Media:
The Potential of Communication Style

Kristina Kleinlercher, University of St.Gallen, Switzerland
Tim M. Boettger, IESEG School of Management, France
Thomas Rudolph, University of St.Gallen, Switzerland

EXTENDED ABSTRACT

Social media (SM) have disrupted marketing communication by enabling brands to communicate with their customers in a very personal way (Labrecque 2014). While high-status brands may use SM to reach a broader and younger customer base and to be the topic of conversation, the free-for anybody claim on SM may jeopardize their exclusive brand image (Quach and Thaichon 2017). In the physical world, luxury brands preserve their exclusive image, for instance, by closing their front doors and keeping them guarded by well-dressed doormen (Dion and Arnould 2011). With no such ways available in SM, luxury brands are challenged to find new ways to make their brand exclusive in this "available for everyone" medium. Our research proposes that luxury brands may use their communication style (CS) in SM, i.e., the way in which they communicate, in order to convey social distance and exclusivity to their customers. We use three studies including field data and two online experiments to show that a brand's communication style is an important but neglected brand positioning tool in SM (see Table 1).

As an important characteristic of someone's CS personal pronouns are a powerful linguistic device to communicate different levels of social distance (Sela et al. 2012). We hypothesize that brands from different status levels use different frequencies of personal pronouns in their SM communication and thus convey different levels of social distance to their customers. Insights drawn from linguistics concerning fingerprints in writing (e.g., Burrows 2007) yield that people may use CSs to recognize and classify brands in SM. Engaging in personal communication with a cordial tone of voice may not be equally beneficial to all brands in social media. High-status luxury brands may prefer a more distant CS to preserve their exclusive image (Dion and Arnould 2011). For instance, Ward and Dahl (2014) show that condescending behavior among sales personnel in a luxury store increases consumers' regard for and willingness to pay for a brand.

Hypothesis 1: In SM, high-status brands use a more socially distant CS as measured by a higher frequency of personal pronouns used compared with low-status brands.

Hypothesis 2: In SM, consumers infer a higher brand status from a socially distant CS than from a socially close CS.

Hypothesis 3: Brand status moderates the effect of a brand's CS on customers' intention to like the brand's message in SM in such a way that high-status brands benefit less from a socially close CS and more from a socially distant CS than low-status brands do.

In Study 1, we classified 67 luxury or non-luxury fashion brands with a pretest among 228 students and collected up to 1,000 tweets for each of them. We used Craig's Zeta formula (Craig and Kinney 2009) to calculate sets of marker words and anti-marker words between luxury and non-luxury tests by splitting them into equally sized sections and comparing the frequency of specific words in each section. We find that non-luxury brands use *you(r)*, *we*, and *our* substantially more often than do luxury brands. Luxury brands tend to use prepositions such as *from* or *by* more often, which indicates that they rather use their brand name (e.g., "the new dress by Chanel") than personal pronouns (e.g., "our new dress") when tweeting about their products/activities.

In Study 2 we manipulated socially close and distant versions of 12 sample tweets. We used the first version of the German translation of you – Du – to manipulate a socially close and the more formal Sie to manipulate a socially distant CS. This manipulation of communication styles in SM has already been used in research (e.g., Steinmann et al. 2015). Participants received the socially distant (Sie) or the socially close (Du) version of each tweet. The content was counter-balanced. For each tweet, we asked participants to indicate the perceived status of the fashion brand and to rate the CS used. We reached a total of 167 (participants) x 12 (tweets) = 2,004 responses to tweets. We used a mixed model approach that treats both participants and stimuli (i.e., tweets) as random. We find a significant main effect of CS on status inference $\chi^2(1)=4.67$, p = .031) such that tweets with a more distant CS were associated with a more luxurious brand status.

In Study 3 we used a 2 (socially close versus socially distant CS) x 2 (high vs. low brand status) between-subjects design and a fictitious fashion brand, named Acadu. We presented Acadu as a high (low)-status brand by using expressions associated with luxury (non-luxury). We used *you* and *we* several times in the socially close condition and replaced them with *from Acadu, by Acadu, the*, and infinitives in the distant condition. We showed participants 12 tweets and asked them to indicate their intention to like the tweet on Twitter and their status perception of Acadu. We reached 315 (participants) x 12 (tweets) = 3,780 responses to tweets. Results reveal a significant interaction effect of CS and the brand status on customers' intention to like a tweet ($\chi^2(1)=3.32$, p = .068). For low-status brands, tweets with a more close CS show higher like intentions ($M_{distant}$ = 3.08 vs. M_{close} = 3.20, z = 2.61, p = .009). Customers' intention to like a tweet did not vary among close and distant CSs for high-status brands ($M_{distant}$ = 2.79 vs. M_{close} = 2.79, z = .02, p = .98).

Our work extends research on brand linguistics (Carnevale, Luna, and Lerma 2017). We show that luxury and non-luxury brand communicate differently in SM. Given that customers recognize different CS in SM and associate them with different brand status levels, the CS is a powerful brand positioning tool in SM. Furthermore, we show that using a socially distant CS in a very close medium such as SM does not harm high-status brands. Thus, we critically reflect on the widely held belief that SM communication has to adhere to the norms of informal and personal communication and give insights to luxury brands on how to use SM without jeopardizing their image.

Consumers Going Green Online: How Online Shopping Stimulates Sustainable Food Consumption

Svetlana Kolesova, Stockholm School of Economics, Sweden
Emelie Fröberg, Stockholm School of Economics, Sweden
Sara Rosengren, Stockholm School of Economics, Sweden

EXTENDED ABSTRACT

With the growing concerns about sustainability and the simultaneous growth of available sustainable alternatives, consumers frequently choose products with at least one environmental attribute even if they are not deliberately intending to purchase one (Tezer and Bodur 2019). Retailers and manufacturers are actively seeking new ways to engage consumers in sustainable consumption. However, even though sales of organic products are growing, the market share of sustainable products varies substantively across categories (Juhl et al. 2017). Considerably low demand for sustainable products and barriers for future growth might be partly explained by a large price premium over other products (Van Doorn and Verhoef 2015). There is also an attitude-behavior gap in the context of sustainable consumption, where ethical intentions are not aligned with actual behaviors (Carrington, Neville, and Whitwell 2014).

At the same time consumers in a search of more convenient and time-effective shopping have started to utilize online channels, even for their routine grocery shopping. Online shopping unlocks potential for consumers to benefit from shopping in several channels simultaneously and satisfy different consumer needs, but also generate more loyalty and profit to the retailers (Melis et al. 2016). With the switch between channels, consumers are likely to change their purchase behavior. Such, online grocery shopping is characterized by choosing fewer vices (Huyghe et al. 2016), more bulky and heavy (Chintagunta, Chu, and Cebollada 2014), less sensory products (Campo and Breulmans 2015) in consumer baskets, and by lower price sensitivity (Degeratu, Rangaswamy, and Wu 2000). Despite the extensive literature on sustainable consumption, previous research did not investigate if sustainable consumption could be enhanced when consumers switch from offline channel shopping to online or multichannel shopping.

We argue that sustainable consumption is driven by utilitarian goals since consumers are motivated to choose sustainable products due to their environmental and health benefits (Bezawada and Pauwels 2013, Van Doorn and Verhoef 2015). Online shopping also offers mainly utilitarian benefits such as search convenience, information availability, speed of delivery (Cervellon, Sylvie, and Ngobo 2015). We propose that the compatibility of goal orientation would impact consumer choices of sustainable products. Specifically, we thus argue that sustainable consumption is driven by utilitarian goals, which are more congruent with online shopping. If our proposal is accurate, actual online shopping behavior should be more sustainable than offline shopping behavior.

We use point-of-sales data from loyalty cards for a Nordic grocery retailer. The data come from one hypermarket in a mid-sized city and the online store of the same hypermarket. We use a period of two years in total (March 16, 2014 - March 15, 2016), where the online channel was introduced on March 16, 2015.

For the analysis, we use a difference-in-difference (DID) estimation approach combined with propensity score matching. Employing difference-in-difference approach allows us to isolate the effect of adding an online channel to the existing offline channel by using a quasi-experiment. Specifically, this approach employs a pre-period (before the online channel introduction) versus post-period (after the online channel introduction) and control versus treatment household groups, that allows excluding other explanation to differences in the shopping behavior such as that household who start purchasing online (further "online households") are different in various behavioral and social characteristics compared to those who shop only offline ("offline households"). We also conducted additional analysis employing propensity score matching, which is a common technique in consumer and marketing research to reduce the selection bias and address possible confounding (Wang, Malthouse, and Krishnamurthi 2015). We match 400 pairs of online and offline households based on Euclidean distances of propensity scores that we estimate using logistic regression with independent variables Recency, Frequency, Monetary values (cf. McCarty and Hastak 2007), Volume (cf. Hernant and Rosengren 2017), and Distance to offline store (cf. Pozzi 2013).

Comparing online and offline behavior, we observe that online consumers overall tend to buy relatively more sustainable grocery products ($\beta = 3.74$, $p < .01$). However, there is also a positive effect of online channel introduction on sustainable purchase behavior of online households (DID estimator) ($\beta = 2.38$, $p < .01$). Even after employing propensity score matching to analyze only similar online and offline household, the DID estimator is still positive and statistically significant, demonstrating that households when shopping online have 2.87% larger share of sustainable product in total sales ($\beta = 2.87$, $p < .05$) compared to matched offline households.

Our study shows that consumers who start shopping for groceries online from the same retailer they have shopped before, purchase a larger share of sustainable products compared to consumers who continue shopping only offline from the same retailer. This effect even holds when we address selection bias and analyze similar online and offline households, providing evidence that the online channel stimulates sustainable consumption among consumers. We suggest that this effect is explained by the compatibility of goal orientations. When consumers have more utilitarian goal orientation, they choose products that have more utilitarian benefits, such that when consumers shop online, they choose more sustainable products compared to when they shop offline.

The present study makes several research contributions. We extend the understanding of sustainable consumption by providing evidence that online shopping channel can be used effectively to stimulate sustainable consumption. Moreover, we contribute to the literature on multichannel retailing by demonstrating further differences in consumer behavior online and offline. Our data provide us with a natural experimental setting because we can trace precisely when the retailer introduced an online channel and consumers started purchasing online. Our results are important not only for the retailers and manufacturers but also for non-profit and governmental organizations because the study demonstrates that the digitalization of retailing stimulates sustainable consumption.

Familiar Foreigners? Collective Consumer Identity (De)Legitimation Dynamics in the Case of Repatriate Migrants

Sonja N. Kralj, University of Augsburg Michael Paul, University of Augsburg, Germany

EXTENDED ABSTRACT

Recently, countries all over the world have begun to invite emigrants to return to their home countries, motivated to counter shrinking populations, by labor shortage or the wish to reunite their people. Because of the favorable starting position vis-à-vis other migrants, one would expect that these returnees adapt easily to the consumer culture back home and will be seamlessly accepted. However, exploring the case of ethnic German repatriates from the former Soviet Union – in whose case consumption was operationalized as a legitimacy criterion –, we found out that their public collective consumer identity is rather negative instead. How did these Germans become Russians in the public view? In order to examine this phenomenon, we ask the following research questions. Which forces and dynamics are involved in the co-construction of the collective consumer identity of repatriates? What is the role of consumption and markets in this process? Addressing these questions, we illuminate the dynamic co-construction of migrants' collective consumer identity.

Most scholars have studied one-way, permanent migration from home to host country, much less is known about other migration patterns such as return migration and reacculturation in the homeland (Ndione, Rémy, and Bah 2017). Moreover, extant consumer acculturation literature has increasingly moved from investigating consumers' individual- level experiences and outcomes (Peñaloza 1994) to exploring relational (Luedicke 2015), structural (Üstüner and Holt 2007), and institutional influences (Veresiu and Giesler 2018).

The latter have been portrayed as internally conflict-free, patterning consumer experience (Üstüner and Holt 2007) or prescribing and enacting a consumer identity without granting migrants much influence in shaping it (Veresiu and Giesler 2018). Theoretically, we build on legitimation and delegitimation, the process of granting or withdrawing legitimacy (Suddaby, Bitektine, and Haack 2017). According to Berger and Luckmann (1966), legitimation entails both cognitive explanation and normative justification, and may be given regulatively through laws and regulations (Scott 2001). Delegitimation is not just the withdrawal of legitimacy, but may also be associated with stigmatization (Suddaby et al. 2017). Other than existing literature, we focus solely on the macro-level co-construction of collective consumer identity in a deeply history-laden case of initially highly legitimate migrants, and find out that institutional forces may actually be contradictory in their ways of co-constructing migrants' collective identity.

Our concrete context is the repatriate migration of ethnic Germans from the former Soviet Union, who lived in the diaspora for generations since 1763, returned from 1951 on and who nowadays constitute the second largest group of people with migration background in Germany (Federal Statistical Office 2019). Our ethnography contains triangulated interview, field, archival, and netnographic data. We conducted 56 interviews in total with repatriate and indigenous consumers as well as institutional representatives. Field data include 551 photographs and videos taken during observations in the marketplace and at events.

Archival data include 197 newspaper articles, 13 court judgments as well as 259 documents representing policy-making and repatriate istitutiojnal work, such as speeches. Netnographic data currently includes 12 YouTube videos with 1,330 comments. Data have been analyzed in an interative process, adhering to Thompson's (1997) principles.

The four key forces we identified are policy-making, market exchange, repatriate institutional work, and repatriate consumer practices. All of them both legitimize and delegitimize repatriate consumers in the collective identity co-constitution trajectory.

Delegitimation dominates these dynamics, as we found much evidence of stigmatization.

Thus, the broader societal identity ascribed to repatriates is polysemic at best, and outright negative at worst.

Policy-making has granted high regulative legitimacy to repatriates in the form of immediate German citizenship and various financial benefits. Remarkably, the state operationalized consumption as a legitimacy criterion: only in case Germans had consumed in a specific way in the former Soviet Union and its successor states (for instance cooking German meals and celebrating German traditions) and formulated these consumption habits during the application process, they counted as 'proof of Germanness' and the migrants were allowed to repatriate. At the same time, this legitimation was delegitimizing, since the state legitimized a version of German consumer culture from 250 years ago, as the consumer culture had not developed much over time in the German diaspora communities. In terms of market exchange, repatriate consumers were suddenly able to participate in the market (in contrast to the Soviet socialist system), but they lacked appropriate market skills. Because of this, they were exploited by sly salesmen, as insurance agent Fabian (40) confirms: "People exploited them, definitely. Cancellation policies and liabilities were different back then, and another sales mentality prevailed. There was a real gold-digger atmosphere in the industry." Repatriate institutional work takes both the form of legitimizing attempts at integration as well as delegitimizing fragmentation. One association's traveling exhibition "shows with which firmness and fidelity they maintained their faith, their customs and traditions" (Landsmannschaft der Deutschen aus Russland e.V. 2016, p. 3), in contrast, many associations were founded which already in their name convey a Russian or Russian-speaking orientation. Lastly, repatriates' consumption practices may legitimize the migrant group predominantly in an online environment, as they advanced a youth subculture celebrating a specific Russian-oriented aesthetic. In contrast, their consumption practices have conveyed traditional values, as former social planner Karl described them as "very modest, they meticulously spent as little money as possible for groceries, Aldi [a German discounter] made money out of them."

Our paper extends consumer acculturation literature. First, we study an underresearched migration pattern which incorporates an important historical dimension (Ger et al. 2018), as repatriates' migration history stretches over centuries. Second, similar to Veresiu and Giesler (2018), our forces create a consumer subject, but we acknowledge migrant consumer practices are important in shaping migrant consumer identity as well.

Furthermore, Veresiu and Giesler's (2018) forces only work in one direction, namely legitimizing the migrant as "other." In contrast, our forces work in both directions. This way we uncover that institutions are actually inconsistent. Therefore, we may be blunt and say that not just migrants, but also institutional forces may have a "shattered identity" (Üstüner and Holt 2007).

iGoofed: How Consumers Assign Blame in Response to AI Accidents

Rebecca J. Krause-Galoni, Northwestern University, USA
Derek Rucker, Northwestern University, USA
Aparna A. Labroo, Northwestern University, USA

EXTENDED ABSTRACT

With the rise in viability of artificially intelligent (AI) technology, it is increasingly important to understand whether blame responses differ for AI agents versus humans. We demonstrate a "blame penalty:" people assign *more* blame to AI agents than humans for accidents due to differences in the counterfactuals consumers generate.

Blame assigned following an accident depends whether the agent *could have prevented* the accident (Alicke 2000). One signal of this is the generation of counterfactuals, or simulated versions of a past sequence of events in which some aspect of the sequence is altered, changing the outcome (Roese 1997). Generating a counterfactual about an agent can influence how blameworthy the agent seems (Creyer and Gürhan 1997; Wells and Gavanski 1989). For example, an individual who experiences a car accident might generate a counterfactual that it would have been avoided if the other driver had not been drunk, resulting in blame towards the drunk driver.

Consumers generate more counterfactuals when expected norms are violated (Byrne 2002; Roese 1997; Sanna and Turley 1996). Despite their recent growth, AI agents represent a departure from the norm. Therefore, we propose consumers generate more counterfactuals that an accident could have been avoided when it involves an AI agent than a human, and accordingly assign more blame.

Across four studies, including six weeks of Twitter data, we find evidence for the blame penalty of AI agents over humans after accidents due to counterfactuals. We also reveal when brands are instead blamed *less* for AI agent accidents. Specifically, when *perceived intent* (Alicke 2000; Malle, Guglielmo, and Monroe 2014) comes into play, humans are blamed more because AI agents are less capable of intention (Haslam 2006; Young and Monroe 2019).

Study 1

Method. Over 6 weeks, we scraped Twitter for posts related to accidents involving artificially intelligent (581 tweets) or human (7000 tweets) drivers and examined differences in blame-related language. We analyzed blame-related words in each Tweet based on a dictionary we created and validated (Humphreys 2010).

Results. Among the AI agent group, 53.5% of tweets contained blame-related content, compared to only 1.1% of non-AI tweets. A logistic regression revealed a significant effect of group on blame content: AI tweets were more likely to contain blame content than non-AI tweets ($B = 4.67$, $SE = 0.14$, $z = 32.68$, $p < .001$, 95% Confidence Interval (CI): [4.39, 4.95]).

Study 2

Method. In study 2 (N = 174 MTurkers, M_{age} = 35.2, 48.1% Female) participants read a mockup newspaper article that described a pedestrian killed in an accident with a [human/ AI/ not specified] Singlecorp truck driver. Participants answered the extent to which Singlecorp's driver was to blame for the accident and the level of punishment and punitive damages Singlecorp should receive (from Schkade, Sunstein, and Kahneman 2000).

Results. One-way ANOVAs revealed the AI was blamed more than the human or control condition agent ($F(2, 170) = 6.77$, $p = .001$, $\eta_p^2 = .074$); the AI agent's brand was punished more than the human or control agents' ($F(2, 171) = 11.53$, $p < .001$, $\eta_p^2 = .119$); and the AI agent's brand was charged more punitive damages than

the human or control agents' brands ($F(2, 125) = 5.00$, $p = .008$, $\eta_p^2 = .074$, see Table).

Study 3

Method. Study 3 (N=222 MTurkers, M_{age} = 35.4, 48.6% Female, preregistered on AsPredicted.org) tested for our proposed counterfactual generation process. Participants saw the same mockup news articles, answered the same questions about blame and punishment as in study 2, and listed their thoughts while making the decisions, rating these thoughts for counterfactual content.

Results. AI agents and their brands were blamed ($F(2, 218) = 3.95$, $p = .021$, $\eta_p^2 = .035$), punished ($F(2, 219) = 12.94$, $p < .001$, $\eta_p^2 = .106$), and charged ($F(2, 219) = 13.59$, $p < .001$, $\eta_p^2 = .110$) more than humans (see Table). A mediation analysis using the PROCESS macro (model 4) in SPSS with 5,000 bootstrapped samples (Hayes 2013) with agent type (AI vs. human) as the independent variable, standardized blame as the dependent variable, and standardized counterfactual rating as the mediator revealed a significant indirect effect (B = 0.14, SE = 0.06, 95% CI = [0.04, 0.28]) such that counterfactuals mediated the effects of agent on blame.

Study 4

Method. Study 4 (N = 177 MTurkers, M_{age} = 33.8, 47.5% Female, Preregistered on AsPredicted.org) tested whether AI agents would be blamed *less* than humans when intentions were ambiguous. Participants were told the family of a boy named Andy was suing a (human vs. AI) cleaning company after Andy sustained an injury. In all conditions, participants read the housekeeper sprayed cleaning fluid, which hit Andy in the eyes and caused his injuries. In the control condition, Andy pops up in front of the housekeeper's spray nozzle just as she/it is about to spray, leaving little ability to avoid the accident. In the ambiguous intent condition, Andy is being annoying and the woman [AI agent] turns and sprays him after a delay.

Results. Two-way ANOVAs showed significant interactions between agent condition (AI vs. human) and intent ambiguity condition (control vs. ambiguous) in predicting agent blame ($F(1, 172) = 29.66$, $p < .001$, $\eta_p^2 = .147$), brand punishment ($F(1, 172) = 11.01$, $p = .001$, $\eta_p^2 = .060$), and log-transformed punitive damages ($F(1, 170) = 8.33$, $p = .004$, $\eta_p^2 = .047$). AI agents were punished more in the control condition, but humans were punished more when intent was ambiguous (see Table).

Discussion

This research enriches the literature on blame, demonstrating when consumers blame AI agents differently than humans. AI agents suffer a "blame penalty" because they elicit certain counterfactuals from consumers. Our Twitter data show a real-world incidence of greater blame in tweets about accidents involving AI rather than human drivers. Understanding the psychology of the response to such accidents, and particularly interventions such as those explored in study 4 which can reverse the blame penalty for AI agents, can help brands manage the consumer response to AI.

Multi-Sensory Experiences in Retail Service Environments

Nina Krey, Rowan University, USA
Barry J. Babin, University of Mississippi, USA
Shuang Wu, Rowan University, USA
Karine Picot-Coupey, University of Rennes, France

EXTENDED ABSTRACT

The study of sensation in marketing contributes to the understanding of relationships between the intersection of consumer psychology, retail environments, and sensation in consumption (Bitner 1992; Krishna 2012). Sensations are inescapable in consumption and drive affective, cognitive, and physiological responses (e.g., Holbrook 1986). However, the explicit reference to the term "sensation" has become more aligned with *sensational* in the marketing literature. Thus, the literature lacks a way of accounting for consumers' varying sensitivities to sensations driven by retail or services environment. The contribution of this research is to explicate theoretically, and present a way operationally, to measure the construct of consumer need for sensation.

Within marketing studies, sensation appears loosely applied and consequently researchers incorporate diverse constructs under the sensation umbrella. In addition, common approaches focus on assessing sensory cues and stimulation of individual senses rather than sensation in unison (Spence et al. 2014). Yet a holistic consumer experience with multi-sensory inputs can create greater value for customers (Krishna, Cian, and Aydınoğlu 2017). Multiple studies support this holistic assessment of environments (e.g., Mattila and Wirtz 2001; Spence et al. 2014). However, while research acknowledges the importance of holistic perceptions of environments and products, the majority of studies still focus on individual senses or single sensory modalities (Coulter and Chowdhury 2006). Consequently, these theoretical underpinnings of multi-sensory research are also evident in sensation measures.

Existing instruments assessing sensational experiences remain closely related to risky behavior (Mehrabian and Russell 1974; Roth, Hammelstein, and Brahler 2007; Zuckerman 1990). While need for touch (NFT) does assess a person's preference for tactile information, it is limited to one sense (Peck and Childers 2003). While the Cross-Sensory Heterogeneity Index (CSHI) acknowledges different senses, its applicability is limited to sensory imagery. Lastly, the Sensory-Processing Sensitivity (SPS) tool captures neurological predispositions making it challenging to administer in survey research. Therefore, no current instrument captures sensation as the biochemical process of sensory stimulation. Furthermore, none of the scales appropriately reflect multi-sensory aspects of consumer sensation.

Therefore, this research follows well-established scale development procedures appropriate for multi-item measures including a comprehensive literature review and qualitative research (Churchill 1979; Gerbing and Anderson 1988). Study 1 generates preliminary scale items via focus group interviews on perceived sensitivity to sensory stimulation and importance of multi-sensory cues in environments (Zeithaml 1988). Results of the focus group interviews identify the importance of source of sensation, ambient scent, and crowding during consumption experiences. Multiple themes emerge about how sensations work in tandem, a focal sensation with supporting sensations, to help create a valuable consumer experience leading to a first pool of 70 initial scale items.

Study 2 first utilizes experts, who are marketing/sensory marketing academics, for item purification and then administers two online surveys for further item assessment. An examination of item distributions, item-total correlations, and communalities leaves a pool of 37 items. Study 3 assesses scale dimensionality of the 37 items with a US panel data (N = 224). Results confirm a two dimensional structure of Need for Sensation (NFS). Study 4 validates the dimensionality with confirmatory factor analysis (CFA) utilizing a new sample (N = 241). Results once again support the two-dimensional structure of NFS. Furthermore, nomological validity assessment confirms the relationship between NFS and established variables such as hedonic value, utilitarian value, and positive affect (Babin, Darden, and Griffin 1994; Hair et al. 2006; Mehrabian and Russell 1974).

This study takes on an exhaustive investigation of sensations contribution to value derived from consumption experiences. Multiple studies explore totality of sensation rather than sense-specific sensation. The key contribution of this research is the development of the NFS scale. NFS reflects an individual characteristic trait representing the tendency of consumers to utilize sensory stimulation to extract value from a consumption experience. The NFS scale encompasses two distinct dimension. Most importantly, instead of associating need for sensation with risky behavior, the new construct incorporates multi-sensory sensation experienced by consumers (e.g., Zuckerman 1990). As such, sensation is associated with incidental or every day sensation that individuals encounter during their daily routine. The new scale goes beyond the scope of traditional theoretical premises within marketing and psychology research by treating sensation holistically from all possible sources.

The present study provides an optimal starting point to further examine the impact of multi-sensory stimulation on consumer cognitive and behavioral responses. The NFS scale can be administered in future research to capture consumers' responses to multi-sensory cues in consumption environments and thus, contribute to the growing literature on multi-sensory marketing (Krishna, Cian, and Aydinoglu 2017). We lay out an agenda for future research involving the scale in understanding consumers' multisensory reactions to retail services environments.

The Future is Fleeting: How Ephemeral Brand Messages Impact Viewing Behavior

Aradhna Krishna, University of Michigan, USA
Ryan Elder, Brigham Young University, USA
Yeonjin Sung, University of Michigan, USA

EXTENDED ABSTRACT

Ephemeral messaging service, such as Snapchat and Instagram stories, allows consumers to send messages that disappear within a specified time after they are opened (Bayer et al. 2016). Our research arises from the observation that ephemerality introduces a new type of time limit. The traditional notion of a time limitation is through a deadline which refers to "until when one can avail of something"; in the messaging context, it means till one can avail of or read the message. Ephemeral messages break up the traditional time limitation into two phases: phase 1 ("opening time")—which is the time from receiving the message to opening it, and phase 2 ("seeing time")—which is the time from opening the message to the time one stops seeing it.

Phase 1 could have a time limit, but this is typically very long for ephemeral messages; phase 2, by definition, has a time limit (or ephemerality) where the ephemeral message is self-destroyed, and this is generally quite short. For example, while the maximum duration Snapchat allows for the viewing time of its disappearing messages is 10 seconds (phase 2 time limit or ephemerality), the messages can remain on the server for up to 30 days if they are not opened (phase 1 time limit; Snapchat Support 2018).

Despite the orthogonality of phase 1 ("opening time") and phase 2 ("seeing time"), we propose that ephemerality ("seeing time limit") impacts consumer decisions about "opening time", such that consumers choose to open more-ephemeral, faster disappearing, messages earlier than less-ephemeral, slower disappearing messages—behaving as if ephemeral messages have a shorter deadline for being opened when in fact they do not. Furthermore, we propose that this effect of the "seeing time limit" impacting "opening time" (ephemerality-urgency effect) is just an operationalization of the sense of urgency that "seeing time limit" (or ephemerality) creates.

Research on time limitation focuses on the traditional notion of deadlines. This type of time restriction has been shown to provide benefits to the marketers as it drives action towards their offerings. Inman, Peter, and Raghubir (1997) show, for example, that time restrictions on a deal tend to signal good value and thus increase purchase likelihood because of scarcity. In a similar vein, the immediacy of anticipatory regret prompts consumers to redeem a coupon as a coupon's expiration date (or time limit) approaches (Inman and McAlister 1994).

Time limits are closely linked to time pressure since time limits can induce time pressure if they lead to a feeling of stress in the individual (Ordonez and Benson 1997). Within a decision-making context, time pressure can cause individuals to more quickly and selectively process information (Payne, Bettman, and Johnson 1988). Individuals under time pressure are also more likely to choose versus defer choice (Dhar and Nowlis 1999).

Perception of time, however, is malleable, and people can feel more time pressure or urgency if they perceive themselves to have less time. Tu and Soman (2014) showed that when participants were asked to complete a task in 5 days ending in the present month, or 5 days ending in the next month, those in the former group initiated the task earlier. The results can be explained by participants in the "present month" feeling more time pressure, even though rationally the time was the same—the urgency was created through calendar categorization. A different mere urgency effect has been shown by

Zhu, Yang, and Hsee (2018), who demonstrate that people prefer to work on low-payoff tasks over high-payoff tasks when the former are perceived to be spuriously urgent whereas the latter are not.

Since ephemeral messaging is fairly recent (Snapchat started in 2011, Instagram in 2016, and Facebook in 2017), there is scant academic literature on ephemerality. Prior research has shown that ephemeral (vs. permanent) messaging increases immersion in the present experiences by anchoring recipient's attention to the present context (He and Kivetz 2015). Furthermore, ephemerality (vs. permanence) can lead to greater disclosure risks by reducing privacy concerns of the sender (Hofstetter et al. 2017). These findings show the consequences of ephemerality on behavior and decision making. They focus on ephemeral versus permanent (i.e. non-ephemeral) messages. We extend these findings on the consequences of ephemerality to ad viewing behavior, and to low versus high ephemerality (i.e., changing the phase 2 time limit to be long versus short; in permanent ads phase 2 is limitless). We examine if the time limit of phase 2, the "seeing time" (i.e., the level of ephemerality), impacts ad viewing behavior, specifically if it can impact phase 1 ("opening time").

We propose that ads that will disappear faster (higher ephemerality) will be opened earlier than ads that disappear more slowly (lower ephemerality). Although the opening time and seeing time are orthogonal to one another, and one should not influence the other, we propose that the urgency created by higher ephemerality in phase 2 will create a feeling of urgency and lead to earlier opening of the ad in phase 1. Our mere urgency effect is similar to prior research on mere urgency that we have discussed—where calendar categorization of time duration to do a task can impact perceived urgency and task initiation (Tu and Soman 2014), and where spurious urgency through irrelevant expiration dates can move people to work on less important tasks over more important ones (Zhu et al. 2018). We propose the following ephemerality-urgency effect:

Hypothesis 1: *Higher ephemerality will lead to greater urgency.*

We also show a boundary condition for the ephemerality-urgency effect by examining perceived control and liquid consumption. Liquid consumption refers to temporary and dematerialized access to products, while solid consumption refers to permanent and tangible ownership of products (Bardhi and Eckhardt 2017). Atasoy and Morewedge (2018) demonstrate that people value physical goods over digital goods because they feel greater psychological ownership to the former, which stems from greater perceived control. In the ephemerality context too, the same process could be at work. Qualitative reports suggest that ephemeral (vs. permanent) messaging also reduces control on the recipient's side—since the recipient cannot possess or control the disappearing messages—while restoring feelings of control on the sender's side (Billings et al. 2017; Hofstetter et al. 2017).

In our context, people receive rather than send ephemeral messages and therefore feel lower control the more ephemeral the messages are. We also know that a lower feeling of control results in greater approach motivation because this is a means of coping by regaining control (Greenaway et al. 2015). In an ephemeral advertising context, approach motivation would be manifested in a sense of

urgency. Thus, higher ephemerality would result in lower perceived control and thereby higher urgency. If indeed this is the process for our ephemerality-urgency effect, the effect should be weaker for those who feel less control and thus are already inclined to approach and open the ads earlier.

Hypothesis 2:   The ephemerality-urgency effect will be attenuated for people who have less perceived control.

We test these hypotheses in eight studies. Study 1a tests the ephemerality-urgency effect using ad opening time as the dependent variable. Study 1b replicates the effect of study 1a, with a comprehension check for ephemerality. Study 2 tests the ephemerality-urgency effect using eye-tracking to capture initial attention. Study 3 uses stated perceived urgency as the dependent variable. Study 4 directly manipulates urgency to show a process through moderation. Study 5 tests for a boundary condition by exploring the role of perceived control on the ephemerality- urgency effect. Studies 6a and 6b test the ephemerality-urgency effect using choice as the dependent variable.

We start by looking at ephemeral ads presented in an online news website setting. Building on the notion that advertising is a form of message that firms send to their consumers, we examine whether consumers choose to see an advertisement earlier if it is more versus less ephemeral. From studies 1a to 5, participants were presented with a fictitious news website that had a banner advertisement. They were told to read the news and to click and view the advertisement. They read "Once you click on the advertisement, it will be available to view for 10 seconds (10 minutes) and then will disappear", in the high (low) ephemerality condition. When they clicked on the banner, participants could view the advertisement as long as they wanted, but within the maximum viewing time. After they finished seeing the ad, they could resume reading news articles. For time data in all studies, we analyze log-latencies (Robinson 2007) but report mean values in seconds to increase interpretability. We report results for only those who were correct on our manipulation check ("What was the maximum time you could view the advertisement?" Participants chose their response from the two options: 10 seconds or 10 minutes). Analyses including all participants did not change the direction and significance of all our results.

Study 1a (N=148) found that people in the high (vs. low) ephemerality condition clicked on the advertisement earlier (M_{High}=23.77 vs. M_{Low}=40.00; t(146)=−2.28, p=.024), supporting our hypothesis (H1). From study 1b on, we gave comprehension check questions before participants could see the website to ensure that participants understood the nuanced concept of ephemerality. Again, study 1b (N=180) found that people in the high (vs. low) ephemerality condition clicked on the advertisement earlier (M_{High}=42.12 vs. M_{Low}=66.98; t(178)=−3.12, p=.002).

Study 2 (N=185) employed an eye-tracking technology to provide additional support that ephemeral ads attract earlier attention. Supporting our hypothesis, participants in the high (vs. low) ephemerality condition fixated on the advertisement earlier (M_{High}=13.714 vs. M_{Low}=18.627; t(183)=−2.06, p=.041).

Study 3 (N=180) sought to directly measure felt urgency by using seven items of perceived urgency (α=.93; e.g. "I would feel pressed for time while I am browsing the website"; Suri and Monroe (2003)). In this study, we also include a permanent condition, in which participants were told, "Once you click on the advertisement, it will be available to view for as long as you wish." After participants read the instructions on news articles and advertisements, they responded to the perceived urgency scale. The main effect of ephemerality on perceived urgency (F(2,177)=23.44, p<.001) was significant. Specifically, high ephemerality led to greater perceived urgency than both the low ephemerality (M_{High}=4.58 vs. M_{Low}=3.15; t(177)=4.20, p<.001) and permanent conditions (M_{High}=4.58 vs. $M_{Permanent}$=2.27; t(177)=6.75, p<.001). Low ephemerality also led to greater perceived urgency than the permanent condition (M_{Low}=3.15 vs. $M_{Permanent}$=2.27; t(177)=2.50, p<.05).

Study 4 (N=383) manipulated urgency directly in the advertisement by changing the year of the event that was advertised in the ad. In the high (low) urgency condition, the banner ad showed that the event would take place in 2020 (2023), which is the year that this experiment was run. If urgency indeed drives earlier opening times for messages with higher (vs. lower) ephemerality, then externally decreasing urgency should result in a moderation of the ephemerality-urgency effect. The main effect of ephemerality ($M_{HighEphemerality}$=43.98 vs. $M_{LowEphemerality}$=90.22; F(1,379)=25.05, p<.001) and the main effect of urgency ($M_{HighUrgency}$=55.42 vs. $M_{LowUrgency}$=78.79; F(1,379)=13.57, p<.001) on ad opening time were significant. The latter shows that our external manipulation of urgency worked. More importantly, the interaction between ephemerality and urgency on ad opening time was also significant (F(1,379)=30.20, p<.001). Specifically, when urgency was high, the ephemerality- urgency effect was significant ($M_{HighEphemerality}$=17.45 vs. $M_{LowEphemerality}$=93.38; t(379)=−7.36, p<.001). When urgency was low, the ephemerality-urgency effect was attenuated ($M_{HighEphemerality}$=70.51 vs. $M_{LowEphemerality}$=87.07; t(379)=.35, p=.272).

Study 5 (N=372) examined the role of perceived control (H2). Participants first responded to the measure of perceived control (e.g. "I am in control of my own life"; Ma and Kay 2017). Subsequent procedures were identical to those of study 1b. A regression on ad opening time revealed the main effect of ephemerality (M_{High}=81.84 vs. M_{Low}=129.66; b=−.47, t(368)=−3.57, p<.001). The main effect of perceived control indicated that lower perceived control was associated with earlier ad opening (b=.16, t(368)=2.74, p=.006), supporting our hypothesis that feelings of low control trigger approach motivation. Importantly, there was an interaction between ephemerality and control (b=−.21, t(368)=−2.60, p=.010; see figure 1).

People feeling high (+1SD) control opened the 10-second (vs. 10-minute) ad earlier (b=−.82, t(368)=−4.36, p<.001), but people feeling low (−1SD) control did not (b=−.13, t(368)=−.69, p=.493).

Studies 6a and 6b test for robustness of the ephemerality-urgency effect in a different experimental setting, and also moves beyond advertising to explore the impact of ephemerality in another domain where ephemerality is inherent in the product characteristics. Additionally, we provide a more externally valid manipulation of ephemerality, removing the need for comprehension checks, and explore the downstream consequences of ephemerality on choice.

Participants in studies 6a (N=200) and 6b (N=200) saw an online video streaming website and were asked which of two movies they would like to watch first. Note that rental videos are ephemeral in nature because they can be opened at will (phase 1 is limitless), but once opened need to be viewed within a time limit (phase 2 has a time limit). In study 6a, the movie choice was between a purchased (permanent or no-ephemerality) and rented (ephemeral) option. In study 6b, the movie choice was between 2 rented options with higher and lower ephemerality. In one condition, Movie A was ephemeral, while Movie B was not as ephemeral (counterbalanced by movie title). Movie A was more likely to be chosen when it was rented (vs. owned; 77.2% vs. 51.5%; χ2(1)=14.44, p<.001) in study 6a, and when it had 24 hours (vs. 72 hours) access as its rental period (i.e., "You have not yet started watching this movie. Once you start, you'll

have access for 24 (72) hours"; 79% vs. 65%; $\chi2(1)=4.86$, *p*=.027) in study 6b.

Our research contributes theoretically to literature on ephemerality, time perception, and mere urgency. We show that the time limitation introduced by the new ephemeral media induces novel time perceptions for consumers—even though the phase 2 limit (seeing time limit) is orthogonal to the phase 1 limit (opening time limit), it still impacts opening time—and does so, even when consumers understand the two phases. This result has added to the literature on ephemerality and on time perception/time limits. We add to ephemerality literature by showing that ephemerality positively affects earlier stages in information processing through enhanced attention towards the ad that is higher in ephemerality. Our research is also the first to focus on different degrees of ephemerality rather than just comparing ephemeral messages to permanent messages. We also contribute to mere urgency literature by showing that ephemerality can create urgency even when there is no rational reason for this urgency; and that this urgency is due to loss of perceived control.

We provide managerial implications by demonstrating the impact of ephemerality in marketing settings—various ads within websites, and online video purchase and rental sites, extending prior research which has focused solely on social media settings (He and Kivetz 2016; Hofstetter et al. 2017). By using two experimental settings that allow for consumer interaction with products or ads, we reveal that ephemerality can affect consumers' intention to approach firm offerings. Furthermore, by showing that ephemerality captures earlier attention, we suggest a possible competitive edge that firms can adopt in the attention economy.

To Delete or to Keep: Effects of Data Request Frames on Consumers' Willingness to Share Their Personal Information

Smriti Kumar, University of Massachusetts, USA
Elizabeth Miller, University of Massachusetts, USA
George R. Milne, University of Massachusetts, USA

EXTENDED ABSTRACT:

Companies are struggling to understand how to give consumers a way to manage their data. Recent legislative actions provide incomplete guidance on this issue as different countries have adopted different practices (e.g., GDPR recommends firms explicitly give consumers the right to deletion, while most US firms require consumers to actively seek this option out). Thus, in this research, we explore the impact of three different data request frames (provide vs. keep vs. delete) on consumers' willingness to share information and how such frames interact with sensitivity of information type and type of recipient (e.g., close friend, trusted marketer, unknown marketer). Building on reactance theory and cognitive evaluation theory, we propose that different frames lead to different levels of autonomy causing a threat to consumers' freedom and subsequent willingness to share information. Consistent with this theory, we find that consumers share the least information in the keep frame and that this framing effect occurs for low and medium sensitive information, but not information high in sensitivity.

Introduction

Consumers' personal data is one of the most important assets of companies these days. Marketers gather consumer's personal data to deliver targeted ads to the consumers based on their online behavior. As personally targeted ads are more relevant and more interesting to consumers, tools such as behavioral targeting/ retargeting (showing consumers ad specific to their behavior/ recently seen products) (Lambrecht and Tucker 2013), keyword based targeting (showing ads to consumers based on the terms searched in search engines) (Desai, Shin, and Staelin 2014; Sayedi, Jerath, and Srinivasan 2014; Yang, Lu, and Lu 2014), content based targeting (showing ads based on what consumer has read) (Zhang and Katona 2012) improve a firm's capacity to better reach and persuade consumers.

On the one hand marketers are benefitted by the personal data consumers share, on the other hand consumers trade their personal information in everyday market-based exchanges to gain relational benefits from firms. For example, in order to get competitive rates on a mortgage loan, individuals often share their social security number; in order to find a suitable life partner, individuals share their personal details such as their height, weight, race etc. on dating sites. However, there are risks associated with the benefits consumers get such as identity theft (Milne 2003), increased annoyance because of selling data to third parties (Culnan 1993), and threat to anonymity (Zwick and Dholakia 2004). Increased consumer data disclosure has heightened concerns for consumers and policy makers who are looking for ways to control their sensitive information while maintaining the relational benefits.

With increased concerns about data privacy, the General Data Protection Regulation (GDPR) aims to provide a set of provisions to consumers to govern the processing of their personal data. One of these provisions is the 'right to erasure' or 'right to be forgotten' which recommends that firms enable consumers to delete some or all of their personal information from the firm's databases permanently if desired (Palmer 2019). In the European Union, GDPR has recommended firms to explicitly give the right to delete to their consumers, however in the United States most firms have implemented a weak

form of transparency, i.e. making this option available to consumers only if they actively seek it out (Kim, Barasz and John 2019).

Companies are struggling to figure out how to give consumers options to control their data. Until now, companies have been using opt-in/ opt-out approach to give consumers an option to have some control over their data by choosing to voluntarily share or not share their data. Literature suggests that opt-in and opt-out leads to differences in the extent of information sharing (Krishnamurthy 2001). Johnson, Bellman and Lohse (2002) showed that consumers share more in an opt-out scenario than in an opt-in scenario. The other aspect of permission marketing is framing. The literature has not said much about framing (except for positive or negative) within the opt-in and opt-out approaches. Consumers share more in negative framing than in positive framing (Johnson, Bellman and Lohse 2002). Building on existing literature on framing effects, it seems likely that how companies frame the data request option to consumers will impact their decisions regarding what information to share. Therefore, we contribute to this stream of research by looking at framing effects within opt-in approach.

This paper investigates three different frames that firms can use to request consumer information (i.e. asking consumers to *provide* personal information vs. asking them to *keep* (already) collected information vs. asking them to *delete* (already) collected information) and how they affect consumers' willingness to share sensitive information. Because the privacy literature identifies contextual factors such as the information type and the recipient of the data as having an effect on consumers' willingness to share their personal information, in this paper, we include the role of sensitivity of information types and the recipient as potential moderators on the effect of framing on consumers' willingness to share different information types.

Building on reactance theory (Brehm 1966) and cognitive evaluation theory (Deci and Ryan 1985), we propose that framing of the information request (provide vs. keep vs. delete) affects consumers' willingness to share sensitive information. Specifically, we argue different frames lead to different levels of perceived autonomy and less/ shared autonomy with the firms then elicits a sense of threat to consumers' freedom of choice leading to differences in willingness to share the personal information. We also propose that this process of reactance is mediated by negative emotions and cognition effect. *Framing of the request* is an important factor that has not been explored before and is practically relevant in the context of deletion option. As data is important for the firms, the effect of framing on information sharing is important to understand.

This research contributes to the framing literature as well as privacy literature by exploring how different deletion framings impacts consumers' willingness to share information. It also adds to our understanding of the moderating roles of contextual factors such as sensitivity of information types and recipients on the relationship of framing and the extent of information sharing.

Literature Review

According to Brehm's (1966) reactance theory, reactance is an unpleasant motivational arousal that occurs when an individual experience a threat or loss to his free will to perform some behavior. State of reactance serves as a motivator to restore the threatened or lost

freedom (Steindl, Jonas, Sittenthaler, Mattausch, Greenberg 2015). When an individual engages in a particular behavior, some aspect of the context initiates or regulates the outcome behavior (Deci and Ryan 1987). Individuals give psychological meaning to the contextual factors which leads to certain types of behaviors (Deci and Ryan 1985). One of the contextual factors we are discussing in this paper is framing of the deletion request as either 'to provide' the data or 'to keep' the (already) collected data or 'to delete' the (already) collected data. We propose that different types of framing will be construed as either supporting the autonomy (i.e. encouraging individuals to make their own choice) or controlling the behavior (pressuring individuals towards certain outcomes). Autonomy being a theoretical concept denotes an inner endorsement of one's actions. Autonomy/ control is not a dichotomous construct but rather a spectrum ranging from full autonomy to least autonomy (control) (Brehm and Brehm 1981). We suggest that sense of autonomy cued by the relationship expectation from the firm will depend on contextual factor (Frame). Different data request frames could mean potential different relationship intentions from the firms, which leads to different levels of autonomy. Less autonomy could be perceived as a threat. For example, when a firm is asking a consumer to provide his personal information, the data request could cue that the firm is interested in maintaining a relationship with the consumer and so far consumer has full control over his information (as it lies with the consumer and not with the firm) which signals full autonomy. This sense of full autonomy over which data to share or not share with the firm will not be perceived as a threat and the consumer will be willing to share the information. In the situation where the firm already has the consumer data and asks consumer which data to delete, this data request could signal a firm is not interested in maintaining the relationship with the consumer and consumer can decide which data to delete from the firm's data base. This relational cue signals that the autonomy is mostly with the consumer and he has to decide. This autonomy level would be less than in the provide request but still autonomy lies with the consumer. There should be some perceived threat and the consumer should be less willing to share the data as compared to provide condition but will still share the data. Finally, in the case that the firm already has consumer data and it asks consumer which data to keep, this signals that firm is interested in maintaining the relationship and already has access to the consumer data. This data request could signal an autonomy that is shared between the firm and the consumer. This shared autonomy could be perceived as a major threat to consumer's free will to their data and thus to restore the freedom, they will share less data (i.e. they will voluntarily choose to not keep the data). The willingness to share the data would be least in the keep data request as the threat to autonomy is the highest. Thus, we predict (H1) that consumer willingness to share information will be less with a 'keep' frame compared to (a) provide and (b) delete frames.

According to reactance theory, reactance (i.e. threat to freedom) leads to restricted behavior through negative emotions and negative cognition (Dillard and Shen 2005; Jonas, Graupmann, Niesta, Zanna, Traut-Mattauscg and Frey 2009). We propose that in keep condition, due to high threat, consumers will experience greater negative emotions and cognitions than as compared to in delete or provide condition, which will further lead to less willingness to share personal information. Therefore, we expect the difference in willingness to share among different frames is driven by negative emotions and negative cognition (H2).

We also examine the moderating roles of perceived information sensitivity and the recipient of the information on the amount of sensitive information shared. Based on previous research, we propose that the effect of framing on willingness to share information will be observed (vs. not be observed) when consumers perceive information to be less (vs. more) sensitive (H3) and when the recipient of information is a trusted (vs. unknown) party (H4).

Study 1: Framing Effect and Moderation through Perceived Sensitivity and Recipient

Our study tests our proposed framing effect i.e. information request in terms of providing vs. keeping vs. deleting leads consumers to share different extent of information (H1). We also test whether framing effect is moderated by the level of perceived sensitivity and the recipient of the information (H3 and H4).

Method

We implemented provide condition as when firm asks consumers' willingness to provide information; keep condition as when firm already has information and asks consumers' willingness to keep the information; and delete condition as when firm already has the information and asks consumers' willingness to delete the information. We use a list of 36 information types from Markoes, Milne and Peltier (2017). We ask participants to indicate their willingness to provide/keep/delete this information and to rate perceived sensitivity of each of these 36 information types. We also manipulated the scenario for the recipient of the information (a close friend vs. a trusted marketer vs. an unknown marketer).

Amazon Mechanical Turk (MTurk) workers (n= 511, Mage = 35-44 years, 51.2% females) completed this survey for a nominal payment. Participants were randomly assigned to one of the 9 conditions in a 3 Frame (provide vs. keep vs. delete) X 3 Recipient (friend vs. trusted marketer vs. unknown marketer) between subjects design. Perceived sensitivity was a within study factor. All the participants were asked to imagine that they created a new account on a social media app.

In friend condition, participants were asked to name one of their close friends. In trusted marketer condition, they were asked to name a social media app that they had a positive experience with and in unknown marketer condition, we told them that they have created an account on a new social media app InstaSocial which is similar to Instagram, Facebook and Snapchat. All participants were given a list of 36 information types. In the provide condition, they were asked "How willing would you be to provide each type of information to [close friend / trusted marketer/ InstaSocial]"? on a scale of (1- Definitely not willing to provide – 7- Definitely willing to provide). In the keep condition, they were told that social media app already populated their information taken from different online sources. "For each of the following types of information, please indicate whether you want to keep this information on the app to be shared with [close friend/ trusted marketer/ InstaSocial]"? on a scale of (1- Definitely do not want to keep – 7- Definitely want to keep). In delete condition, they were told the same story as in keep condition and were asked, "For each of the following types of information, please indicate whether you want to delete this information from [social media app/ trusted marketer/ InstaSocial]?" on a scale of (1- Definitely do not want to delete – 7- Definitely want to delete) [R].

Participants then reported their perceived sensitivity for each of the 36 information types by answering "How sensitive would you consider each of the following types of information?" on a scale of (1- Not Sensitive – 7 – Very Sensitive).

Results

Manipulation Check: We asked participants "In the task earlier in the survey, you were asked to _____ the information on the social media app" and participants had to select provide, keep,

or delete. Participants who didn't provide the correct response were eliminated, final N=511.

Repeated Measure ANOVA Analysis: We created three levels of sensitivity at -1SD (low), between -1SD to +1SD (medium) and above +1SD (high). Accordingly, we created three variables of willingness to share (WTS) at low, medium and high sensitivity levels. We ran a repeated measures ANOVA with 3 WTS dependent variables.

The repeated measure ANOVA revealed a significant main effect of framing ($F_{(2,502)} = 11.77$, p <0.01) on the willingness to share. Consistent with H1, participants in the keep condition were significantly less willing to share information ($M_{keep} = 2.51$, SD = 0.09) than in provide ($M_{provide} = 3.00$, SD = 0.08, p <0.001) and in delete ($M_{delete} = 3.09$, SD = 0.09, p <0.001) conditions. There was no significant difference in willingness to share in delete and provide (p > 0.05) conditions. Consistent with prior findings, there is a significant main effect of recipient of the information ($F_{(2,502)} = 59.41$, p <0.01) on the participant's willingness to share; participants in the close friend condition shared significantly more ($M_{friend} = 3.65$, SD = 0.09) than participants in trusted marketer ($M_{TM} = 2.52$, SD = 0.09, p<0.01) or unknown marketer ($M_{UM} = 2.43$, SD = 0.08 p<0.01) conditions. Interestingly, there was no difference in the willingness to share the information for the trusted and unknown marketer (p>0.05), which is different from what Markos, Labrecque, Milne (2018) found in their paper (partial support for H4). The analysis also showed a significant interaction between frame and sensitivity, Wilk's Lambda =0.92, ($F_{(4,1002)} = 10.99$, p <0.001). The framing effect persisted in low and medium sensitivity but mitigated for highly sensitive information types (see Table 1a) providing support for H3. For low and medium sensitive information, there was no difference between the provide ($M_{provide, low} = 4.2$; $M_{provide, medium} = 3.32$) and delete ($M_{delete, low} = 4.37$; $M_{delete, medium} = 3.25$, p>0.05; p>0.05) conditions. Confirming previous findings, there is a significant interaction between recipient and sensitivity, Wilk's Lambda = 0.93, ($F_{(4,1002)} = 8.67$, p<0.001). Participants share significantly more information with a close friend than a trusted marketer and unknown marketer and the extent of sharing decreases as sensitivity of information increases from low to high (see Table 1b). There is also a significant 3-way interaction between frame, sensitivity and recipient, Wilk's Lambda = 0.95 ($F_{(8,1002)} = 3.44$, p=< 0.001). Frame effect is strongest in the close friend condition and with increasing sensitivity, the extent of information sharing is decreasing (Table 1c). Figure 1 shows the willingness to share information for 36 information types with different perceived sensitivity for each of the recipient types.

Discussion

Our study shows that different frames affect the willingness to share the information. More specifically, consumers share significantly less in the keep condition as compared to provide and delete conditions. Overall, there was no difference in delete and provide conditions in the extent of information sharing. Framing effect was evident for low and medium sensitive information types but not for high, which was expected considering the risk of sharing information such as your SSN, passport id, credit card numbers etc. We also replicated the effect of recipient on willingness to share the information previously found in the literature. Extent of information sharing reduces as sensitivity of the information increases and trust in recipient decreases.

A second study will explore the mechanism (H2) underlying the observed framing effect using a 3(frame: provide, keep, delete) x 3(sensitivity: low, medium, high) design and including measures of negative emotions and negative cognition(time latencies and thoughts generated).

Implications

With the implementation of the General Data Protection Regulation (GDPR) and the California Consumer Privacy Act (CCPA), the consumer data privacy landscape is changing. Both laws include provisions for consumers to have data erased (GDPR) or deleted (CCPA), but the implications of how the ability to delete data will impact consumers and their data sharing has not been explored. In particular, while both laws assert that consumers have the right to request removal of their information, guidelines regarding how this option should be communicated to consumers have not been provided. Given existing work on framing effects in the consumer decision making literature, it seems likely that how this request is framed will impact consumer responses. Thus, in this research, we explore the implications of asking consumers to keep or delete information and compare this with the more traditional situation of consumers providing information. Our findings indicate that the framing of the request does indeed impact consumers' likelihood of sharing personal information, with consumers least likely to share information in the keep frame. Surprisingly, we do not observe differences in the amount of information shared between the delete and provide frames. An additional planned study will investigate the mechanism underlying these effects.

Together, these findings have practical implications for policy and for marketers by highlighting situations in which consumers may be more or less likely to share personal information. Further, by shedding light on the mechanism underlying these effects, this research contributes to the consumer literature on framing by highlighting new pathways by which linguistic frames impact decision-making. Finally, this research also contributes to the privacy literature by providing an increased understanding of how the option to delete information impacts sharing behavior and factors which moderate these effects.

Price Based Evaluation of Eco-Friendly Products: The Mediating Role of Perceived Investment by the Firm

Amogh Kumbargeri, Indian Institute of Management Ahmedabad, India
Sanjeev Tripathi, Indian Institute of Management Indore, India

EXTENDED ABSTRACT

In this research, we propose a novel lay belief – consumers believe that firms invest significantly more resources to develop and manufacture eco-friendly products as compared to conventional products. Lay theories or lay beliefs reflect people's common sense understanding of how the world works (Furnham 1988; Haws, Reczek, and Sample 2016. Research shows that firms primarily price their products either based on the cost of manufacturing or on the basis of the perceived value of the products (Liozu et al. 2012). In the case of eco-friendly products, green firms and popular media typically highlight a cost-based approach as the justification for the higher prices (Kathy 2019; "Why are eco-friendly products so damn expensive?", 2019). Common arguments include higher prices of sustainable raw materials, increased manufacturing cost due to small scale inefficient processes, and increased emphasis on fair wages (Kathy 2019). We argue that frequent exposure to high prices of eco-friendly products and such justifications for the high prices act as the source of the proposed belief.

If consumers hold such a lay belief, we expect consumers' green perception of the product (Gershoff and Frels, 2015), to be positively correlated with their perception of the resources invested by the firm in developing the product. Further, driven by the belief that green products need higher investment by the firm, we predict that consumers will perceive higher-priced products to be eco-friendlier as compared to lower-priced products, and this effect is mediated by the perceived investment of the firm in manufacturing the product. Formally stated,

Hypothesis 1:   *Green perception of an eco-friendly product is positively correlated with the perceived investment by the firm in developing and manufacturing the product*

Hypothesis 2:   *Consumers perceive higher-priced green products to be eco-friendlier as compared to lower priced green products*

Hypothesis 3:   *The effect of price on the green perception of eco-friendly products is mediated by the perceived investment by the firm in manufacturing the product*

Trust plays a very important role in the evaluation of eco-friendly products as the 'green' claims of such products are tough to verify and have to be accepted at face value (Darby and Karni 1973; Nelson 1970). When consumers do not trust green claims of the products, perceived investment by the firm will have no impact on the green perception of the product. Hence, we expect the perceived investment by the firm to mediate the effect of price on the green perception only when consumers trust the green claims. Formally,

Hypothesis 4:   *The mediation by perceived investment is moderated by the trust in the green claims*

In Study 1, all participants (N=106) saw the images and attribute details for two backpacks. One backpack was manipulated to be eco-friendlier than the other using product attributes and eco-certi-

fication. Participants comparatively evaluated the perceived investment and green perception for both backpacks. Results indicated that the green perception is significantly and positively correlated with the perceived investment, r=0.639, n=106, $p < .001$ (H1).

The objective of Study 2 was to test the predicted effect of the price of green perception (H2). Students (N = 151) from a large B-School volunteered to participate in this study. The study employed one factor (Price-level: High/Low) between-subjects design such that only the price of the target eco-friendly backpack differed in both the conditions. Results showed that participants in the high price-level condition ($M = 4.91$, $SD = 1.22$) rated the eco-friendly backpack significantly higher than those in low price-level ($M = 4.50$, $SD = .20$) condition, $t (1,149) = 2.051$, $p = .042$).

The goal of Study 3 (N = 51) was to rule out the perceived-quality based alternative account. This study employed a 2(Price-level: High/Low) x 2(Perceived Quality: High/Low) mixed design wherein the price-level is manipulated within-subjects, and perceived quality is manipulated between subjects. Participants were asked to evaluate the green perception of both high and low-priced backpacks in high as well as low-quality conditions. Results revealed that the price level has a significant main effect on green perception ($M_{High} = 4.726$, $M_{Low} = 4.386$; Wilks' Lambda = 0.863, $F (1, 49) = 7.808$, $p = .007$) and perceived quality has no significant main effect ($F (1, 49) = 1.686$, $p = .20$), moreover there is no significant interaction ($F (1, 49) = .539$, $p = .466$ between price-levels and perceived quality.

Study 4 (N = 134) aimed to test the proposed moderated mediation model (H3 and H4). This study employed a 2(Price level: High/Low) x 2(Trust in green claims: High/Low) between-subjects design. Results revealed a significant indirect effect for price on green perception through perceived investment (b = .63, SE = .24, 95% CI [.17, 1.12]). Further, a moderated-mediation analysis (Hayes process model 14) revealed a significant moderated mediation index (b = .70, SE = .37, 95% CI [.02, 1.46]).

Finally, in Study 5 (N=136), we aimed to demonstrate how the proposed lay belief can lead to biased evaluation of greenness. This study used a 3-condition (inconsistent vs. consistent vs. control) between-subjects design. In the inconsistent condition high-eco-friendly backpack was priced lower than the low-eco-friendly backpack and vice versa in the consistent condition. No price information was provided in the control condition. The results revealed that the green perception scores for the high-eco-friendly backpack in the inconsistent condition ($M = 5.23$, $SD = 1.34$) were significantly lower than in the control ($M = 5.82$, $SD = 0.62$; $t (68) = -2.308$, $p = .024$) and consistent ($M = 5.71$, $SD = 0.72$; $t (79) = -2.043$, $p = .044$) conditions.

Our findings make two important contributions. First, we extend the understanding of how consumers evaluate the greenness of eco-friendly products (Gershoff and Frels 2015; Pancer et al. 2017; Lee et al. 2017) by identifying the role of price. Second, we build over the existing literature on consumer lay theories (Raghunathan et al. 2006; Haws et al. 2016) by identifying a novel lay theory and testing its causal impact on information processing and consumer judgment.

Picture or Text Superiority? The Two Forces
of Element Size on Communication Effectiveness

Canice M. C. Kwan, The Open University of Hong Kong, Hong Kong, China
Chu (Ivy) Dang, The University of Hong Kong, Hong Kong, China
Yang Shi, Shenzhen University, China

EXTENDED ABSTRACT

Conventional wisdom suggests that a picture is worth a thousand words. Despite the large number of studies supporting this picture superiority notion, emerging evidence shows that enlarging pictures may sometimes hurt communication effectiveness (e.g., Kwan et al. 2017). Current understandings are however surprisingly limited regarding the allocation of surface size between pictures and text (i.e., element size). To reconcile the mixed effects concerning picture versus text superiority, this research provides a theoretical lens that disambiguates the element size effects along two routes—*impression formation* and *message persuasion*. We propose that these routes work in opposite directions in determining communication effectiveness. Depending on *product involvement* and *brand positioning*, the relative importance of impression and persuasion varies and leads one route to override the other.

Advertising research shows that pictures can create a holistic impression by evoking self-relevant narratives (Adaval and Wyer 1998) and emotion-laden responses (Miniard et al. 1991). Pictures also convey abstract qualities such as prestige (Pracejus et al. 2006). Rather than attempting to impress, however, many communications are designed to persuade (e.g., illustrating scientific findings). In these cases, the presence of pictures may shift attention away from text and interfere with the comprehension of verbal arguments (Wyer et al. 2008). Moreover, element size can serve as an indication of emphasis: the larger the text, the stronger the conviction it carries (Kwan et al. 2017). These findings suggest that enlarging pictures (relative to text) can facilitate impression formation while dampening message persuasion, producing opposing effects on communication.

So, when should practitioners allocate more space to pictures or to text? The answer concerns marketing objectives—if the goal is to *impress* or to *persuade*. We reason that enlarging pictures promotes the cognitive processes underlying impression formation while impeding the processes underlying message persuasion, and vice versa. As a result, pictorial size has a net positive effect in contexts weighted toward impression, and a net negative effect in more persuasive contexts. Concerning the relative importance of these marketing objectives, we find that product categories and brands vary systematically. This enables us to validate our reasoning by examining the moderating role of product involvement and brand positioning. Assuming that impression is likely emphasized over persuasion for high-involvement products and high-end brands, we predict that enlarging pictures produces more favorable responses for these products and brands.

We first identified a diversity of products across categories with established indicators of involvement (Laurent and Kapferer 1985). Then we determined a list of brands for each product category that includes high and low-end brands based on public rankings and industry reports. In later analyses, each brand was assigned a corresponding level of brand positioning and product involvement (high vs. low). This assignment was verified by judges who were unaware of the research purposes. Based on the list, we sampled posts from the Facebook business pages of the brands. We focused on Facebook cover photos because they are an essential component of all business pages, are under full control of managers, and are used strategically to convey a designated image and/or message to target audiences. From 114 pages across regions pertaining to 69 brands in 9 categories, we collected a total of 4,383 cover photos along with the number of likes for each post and other information about the pages. To measure element size, we leveraged EAST (Efficient and Accuracy Scene Text detector, Zhou et al. 2017), a deep learning-based computer vision technique. This technique automatically detects text elements in multiple colors, irregular fonts, and complex layout, and isolates them from backgrounds so that we can estimate the ratio of picture size to text size (i.e., size ratio; Pieters and Wedel 2004). Finally, we obtained an augmented dataset with all necessary statistics about the cover photos and business pages, the size ratio, and a list of products and brands coded with respect to the relative importance of the two marketing objectives.

In a series of multivariate regressions, we investigated the relationship between the size ratio and communication effectiveness (measured by the number of likes) by analyzing the moderation effect of product involvement and brand positioning. In addition, we controlled for the effect of relevant factors including the presence of text content and human faces, aspect ratio, visual complexity, and post duration. We also included random coefficients in the models to capture the effects of unobserved factors at the brand level and the product category level. Specifically, we first built a null model (model 1) with the size ratio and all control variables as predictors. Its results fit with the notion that enlarging pictures enhances communication effectiveness (i.e., the picture superiority notion). When we entered involvement (positioning) and its interaction with the size ratio in model 2 (model 3), however, we found that both involvement and positioning significantly moderated the size effect while the effect of all control variables remained as in the null model. As predicted, enlarging pictures was beneficial to high-end brands and detrimental to low-involvement products. We obtained significant effects of similar size and direction when entering both moderators and their interaction with the size ratio simultaneously (model 4). Results support the idea of coexistence between the effects suggested by the notions of picture and text superiority: enlarging pictures enhances (hinders) communication effectiveness when impression (persuasion) weighs more in the context.

Theoretically, this research sets out a lens to understand the differential effects of element size and shows that their dominance depends on *the objectives to impress and to persuade*. Managerially, our findings highlight the importance that to maximize effectiveness, practitioners should adjust element size strategically and without necessarily following conventional wisdom. It is possible that enlarging pictures can produce a negative effect when Tesla (a high-end brand) attempts to convey a persuasive message, and a positive effect when Crest (a low-involvement product) relates itself to upper strata. Practically, our present application of deep learning-based computer vision technique guides future endeavors to explore visual effects and generate insights from real-world big data sets on visual optimization and content customization.

A Commons Approach to Consumer Ethics

Mikko Laamanen, Emlyon Business School, France
Giana M. Eckhardt, Royal Holloway University of London, UK

EXTENDED ABSTRACT

Within consumer research, an understanding of consumer ethics has tended to focus on individual consumer's action in the marketplace: how and why consumers make decisions to buy ethically, how and why there is an attitude-behavior gap between what consumers say they care about and what their actual purchasing behavior looks like, and which mechanisms can be utilized to push consumers to more ethical purchasing (Devinney et al., 2010). The consumer ethics literature is premised on the notion of consumer responsibilization (see Giesler and Veresiu, 2014). Dominant market forces ascribe the consumer an obligation to address social and environmental issues through their consumption, reducing consumer agency to their capacity to make 'correct' choices in the marketplace. This literature has demonstrated the limitations of consumers acting on their ethical beliefs in the marketplace: to a large extent, the ethical consumer is a myth (Devinney et al., 2010). Miller (1998) points out that expecting the consumer to make an ethical choice, for instance, one good for the environment, often puts them at odds with another moral choice, such as doing the best thing for one's family. Thus, there is a need to think about other ways in which consumers can enact their agency to bring about change beyond their individual purchasing choices. Indeed, consumers resist being responsibilized (Eckhardt and Dobscha 2019), and there is evidence that they can turn to broader forms of action to address social issues, e.g. with political consumption (Dubuisson-Quellier, 2013; Micheletti, 2003).

Recent consumer research has brought forth a variety of 'alternative' structures–the sharing economy (Belk et al. 2019), access-based consumption (Bardhi and Eckhardt 2012) and collaborative consumption (Wahlen and Laamanen, 2017)–highlighting consumer-led exchange of goods, services and ideas mediated by reciprocal relations and technological platforms. Resource circulation can be connected to principles of sharing (Belk, 2010), mutuality (Arnould and Rose 2016) and householding (Laamanen et al., 2018; Sahakian, 2017). Configurations of interactions, responsibilities and infrastructures among consumers suggest a more collective approach for engaging in ethical consumption. That is, rather than being focused on individual choice in the marketplace, and individualized collective political action, such as whether to participate in a boycott or not, collective systems themselves can make a difference. Yet, sharing and access systems has been shown to not have resulted in expected societal benefits (e.g. Schor 2020) and rather have facilitated negative reciprocities and exclusion (e.g. Bardhi and Eckhardt 2012; Ladegaard, 2018).

To advance theorizing on how collective resource systems can create collectivized ethical action, we put forward a commons-based view. Commons are proposed as a cultural shift and a means for a more sustainable future (e.g. Helfrich and Bollier, 2019). This construct has yet to be fully explored in the consumer research literature. What has been explored to date dialogues with Hardin's (1968) "tragedy of the commons". In relation to consumption, the tragedy is framed as that when consumers don't feel a sense of ownership (and subsequent responsibility) or when actors in resources-sharing systems are not morally aligned to take care of shared resources (see Bardhi and Eckhardt 2012; Duffy et al., 2017; Shultz and Holbrook 1999). Ways to overcome the tragedy, as Shultz and Holbrook (1999) suggest, are increasing control through privatization, fees, partnerships and dialogue to manage individual engagement with common resources. Commons are, however, not merely pools of resources. Importantly, commons incorporate relational stewardship of governing the resource(s) in question as well as the commoners' relations with one another. This is known as the practice of commoning.

In contrast to Hardin, Elinor Ostrom (2010) suggests that the vitality of commons does not result from further enclosures but from a polycentric governance. Polycentric governance creates a process of rulemaking to allow citizen-led and democratic participation (see also Laamanen et al., 2020). This calls for the creation of citizen-based institutions to govern the commons, their resources and practices of engagement. The ensuing commons are self-sufficient and free from an external ruling authority; open, yet ideological, spaces for economic and solidaristic experimentation. In this paper, we propose a commons-based consumer ethics, which is founded on norms, practices and institutions (see table 1) as the basis for resources and relations in the commons.

We see this framework as providing a path forward for the consumer ethics literature which can go beyond the attitude behavior gap, for example, by highlighting infrastructures and other systemic aspects of consumption. For example, Laamanen and his coauthors (2018) demonstrate how commons communities create normative moral justifications for collective action. First, they contribute to social good and sustainability by increasing ability to participate in social interaction and sharing around common resources in the local setting. Second, their practice establishes an alternative valuation that allows participants to evaluate, value and trust each other's contributions to the community (e.g. receiving from the community as based on their need and giving back according to capacity). Third, local institutions build grassroots capacity where the community does not have to rely on established institutional governance models but create and rely on their norms and rules (supporting Ostrom's thesis). Finally, community norms and practice aim to reform the neoliberal subjectivity and institutions by engaging with and redefining the way in which individuals see themselves as economic actors and how they may collaborate with existing institutional forces (cf. Luedicke et al., 2010),

An introduction of a commons-based perspective to consumer ethics can redress the limits of the sustained focus on individual decision-making in consumption. Our approach can guide future empirical research examining consumers as the constructors of moral order and managers of shared resources and relations–commons and commoning–within their collectives.

Measuring Evidence For Causal Mediation When the Mediator is Not Directly Observed

Arash Laghaie, Goethe University Frankfurt, Germany
Thomas Otter, Goethe University Frankfurt, Germany

EXTENDED ABSTRACT

Mediation analysis is a tool to corroborate hypotheses about the process by which the experimental treatment brings about its effect on the dependent variable. Establishing mediation is fundamental to scientific research that seeks to understand "how the world works" in situationswhere the process connecting a manipulation to an outcome of interest is not directly observable. A finer process understanding itself is particularly important in situations where the manipulation under investigation brings about an effect one would like to control in the absence of direct control over the manipulation, e.g., the exposure to a virus, or in situations where the manipulation is required for other reasons, e.g., surgery. Knowledge of how to block the causal path from virus exposure to a disease through immunization helps avoid the negative consequences from the potential exposure to a virus, which cannot be directly controlled. Knowledge of how to block the transmission of nerve signals activated by a surgical incision makes it possible to conduct necessary surgery without the patient experiencing pain.

Finally, mediation is at the heart of a structural understanding of the world that would otherwise require a new theory for every manipulation studied. For example, the observation that color contrast (Thompson and Ince, 2013), typicality (Landwehr et al., 2011, 2013), exposure (Ferraroet al., 2008; Landwehr et al., 2017), or pronounceability (Alter and Oppenheimer, 2008; Song and Schwarz, 2009) manipulations all bring about effects on a variety of dependent variable mediated by processing fluency, parsimoniously structures our causal understanding of the world (Graf et al., 2018 . Relatedly, mediation defines subsets of variables that can be validly studied in isolation. For example, the understanding that the effect of variable production costs on demand is fully mediated by retail price allows for the exclusion of variable production costs from the price-demand model (and makes variable production costs a potential instrumental variable for price).

In the context of corroborating hypotheses about unobserved processes such as mediation, it is useful to distinguish between uncertainty about the strength of unobserved connections that are beyond questioning per se, and uncertainty about the connective structure itself. Empirical testing of the strength of connections in a given, undisputed model is a standard statistical exercise that may require sophistication nevertheless. Resolving uncertainty about the connective structure, and ideally establishing a unique causal interpretation of the connective structure supported by the data, is usually more difficult and often beyond reach in the context of observed data.

The goal of mediation analysis in practice squarely falls in the latter class of problems. When conducting mediation analysis, researchers do not ask for measures of coefficients in a model they know a priori. Instead, researchers ask what model generated the data. To this end, this paper provides tools and a procedure aimed at measuring data-based evidence for mediation. Our contribution is the synthesis of i) the causal identifiability of full mediation from observed variables (Glymour, 2001; Pearl, 2009), ii) Bayes factors as a measure of empirical evidence supporting full mediation (Nuijten et al., 2015), and iii) explicit models of measurement error (Holmbeck, 1997; Bolger, 1998; Hoyle and Kenny, 1999; Cole and Maxwell, 2003; MacKinnon, 2012). Our synthesis results in a procedure that can firmly establish the intended causal meaning of mediation analysis in so called measurement-of-mediation designs, or reveal that the causal interpretation of estimated coefficients, i.e., conclusions about the presence of mediation, depend on prior assumptions about the data generating mechanism. Importantly, our procedure distinguishes between measurement error as a reason for (causally) inconclusive results and other reasons.

We apply the proposed approach to mediation studies with open-data badge published in *Psychological Science* between January 2015 and September 2018. We compare our results to those from using Preacher and Hayes's bootstrapping approach. The proposed method offers three improvements in these studies: First, it measures the evidence in favor of full mediation through Bayes factor and distinguishes evidence for full mediation as the underlying causal structure from insufficient statistical information about a potential direct effect. Second, it affirms full mediation at the causal theory level, when the implied conditional independence relationship is obfuscated by measurement error or categorization. Third, in cases where even after accounting for potential measurement biases conditional independence is rejected, the proposed approach improves inference for indirect effect estimates, if one is willing to assume mediation as the causal model a priori.

Doing More for Less: The Easy Addendum Effect in Goal Pursuit

Edward Yuhang Lai, Virginia Tech, USA
Julio Sevilla, University of Georgia, USA
Mathew S. Isaac, Seattle University, USA
Rajesh Bagchi, Virginia Tech, USA

EXTENDED ABSTRACT

"Much of consumer behavior is goal-directed" where consumers try to complete tasks and achieve goals (Bagozzi and Dholakia 1999, p. 19). Often, multiple similar tasks are performed successively in the pursuit of a single goal. For example, a student may have to study different chapters in a book (one after the other) to prepare for an exam, while a professor may have to grade one exam after another sequentially. A key factor that affects goal setting and overall goal pursuit in such contexts is perceptions of goal attainability; indeed, people prefer goals that are easier to attain—thus, even at goal initiation, they adopt goals with a multiple-means structure (Huang and Zhang 2013) or with more varieties of means (Etkin and Ratner 2012). We propose a novel approach to reduce effort perceptions: adding easier tasks at the end of a sequence of difficult tasks can sometimes reduce effort perceptions of the overall task.

We draw from the literature on assimilation of affective experiences to explain how individuals might retrospectively judge effort investment in our contexts. Research suggests that when evaluating a set of affective experiences, such as pain, people use the peak-end rule; that is, people take the weighted average of the peak amount and the final amount of pain experienced to judge the overall level of pain experienced (Fredrickson and Kahneman 1993; Thomas, Olsen, and Murray 2018). Though these effects have been demonstrated in medical contexts (Redelmeier and Kahneman 1996; Redelmeier, Katz, and Kahneman 2003), they do not always emerge (Thomas et al. 2018; Tully and Meyvis 2016). Extending these effects to goal pursuit, we propose that a saliently different, albeit easier, ending will lower overall effort assessments. This effect is driven by perceptions of overall task difficulty (a difficulty-effort bias). Five experiments demonstrate this effect and provide evidence for the process.

In Study 1, 210 undergraduate students completed a typing task. In the control condition, participants typed 10 difficult codes, each comprising of 10 characters. In the easy addendum condition, we added three additional easy codes, each comprising of three characters. Participants then reported how much effort they spent on the task. Participants in the easy addendum condition believed they spent less effort, even though they had actually typed three extra codes.

In Study 2, 288 MTurk workers performed the same typing task as in Study 1. Participants in the easy addendum condition perceived that they exerted less effort than those in the control condition and felt the task was less difficult, which mediated our results.

In Study 3, we demonstrate how our effects influence a marketplace variable—pay. We presented 194 undergraduate students with an invisible slider that was anchored by 0 and 100. In the control condition, participants were given 10 numbers (sequentially; e.g., 5, 15) and were asked to identify the position of the numbers on the sliders. In the easy addendum condition, we appended three easy sliders at the end, each with 10 other numerical anchors between 0 and 100, making position identification easier. We added another "false easy addendum" condition, where only one (vs. three) easy slider task was appended at the end. In order for the "easy addendum" effect to emerge, it is important for the easy sliders to obfuscate the effects of the difficult tasks. This can only occur if the easy tasks are judged as a category. Results showed that participants in the "easy addendum" condition indicated that they deserved a lower pay than those in the other two conditions.

In Study 4, 291 undergraduate students from two large universities participated in the same task as in Study 3. We kept the same control and easy addendum conditions and added a new third condition—the "unrecognized easy addendum" condition. In the third condition, the three additional sliders looked the same as those in the control condition. However, we accepted a larger range of solutions. For example, participants did not have to find the exact position of 45 but merely hit any position in the 40-50 range. Therefore, these additional slider tasks looked identical to the other sliders but were easier. After completing the task, participants reported their effort and difficulty perceptions. Participants in the easy addendum condition felt they spent less effort and that the task was easier than those in the other two conditions. A multi-categorical mediation analysis using Process Model 4 (Hayes 2018) revealed that the perceived overall task difficulty only mediated the effect between the control and the easy addendum conditions.

In Study 5, we presented 255 undergraduate students with a hand grip dynamometer and asked them to apply pressure at a specified strength level for 10 seconds. In the control condition, they completed 9 difficult levels (varied by gender, based on pre-test). In the "easy addendum" condition, three easy levels were appended to the task. Then, participants indicated how much effort this task required and how difficult it was. We conducted a 2 (control vs. easy addendum) X 2 (gender) ANOVAs to control for gender effects. The interactions were not significant for either of the two measures. Participants in the easy addendum conditions thought they spent marginally less effort than those in the control condition. They also perceived the task as less difficult. More importantly, the mediation of perceived difficulty was significant.

More often than not we have little control on the nature of the tasks assigned to us. Employees may not be able to choose which tasks to do and which not to. Consumers cannot choose to bypass certain tasks when pursuing their loyalty program goals. Teachers cannot significantly lower the difficulty of an important assignment just to make students happy. However, we show that keeping difficulty constant, perceptions of difficulty associated to a task can be reduced by merely adding simple items at the end. Hence, the present findings may have a profound impact on how to structure a task, allocate workload at the workplace, as well as design an optimal consumer loyalty program to enhance engagement and well-being.

Understanding the Power of the Temporal Retention of e-Commerce Websites Thanks to the Stated Preferences Approach – a First Step

Dimitri Laroutis, EM Normandie Métis Lab, Le Havre, France
Philippe Boistel, ESC Amiens, Amiens, France
Yann Tournesac, ESC Amiens, Amiens, France

EXTENDED ABSTRACT

In 2018, Facebook announced a fall of 7% in the amount of time users spent on the website (around 2 minutes a day). In parallel, Facebook's share price fell 20% (about 100 billion dollars).

The time users spend on websites is called stickiness. For Zott *et al.* [1], stickiness "involves the ability of websites to draw and retain customers." This retention capacity appears as one of the keys to profitability [2]. While recent research [3] has underscored the importance of stickiness in acquiring a competitive advantage by retaining visitors, gaps remain in our understanding of this indicator. The explanatory factors regarding a website's stickiness remain indefinite, especially for e-commerce businesses.

The aim of this study is to identify the explanatory factors underlying the stickiness of French online retailer websites and to measure their respective importance. By adopting the stated preferences approach, a quantitative study was conducted with 245 online buyers.

Literature Review

No studies have focused on stickiness [4], many scholars on consumer and e-consumer purchasing behaviour have referred to both the importance of time spent on a website and the interest of certain factors that could influence this behaviour.

Lemoine [5] highlights factors linked to time spent lingering, including the visuals. Website aesthetics play a crucial role with regard to the amount of time visitors spend on a website. Reichheld and Scheffer [6] note that a website with good visuals influences the amount of time users stay on the site. Rayport and Svioka [7] suggest that a website's value is defined by the information given, the site format and the infrastructure providing the connection. Lippert and Wilder [8] argue that the intention to return is influenced by the perception of the website's value.

It is crucial to work on creating a strong affective relationship with the brand in order to prevent customers from migrating [9]. The more a customer trusts a website, the stronger the resulting stickiness, and the greater the purchasing intent [2]. Gefen *et al.* [10] however argue that trust needs time to develop and numerous exchanges and interactions that require significant budgets. Website's customers express requirements similar to those of traditional commerce: politeness, flattery and social identity [11].

The purchasing environment can impact on individuals' emotional and attitudinal responses [20]. For Volle and Florès [12], "the main factor which appears to trigger the intention to visit a site again is the quality of the online experience."

Methodology

The methodology adopted is the stated preferences approach. It was developed by two Nobel prize-winners ([13]) in order to understand the willingness of individuals to undertake action when faced with the challenges of the market. Individual willingness to stay on an e-commerce website is evaluated through the administration of a questionnaire and econometric modelling of the data. The questionnaire was pre-tested (11 persons). The questionnaire was designed in accordance with the directives of Arrow *et al.* [13] and Johnston *et al.* [14]. We adopted several existing measurement scales ([15], [16]). The questionnaire contained 56 questions and was given to 245 internet users.

Results

Use of the stated preferences method requires an econometric approach (Tobit type model - because of censored variable). Tables 2 and 3 present the significant variables of the Tobit model.

We confirm that a site with impressive visuals will encourage a user to stay longer. Individuals perceive aesthetics as a guarantee of quality, simultaneously arousing their curiosity and creating proximity with the company. Computation of the marginal effects enabled us to evaluate the impact on stickiness at 4 minutes.

Ergonomics and customer experience are significant factors. By calculating the marginal effects, we estimate the impact of ergonomics at 17 minutes.

We constate the importance of a social presence and the need for interaction between present and future customers. This search for objective relational information increases the presence of visitors by 5 minutes.

When browsing an e-commerce website is enjoyable, visitors will spend more time on it. A 'wellbeing' environment encourages positive emotions and behaviour (10 minutes more than other).

We identified two other significant variables: the price variable and the gender variable. Competitive price positioning encourages visitors to stay longer on the site (11 minutes). No other study has included the impact of price on stickiness. We showed that gender is a factor in the time spent on a website. Women generally spend longer (around 10 minutes) than men.

We can split the variables into 3 main groups (Table 4): a low impact (5 minutes), real impact (10 minutes), decisive impact (17 minutes). The complexity of stickiness is illustrated (Figure 1) by the presence of the violet areas.

Management implications

Ergonomics is the central variable keeping visitors on a website (17 minutes). The site's ergonomics must include customer feedback in a coherent way. Information about other customer reviews helps to increase stickiness from 4 to 5 minutes. We recommend incorporating 2 features for consumers: the possibility to rapidly consult the customer reviews; the possibility to post a message as soon as the product has been purchased or delivered.

Sites should highlight low prices to make their website stickier (a comparative table of prices would add value to the offer and reassure buyers). Highlighting the quality of a service with a score from the customers regarding the service will reinforce the site's stickiness.

Since we saw that gender has a strong impact on the desire to stay on a site, should websites develop different content for women and for men?

Conclusion

Use of the stated preferences approach enabled us to identify the willingness of individuals to linger on a website, defining the factors that help to enhance the stickiness. This method is flexible and helps to extend the scope of investigation. Concerning the theoretical

contribution, our study set out to define the concept by identifying its main factors. Our managerial contribution involved clarifying which factors influence the stickiness. Companies can now rank the actions it needs to implement as a priority.

Our study nonetheless has some limitations. We adopted an exploratory approach and our questionnaire was broad. Our approach is relatively novel. Finally, this study is just a first step in defining the stickiness concept.

How Can Consumers Both Value and Resist Consumption? An Exploration of Consumer Relationships with Possessions in Their Pursuit of Happiness

Hsin-Hsuan Meg Lee, ESCP Business School, UK
Charlotte Gaston-Breton, ESCP Business School, Spain

EXTENDED ABSTRACT

Will mindful consumers ever find happiness? Alternatively, and maybe more realistically, will happy consumers ever be mindful? Creating happiness is often seen as the central idea of businesses to encourage consumption, which is inherently in contradiction with the movement of mindful consumption where the pursuance of happiness is built upon the reduction of consumption (Lee & Ahn, 2016). The incongruity perhaps lies in what types of happiness or unhappiness consumers attribute to their consumption and the relationships they have with their possessions.

While consumer happiness has been well investigated in the past, prior research tends to focus either on the acquisition, i.e., the moment of purchase (e.g., Nicolao, Irwin & Goodman, 2009), or dispossession, i.e., the moment of disposition (e.g., Donnelly et al., 2017). Much of our understanding of consumer relationships with objects is centered around these two momentary stages. Once an item is in our possession, we, however, form a long-term relationship with it. In this study, we argue that how consumers define and understand their subject-object relationships, and how they obtain happiness through possessions would eventually influence their decisions on dispositions and, in turn, on future consumption.

Prior research suggests that consumers may find happiness in thinking they are contributing to the greater good, which can be associated with eudaimonic wellbeing as it emphasizes on meaning and purpose in life (Ryan, Huta, & Deci, 2008). Alternatively, it may also come from the feeling of regaining control of oneself and reduced stress level that is related to the variety and the number of choices offered in the marketplace (Lee & Ahn, 2016). This wellbeing is indeed more individual and hedonic. A prior study found that egoistic motivations are more effective than altruistic ones in driving consumers' mindful consumption (Birch, Memery & Kanakaratne, 2018). This seems to create a paradox where the over-emphasis on hedonic and personal wellbeing may end up encouraging more consumption, albeit mindful. We argue that the difference in motivations and focuses of wellbeing could lead to distinct and sometimes opposite results in one's view on consumption.

Using the popular Marie Kondo's decluttering method (2014) as the backdrop, this study conducted a content analysis on 39 blog narratives of the KonMari converts (Yourgrau, 2015) to understand how consumer's relations with the objects enhance their individual and/or collective happiness to transform their consumption patterns. The blog transcripts, the verbal and visual content of the documentaries, were analyzed. An initial coding scheme was developed based on the steps identified in the KonMari method as well as the three critical stages in our study: motivations and reflections, dispossession and repossession, and consequences on future consumption. The analysis was built on continual comparisons between the data collected from different participants.

The results indicate that the KonMari method prompts people to revisit why they own what they own and how it contributes to their wellbeing. The mindfulness experienced while decluttering leads to reinforce or reduce the pursuit of either individual and/or collective wellbeing in future consumption. Contrary to popular belief that the method can encourage the pursuance of a sustainable lifestyle, most respondents reported feeling liberated. They seemed to find the excuse to prioritize their wellbeing, which justified the decisions of discarding usable items. In pursuing this individual wellbeing, societal and environmental wellbeing may be sacrificed. Under such conditions, a few, but still, reported a positive influence on their future sustainable behavior. This may result from their distinct motivations and aspects in subject-object relationships that they prioritize.

There is a distinct difference in how people view their possessions. Some saw their possessions as their extended selves. Respondents who support this view appeared to focus more on the momentary value of the possessions; the happiness came from the moment of consumption, which represented who they were. It also seems common to acknowledge the notion that people can change. The combined arguments make it easier to discard items. This emphasis on the present term, naturally, prohibits the long-term and sustainable view of consumption.

On the flip side, when the possessions are here to serve a need, and the respondents hire objects "to accomplish a job," this distance between the subject and object made it harder to discard an item. This is because such a relationship between subject and object has a likelihood to continue even though the participants may have changed. This sometimes intertwined with the view that possessions can provide happiness, and consumption can bring wellbeing. Those who can see the time value of items, be able to justify the future use or the continuous benefits an object can bring, they ended up having reinforced relationships with their possessions. This repossession can make them cherish the objects even more.

The practice of decluttering that focuses on wellbeing signifies the attribution of the source of happiness or unhappiness. One observable difference is that some people would attribute objects to be the source of their joy. Many participants who agreed with this line of arguments, albeit reporting being more mindful, did continue their consumption, only focusing more on items that would create hedonic happiness. The others who attribute objects to the source of their unhappiness, whether because of the volume or the value of the possessions, tend not to seek wellbeing through consumption. They would argue that happiness comes from their family, friends, and other pursuits in life. These are the people who would report mindful consumption that is more sustainable as well. Their quest for happiness would tend to be more eudaimonic.

In answering our research questions, we provide insights on how wellbeing can be enhanced throughout the relationships between subject and object(s) in order to drive mindful or sustainable consumption. We highlight the potential damage one can create by being sustainable-driven, as well as the potential benefits on societal wellbeing while focusing on personal wellbeing. Since we only focused on subject-object relationships under a particular backdrop, the motivations and the characteristics of the participants can be biased. Future research can include scenarios where people are relocating and examining their decision processes.

Consumers' Inconsistence About Hypocrisy: RevisitingThe Concept of Corporate Hypocrisy

Susanne Täuber, University of Groningen, The Netherlands
Marijke C. Leliveld, University of Groningen, The Netherlands

EXTENDED ABSTRACT

With increasing CSR engagement from companies, there is also a call for understanding corporate hypocrisy: consumers oftentimes observe inconsistencies between words and deeds. Consumers' perceptions of a company as hypocritical form a key mechanism that critically affects consumers' overall attitudes towards the company. Corporate hypocrisy is commonly defined in alignment with interpersonal hypocrisy, namely as resulting from inconsistencies between an organization's statements and behaviors (Wagner et al., 2009). Consensus about the association between inconsistency and hypocrisy in interpersonal judgments is lacking. In particular, some scholars claim that people can be inconsistent without being seen as hypocritical (e.g., Alicke et al., 2013). Others claim that people can be hypocritical without being seen as inconsistent (e.g., Monin & Merritt, 2012). Yet others claim that perceived inconsistency will invariably elicit hypocrisy judgments (e.g, Effron, Luca, & O'Connor, 2015). This warrants more research into the proposed relationship in consumer contexts.

We propose that a finding from interpersonal hypocrisy research that has been less well explicated and tested in consumer research, may be helpful in identifying boundary conditions for the relationship between factual inconsistency, perceived inconsistency and hypocrisy. This proposition concerns the aggravation of hypocrisy judgments when the other person evinced an *air of superiority*. In organizational contexts, superiority is commonly associated with organizations' morality, which refers to corporate social and environmental responsibility as indicating virtuousness (Cameron et al 2004). We therefore propose that moral positioning might aggravate perceptions of corporate hypocrisy. Thus, while research suggests that companies benefit from moral positioning because it allows them to distinguish themselves positively from their competitors (Sen et al, 2016), it might also make them more susceptible to ascriptions of hypocrisy from consumers. Put formally:

Hypothesis 1: *Inconsistencies – as opposed to consistencies - between saying and doing result in perceptions of corporate hypocrisy.*

Hypothesis 2: *This effect is stronger for organizations positioning themselves as moral, compared to organizations positioning themselves as competent.*

Note that we also measured perceived inconsistency, which lacks the strong moral connotation of hypocrisy, and that we studied inconsistencies with and without transgressions, to explore in more detail how the aggravation works exactly.

Aiming to conceptually replicate prior studies (e.g., Wagner, et al., 2009), we tested the effect of inconsistency on consumer punishment intentions towards actual brands as mediated by perceived corporate hypocrisy.

Hypothesis 3: *Perceived corporate hypocrisy mediates the effect of objective inconsistency on punishment intentions.*

The complete model thus tests a moderated mediation:

Hypothesis 4: *Perceived corporate hypocrisy mediates the interactive effect of objective inconsistency and company positioning on punishment.*

Study 1 examined whether organizations' positioning is consequential for consumers' perceptions of inconsistency. 458 participants recruited through MTurk were randomly assigned to the conditions of a 2 (Positioning: moral vs. competent) x 3 (Inconsistency: none vs. without transgression vs. with transgression) between-subjects design. Participants read that Company X's aim was to produce in more sustainable [efficient] ways to improve the environment [product quality]. They were striving to improve 10 points on the "consumer score" (a supposedly objective measure of performance). The score reflecting Organization X's achievements regarding this specific aim went up by 10 points (+ 10)/ remained unchanged (+/- 0)/ went down by 10 points (-10) (respectively consistency, inconsistency without transgression, and inconsistency with transgression). Participants then indicated the extent to which Company X's behavior was consistent and inconsistent (reversed coded) with their aim (1 = *not at all; 7 = completely; r =* .86, *p <* .001*)*.

Results showed main effects of both independent variables, F's > 10, p's = .001. Importantly, the interaction term was also significant, $F(2,452)=16.07$, $p<.001$, $\eta_p^2=.07$. Tests for simple main effects revealed that *Positioning* did not affect perceived consistency when the organization's behavior was consistent with their aim, and when the inconsistent behavior did not involve a transgression, both F's < 0.27, p's > .60. By contrast, when the company's inconsistent behavior involved a transgression, the company with the moral aim was perceived as significantly less consistent (M=1.94) than the organization with the competent aim (M=3.39), $F(1,452)=41.99$, $p<.001$, $\eta_p^2=.09$.

Study 2 tested the entire conceptual model. A representative sample of Dutch consumers ($N = 522$) evaluated Dutch chocolate brands with a moral (Tony Chocolonely) vs. a competent (Verkade) reputation, as established through a pre-test. After reading the description of the brand's aims and behavior, participants indicated perceived consistency and inconsistency. We further measured perceived hypocrisy using the scale of Wagner et al. (2009; α = .93). Finally, participants were presented with a list of 5 options (e.g., participating in a test panel, receiving the brand's newsletter) which they had to actively uncheck if they did not want to make use of it. The number of remaining checked options were used as an index of brand-engagement.

For perceived consistency, we found an Inconsistency effect (no Brand effect) which was qualified by an interaction with Brand, $F(2,514)=4.89$, $p = .008$. Inconsistency significantly affected perceived inconsistency of the moral brand Tony Chocolonely, $F(2,514)=14.80$, $p < .001$, but not of the competent brand Verkade, $p > .72$. Further, replicating Study 1, moral brand positioning led to aggravated perceptions of inconsistency only when inconsistency involved a transgression, $p = .035$, and not inconsistency without transgression: $p = .967$. We found similar pattern of results for hypocrisy. The main effect of Inconsistency was qualified by an interaction with Brand, $F(2,510)=5.29$, $p = .005$. Objective inconsistency significantly affected perceived hypocrisy of the moral brand, $F(2,510)=14.70$, $p < .001$, but not of the competent brand, $F<2.10$, $p > .13$. PROCESS

analyses (model 7) showed that while manipulated inconsistency directly affected brand-engagement (effect = .16, t = 3.13, p = .002, $CI_{95\%}$ .061, .265), the indirect effect through perceived corporate hypocrisy was significant for the moral brand ($CI_{95\%}$ -.141, -.055) but not for the competent brand ($CI_{95\%}$ -.051, .022). The Index of Moderated Mediation was significant (effect = .10, $CI_{95\%}$ .042, .165).

The studies suggest that the benefit of moral positioning can turn into a backlash prompting consumers to perceive the brand as more inconsistent and hypocritical than their competently positioned competitors, resulting in lower brand-engagement.

The Neglected Victim Effect

Liat Levontin, Technion University, Israel
Danit Ein-Gar, Tel Aviv University, Israel
Tehila Kogut, Ben Gurion University, Israel

EXTENDED ABSTRACT

People are kind by nature, and it is most often the case that they help when others are in need (De Dreu, Balliet, & Halevy, 2014). In this paper, we show that sometimes people find it difficult to help others—not because help is beyond their reach, but rather because providing help conflicts with the wish to do so in a fair manner. Consider the case where you have a single bill of money and need to decide which of two beggars should receive it. On the one hand, any help is better than no help—so you tend to be kind and helpful, and choose to give the bill to one of the beggars. On the other hand, helping one beggar and not the other is unjust.

The dilemma of choosing whom to help from a choice set of several identifiable victims is a prevalent phenomenon. Many charitable organizations such as organizations dedicated to helping children of developing countries, helping students who cannot afford tuition fees and even saving wildlife or companion animals offer potential donors the option to view many victims and decide to whom to dedicate their donation. Interestingly, however, the question as to whether or not offering donors the option to choose from a choice set of identifiable victims is beneficial has yet to be answered.

The present research proposes that donation appeals that require the prospective donors to choose one identifiable victim from a choice-set of two inevitably also involves deciding who is neglected and not helped. While individuals want to help, and to feel good about doing so (such as feelings of "warm glow"—Andreoni 1990), the choice context, by default, creates a conflict between this and their wish to be fair and just. We argue that the conflict between the wish to help and the wish to be fair eventually leads prospective donors to avoid making any donation whatsoever—a phenomenon that we term the Neglected Victim Effect. We show that, counter-intuitively, the practice of offering a choice-set, which works so well for consumer goods and services (e.g., Adomavicius & Tuzhilin, 2005), backfires when it comes to charitable giving.

Most studies on donation-giving focused on the intention to donate, and how much to give, while not presenting the option of not to donate (at least, not explicitly). When considering donation-giving behavior, the option to refrain from donating is as vivid and valid as the decision to make a choice and donate. Research on choice has shown that when a no-choice option is presented in an equally compelling fashion, consumers' decision considerations change (e.g., Dhar & Simonson, 2003). The question we set out to answer, therefore, is how donors would respond when presented with a choice-set of several identifiable victims and are given an explicit "no-choice" option?

According to rational choice theory, when presented with a choice set of several options, individuals tend to choose the option that maximizes their interests and provides them with the greatest utility or benefit (e.g., Friedman, 1953). However, when no single alternative has a decisive advantage, and the option not to choose any of the alternatives is available, consumers prefer the "no-choice" option to an alternative that is difficult to justify, to avoid criticism, or regret (Dhar, 1997; Dhar, & Simonson, 2003).

Choice in the context of charitable giving is unique for many reasons, but the most important one - is that the decision affects other people and their lives (Beattie, Baron, Hershey, & Spranca,1994) and therefore raises moral considerations. Most people want to help others in need and feel good after doing so (Andreoni, 1990; Dorfman, Eyal, & Bereby-Meyer, 2014). Therefore, generally, we would expect individuals faced with a choice-set, to choose to help one of the victims. However, by choosing one victim, they also deny help from the non-chosen victim. This decision to neglect a victim is perceived as unfair. Being fair and just, while avoiding unjustifiable favoring of one person over the other, is a virtuous behavior (Blasi, Kurtines, & Gewirtz, 1994). When resources are limited and can only be shared with one of two equally deserving individuals, people tend to discard the resource rather than allocate it unequally (Shaw & Knobe, 2013; Shaw & Olson, 2012). In this research, we argue that choice in the context of charitable giving triggers a conflict between the wish to donate and do good, and the wish to be fair and impartial. This conflict, we suggest, may lead to choice-avoidance and opt-out. We term this the Neglected Victim Effect. The Neglected Victim Effect hypothesis suggests that when prospective donors are asked to choose their donation target from a choice-set of more than one identifiable victim—which means they would help one victim but neglect the other—they choose to opt-out and refrain from donating altogether, more often than when faced with a donation request for a single identifiable victim. We suggest that the conflict between the wish to be helpful and the wish to act fairly is the underlying driver of the Neglected Victim Effect—such that we would expect a stronger conflict among prospective donors who are asked to choose a single donation target out of several, than those who are solicited for a donation for a single identifiable victim.

Experiment 1 (N=306) compared the opt-out rates (i.e., the percentage of participants who refrained from donating altogether) between two conditions. In both conditions, participants were presented with two identifiable victims, with the same need and similar characteristics. However, in the Neglected Victim (NV) condition, participants were asked to choose whom to donate to (and whom to neglect), while in the Multiple Identifiable Victims (MIV) condition, they were asked to donate for only one of the two victims. Participants were informed about an organization dedicated to helping children in need ("The Good Neighbor Association"). In the NV condition, participants were told about two girls in need of donations—"Caroline" and "Agnes," both of whom were introduced with a photograph and a short description—and asked to choose between donating to one of them, or not donating at all. In the MIV condition, they were told about the same two girls but asked whether they would like to donate to one girl or the other (assigned to the participants at random)—i.e., they did not need to choose between the two girls. After making their decision, participants who had decided to donate indicated on a 100-point scale (ranging from $0 to $1) how much of their bonus money they were willing to donate We hypothesized that, in the NV condition, the number of participants deciding to opt-out and not to donate would be higher than in the MIV condition.

Overall, more participants chose to donate ($N = 203$; 66%) than to opt out ($N = 103$; 33%). Importantly, as hypothesized, significantly more participants refrained from donating and chose to opt out in the NV condition ($N = 50/102$; 49%) than in the MIV condition ($N = 53/204$; 26.0% χ^2 (1) = 16.16, $p < .001$). Interestingly, those who donated in the NV condition did not donate higher amounts ($M = .53$; $SD = .37$) than donors in the MIV condition ($M = .49$; $SD = .34$; F (1,184) = .45, $p = .504$).

Experiment 2 (N=419), further tested the Neglected Victim Effect using the same stimuli as in Experiment 1, but comparing opt-out rates between three conditions: (1) The neglected victim (NV) condition (as in experiment 1); (2) A control condition seeing two victims but considering only 1 (MIV; as in experiment 1); and (3) A control condition of a single identifiable victim in which participants were told about one girl in need (randomized between "Caroline" and "Frida"), and asked whether they would be willing to donate to her or not without being aware of any other girl in need (SIV). After making their decision, participants reported which of two considerations was more prominent when making their choice, the wish to help others (0) or the wish to be fair and impartial (1).

Consistent with the results of experiment 1, more participants chose to donate ($N = 268$; 64%) than to opt-out ($N = 151$). Importantly, significantly more participants opted out of donating in the NV condition ($N = 75/143$; 52.4%) than in either control conditions ($N_{MIV} = 33/140$; 23.6%; $N_{SIV} = 43/136$; 31.6%; $\chi^2(2) = 27.30$, $p < .001$).

As hypothesized, of participants who reported the wish to be fair and impartial as their dominant consideration, 50.7% were in the NV condition ($N = 75/148$) while only 24.3% were in the MIV condition ($N = 36/148$), and only 25.0% in the SIV condition ($N = 37/148$). Of those who reported the wish to help others as their dominant consideration, 25.1% were in the NV condition ($N = 68/271$), 38.4%, were in the MIV condition ($N = 104/271$), and 36.5% in the SIV condition ($N = 99/271$; $\chi^2(2) = 27.94$, $p < .001$). As expected, among participants who opted out, the majority reported the wish to be fair and impartial as their dominant decision consideration ($N = 118/151$; 78.1%) as opposed to the wish to help others ($N = 33/151$; 21.9%). Among those who decided to donate, more reported the wish to help others as their dominant decision consideration ($N = 238/268$; 88.8%) as opposed to the wish to be fair and impartial ($N = 30/268$; 11.2%; $\chi^2(1) = 189.50$, $p < .001$).

Experiment 3 (N=420) provided additional evidence that donors' inner conflict drives the neglected victim effect using a different, timely context (helping lonely people in a time of social distancing) and different victims (elderly men instead of young girls). This experiment included three conditions as in Experiment 2, however unlike Experiments 1 and 2 which asked participants to donate money, here participants were asked to volunteer, and after making their decision, they reported their decision considerations on two separate items (to what extent their decision was influenced by the wish to be fair and impartial, and to what extent by their wish to help others).

Consistent with the findings of experiments 1 and 2, more participants chose to volunteer ($N = 322$; 77%) than to opt-out ($N = 98$; 23%). Importantly, significantly more participants opted out from volunteering in the NV condition ($N = 42/141$; 29.8%) than in the two control conditions ($N_{MIV} = 34/140$; 24.3%; $N_{SIV} = 22/139$; 15.8%). $\chi^2(2) = 7.73$, $p = .021$.

Furthermore, as hypothesized, the consideration conflict (help-fair) mediated the effect of experimental condition on the percentage of opt-outs; the relative indirect effect of the NV condition vs. SIV condition on the decision to volunteer or not through the Consideration-Conflict variable was positive and significant ($B = .75$, $SE = .24$, 95% CI [.36, 1.28])—as was the indirect effect of the NV condition vs. MIV condition ($B = .63$, $SE = .25$, 95% CI [.20, 1.20]. This suggested a greater conflict in the NV condition than in either other condition.

The results of these studies support our hypothesis that potential donors are more likely to refrain from donating altogether when they need to choose between two identifiable victims—i.e., help one victim yet neglect another—than when merely asked to donate to one victim. The results show that it is the presentation of a choice that prompts higher rates of opt-out, rather than the number of victims presented. Our findings provide additional support for the conflict between the wish to be helpful and the wish to be fair, as the mechanism behind the effect. The findings also demonstrate that NV-condition participants who donated did not "compensate" for those who opted out. This finding bears profound implications for charity's bottom line since asking donors to choose between two identifiable victims results in a smaller number of donors—and commensurately, a smaller donation amount overall than when donors are simply asked to donate to one specific victim, without being obliged to choose.

Freedom of choice does not necessarily mean that individuals make optimal choices (Botti & Iyengar, 2006). However, in almost any consumption decision, consumers choose from the wealth of options surrounding them. This wealth of options exists in donation decisions as well, and charitable organizations try to utilize donors' choices by presenting prospective donors with customized choice-sets—on the assumption that doing so is an effective strategy of eliciting more donations. However, the studies of the present research indicate that asking donors to choose from a choice-set of single identifiable victims, coupled with the explicit option of not choosing either one (as occurs in real-world donation appeals), induces donors to refrain from donating altogether. The choice literature has shown that when the choice between options is difficult, and an explicit no-choice option is provided, individuals prefer the no-choice option. The present research tested this prediction in the context of donation-giving and found across all studies, using various conditions, that the no-choice option (i.e., the option to opt-out and not to donate to any of the victims), was not the preferred option. Furthermore, according to the choice literature, the no-choice option is preferred mainly because of the difficulty of choosing between options, or of justifying the preference of one option over another. In the present research, we found that, in fact, in the case of donation choices, a preference for the "no-choice" option is a result of a unique conflict between the wish to be helpful, and the wish to be fair. This is the first study to focus on how the consequences of choosing one victim while neglecting another lead to a "lose-lose" situation, in which many prospective donors prefer to avoid donating altogether. Our findings offer practical implications for donation-raising efforts. When a charitable organization is seeking to raise money for multiple victims, it should consider presenting each victim separately, without comparisons with others, to avoid activating an inner struggle, which may drive potential donors away from their initial tendency to help.

Why Consumers Disproportionately Invest to Improve Outcomes That Are Already Favorable

Joshua Lewis, New York University, USA

EXTENDED ABSTRACT

Introduction

The more people consume, the less value they derive from further consumption (Hsee and Rottenstreich 2004; Hsee, Rottenstreich, and Xiao 2005; Kahneman and Deaton 2010). By this logic, a consumer who is guaranteed to receive two Kit Kats should be less motivated to acquire a third Kit Kat than a consumer who is guaranteed to receive just one Kit Kat. An employee expecting a $700 bonus should be less motivated to increase her bonus by $100 than an employee expecting a $200 bonus. In stark opposition to this principle, the studies herein show that consumers disproportionately invest to improve *more* rather than *less* favorable outcomes. This behavior is potentially detrimental to consumer welfare: consumers might focus on improving outcomes that are already favorable rather than on improving what is most in need of improvement.

Why would consumers behave in a seemingly suboptimal way, defying the predictions of so much previous research? The studies herein suggest that consumers succumb to a novel bias in how they evaluate improvements. For example, imagine that one consumer can make a credit card purchase that increases her accumulated cashback reward from $70 to $80 while another consumer can make a similar credit card purchase that increases his accumulated cashback reward from $20 to $30. The consumer who can improve her cashback reward from $70 to $80 might more easily justify the purchase because she will ultimately be owed a substantial $80 in cashback. Because there is less need to justify the *lack* of a purchase, she might insufficiently adjust her enthusiasm for the fact that she would have received a cashback reward of $70 in any case. Meanwhile, the consumer who can improve his cashback reward from $20 to $30 might find this credit card purchase harder to justify with his relatively meager resulting cashback of $30, and might insufficiently adjust his hesitancy for the fact that he would only have been owed $20 without the purchase. In sum, when contemplating an improvement, consumers may succumb to a bias in which they focus on the potential improved outcome and insufficiently account for the outcome that they would have attained without the improvement.

Studies

Three preregistered studies examine this psychology. Studies 1 demonstrates the bias in incentive-compatible decisions about improving monetary rewards, Study 2 explores the bias in incentive-compatible decisions about increasing consumption of various goods and reconciles it with the previous literature on diminishing marginal benefit, and Study 3 suggests that the bias might apply even to improvements in consumer experiences that are harder to quantify.

In Study 1, 1,190 MTurkers made a series of incentive-compatible yes-no decisions about whether to improve each of 16 potential payments by doing an effortful button pushing task. To ensure participants were motivated to make decisions according to their true preferences, one of these 16 decisions was randomly selected to count for real.

Both the size of the improvements and the amount of the possible bonus payments varied across these decisions in a within-subjects (low rewards vs. high rewards) design. For each decision in the low rewards condition, the potential unimproved bonus payment was uniformly drawn from between 20 and 30 cents, and for each deci-

sion in the high rewards condition, from between 70 and 80 cents. In each decision, the reward could be improved by an amount drawn uniformly between 10 and 15 cents. For example, a low rewards question might read:

Would you type "ab" 300 times to increase a bonus by 10¢ from 20¢ to 30¢?

A high rewards question might read:

Would you type "ab" 300 times to increase a bonus by 10¢ from 70¢ to 80¢?

Participants chose to improve low rewards just 42% of the time, but high rewards 56% of the time, $p < .001$.

Given that people are usually *diminishingly* sensitive to the size of monetary gains, why are people ostensibly *increasingly* sensitive in this context? Why are they more willing to improve a reward from 70 to 80 cents than from 20 to 30 cents? In line with the mechanism proposed in the Introduction, it could be because they find their effort easier to justify when it will be rewarded with 80 cents (rather than 30 cents), and so they neglect the fact that they would still have had 70 cents (rather than 20 cents) without exerting effort. A decision *not* to exert effort, after all, does not usually require much extra justification besides avoiding that effort (Lewis and Simmons 2019).

To test this mechanism, participants in Study 1 made an additional improvement decision while knowing only *one* of the potential rewards. If participants preferred to base their improvements decisions on the potential improved outcome rather than the initial unimproved outcome, then they would most likely choose to make that additional improvement decision while knowing their potential *improved* reward. So, before participants made their additional improvement decision, they answered another question:

To help you decide whether to do the next typing task, would you prefer to know the unimproved bonus payment that you can get without typing, or the improved bonus payment that you can get by typing?

Consistent with the proposed mechanism, 62% of participants chose to know the potential improved reward (more than 50% at $p < .001$). Moreover, there was a significant interaction such that the effect of participants more often choosing to improve higher (vs. lower) rewards across the original 16 decisions was much greater for the 62% of people who chose to know this potential improved reward in the additional judgment, $p = .005$. Thus, a focus on the potential improved outcome (which could serve to justify any effort exerted to attain it) seems to drive this effect and outweigh the opposing force of diminishing sensitivity to monetary gains.

While *increasing* sensitivity to gains would not predict this interaction and would be very surprising considering previous research on diminishing sensitivity (e.g. Kahneman & Tversky 1979), Study 2 attempts to rule it out in two additional ways. First, instead of monetary gains, the rewards were physical prizes such as highlighters, pens, and snacks — goods which should satiate consumers rapidly. Second, participants also answered questions about their risk preferences with respect to the amount of these goods that they received, which should theoretically reflect whether they received increasing or diminishing marginal benefit from those goods (Kahneman and Tversky 1979). For example, in one question, participants faced a choice between receiving two tea bags for sure, and a lottery in which they would have a 50/50 chance of receiving either one or three tea bags (or they could indicate no preference and let the

survey decide for them). If participants gain more marginal benefit from receiving three bags instead of two than they gain from receiving two tea bags instead of one (i.e. increasing marginal benefit), then they should choose the lottery, as it presents the possibility of receiving three tea bags instead of two at the expense of the possibility of receiving two tea bags instead of one. By the same logic, if participants gain more marginal benefit from receiving two tea bags instead of one than from receiving three tea bags instead of two (i.e. decreasing marginal benefit), then they should refuse the lottery and choose to receive two tea bags for sure. Thus, if participants refuse the lottery but indicate that they would do more work (i.e., type "ab" more times) to increase the amount of tea bags they receive from two to three than from one to two, then the psychological mechanism that drives participants' decisions about improvements would seem to be distinct from that which drives their decisions about risk.

Thus, for each of eight potential prizes, 220 laboratory participants in Study 2 made incentive-compatible decisions about the quantities of that prize they would receive in both a risk condition and an improvement condition (so, risk vs. improvement was manipulated between-subjects for each prize). In the risk condition, participants chose between receiving two units of each prize for sure and a 50/50 lottery to receive either one or three units of that prize. In the improvement condition, participants made two decisions — one about how many times they would type "ab" on a keyboard to improve the quantity of the prize they would receive from one to two, and the other about how many times they would type "ab" to improve from two to three. In the risk condition, participants were more likely to choose the sure thing than the lottery, $p < .001$, which suggests that they experienced diminishing marginal benefit from each extra unit of consumption. However, participants' judgments in the improvement condition were significantly less likely to imply diminishing marginal benefit, $p < .001$. In fact, participants were willing to work directionally more to improve the quantity of the prize they received from two to three than from one to two, $p = .171$,[1] which would imply that they experienced *increasing* marginal benefit from each extra unit of consumption. This seeming contradiction can be reconciled if participants in the improvement condition were focusing on the potential improved prize, rather than the difference between the improved and unimproved prizes. Three units of a prize will usually be worth more to participants than two units of a prize, even if the *marginal* benefit is decreasing. Thus, participants may *experience* diminishing marginal benefit from increasing the quantity of these prizes but simultaneously make improvement *decisions* that defy these preferences due to their tendency to focus on the potential improved prize.

A limitation of Study 2 is that participants' risk preferences may overstate the extent to which they truly experience decreasing marginal benefit from increased quantities of the goods. For example, they might succumb to direct risk aversion (Gneezy, List, and Wu 2006) and — if the decision in the risk condition induces an expectations-based reference point of two units of the good — loss aversion (Kahneman and Tversky 1979; Kőszegi and Rabin 2006). Thus, it is still conceivable that participants exhibit risk aversion even while experiencing *increasing* marginal benefit from additional units of the prize.

---

1   This preregistered analysis included only participants who passed three comprehension checks each within one attempt. Unfortunately, only 114 out of 220 participants did so. Including all participants who passed the three comprehension checks each within two attempts increases the sample size to 174 and reveals a significant effect, p = .009, and a previous hypothetical online pilot study replicated the effect, p < .001. Thus, the evidence against the null hypothesis is stronger than the reported p-value suggests.

Study 3 addresses this possibility more directly, employing a two-cell between-subjects design with 1,925 MTurkers. After reading one of three vignettes, participants either chose which out of two experiences (better vs. worse) they would invest in improving (choice condition) or judged which of those two possible experiences would be more improved by that investment (marginal benefit condition). For example, one scenario stipulated:

Imagine that you're going to two concerts towards the end of this month with a friend. One is to see your very favorite band, the other is to see a band that you are relatively indifferent to. You budget a fixed amount of money for spending on your social life each month, but you realize you still have a spare $10 to spend on drinks or food at either one of these concerts.

In the choice condition, participants were then asked:

Given that you are going to go to both concerts, which concert would you choose to improve by spending the $10?

In the marginal benefit condition, they were instead asked:

Given that you are going to go to both concerts, which concert experience do you think would be more improved by spending the $10?

In both cases, participants could choose from three response options (the better experience, the worse experience, and no preference). If participants choose which improvements to make based on the marginal benefit of those improvements, then their answers in the choice condition should exactly reflect their answers in the marginal benefit condition. For example, if a participant believes the worse experience would be more improved, then that participant should also choose to improve the worse experience. However, if participants use the quality of the potential improved experience to justify investing in the improvement, then they should be more likely to improve the better experience than their judgments of marginal benefit would suggest. For example, a participant might believe that the worse concert would be more improved by spending the $10 but still choose to spend the $10 on the better concert, for which the potential improved experience would make spending that $10 feel more worthwhile. Consistent with this hypothesis, participants were more inclined to improve the better experience than they were to indicate that the better experience would be more improved, $p < .001$.

DISCUSSION

While consumers may *experience* diminishing marginal benefit from extra consumption, their decisions about improvements often fail to reflect that experience. This is because, when consumers consider investing resources in improving a future outcome, they focus on the potential improved reward (which would justify the cost of the improvement) and neglect to sufficiently account for the potential unimproved reward that they would have received at no cost. Consequently, they invest more effort in improving larger vs. smaller monetary rewards (Study 1), they invest more effort in increasing larger vs. smaller quantities of consumer goods (Study 2), and they are more inclined to improve better experiences vs. worse experiences than their perceptions of the possible improvements would suggest (Study 3). The ramifications of this psychology could be large. For example, charitable donors may avoid giving to the neediest beneficiaries because the potential improved outcome for those beneficiaries would still be too bad to make the investment feel worthwhile. Indeed, this might explain why US donors send such a small fraction of their donations to poor countries, where those donations would have a far greater impact (MacAskill 2015). The bias could also affect consumers' own welfare. Consumers may overinvest in improving an already-lavish vacation but neglect to improve more mundane aspects of their life.

In sum, research from a wide variety of literatures spanning economics, psychology, and consumer behavior supports the notion of diminishing marginal benefit: people experience an ever-smaller benefit from incremental increases in consumption. Yet, when people make decisions about improvements, they violate this principle. Future work across all of these disciplines should explore the ramifications of this bias and work towards alleviating its adverse effects.

When and Why Are Consumers Reluctant to Seek for Help When They Encounter Difficulties in Using the Products? The Role of Consumption Type

Shaobo (Kevin) Li, Southern University of Science and Technology, China
Xun (Irene) Huang, Nanyang Technological University, Singapore
Yuwei Jiang, The Hong Kong Polytechnic University, China

EXTENDED ABSTRACT

Consumers often encounter difficulties—ranging from how to assemble a complex Lego model to how to utilize a newly-launched mobile app—when utilizing new products. Some consumers resolve the difficulties themselves, while many others seek help (e.g., calling the call center or posting questions in the forums). Given the augmented need of consumer help seeking, marketers need to understand when and why consumers seek assistance in product usage.

The foregoing situation led the current research. Specifically, we propose that when consumers engage in hedonic (vs. utilitarian) consumption, they focus more on the process (vs. outcome) of the consumption. As such, difficulties are considered to be an inherent part of the consumption process and consumers are more (vs. less) likely to tolerate problems that arise in the process of hedonic (vs. utilitarian) consumption and, consequently, are less (vs. more) likely to seek aid in that situation.

Help seeking was defined as the act of asking others for assistance and information to solve problems (Lee 2002). Marketing literature has mainly focused on examining consumers' help giving behavior (Winterich and Zhang 2014), research on consumers help seeking behavior is scant. Related to consumers' help seeking behavior, only some researchers have investigated the factors (e.g., level of difficulty; specific emotion) influence consumers' advice seeking tendency (Gino, Brooks, and Schweitzer 2012; Schrah, Dalal, and Sniezek 2006). To fill in the research gap on consumers' help seeking, we examine how consumption contexts influence consumers' help seeking tendency.

Products can be classified as hedonic and utilitarian (Alba and Williams 2013). Hedonic consumption is mainly driven by the desire to enjoy the process, or the affective experience engage in hedonic consumption, whereas consumers engage in utilitarian consumption for accomplishing a task or fulfilling a goal (Dhar and Wertenbroch 2000; Whitley, Trudel, and Kurt 2018). We argue that consumers are motivated to enjoy the process and experience of the hedonic good since they focus on the affective experience. Even the difficulties in hedonic consumption (e.g., difficulties in assembling a house by Lego blocks) is part of the experience that consumers enjoy, thus consumers have a higher tolerant for difficulties in hedonic consumption. However, In the utilitarian consumption context, consumers focus more on fulfil a goal or accomplish a task, seeking for others' help when facing difficulty can help consumers achieve the final goal more efficiently. More formally,

Hypothesis 1: *Consumers are more (vs. less) reluctant to seek for others' help when they encounter difficulties in the hedonic (vs. utilitarian) consumption.*

Hypothesis 2: *Process (vs. outcome) focus mediates the above relationship.*

Moreover, individual difference on Protestant work ethics (PWE) moderates the before-mentioned effect. Individuals with high PWE believe that you will succeed if you work hard (Cheng, Mukhopadhyay, and Schrift 2017). Even in utilitarian consumption, which is more outcome-driven, consumers with high PWE beliefs will tolerate challenges more as they believe tough process leads to good outcome, thus are less likely to seek help. Therefore, we predict that, for consumers with high PWE beliefs, the proposed effect of consumption type on help-seeking behavior will be weakened. Putting together,

Hypothesis 3: *The reduced help-seeking intention in hedonic (vs. utilitarian) consumption is less evident among consumers with high PWE beliefs.*

In study 1, we first selected top 30 apps of all 23 categories defined by Apple in US market and then asked participants from M-Turk to rate the utilitarian-hedonic level of each app on a 7-point Likert scale (1 = very utilitarian; 7 = very hedonic). Second, by using a web-crawler program, we counted the number of questions people asked for each app on *Quora.com* as a proxy of helping seeking tendency. We found that customers asked significantly less questions for hedonic apps as compared to utilitarian apps, supporting our hypothesis.

In Study 2, we asked participants to indicate their help seeking tendency when they encounter difficulties in 8 different consumption situations (e.g., business trip, leisure trip) on a 6-likert scale. We found that participants are more (vs. less) reluctant to seek for help when engaging in hedonic (vs. utilitarian) consumption.

In study 3, we asked participants to indicate their help seeking tendency when they encountering difficulties in online course (vs. online game) scenarios and measured their process-outcome orientation in these two scenarios. We found that participants are more (vs. less) reluctant to seek for help in the online game (vs. online course) consumption context. Moreover, participants focused more on the process (vs. outcome) in the online game (vs. online course) context. Importantly, process-outcome orientation mediates the main effect.

Study 4 is a 2(consumption context: hedonic consumption vs. utilitarian consumption) * 2(continuous PWE scale) designed study. We measured participants' help seeking tendency by using the same scenario in Study 3. Moreover, we also measured participants' PWE (Mirels and Garrett 1971). First, we replicated the main effect of consumption context. More importantly, we found a significant interaction. Specifically, among participants with low PWE, they are more reluctant to seek for help in the hedonic consumption condition than in the utilitarian consumption condition; among participants with high PWE, there is no significant difference.

Our findings contribute to the helping literature by shedding light on consumers' help seeking behavior since prior helping literature has mainly focused on consumers help giving behavior (Winterich and Zhang 2014) and ignored the other side of the equation (consumers help seeking behavior). Furthermore, we add to the emerging stream of literature on understanding the difference between hedonic versus utilitarian consumption (Chitturi, Raghunathan, and Mahajan 2008; Alba and Williams 2013). Managerially, the findings of this research can inform companies the importance of providing appropriate assistance and service to consumers depending on consumption contexts (e.g., hedonic consumption or utilitarian consumption).

The Sharing Economy Shapes and Is Shaped by Consumers:
The Mediating Role of Consumer Reflexivity in Sharing

Stella Yiyan Li, Northern Arizona University, USA
Antje Graul, Utah State University, USA
John Jianjun Zhu, New Mexico State University, USA

EXTENDED ABSTRACT

The sharing economy incorporates new challenges for firms to rethink and redefine their roles in a new consumer journey, with consumers actively participating in both the production and consumption process (Dellaert 2019). Findings on the significant change of the total consumption utility and welfare of consumers who engage in sharing as co-producers (i.e., those who share their possessions with other consumers) (Dellaert 2019) raise a similar question regarding the potential impacts of sharing at the individual consumer level for the participants who temporarily access shared products instead of permanently owning them. Will such sharing experiences transform their consumption preferences, norms, beliefs, and behaviors, fostering a decrease in attachment to and the important meaning of possessions?

This study aims to fill this crucial void by introducing the concept of consumer reflexivity as the underlying social-psychological mechanism explaining how the rapidly growing sharing practices might affect the participating consumers and their intention to re-engage in sharing. Drawing on previous research on reflexivity in multiple disciplines including sociology, education psychology, and organizational psychology, we conceptualize consumer reflexivity as a state of self-reflection involving a strong sense of self-awareness, self-regulation, and identity construction in the consumption process.

We propose that consumer reflexivity increases when consumers juxtapose distinct economic (i.e., flexibility and mobility), social (i.e., bonding with other shared minded participants) or environmental (i.e., saving natural resources, energy, and being sustainable) benefits of sharing to their beliefs and experiences with traditional ownership-based consumption models. We theorize that the perceived disruptiveness of sharing derived from consumers' sharing experience and perceived sharing benefits triggers their reflection and perception regarding future sharing experiences, which in turn affects consumers' intention to re-engage in sharing. Moreover, we suggest that the process of consumer reflection is contingent on individual differences including the type of sharing schemes experienced and the biospheric value orientation of the individual consumer.

Method and Data

To test whether engaging in sharing might trigger consumer reflexivity and influence consumers' intention to re-engage in a sharing, we first surveyed 200 consumers who have previously participated in sharing schemes in order to validate the existence and roles of a three-dimensional consumer reflexivity (i.e., self-awareness, self-regulation, and identity construction) in a sharing consumption context. We next establish the causality of the theorized effects through experiments that prime high versus low levels of consumer reflexivity with 118 respondents recruited online, and then another experiment both prime consumer reflexivity and manipulate the perceived sharing experience of another 1020 respondents recruited online. To enhance the robustness of our findings, we replicate our model with an alternative measure of future sharing intention and separate tests on the mediation effects of each sub-dimension of consumer reflexivity. We further demonstrate significant moderation of the type of sharing schemes experienced and the biospheric value orientation on the mediation role of consumer reflexivity.

Summary of Findings

Adapting the conceptualization and measures of reflexivity across different fields, we have developed and validate a three-dimensional measure of consumer reflexivity. Findings in our surveys and experiments show that three perceived sharing benefits—namely economic utility, social value, and sustainability potential—trigger consumer reflexivity. However, consumer reflexivity only mediates the effects of social value and sustainability potential of sharing on consumers' intention to reengage in sharing. Moreover, results from our survey also demonstrated that a consumer's past B2C sharing experience weakens the positive meditation of consumer reflexivity on the effects of perceived social benefits of sharing on the intention to re-engage in sharing whereas it strengthens the mediation effect of consumer reflexivity of the perceived sustainability benefits of sharing. Meanwhile, a consumer's biospheric value orientation weakens the positive mediation by consumer reflexivity on the effects of perceived social value of sharing schemes on intention to re-engage in sharing whereas it strengthens the positive mediation of consumer reflexivity on the effect of sustainability potential of sharing schemes. Individual differences did not affect the effects of economic utility on one's intention to re-engage in sharing.

Discussion

Over three studies, we investigated the connections between sharing and consumer reflexivity. The rise of service, knowledge, and digital economies has significantly challenged the maintenance of traditional consumption orientation, life trajectories, and long-term thinking of consumers (Bardhi and Eckhardt 2017). We believe that sharing practices also help consumers to step back and reflect on their consumption behaviors. The findings from our online survey and experiments allow us to explore whether and how sharing affects consumer reflexivity, which then motivates their reengagement in sharing. Conceptually and theoretically, we contribute to the literature in the following ways. First, our results provide the first empirical account addressing the present gap in the literature by showing the mediating effects of consumer reflexivity and the boundary conditions for such mediation effects. Second, our findings of the existence of consumer reflexivity in the sharing consumption context and the specific factors (i.e., perceived sharing benefits as indicators of perceived disruptiveness of sharing) that stimulate consumers to critically reassess their prior consumption beliefs, identity, and behavioral intentions complements prior arguments that reflexivity can only be triggered by unexpected traumatic life events (e.g., cancer, divorce) discontinuing daily routines and lifestyles (Pavia and Mason 2004; Thompson et al. 2018). Finally, our argument that reflexivity can increase consumers' identification with the *consumption practice* of sharing itself rather than the products accessed in the scheme extends recent research on liquid consumption which suggests that consumers tend to avoid identification with products through product ownerships or materialistic possessions (Eckhardt and Bardhi 2015). Notably, our results also provide important implications and valuable insights for managers and practitioners of sharing schemes.

Focusing on Experiential (vs. Material) Aspects of Goal-Related Products Increases Motivation

Sarah Lim, Cornell University, USA
Kaitlin Woolley, Cornell University, USA

EXTENDED ABSTRACT

Consumers purchase products to help them pursue their goals. To be physically fit, they purchase gym memberships and/or new workout equipment; to eat healthier, they take cooking classes and/or purchase kitchenware; to ace the GRE, students can enroll in a GRE class and/or purchase exam-prep books. Although these different sets of purchases are made to pursue a specific goal, they have a key distinction. One set of purchases is more *experiential*; they are made to gain an experience that consumers will live through. The other set of purchases is more *material;* they are made to acquire a tangible object that consumers can own (Gilovich and Gallo 2020; Gilovich, Kumar, and Jampol 2015).

Prior research has focused on how these different types of purchases influence consumers' happiness (Carter and Gilovich 2012). However, in the current research, we examine a different question — how the experiential versus material nature of a goal related purchase affects consumers' motivation to pursue their goals. On the one hand, material purchases related to a goal could be more motivating because material tangibility functions as a physical reminder of the goal. On the other hand, experiential purchases related to a goal could be more motivating. Compared to material purchases, experiences are more central to one's identity (Carter and Gilovich 2012). Experiential goal-related purchases could therefore lead consumers to identify more with their goal.

We propose and demonstrate that making experiential (vs. material) purchases, or focusing on the experiential (vs. material) features of goal-related products, leads consumers to identify more with their goal, which increases their motivation to pursue the goal. We provide evidence for this proposed mechanism by demonstrating 1) mediation through goal identification and 2) moderation by chronic goal identity centrality, such that the effect of experiential (vs. material) focus on motivation attenuates for goals that are chronically central to one's identity. Eight studies provide converging evidence for this proposition.

Study 1a demonstrated that consumers who made more experiential (vs. material) purchases related to their fitness goals spent more time pursuing these goals (B = 3.52, $t(156)$ = 2.28, p = .024). Generalizing to other domains, study 1b showed that participants who perceived their recent goal related purchases as more experiential (vs. material) reported greater success in pursuing their fitness, healthy eating, and educational goals during the past two weeks ($F(1, 1435)$ = 26.12, $p < .001$).

Our remaining studies provide a causal test of this hypothesis, holding the actual goal related product constant and manipulating people's focus on the experiential (vs. material) aspects of the product. Study 2a demonstrated that Apple Watch users were more motivated to work out when focusing on the experiential (vs. material) aspects of their Apple Watch ($M_{experiential}$ = 5.37; $M_{material}$ = 4.87; $t(149)$ = 2.37, p = .019, d = .39). Studies 2b and 2c replicated this effect for students thinking about different aspects of their workout headphones ($M_{experiential}$ = 4.28; $M_{material}$ = 3.86; $F(1, 211)$ = 5.99, p = .015, μ_p^2 = .03) and for online participants focusing on different aspects of their workout t-shirt ($M_{experiential}$ = 5.09; $M_{material}$ = 4.72; $t(299)$ = 2.26, p = .025, d = .26).

Study 3 examined whether the motivating effect of experiential (vs. material) focus is mediated by goal identification. An experiential (vs. material) focus increased participants' motivation to work out ($M_{experiential}$ = 4.82; $M_{material}$ = 4.15; $t(398)$ = 3.77, $p < .001$, d = .38) and caused participants to identify themselves more as an athletic person ($M_{experiential}$ = 67.96; $M_{material}$ = 63.10; $t(398)$ = 2.21, p = .028, d = .22). Supporting our proposed process, goal identification mediated the effect of product focus on motivation ($B_{indirect}$ = .10, 95% CI = [.01, .18]).

Study 4 examined whether the effect of product focus is moderated by goal identity centrality. If an experiential focus affects motivation by increasing goal identification, product focus should have a weaker effect on motivation for goals that people already strongly identify with. To test this, we manipulated goal identity centrality by asking students to think about an academic goal, which is more central to their identity, and a fitness goal, which is less central to their identity (e.g., Ferguson 2008). We found the predicted interaction between product focus and goal identity centrality ($F(1, 204)$ = 4.14, p = .043, η_p^2 = .02). An experiential (vs. material) focus increased motivation to pursue a fitness goal ($M_{experiential}$ = 4.10; $M_{material}$ = 3.44; $F(1, 204)$ = 5.90, p = .016, η_p^2 = .03), with no significant effect of product focus on motivation to pursue an academic goal ($F < 1$).

Our final study examined how adopting an experiential (vs. material) focus affects actual goal persistence. Participants in a multi-day fitness challenge focused on either the experiential or material features of their fitness related products. Focusing on the experiential (vs. material) aspects of their fitness related products increased average time spent exercising during the challenge ($M_{experiential}$ = 43.06 minutes; $M_{material}$ = 27.45 minutes; $t(42)$ = 2.30, p = .026, d = .69) and increased the likelihood that participants completed the number of days of the challenge that they signed up for (45.5% vs. 9.1%; $\chi2(1, N = 44)$ = 7.33, p = .007, ϕ = .41).

Adding to prior research that has focused on hedonic benefits of experiential (vs. material) purchases (Carter and Gilovich 2010; Gilovich and Gallo 2020; Nicolao, Irwin, and Goodman 2009; van Boven and Gilovich 2003), the current research identifies an experiential advantage in goal pursuit. In doing so, this research proposes a simple intervention to help motivate consumers: focus on the experiential (vs. material) aspects of goal related products. This research thus offers practical advice for many consumers who make goal related purchases in the hopes of achieving specific goals (Schroeder 2018) yet struggle to attain them.

#Cyborgs Are in Your Dreams, Thoughts, Talks, and Perhaps Next Door

Vitor M. Lima, York University, Canada
Luís Pessoa, Pontifical Catholic University of Rio de Janeiro, Brazil
Russell W. Belk, York University, Canada

EXTENDED ABSTRACT

Elon Musk, the Neuralink CEO, says that we are already cyborgs (Musk 2018). Is he right? Are our smartphones us? Throughout time, we can find myths (e.g., Talos), comic books (e.g., Doktor Sleepless), and TV series (e.g., Years and Years) depicting the dynamics and tensions arising from our consumption and interaction with different types of technologies (Belk, Humayun, and Gopaldas 2020). Although prior studies investigated technology consumption grounded in different perspectives (e.g., Hoffman and Novak 2018; Xiao and Kumar 2019), they mostly have employed an instrumental approach (Heidegger 1977). In these conceptualizations and portrayals, as a depiction of the consumer-technology relationship, humans are always portrayed as playing the role of masters, whereas technological solutions are the servants (Schweitzer et al. 2019). However, due to the development and volitional consumption of emergent technologies, such as CRISPR and embedded near-field communication (NFC) microchips, consumers are physically becoming one with technology. Sometimes, it is hard to distinguish what is what and who is who. From this standpoint, the way that we have been experiencing the literal dissolving of human/technology boundaries over time remains neglected. Therefore, our research questions are: *How do consumers experience the phenomenon of the human-tech merger? Do they reconcile such blending?* To address these questions, from 2018 to 2020, we conducted a netnography by following consumers' narratives on social media that were tagged with the hashtag #cyborg (Kozinets 2019). Our final dataset is comprised of approximately 15,000 entries from Facebook, Twitter, Instagram, and Youtube. Data interpretation followed discourse analysis methods (Greimas and Courtes 1982).

Supported by our data and the literatures on cyborgs (e.g., Clynes and Kline 1960) and Jungian archetypes (Jung 1959), our findings point to four distinct narratives. In each one, archetypal manifestations about cyborgization portray different psycho-social effects but tied by a common reason: the control over our sense of humanness. The first narrative, *Imagining the cyborg,* is represented by the Trickster archetype. This archetype is manifested through acts of creation and devastation in which the moral pillars of traditional society collapse (Jung 1959). The tricky and pricy enchantment of this archetype is represented in the Norse mythology by the God Loki, the master of shapeshifting performance. Due to the considerable volume of such portrayals of the trickster in the netnography, it is possible to assume that the cyborg is an entity to admire. Some of the references on social media relate to performances from artists such as Neil Harbisson, the first legally recognized cyborg. Artistic enactments can be taken as a reference to the exercise of imagination and volitionality in building "more than human" identities (Schau 2018). For example, Users 1 and 2 (Instagram, 2019) posted:

> Post: "Cyborg artist J. D. transpecies surgery - new sense to explore echolocation #cyborg #echolocation #cyborgart #transpecies #extrasense #senses #bodyart #newsense #bodyhacking #surgery"
> Comment: "awesome!"

Being the cyborg, the second narrative, encompasses references to the Hero archetype and his/her journey. Here, despite the terrible suffering, there is always a superior purpose to be achieved at the end of the trail (Jung 1959), as foreseen by the Prometheus myth and Captain Marvel. In this heroic storyline, the sense of positive morality is clearly associated with cyborgization through restoration of human health. Although sounding contradictory, consumers regain control over their sense of humanness by blending with technology. Eventually, as in the case of pacemakers, it is the only way to stay alive (Oudshoorn 2020). Thus, this practice depends directly on a therapeutic justification since, from a bioethical and religious perspective, such blending may not violate the values of the body and soul (Hrynkow 2020), as follows (Users 3 and 4, Twitter, 2018):

> Tweet: "Thanks for following & you'll continue to see tweets that give you insight into what "normal" life is like when you're a little bit robot - & also kind of a dork ¯_(□)_/¯, #bebionic #cyborg"
> Comment: "You are a brave person and fighter…God blessed you."

The third narrative, *Avoiding the cyborg,* is grounded in the Self archetype. It symbolizes the wholeness (or perfect psychic assimilation) since it is responsible for the coordination of opposing or conflicting elements in our psyche (Jung 1959). This narrative is marked by possible aspects of the Self that remain unintegrated and may be destructive. In the Christian perspective, for instance, this obscure side is "feminine, the material, and ultimately the "Antichrist," who personifies dark aspects of the Self split off during the development of the positive god image" (Ensign 2005, 18). By this logic, to prevent the rise of the Antichrist, we must avoid falling into sin by trying to become "more than humans." Here, one of the most remarkable products associated with a possible heresy is the NFC microchip, which is usually implanted in a person's hand between the index finger and thumb. To some, this object represents the Mark of the Beast (see Revelations, 13:16-17), and should be avoided at all costs (Users 5 and 6, Youtube, 2018):

> Post: "The Day I Got Microchipped"
> Comment: "I say NO to the microchip, guys please don't take the microchip is evil"
> Comment: "This is MARK OF THE BEAST. Stay away from this AMEN."

The fourth narrative, *Fearing the cyborg,* involves the Shadow archetype as its exemplar, which is composed of every repressed, undeveloped, and denied thing in our unconscious (Jung 1959). Cyberpunk images of cyborgs as weapons or as entities controlling weapons only increases the sense of dehumanization and the perceived threat to human existence. References to such anthropomorphized armament can be considered as warnings of a hypothesized machine takeover. The human-like machine versus machine-like human tension is highlighted by discussions of human enhancement through artificial intelligence, which is feared to be the most significant threat to humanity (Fukuyama 1992). The following example illustrates this theme (Users 7 and 8, Twitter, 2019):

> Tweet: "Would you let Elon Musk insert electrodes in your brain? Musk's #Startup #Neuralink wants to explore the frontier of #BCI #cybernetic enhancement with #AI."

Comment: "I am not happy about the future with all this AI […] it is the beginning of the end!"

Although the line that separates gods and demons, the sacred and the profane, is not always easy to be established, a common point in the West is the fear of punishment by an omniscient, omnipresent, and omnipotent deity for our transgressions (Johnson and Krüger 2004). In this last narrative, humans must not behave in a hubristic way, like Prometheus, who created humans and stole the fire from Zeus. Otherwise, the wrath of the gods might be sparked and, consequently, humanity punished similarly to Prometheus.

Our findings are not solely about technophobic/technophilic archetypal manifestations of what humans can *do* with technology but what can and cannot be done by "*becoming* technology." The contribution of this research lies in the thus far neglected role of technologies in changing the human condition by destabilizing humanity's ontological framing. Having this in mind, future investigations should embrace the promises, perils, and consequences of consumers' freedom and choices in becoming cyborgs, so that a deeper understanding of its psycho-social effects can be imagined. In our current philosophical and cultural framing, the perpetual and mutual influence among archetypes, myths, technologies, and consumers' narratives do not allow any boundary that sets cyborgs aside without symbolizing transcendence or transgression. Moreover, the observed complexity of consumer-technology relationships only reinforces the necessity of broader and more critical discussions about new forms of life. So, is Elon Musk correct? Are we already cyborgs? Are we our hearing aids, modified genes, smartphones, AirPods, and NFC Microchips? Is it up to the gods or to us to decide the limits or boundaries of being human?

The Egalitarian Value of Counterfeit Goods: How Perceptions of Inequality Illuminate the Hidden Egalitarian Value of Counterfeit Goods

Joyce Jingshi Liu, Hong Kong University of Science and Technology, Hong Kong, China
Wiley Wakeman, Stockholm School of Economics, Sweden
Michael Norton, Harvard Business School, USA

EXTENDED ABSTRACT

Counterfeit goods are tied to individual unethical behaviors (Gino et al. 2010), as well as broader criminal activity and safety hazards (International Anti-Counterfeiting Coalition 2005). Yet, the market for counterfeit goods continues to grow, projected to reach $4.2 trillion USD by 2022 (Frontier 2016). Willing purchase of counterfeits can be attributed to various sources of value, including economic and status signaling benefits of these produces (Wilcox et al. 2009). In this research, we explore another value of counterfeit goods that drives purchase, namely, the value counterfeits have in bolstering the impressions of social equality. We argue that counterfeits may be seen as addressing social inequality – an outcome we introduce here as the "egalitarian value" of consumer goods.

We argue that perceptions of this egalitarian value arise specifically when income inequality is salient. Because income inequality motivates concerns regarding social comparisons (Podder 1996; Cheung and Lucas 2016), consumers may be drawn to acquiring resources that are scarce, signaling their superior status in the hierarchy (Sharma and Alter 2012). However, and critical to this research, because inequality also motivates concerns regarding fairness (Oishi et al. 2011), consumers may be drawn to strategies that in fact reduce the exclusivity of scarce resources that are otherwise held by only the rich, leveling the playing field for all. We argue that counterfeit goods can serve the function of the latter. Thus, we explore the role that income inequality plays in motivating the recognition of this egalitarian value of counterfeit goods, as well as how this value motivates consumers' purchase intentions.

Indeed, in a pilot survey conducted in eight countries (N=1,463)[1], the social acceptance and prevalence of counterfeits increase, as the country-level income inequality, as well as individuals' perceptions of income inequality, increase. One reason for this relationship may be that counterfeits offer the appearance that society is fair, acting as a type of compensatory consumption mechanism (Sivanathan and Pettit 2010).

Three studies test our theorizing. Study 1 (N=208) has a 3 (video: inequality, control, equality; between-subjects) x 2 (products: counterfeit, legitimate; within-subjects) design. The inequality (vs. control vs. equality) condition watched a video about income inequality in the U.S. (vs. brain science vs. increasing equality), and rated an iPhone and a Goophone (a counterfeit iPhone) on their hedonic, utilitarian, economic and, critically, egalitarian values, and reported likelihood to purchase a counterfeit. We computed the relative values associated with a counterfeit versus a legitimate product[2]. Income inequality increased the relative egalitarian value associated with the counterfeit ($M_{inequality}$=1.36, $M_{control}$=.99, $M_{equality}$=.94, Table 1). Moreover, this egalitarian value mediates the effect of inequality (vs. control, equality) on purchase intentions toward a counterfeit (Bootstrap sample=5000, inequality vs. control 95% CI=[.008, .362];

inequality vs. equality 95% CI=[.0125, .4127]), independent of the other values (Table 1).

Study 2 tests individuals' social dominance orientation (SDO; Pratto et al. 1994) as a moderator and predicts that the observed effect will *not* hold among high SDO consumers, who endorse inequality. Participants (N=301) completed the same procedure as the inequality and control conditions in Study 1, in addition, they completed a Social Dominance Orientation Scale (Sidanius et al. 2000; α=.96). We found an inequality main effect (1=inequality, -1=control, β=.16, p=.033), qualified by an inequality X SDO interaction on relative egalitarian value (β=-.20, p=.008). Inequality (vs. control) increased the relative egalitarian values associated with a counterfeit among low SDO participants (-1 S.D.; β=.36, p<.001), but not high SDO participants (+1 S.D.; β=-.04, p=.709). Moreover, egalitarian value mediates the effect of inequality, moderated by SDO, on willingness to buy a counterfeit over a legitimate phone (Bootstrap sample=5000, 95% CI=[-.222, -.023][3], independently of the other values (Table 1). Thus, the egalitarian value associated with a counterfeit over their legitimate counterparts particularly appeals to those who support social equality.

Egalitarianism can be achieved by either reducing the status of the overprivileged, or by increasing the status of the underprivileged. Study 3 tests which motive more directly motivates counterfeit consumption. Participants (N=287) watched the same videos as in Study 2, and rated the relative hedonic, utilitarian, economic, status, and egalitarian values of an iPhone and a Goophone. Then, they reported the relative extent that the counterfeit is associated with a *spiteful egalitarianism* motive ("pulling down" those on the top) and that with a *benevolent egalitarianism* motive ("pushing up" those at the bottom), and their purchase preference for a counterfeit vs. legitimate phone. As before, income inequality (vs. control) increased the relative egalitarian value of a counterfeit ($M_{inequality}$=5.23, $M_{control}$=4.89, p=.011) and preference for a counterfeit ($M_{inequality}$=4.78, $M_{control}$=3.88, p=.022). Moreover, inequality (vs. control) increased the spiteful egalitarian motive associated with a counterfeit ($M_{inequality}$=5.24, $M_{control}$=4.81, p=.007); but did not affect the benevolent egalitarian motive ($M_{inequality}$=5.77, $M_{control}$=5.58, p=.228). The effect of inequality on purchase preference was mediated by spiteful egalitarian motive (Bootstrap sample=5000, 95% CI=[.017, .124]), but not benevolent egalitarian motive (95% CI=[-.018, .095]). Thus, income inequality increases counterfeit purchase, because it increases the perception that counterfeits, relative to legitimate goods, can improve social equality by reducing the privileges of those on the top.

In sum, under conditions of income inequality, counterfeit goods can be seen as "good" by making the world a fairer place, explaining the ongoing demand for these products.

---

1   Participants were recruited from China, India, Pakistan, UK, Spain, Russia, Chile and Mexico. A multi-level linear model regression was conducted, where the country-level Gini coefficients entered the model as a group-level variable, and the perceived income inequality entered the model as an individual-level variable.

2   We subtracted the rating of a counterfeit by the respective rating of a legitimate good for each value measured.

3   Note that for the moderated mediation model, the 95% CI are negative because the interaction of inequality prime (1=inequality, -1=control) and SDO on relative egalitarian value and on product preference both have negative coefficients, indicating that the effects are driven by those with low SDO. As such, the moderated mediation effect is also driven by those with low SDO (conditional indirect effect: 95% CI=[.0454, .3987]), and not those with high SDO (condition indirect effect: 95% CI=[-.1068, .0657]).

The (Mis)Perception of Altruistic Individuals: An Inference of Intertemporal Preferences

Yidan Yin, Wendy Liu, University of California San Diego, USA

EXTENDED ABSTRACT

INTRODUCTION

Alice is known by her friends and colleagues to be charitable. She volunteers in a local soup kitchen on weekends and donates to charity on a monthly basis. Recently, Alice received a promotion at work, and her friends would like to buy her a gift to celebrate. They are debating whether to buy her something that offers immediate gratification such as cupcakes, or something that provides benefits in the long-run such as a book on career management. More generally, will people's impression of Alice as a charitable person affect their prediction of Alice's intertemporal preference? Later, a new position is opening up at her company that is responsible for meeting a short-term deadline (versus a long-term corporate goal). Alice is interested in the position. When interviewing for the position, should Alice make a point to highlight or downplay her charitable efforts?

Altruistic behaviors and intertemporal behaviors are two of the most important and often-studied concepts in psychology, garnering interest among researchers in many subfields of behavioral science including social and cognitive psychology, neuroscience, behavioral economics, as well as marketing, managerial and medical decision making. An intriguing question is whether people perceive a relationship between these two behaviors, and what might be the underlying inference process. This perception is important to study because the perceptions of altruistic individuals affect how altruistic people are treated by others, which in turn can create positive or negative reinforcements for altruistic behaviors in society.

In five studies, three with real incentives for prediction accuracy, we propose and find that there is a strong social perception of a positive relationship whereby altruistic individuals are perceived to be focused on the long run. Importantly, and ironically, we also find that altruistic individuals are misperceived—in fact, in actual behavior, there is no relationship between altruism and intertemporal choice—a result that is consistent with past research showing mixed patterns of actual relationship (Bartels, Kvaran & Nichols 2013; Hershfield, Cohen & Thompson 2012; Rand 2016; Rand et al. 2012).

We propose three potential inference mechanisms through which the (mis)perception of altruism's link to intertemporal preferences can occur, and we test each in our studies. First, when observing a person behaving altruistically, people perceive the individual to care more about others (Carlson & Zaki, 2018). Research shows that the mental representations of others and the distant future are similar in that both are more psychologically distant than the present self (Fiedler et al., 2012; Soderberg et al., 2014; Trope et al., 2007). In fact, research has shown that people may view the self in the distant future as if it were another person, and as such may think about their future selves in similar ways as they think about other people (Bartels & Urminsky, 2011; Hershfield, 2019; Hershfield et al., 2011). Thus, a lay theory may draw on intuitions about psychological distance, and infer that an altruistic individual may have a broader construal beyond the present self, that includes not only others but also oneself in the distant future. Consequently, the altruistic person is perceived to care more not only about others, but also about the self in the future.

Hypothesis 1: *Altruistic people are perceived to put greater weight on the future due to their perceived broader construal that includes others and the self in the future.*

A second possibility is that people may have lay theories about how altruism and long-term versus short-term interests are related. Research has shown that altruism can also provide benefits to the self, such as a reputational benefit (Barclay 2006), a reciprocal favor (Fehr & Gachter 2000), or increased happiness (Dunn, Aknin & Norton 2008). Extending past research, we observe that often the costs and benefits of giving to the self can occur at different points in time. Specifically, when someone helps another person, there is an immediate cost to the self, however the downstream benefit to the self such as reputation, reciprocation, or long-term happiness and health (Post 2005) often occurs later in time. Therefore, we propose that there may be a lay perception that altruism, while costly in the short run, is good for the self in the long run. Further, people may perceive that one of the reasons why an individual behaves altruistically is because that individual believes in the long-term benefit of altruism. Such a belief aides them to overcome the aversion to the short-term cost to the self in order to choose to help others. Building on this lay belief, people then generalize the inference to a belief that the altruistic individual tends to care more about the long-term rather than short-term consequences of their actions in general. Thus, we hypothesize a second inference mechanism between perceived altruism and long-term importance:

Hypothesis 2: *Altruistic people are perceived to believe in the long-term benefits of giving, and they prioritize this long-term benefit over the short-term cost.*

This perception is then generalized to the belief that altruistic individuals are focused on long-term benefits over short-term interests in general.

Finally, yet a third path through which people may perceive a link between altruistic behavior and long-term preference is that altruistic individuals may be perceived to have better impulse control. Specifically, even when two individuals equally recognize and value long-term interests, they can still differentially struggle to override the impulse to pursue immediate interests (Figner et al. 2010). Altruistic individuals may be perceived to be more "disciplined" and better at regulating themselves towards their long-term goals.

Hypothesis 3: *Altruistic people are perceived to have better impulse control, and hence are more likely to act responsibly and help others.*

In summary, we propose an intertemporal dimension to the perception of altruistic individuals, whereby they are perceived to be more long-term oriented. Notably, this lay perception persists regardless of the actual relationship between altruistic behavior and long-term preference. We test this perception, its downstream consequences, and three potential underlying inference paths, in five studies.

Study 1

In Study 1, we used real incentives to test whether people believe more altruistic individuals are more likely to choose a later larger reward over an immediate smaller reward. Further, we examine whether there is an actual link between individuals' intertemporal choice and altruistic behavior.

Method

A total of 301 adults on mturk participated as "choosers" (M_{age} = 35.85, SD_{age} = 12.48; 171 men, 128 women, 2 participants declined to report).

Choosers were told that they would complete several short tasks linked together for convenience. In the first task, they made a choice between receiving $100 today or $110 in three months, knowing that there is a chance to receive the money for real. To reduce demand effects (of linking the intertemporal choice with the charity choice), next, choosers made two filler choices, namely, to choose their favorite fruit and ice cream flavors. Lastly, choosers decided whether to help a charity by completing an additional 3-minute survey about the charity for free. Those who said yes then proceeded to the additional survey.

In the second "guessers" phase of the study, 299 adults took part as guessers, among which 29 participants did not pass the attention check and were excluded from analyses, leaving 270 participants in the analyses (M_{age} = 36.61, SD_{age} = 11.16; 146 men, 123 women, 1 participant declined to report).

Each guesser was randomly paired with a chooser (drawn at random with replacement from the pool of 301 choosers): 43.0% (57.0%) guessers were paired with an altruistic (vs. non-altruistic) chooser. Guessers were shown the decisions the chooser made: their favorite fruit, their favorite ice cream flavor, and their decision of whether to help a charity. Guessers were then incentivized to guess whether the chooser chose to receive $100 today or $110 in three months. They would receive a $0.25 bonus if their guess matched the chooser's actual choice.

Results

As predicted, guessers were significantly more likely (in fact 4 times as likely) to guess their paired chooser chose $110 in three months when the chooser had decided to help a charity (M = 39.7%, 95% CI [30.7%, 49.2%]), than when the chooser had decided not to help (M = 9.74%, 95% CI [5.55%, 15.6%]), $\chi^2(1)$ = 32.17, p < .001, d = 0.74.

In actual behavior, however, the proportions of choosers choosing $110 in three months did not significantly differ among those who decided to help (M = 25.9%, 95% CI [18.2%, 34.8%]) and those who decided not to help (M = 22.1%, 95% CI [15.8%, 29.5%]), $\chi^2(1)$ = 0.33, p = .56, d = 0.07.

Discussion

Study 1 showed that although an actual relationship between altruistic behavior and intertemporal preference was absent, lay participants had a clear prediction that the altruistic individual would have greater long-term preference.

Study 2

Study 2 replicated study 1 findings using a similar design, with 297 "choosers" and 279 "guessers". Under real incentives for accuracy, guessers again were significantly more likely to guess their paired chooser chose a larger sum in three months over a small immediate sum when the chooser volunteered (M = 42.0%, 95% CI [30.2%, 54.5%]), than when the chooser did not volunteer (M = 14.3%, 95% CI [9.85%, 19.8%]), $\chi^2(1)$ = 22.34, p < .001, d = 0.59. However, again, the actual proportions of choosers choosing the larger sum in three months did not significantly differ among those who volunteered (M = 24.6%, 95% CI [15.0%, 36.5%]) and those who did not volunteer (M = 27.1%, 95% CI [21.2%, 33.7%]), $\chi^2(1)$ = 0.06, p = .80, d = 0.03.

Further, after controlling for perceived wealth in money, guessers were still more likely to predict long-term choice when choosers volunteered (vs. did not volunteer), $\chi^2(1)$ = 18.41, p < .001. Thus, perceptions of wealth in time and money cannot explain our results.

Study 2 then probed whether perceived long-term weight and/or perceived impulse control drove the effect. Mediation analyses using the mediation package in R (Tingley, Yamamoto, Hirose, Keele, & Imai, 2014) found only a significant indirect effect through perceived long-term weight, estimate = 0.16, 95% CI [0.10, 0.23], p < .001, but not impulsiveness. Thus, H3 was not supported. In sum, the belief that altruistic individuals are long-term oriented is due to their perceived greater prioritization of long-term interests, rather than reduced impulsiveness.

Study 3

Study 3 examined the downstream consequences of the perception. In a task with real incentives tied to outcomes, participants had to choose a person to lead a project with either a long-term or short-term profit goal. Participants were given the profile of two candidates. One of the candidates was manipulated to be more altruistic. Results showed that when choosing a candidate to lead a project with a long-term profit goal, 66% of participants voted for the more altruistic candidate, significantly more than 50%, p < .001, 95% CI [56.7%, 75.1%]. In contrast, for the project with a short-term goal, 31% voted for the more altruistic candidate, significantly less than 50%, p <.001, 95% CI [22.1%, 40.6%]. This study shows the perception of altruistic individuals has real consequences for when altruistic individuals would be favored in social contexts.

Study 4

Study 4 aimed to conceptually replicate S3. Further, Study 4 aimed to provide process evidence by testing H1 and H2, i.e., whether the effect is driven by an inference that altruistic individuals have a big-picture construal and focus on psychologically distant entities, or an inference that altruistic individuals believe in the long-term benefit of giving.

Results replicated study 3 where the altruistic individual is preferred only for tasks with long-term goals (84% participants appointed the more altruistic candidate to be the manager, significantly more than 50%, p <.001, 95 CI [75.3%, 90.9%]. When there is a mid-term goal, the altruistic individual is selected to the same extent as the non-altruistic individual (55% selecting, not significantly different from 50%, p = .49, 95% CI [42.7%, 66.2%]).

The more altruistic candidate was perceived to be more likely to see the big picture, as well as more likely to believe helping others pays off for the self in the long run. Mediation analyses showed that both inferences are significant drivers of the greater importance altruistic individuals place on the long run, which in turn drove the choice of the altruistic individual for tasks with long-term goals. Thus, both H1 and H2 are supported as the driver of the perception.

Study 5

One alternative account of the effect is that, to the extent having a long-term preference and altruism are considered desirable traits, people are simply seeing an association between two positive traits. If this was true, then people should see individuals with other positive traits such as likeability to have a long-term preference as well. In Study 5, we aimed to rule out this alternative explanation by manipulating perceived likeability versus perceived altruistic, imbedded in descriptions of many other traits. Participants made predictions about the target person's intertemporal choice. The study was therefore a 2 (trait presented: altruism, likeability) x 2 (level: high,

low) between-subjects design, and we predicted an interaction effect. We had 762 participants after exclusions for attention.

The main effects of trait level, $\chi^2(1) = 0.50$, $p = .48$, and trait type, $\chi^2(1) = 1.94$, $p = .16$, were non-significant. As predicted, the interaction was significant, $\chi^2(1) = 13.14$, $p < .001$. Participants were significantly more likely to guess the target person chose the future reward when the target person had high-level altruism ($M = 23.4\%$, 95% CI [17.6%, 30.1%]) than when the target person had low-level altruism ($M = 11.7\%$, 95% CI[7.41%, 17.4%]), $\chi^2(1) = 7.90$, $p = .005$, d = 0.30.

In contrast, participants were significantly more likely to guess the target person chose the future reward when the target person had low-level likeability ($M = 17.9\%$, 95% CI [12.8%, 23.9%]) than high-level likeability ($M = 10.3\%$, 95% CI [6.38%, 15.4%]), $\chi^2(1) = 4.06$, $p = .044$, d = 0.20. Thus, the perceived association with long-term focus is specific to altruism, rather than extending to all positive traits.

GENERAL DISCUSSION

How are altruistic individuals perceived by others? We found that they are perceived, erroneously, to prefer long-term interests. Further, people then favor altruistic individuals for tasks with long-term objective, while disfavoring altruistic individuals for short-term goals.

Consumers can use this knowledge to understand how altruism can aid versus hinder personal goals. For example, in the opening example, when marketing oneself for a long (vs. short)-term task, one should highlight (downplay) one's charitable behaviors. For marketers, it might be useful to consider the relationship between the firm's CRM (cause-related marketing) efforts, and the public's perception of the brand and the company. For example, do financial analysts forecast greater long-term profits for a firm upon a firm's CRM news announcements? Do consumers perceive a brand with significant CRM as a better (worse) long (short)-term purchase? These questions will be interesting to answer in future research.

To Touch or Not To Touch? The Effect of Product Touch on Consumers' Product Attribute Processing and Preference

Wumei Liu, Lanzhou University, China
Echo Wen Wan, the University of Hong Kong, China
Haizhong Wang, Sun Yat-Sen University, China

EXTENDED ABSTRACT

Introduction

Existing touch research examined the effect of product touch (versus no touch) on overall evaluation (Grohmann et al. 2007), purchasing likelihood (Citrin et al. 2003; McCabe and Nowlis 2003), ownership perceptions (Peck and Shu 2009), risk perceptions (Liu et al. 2017), and valuation (Peck and Shu 2009; Peck et al. 2013) of the product being evaluated, and on consumers' subsequent choice and purchase of other products (Streicher and Estes 2016; Ringler et al. 2019). *However,* function and appearance are of a product's two basic attributes (Townsend et al. 2011). Consumers' evaluation and preference of functional attributes and appearance (hedonic, aesthetics) attributes can be affected by several consumer-level (e.g., Bloch et al. 2003; Wan et al. 2017), contextual level (e.g., Chen et al. 2017; Chitturi et al. 2007), and product-level (e.g., Okada 2005; Wan et al. 2017) factors. *It is unclear whether product touch affects consumers' processing of and preference for a specific product attribute.* This research gap motivated our paper.

Hypotheses

Mental simulation (reenactments of previous experiences that have been stored in memory, Papies et al. 2017), often comes from individuals' sensory experiences and bodily activities (Elder and Krishna 2012; Papies et al. 2017; Krishna and Schwartz 2014). Touching a product involves actions of trying and using the product. Therefore, product touch (versus no touch) should increase usage simulation (mentally simulate the action of using the product). Because mental simulations of a motor activity subsequently engender consumers' desire to actually perform this action, due to activation of approach responses (Elder and Krishna 2012; Liu et al. 2018; Papies et al. 2017; Ping et al. 2009). Therefore usage simulation will trigger consumers a strong goal to subsequently know more about the product's usage (usage goal). Usage is often more closely linked with function rather than appearance. So, product touch (versus no touch) will increase consumers' processing and preference for the product's functional rather than appearance attribute information (*Hypotheses 1-2*), due to increases in usage simulation and usage goal (*Hypothesis 3*). This effect will disappear (versus be more evident) when the product is dominant in appearance (versus function) (*Hypothesis 4*), because usage simulation and usage goal will not occur when evaluating an appearance-dominant product.

Overview of Experiments

Experiments 1-2 tested the effect of touch on functional attribute processing (H1) as well as the serial mediation process (H2), via an information searching task (Wan et al. 2017). Experiments 3-4 next tested the downstream marketing consequences of functional attribute processing, functional attribute preference (H2), and the underlying mechanisms (H3) in lab (Experiments 3) and field (Experiment 4). Finally, Experiment 5 tested H4. *See Table 1 for details of each experiment.*

Experiments 1-2

Experiment 1 first randomly assigned participants to one of four treatments (product touch vs. no touch vs. product image touch vs. neutral/baseline), and then invited participants to complete a product attribute searching task (Wan et al. 2017). The number of coins participants spent in searching for functional attribute and appearance attribute information were recorded, and were generated into a functional attribute searching ratio. As expected, the ratio in the product touch condition was higher than that in the no touch ($t(88) = 2.35$, $p = .021$), picture touch ($t(88) = 2.11$, $p = .038$) and baseline ($t(86) = 2.45$, $p = .016$) conditions. However, the ratio among the latter three conditions were similar, $F(2,130) = .039$, $p = .961$, supporting H1 and suggesting that the touch effect on functional attribute processing was 1) driven by *touch* rather than by *no touch*, and 2) unique and cannot be replaced by picture touch.

Experiment 2 first randomly assigned participants to one of two treatments (touch vs. no touch), and then invited participants to wear an eye-tracker to browse the product's functional attribute and appearance attribute information for 1 minute. As expected, participants fixated longer duration ($F(1,102) = 3.95$, $p = .049$) and more frequent times ($F(1,102) = 3.99$, $p = .048$) of the functional attribute information after touching versus not touching a product, supporting H1. A bootstrap analysis showed that usage simulation and usage goal serially mediated the touch effect on functional attribute fixation duration (indirect effect = .0439, 95% CI [.0012, .2048] excluded zero) and fixation times (indirect effect = 1.3211, 95% CI [.0390, 5.9503]), supporting H2.

Experiments 3-5

Experiments 3 and 4 both employed a touch manipulation (touch vs. no touch) one-way between-subjects design. Experiment 4 was run by a salesperson in a university store after training. As expected, participants in Experiment 3 preferred to upgrade the product's function rather than appearance after product touch (versus no touch), $t(156) = 2.30$, $p = .023$. This effect was mediated by usage simulation and usage goal (indirect effect = .0462, 95% CI [.0012, .1489] excluded zero). Experiment 4 showed that a higher percentage of consumers favored the pen's new version to be superior in function after being encouraged to touch (versus not touch) the pen, Pearson $\chi^2(1) = 4.25$, $p = .039$.

Experiment 5 employed a touch manipulation (touch vs. no touch) x product type (function dominant vs. appearance dominant) two-way between-subjects design. As expected, after evaluating a function-dominant product, participants in the touch (versus no-touch) condition reported a higher preference to upgrade the product's function, $F(1,186) = 6.97$, $p = .009$. This difference disappeared after evaluating an appearance-dominant product, $F(1,186) = .09$, $p = .707$, supporting H4. A bootstrap analysis showed that this moderation effect was mediated by usage simulation and usage goal (indirect effect = -.0245, 95% CI[-.0686, -.0061]).

Discussion

First, we identified a novel outcome (functional attribute processing and preference) of consumers' product touch behavior. Second, we identified a novel antecedent (product touch) of consumers'

functional attribute processing and preference. Third, we observed a new form of mental simulation (usage simulation) and found it increased functional attribute processing and preference. This paper also has rich implications to online and offline retailing, and to product attribute design.

Food Packaging and Guilt: The Effects of the Color Red and Negative Cognitive Associations for Vice Versus Virtue Food Products

Renaud Lunardo, Kedge Business School, France
Camille Saintives, INSEEC Business School, France
Damien Chaney, South Champagne Business School, France

EXTENDED ABSTRACT

Through three studies, we demonstrate that because of the association of the color red with transgression, consumers feel more guilt when exposed to a red (versus green or blue) food packaging. This effect depends on the vice categorization of the food, red leading to stronger guilt for vice products.

Influencing evaluations (Mai et al 2016) and choice (Genschow et al. 2012; Madzharov et al. 2016), color can act as a powerful cue for food packages. In particular, research has stressed the role of cognitions in people's responses to color on food packages (Spence 2018). However, in spite of the negative meanings of the color red and specifically its association with mistakes and transgression (Mehta and Zhu 2009), no research to date has examined how such negative associations might negatively affect emotions and behavior toward red-colored food products. What we suggest is that because of such meanings, the red color may prompt guilt, a negative emotion that is closely linked to transgression (Baumeister et al. 1994). Building on the notion of self-signaling (Prelec and Bodner 2003), we demonstrate in three studies the notion that red (versus green, blue) leads to stronger negative associations and guilt – and eventually on behavior –, especially when used for vice (i.e., unhealthy; Chernev and Gal 2010; Mishra and Mishra 2011) products.

THEORETICAL BACKGROUND

Colors can lead people to form cognitive responses that then influence their behavior (Elliot et al. 2007). Because the color red carries specific meanings related to the negative notions of transgression (Mehta et al. 2017) – red being used for traffic lights and stop signs (Elliot et al. 2007) –, being exposed to the color red on a food package may lead people to make negative inferences about the food product. To this regard, research shows that the red color color makes people more vigilant and leads to a change in more conscious attitudes (Crowley 1993). Because guilt is a negative and self-conscious emotion generated in response to transgression (Baumeister et al. 1994), exposure to the color red may lead consumers to be more aware of their misbehavior (De Bock et al. 2013) and to exhibit guilt feelings. Therefore, we propose that because red is associated with transgression (Elliot et al. 2007), it will cause people to anticipate or experience more guilt from the consumption of the colored stimulus, leading to negative behavioral responses. This effect may occur when red is contrasted with green, which is widely considered the opposite of red (De Bock et al. 2013; Schloss and Palmer 2011) and carries positive meanings for food products (freshness, …). Hence:

Hypothesis 1: *The red color of food packages leads to stronger negative cognitive associations than the green color.*

Hypothesis 2: *Negative cognitive associations positively affect guilt (H2a) and thus mediate the effect of the color red (versus green) on guilt feelings (H2b).*

The question remains whether the indirect effect of the color red (versus green) on guilt occurs for any food product's package. In this regard, in the food domain, people categorize products according to a good/bad dichotomy of virtues and vices (Chernev and Gal 2010; Mishra and Mishra 2011). Virtue products are those that are consistent with long-term self-control goals, and vice products represent those that are consistent with goals of immediate gratification (Chernev and Gal 2010). Given this characterization, vice food products are usually viewed as unhealthy and virtue products as healthy (Dhar and Wertenbroch 2012; Sela et al. 2009). Building on the notion of self-signaling (Prelec and Bodner 2003), Dhar and Wertenbroch (2012) showed that the consumption of vice products leads consumers to believe that they lack the ability to resist temptation. With these negative beliefs prompted by vice products and also because the color red makes people more vigilant (Elliot et al. 2007) and conscious (Crowley 1993), vice products may reinforce the negative cognitions that people associate with red vice products. Therefore:

Hypothesis 3: *The vice versus virtue product type moderates the effects of the color red (versus green) on negative cognitive associations, such that red leads to stronger negative cognitive associations for vice (versus virtue) products (H3a). It also moderates the indirect effect of the color red (versus green) on guilt through negative cognitive associations, with red leading to stronger negative cognitive associations and guilt feelings for vice (versus virtue) products (H3b).*

Extant literature provides evidence on how guilt precludes people from engaging in the consumption of what causes this emotion (Duhachek et al. 2012; Matherly et al. 2019), suggesting the following:

Hypothesis 4: *The vice versus virtue product type moderates the serially mediated indirect effect of the color red (versus green) on behavioral intentions through negative cognitive associations and guilt. Specifically, for vice (versus virtue) products, red indirectly leads to lower behavioral intentions through the mediating effect of negative cognitive associations and guilt feelings.*

STUDY 1

Procedure

This field experiment manipulated the red versus green color of a food packaging, more precisely a squared box that researchers covered with either red or green paper and that differed in hue (red versus green) but—as much as possible—not in saturation and value. This experiment took place over two morning master-level classes. At the beginning of the class, students were exposed to one of the red and green boxes that was placed on a table. The boxes had been filled with chocolate—all of the same size, taste, and brown color—and students were told that they were allowed to approach the box to pick some chocolates, which they should completely consume. Three hours after having picked some chocolates, students were given a questionnaire. Two students did not agree to participate, making

the sample composed of 97 individuals (55.7% female). None was color-blind.

Participants rated the degree of guilt they felt after having eaten the chocolates (*guilty/culpable/remorseful*; α=.84; Agrawal and Duhachek 2010). Then, to measure negative cognitive associations, participants rated the degree to which they associated the color of the boxes with two words (*transgression* and *forbidden*; α=.70; Elliott et al. 2007). In order to rule out the explanation that it is the color green that negatively affects guilt because of its positive meaning (Mai et al. 2016), the positive cognitive association of "freshness" was measured. In addition, participants were asked to indicate the number of chocolates they had picked from the box.

Covariates were then measured. Because the study took place during the morning, participants were asked if they had breakfast before the study (0=No, 1=Yes). Also, a four-item measure of diet habits (Mohr et al. 2012; α=.82) was included. Further, because the color red is associated with sugar tastes (Spence, 2018), an item was added asking to what extent participants associated the color red with sugar tastes to rule out the notion that the lower number of chocolates picked could not be due to such associations. Finally, participants indicated on two mono-item scales their attitude toward the color of the box and chocolates in general. All scales were 7-point Likert scales.

Results

An ANCOVA that the color condition (0=Green, 1=Red) as the fixed factor, negative cognitive associations as the dependent variable, and the aforementioned covariates, revealed significantly stronger negative cognitive associations in the red condition (M = 3.32) than in the green condition (M=1.31, $F(1, 88)$=56.45, p<.001), supporting H1. Covariates had no significant impact (p's>.05). Supporting H2, a mediation analysis (Process, Model 4) then revealed a significant indirect effect of the color red versus green on guilt (β=.54, 95% CI=.092, 1.157). Specifically, the color red increases negative cognitive associations (β=2.05, p<.001), which then positively affects guilt (β=.26, p<.05). This indirect effect of color on guilt was replicated without the covariates (95% CI=.183, 1.126). No direct effect was observed (p>.05). Importantly, the alternative explanation that green could exert a negative effect on guilt due to the positive meaning associated with this color was ruled out (95% CI=-.392, .154).

Finally, and although no hypothesis was stated about an effect of the color red on choice, a significant serial mediation (β=−.11, 95% CI=−.348, −.011) indicated that the positive indirect effect of the color red on guilt through negative cognitive associations is followed by a decrease in the number of chocolates chosen (β=−.21, p<.05).

Discussion

Study 1 demonstrates that it is because the red color evokes transgression that people feel more guilt consuming some foods from a red versus green package. Study 1 also shows that guilt ultimately leads people to choose less of a food product from a red versus green package.

STUDY 2

Study 2 aims to test the moderating effect of vice and virtue on the red color–guilt relationship.

Procedure

Two hundred forty individuals were recruited online. Because of seven people being color-blind, the final sample included 233 ob-

servations (53.2% male; M_{Age}=30.35). The experiment employed a 2 (predominant food package color: red versus green) × 2 (product type: vice versus virtue) between-subjects design. Participants read a short scenario that asked them to imagine being at home in the middle of the morning, getting hungry, and finding a cereal bar in a kitchen cupboard. The cereal bar served as the focal product because it can have both virtue and vice connotations. Following previous manipulations of vice and virtue (Mishra and Mishra 2011), the emphasis in the vice condition was thus on the calories of the bar, while in the virtue condition the claims were about the product's healthfulness. After exposure to the stimuli, participants complete the same measures as previously (α_{Guilt}=.87; α_{Negative associations}=.80). For manipulation check purposes, participants rated how unhealthy the cereal bar was (1="not at all unhealthy"; 7 "very unhealthy").

Results

Participants perceived the cereal bar in the vice condition as significantly unhealthier (M_{Vice}=4.08; M_{Virtue}=2.32; $F(1, 232)$=73.53, p<.001), and the interaction between color and the vice versus virtue manipulation was not significant (p>.10), making the manipulation of vice versus virtue successful.

Supporting H1, an ANOVA showed that negative cognitive associations were stronger when the package was red (M_{Red}=2.20; M_{Green}=1.86; $F(1, 232)$=4.77, p<.05). Then, a mediation analysis replicated the mediating effect of negative cognitive associations (95% CI=.035, .483), with the color red (versus green) prompting negative cognitive associations (β=.33, p<.05), such associations increasing guilt feelings (β=.76, p<.001).

Next, a moderated-mediation analysis tested the moderating role of the vice versus virtue property of the food product. The results revealed a significant interaction of color and product type on negative cognitive associations (β=.72, p<.05; Figure 1) and no main effects of color and product type (p's>.05; Figure 2). Independent samples *t*-tests performed in each product type condition revealed no significant mean difference of negative cognitive associations in the virtue condition (t=.852, p>.05) but a significant difference in the vice condition (M_{Green}=1.98, M_{Red}=2.68; t=−3.06 p<.01), supporting H3a. Furthermore, the analysis revealed a significant index of moderated mediation (95% CI=.118, .990), such that negative cognitive associations mediated the effects of the color red on guilt feelings in the vice product condition (95% CI=.193, .865) but not in the virtue condition (95% CI=−.298, .233), supporting H3b.

Finally, a moderated serial mediation analysis (95% CI = −.313, −.015) – which included a single-item measure of behavioral intentions ("To what extent would you like to eat this crunchy bar?"; 1 = "not at all" and 7 = "very much") as the dependent variable –revealed a serially mediated effect of the color red on intentions only in the vice condition (95% CI=−.275, −.023) and not in the virtue condition (95% CI=−.054, .087). In the vice condition, the color red increases negative cognitions (β=.69, p<.01), which increase anticipated guilt (β=.70, p<.001), such guilt decreasing behavioral intentions (β=−.39, p<.001).

Discussion

Study 2 shows that red has stronger effects on negative cognitive associations, anticipated guilt feelings and intentions when the food is a vice product. In study 3, because red is sometimes opposed to blue (Bagchi and Cheema 2013; Mehta and Zhu 2009), we aim to replicate the current findings when opposing a red food package to green and blue food packages.

STUDY 3

Procedure

This experiment was completed online by 481 individuals (0 color-blind; 67.4% female, M_{Age} = 36.03). Color was manipulated at three levels (red versus green versus blue). Packages of chips were designed that differed only in their red, green, or blue hue. To manipulate their vice versus virtue property, the flavor of the chips was either "cheese and bacon" (vice condition) or "veggie" (virtue condition). Participants read a short scenario adapted from that of study 2 and completed the same measures as previously (α_{Guilt}=.81; $\alpha_{Negative\ associations}$=.68).

Results

Participants in the vice condition perceived the package of chips as unhealthier (*M*=5.39) than those in the virtue condition (*M*=4.26; *F*(1, 479)=79.52, *p*<.001), making the manipulation of vice versus virtue successful. Healthiness perception did not vary with color (*p*>.60).

An ANOVA followed by a Least Significant Difference (*LSD*) test supported H1, with a significant difference of negative cognitive associations across colors (*F*(2, 478)=4.91, *p*<.01), and the color red (*M*=2.37) leading to significantly stronger negative cognitive associations than the colors green (*M*=1.94, *p*=.002) and blue (*M*= 2.06, *p*=.031).

Then, two mediation analyses were conducted, respectively opposing the color red to the color green and blue. Supporting H2, results revealed a mediating effect of negative associations in both analyses ($\beta_{Red/Green}$=.24, 95% CI=.074, .417; $\beta_{Red/Blue}$=.07, 95% CI=.003, .172).

Testing H3, two moderated-mediation analyses were performed, again opposing the color red to either green or blue. When opposed to green, the red color significantly interacted with the vice versus virtue property of the chips (β=.56, *p*<.05; Figure 1). More specifically, a significant difference of negative cognitive associations emerged in the vice condition (M_{Green}=2.01, M_{Red}=2.70; *p*<.001), but not in the virtue condition (*t*=.73, *p*>.05). Results also revealed a significant index of moderated mediation (β=.34, 95% CI=.022, .684), with an indirect effect of the color red on guilt in the vice condition (95% CI=.170, .662) but not in the virtue condition (95% CI=−.159, .292).

The moderating-mediation analysis that opposed the colors red and blue revealed a marginally significant interaction between color and vice (β=.23, *p*=.09), followed by a non-significant index of moderated mediation (95% CI=−.080, .245). This indicates that the vice property of a food product's packaging does not change the indirect effect of the color red on guilt feelings when such color is opposed to blue.

Finally, a moderated serial mediation analysis opposing red to green (using the same dependent variable as in study 2) revealed a significant index (95% CI=−.211, −.002). As previously, a significant serially mediated effect of the color red on intentions was observed in the vice condition (95% CI=−.222, −.015) but not observed in the virtue condition (95% CI=−.088, .039). Hence, when the food product is considered a vice, the red package color leads to lower consumption intentions due to the negative cognitive associations and subsequent guilt. When opposing the red and blue colors, no moderated serial mediation was observed (95% CI=−.064, .007).

CONCLUSION

This research contributes to the recent stream of literature on the influence of food package color (Madzharov et al., 2016; Mai et al., 2016) by showing that merely being exposed to the color red on food packaging can heighten negative cognitions and the particular emotion of guilt. The three studies show that such effect is due to the negative associations of red with transgression, and is observed when red is opposed to green – not blue – and featured on vice food products.

Warmth Versus Competence Positioning: Impacts of Human-Like Body Shapes of Anthropomorphized Products on Consumers

Yixia Mai, Sun yat-sen University, China
Bing Shi, Sun Yat-Sen University, China

EXTENDED ABSTRACT

Anthropomorphism refers to the way of imbuing non-human agents with humanness (Epley, Waytz, & Cacioppo, 2007). Prior research focuses on endowing a product/brand a human-like face (Aggarwal & McGill, 2007) or body parts (Touré-Tillery & McGill, 2015), whereas little attention is paid to the overall body shape of an anthropomorphized product/brand. Note that mimicry of human body shapes is common in the market, such as Mr. Juicy curve-shaped bottles and Air Jordan's basketball-man-silhouette logo. How human-like product body shapes affect consumer perception and behavior is of great interest to marketing researchers and practitioners.

Perceived traits for chubby versus thin body shape

Social psychologists have demonstrated that body shapes lead to different impressions (e.g., Brodsky, 1954). Recent findings highlight variability in people's spontaneous associations of personality traits with body shapes (Hu et al., 2018). For instance, fatness when being perceived positively (or "chubbiness" as termed in this research—being plump and round in a pleasantly looking way, not too overweight) is more likely associated with friendliness and interpersonal warmth (Vallen et al., 2019). Consistently, round logo shapes, as compared to angular shapes, are related to characters such as friendliness, approachableness and gentleness (Jiang et al., 2016).

By contrast, thin bodies (i.e., individuals with lower amount of body fat than average-weight individuals, but not ultra-skinny) are perceived as independent, dependable, efficient and disciplined (Hu et al., 2018; Tiggemann & Rothblum, 1988). Young adults with slim physique are found to have a higher socio-economic status than fat counterparts (Muñoz-Cachón et al., 2007). Thin individuals are perceived as self-controlled, intelligent (Robertson & Vohora, 2008), competent (Tiggemann & Rothblum, 1988), and confident (Hu et al., 2018). According to the Big Five personality model (Barrick, Mount, & Judge, 2001), conscientiousness is associated with dependability, achievement-striving, and planfulness. Taken together, we predict:

Hypothesis 1:   *A chubby humanized shape of a product is more likely to trigger consumers' perception of agreeableness whereas a thin humanized shape is more likely to trigger perception of conscientiousness.*

Warmth and competence product positioning

In marketing, products are often positioned with key attributes which communicate benefits and help establish the product/brand images (Schiffman & Wisenblit, 2015). Body shapes of anthropomorphized products represent product design features. How product design interacts with the positioning is important to marketers/advertisers. Moreover, in marketing/advertising practices, a product is typically promoted in combination of images and verbal information (Jiang et al., 2016). Considering these, we further focus on the interplay between pictorial, anthropomorphized product body shape and verbally described product positioning upon consumers.

Two types of positioning—warmth and competence—are the core dimensions proposed in Brands as Intentional Agents Framework (BIAF; Kervyn, Fiske, & Malone, 2012). BIAF defines warmth as perceived intentions of a product/brand and competence as its ability to enact these intentions (Kervyn et al., 2012). Bridging social cognition and marketing practices, the warmth dimension corresponds to perceptions about humans which capture characteristics including friendliness, sincerity and trustworthiness, closely associated with Agreeableness (Kervyn et al., 2012). The competence dimension reflects characteristics such as intelligence, determination, persistence and efficacy/efficiency, which are projected mostly onto Conscientiousness and Openness of the Big Five personality model (Fiske, Cuddy, & Glick, 2007). Based on the foregoing discussion on Hypothesis1, and considering that evaluation of an anthropomorphized product depends on how well its anthropomorphic characters fit the relevant human schema (Aggarwal & McGill, 2007), we predict:

Hypothesis 2:   *Product attitude will be more favorable and purchase intention (PI) will be higher when product humanized body shape matches the positioning (i.e., chubby shape-warmth positioning or thin shape-competence positioning) than when they mismatch.*

Furthermore, regarding the proposed association of chubby body shapes with Agreeableness and thin body shapes with Conscientiousness, variability in the effects of product body shapes by positioning potentially occurs via the trait perception triggered by the product shape.

Hypothesis 3:   *When a humanized product centers on warmth positioning, perceived agreeableness, rather than conscientiousness, is more likely to mediate the effect of product humanized body shape on consumer attitudes and PI; but the mediation of conscientiousness tends to occur when the product focuses on competence positioning.*

Pilot Studies

We conducted a series of pilot studies including individual interviews and survey studies to identify appropriate measurement items for five personality traits: Agreeableness (A-Trait), Conscientiousness (C-Trait), Neuroticism (N-Trait), Openness (O-Trait), and Extraversion (E-Trait). At last, the revised TIPI scale (TIPI; Gosling, Rentfrow, & Swann, 2003) comprising seven 10-point positively-framed items was finalized. The items are: two A-Trait items (sympathetic, warm; easygoing, friendly), two C-Trait items (dependable, self-disciplined; efficient, competent) and one item for each of the other three (N-Trait: calm, emotionally stable; O-Trait: open to new experiences, complex; E-Trait: extraverted, enthusiastic). This scale was used in the following studies.

Pretests with recruitment of different samples were conducted independently for trial-and-testing the chubby versus thin anthropomorphized product stimuli across the studies. Details will be available via contact with the authors.

Study 1: Personality Perceptions of Chubby versus Thin Anthropomorphic Products

Seventy-four participants (55.4% female; M_{age} = 20.66, SD = 1.85) were recruited and asked to view either a chubby- or thin-shaped water bottle, and then complete a questionnaire including the revised TIPI scale. Chubbiness was measured on a verbal item ("Viewing it as a human, what do you think of its body shape?"; 1 = very thin, 9 = very chubby), and a graphic one adopted from Contour Drawing Rating Scale (Thompson & Gray, 1995).

Note that all reliability scores for measures throughout this research were satisfactory (αs > .75) except these two acceptable reliability values (C-Trait perception and warmth perception in Study 2, α = .69 and .68 respectively).

Results

The chubby-shaped products were perceived as chubbier than the thin-shaped ones (ps < .001). A 2(product shape)×5(personality trait) mixed ANOVA, with ratings of the revised TIPI items as the dependent variable, revealed the main effect of personality trait ($F(4, 292)$ = 7.73, p < .001) was significant. Moreover, a significant product-shape-by-trait interaction ($F(4, 292)$ = 16.04, p < .001) was reported. Planned contrasts further showed higher A- and lower C-Trait ratings for chubby-shaped than thin-shaped products (A-Trait: $F(1, 73)$ = 16.02, p < .001; C-Trait: $F(1, 73)$ = 36.3, p < .001). This pattern is consistent with H1.

Discussion

Findings in this study present support for H1. In Studies 2a-b, we aimed to elaborate on the applications of the inferences of personality traits from humanized product shapes to marketing situations, one of which involves users with various personality trait (Study 2a) and the other concerns buyers'/users' occupations featuring warmth or competence (Study 2b).

Study 2a: Human-like Product Shapes and Agreeable versus Conscientious Buyers/Users

Sixty-four undergraduates (59.4% Female, M_{age} = 20.69, SD = 1.79) were included in this between-subjects (target user's personality: A-Trait/C-Trait) study. They first viewed a verbal description of an imagined user that highlighted either agreeableness or conscientiousness trait. Agreeable-user scenario contained A-Trait-related words (e.g., warm-hearted) while Conscientious-user condition stressed C-Trait-related descriptors (e.g., industrious) (the manipulations were pretested). Participants were then asked to make a choice between the chubby versus thin models of a toothbrush product to match the described user and, finally, to report the perceived A- and C-Trait of the chosen product.

Results

A Pearson's Chi-square test revealed that participants were more inclined to match an agreeable person with a chubby-shaped product model (87.9%) and a conscientious person with a thin-shaped one (71.0%; χ2(1) = 22.95, p < .001). Consistent with H1, the ones who selected the chubby-shaped model (N= 38) for the target user rated higher scores on A-Trait than C-Trait (p = .018), but the reversed was observed for those who chose the thin-shaped model (N = 26; p = .007).

Study 2b: Anthropomorphically-Shaped Products and Occupations

Participants from Study 2a were further included in a between-subjects choice task. They viewed a product (mini wireless stereo/ electric toothbrush, counterbalanced) of either a chubby (N = 31) or thin (N = 33) shape, and then chose one from a pair of occupations to which they thought the focal product fitted more. Finally, they answered the remaining questions as instructed.

Based on pretests, we selected two occupation pairs, bank manager–psychological consultant and accountant–teacher as a proxy for Competence-versus-Warmth contrast. No difference was found between stereotypical body shapes within each occupation pair (ps > .20).

Results

Participants' choices of occupations (1 = competence-related; 0 = warmth-related) were regressed on anthropomorphic body shape (1 = thin; 0 = chubby) in a logistic regression with mood and familiarity of product shape controlled. For the accountant-teacher contrast, results indicated a significant effect for the product type of toothbrush (Wald $\chi^2(1)$ = 5.23, p = .022) and a marginally significant effect for mini stereo (Wald $\chi^2(1)$ = 3.07, p = .080) with an expected direction. Consistent with H2, relatively more participants (toothbrush, 71.0%; mini stereo, 61.3%) in the thin-shape condition appointed the product to an accountant featuring competence, while the percentage was significantly lower (toothbrush: 36.4%; mini stereo: 39.4%) in the chubby-shape condition. As for the bank manager-psychological consultant contrast, the matching pattern was the same except that, for toothbrush, the coefficient failed to be significant although its direction was as expected. The participants matched bank manager with the thin-shaped product more than with the chubby-shaped product (toothbrush: 54.8% vs. 39.4%, Wald $\chi^2(1)$ = 2.62, p = .105; mini stereo: 58.1% vs. 30.3%, Wald $\chi^2(1)$ = 4.97, p = .026).

Study 3: Investigating the Roles of Product Shape and Positioning

A 2(product body shape) × 2(product positioning: warmth/competence) between-subjects design was adopted. Participants (N = 153; 64.7% female; M_{age} = 21.33, SD = 1.04) viewed an ad picture featuring a humanized product (shampoo/power bank, counterbalanced), either chubby or thin, with verbal headlines and description stressing warmth or competence. They then completed a questionnaire.

Measures

Control variables We adopted two items (1 = not at all happy/cheerful, 7 = very happy/cheerful) for the measurement of mood. Product height/length, width and roundness perception and product shape familiarity were measured on a single 7-point item respectively. Participants' own appearance self-esteem (ASE) was measured on six 5-point items (e.g., "I am dissatisfied with my weight"; Heatherton & Polivy, 1991).

Perceived chubbiness Chubbiness was measured with the same two items in Study 1.

Perceived positioning Warmth and competence positioning types were rated on two items (warmth: 1 = not warm/friendly at all, 9 = very warm/friendly; competence: capable/competent).

Product attitude Product attitude was measured on two 10-point items (1 = bad/not at all like it, 10 = good/like it very much).

Purchase intention (PI) We adopted two measurement items (1 = very unwilling to buy it now/very impossible to buy it in the coming 30 days, 10 = very willing to buy it now/very possible to buy it in the coming 30 days).

Results

Mood was positively correlated with product attitude ($ps <$ .005) and PI ($ps < .001$). The other control variables were not significantly related to product attitude or PI ($rs < .15$, $ps > .10$). Given collaborative roles of determining (body) shapes, these control variables were still included in subsequent analyses.

Verbal cues in the warmth-positioning condition produced higher warmth ratings than those in the competence-positioning condition ($ps < .026$), and the reverse held for perceived competence ($ps < .06$). The chubby-shaped products were perceived as chubbier than the thin-shaped ones ($ps < .001$).

Results of 2(product body shape)×2(positioning) ANCOVAs showed a significant shape-by-positioning interaction on product attitude with covariates controlled (shampoo: $F(1, 140) = 10.11$, $p =$ .002, $\eta_p^2 = .07$; power bank: $F(1, 140) = 33.60$, $p < .001$, $\eta_p^2 = .19$). Planned contrasts further showed that attitude was more positive in the chubby-shape-warmth-positioning condition than chubby-shape-competence-positioning condition (shampoo: $F(1, 140) = 6.01$, $p =$ .015; power bank: $F(1, 140) = 29.78$, $p < .001$), and more in the thin-shape-competence-positioning condition than thin-shape-warmth-positioning condition (shampoo: $F(1, 140) = 4.15$, $p = .040$; power bank: $F(1, 140) = 7.63$, $p = .006$).

A bootstrapped moderated mediation analysis (Model 7; Hayes, 2012) with covariates controlled, product shape (chubby = 0, thin = 1) as independent variable, product positioning (warmth = 0, competence = 1) as moderator, agreeableness/conscientiousness perception ratings for the product as mediators, and product attitude as dependent variable, revealed significant conditional indirect effects of agreeableness and conscientiousness perceptions (A-Trait: for shampoo, $b = .36$, SE = .21, 95% CI [.00, .83]; for power bank, $b = .34$, SE = .18, 95% CI [.01, .72]; C-Trait: for shampoo, $b = .37$, SE = .19, 95% CI [.05, .80]; for power bank, $b = .32$, SE = .17, 95% CI [.05, .71]).

More specifically, the indirect effect of A-Trait perception on product attitude was observed only in the warmth-positioning condition (shampoo: $b = -.39$, SE = .16, 95% CI [-.74, -.12]; power bank: $b = -.38$, SE = .14, 95% CI [-.68, -.12]) but not in the competence-positioning condition (shampoo: $b = .03$, SE = .14, 95% CI [-.30, .25]; power bank: $b = -.04$, SE = .14, 95% CI [-.30, .25]). By contrast, the indirect effect of C-Trait perception was found only in the competence-positioning condition (shampoo: $b = .50$, SE = .16, 95% CI [.22, .86]; power bank: $b = .32$, SE = .16, 95% CI [.07, .68]) but not in the warmth-positioning condition (shampoo: $b = .13$, SE = .13, 95% CI [-.13, .39]; power bank: $b = .00$, SE = .12, 95% CI [-.23, .20]). Note that N-, O- and E-Traits failed to be significant mediators in the models.

Regarding PI, results revealed a similar product-shape-by-positioning interaction pattern as that for product attitude. The moderated mediation for PI was replicated as well. We also analyzed ASE×product body shape interactions and found no significant effects on either PI or product attitude ($ps > .20$). Considering non-significant findings, we did not report results regarding ASE.

Discussion

Study 3 supported H2-H3 by illustrating that a product with a chubby human-like shape is preferred when it is positioned as warmth instead of competence. But the opposite holds when the product humanized shape is thin. The product-body-shape-by-positioning interaction is mediated by perceptions of A- and C-Trait, with the relative effects of the mediator contingent upon the given positioning.

General Discussion

The studies demonstrate people making A- and C-Trait inferences from anthropomorphic product shapes: associating higher A-Trait with chubbiness and higher C-Trait with thinness. A shape-positioning congruity effect exists in product evaluation contexts as well as in a buyer-/user- or occupation-product matching scenario. The effect is generalizable across various product categories.

To our knowledge, this research is important in introducing body-shape-and-trait associations into the anthropomorphism marketing literature. The findings should help promote anthropomorphic product design with consideration of product/brand positioning. Also, it provides insights on how to segment and target consumers based on positioning and product design, which may be valuable in real-life contexts such as gift choosing/giving.

Some questions remain for future research. First, a more stringent operational definition of "body shape" needs to be made. Future research may need to employ a more objective classification method or standard to define products' "body shapes". Next, what roles the other personality traits play in product shape anthropomorphism remain less clear. Future work is necessary to explore the boundary conditions, if any, of the other three personality traits to come into play. Finally, it is worthwhile to examine the observed congruity effects further by experimenting with more product categories and manipulating levels of consumers' familiarity with the product and its shape.

The Impact of Comparative Product Quality Information in a Multi-Product Context

Christoph Mai, University of Erlangen-Nuremberg, Germany
Nicole Koschate-Fischer, University of Erlangen-Nuremberg, Germany
Andreas Fürst, University of Erlangen-Nuremberg, Germany

EXTENDED ABSTRACT

Firms must develop strategies to influence consumers to their advantage at the point of sale (Bettman, Luce, and Payne 1998; Nies and Natter 2010). Therefore, they often use TPPRs (third-party product reviews) on the product package (Chen, Liu, and Zhang 2012) because consumers "increasingly rely on product quality information provided by third-party product ratings organizations" (De Maeyer and Estelami 2011, p. 1067).

However, research on this topic is rather scarce. Prior studies focus on how a TPPR positively affects the *rated product* (e.g., Aiken and Boush 2006). Nevertheless, given theoretical support that TPPRs can reduce competitors' profits (Shaffer and Zettelmeyer 2002) and that TPPRs include a comparative component (e.g., Dean and Biswas 2001), TPPRs may negatively affect *competitive products* (products of a firm's competitors).

TPPRs test products against one another (e.g., Chen, Liu, and Zhang 2012; Dean and Biswas 2001). Hence, they lead consumers to engage in comparative judgments between the products in a purchase situation (e.g., Dean and Biswas 2001). Following the selective accessibility model (Mussweiler 2003), these comparative judgments trigger anchoring effects between the products, while the model explains whether contrast or assimilation emerges. Individuals form a surface-level judgment of the perceived (dis)similarity between the products. When individuals perceive the products as (dis)similar, they search for information supporting the impression of (dis)similarity (i.e., contrast vs. assimilation). When evaluating a competitive product (which does not have a TPPR), the *apparent difference* concerning a TPPR between the products should result in a high perceived product dissimilarity, leading to contrast (i.e., a negative effect of a favorable TPPR). Further, we focus on three potential boundary conditions: A TPPR of the competitive product, the brand equity of the rated product, and the consumer comparison mindset. These influences are related to TPPRs or have shown to determine the effectiveness of such product quality information and will therefore add to a more comprehensive understanding (e.g., Brady, Cronin, Fox, and Roehm 2008; Dean and Biswas 2001; Kwong and Wong 2014).

In Study 1, participants saw six sunscreens. One sunscreen showed the favorable TPPR ("very good"). As baseline condition, we used a dummy label ("new") to ensure information parity. Further, we included three control groups with no label, a favorable front-of-package-claim, or a positive online consumer review. Participants evaluated the perceived quality of the competitive sunscreen. Results showed only a negative effect of a TPPR.

In Study 2, we showed six sunscreens including the TPPR (vs. dummy label). Participants also evaluated the perceived product dissimilarity, which was higher for a TPPR. Mediation analysis revealed that perceived product dissimilarity mediated the negative effect on perceived quality (Hayes 2017).

In Study 3, participants saw TPPRs (vs. dummy label) for two sunscreens and evaluated the perceived quality of the competitive product. The negative effect varied depending on a TPPR of the competitive product, appearing only when the competitive product had no TPPR.

In Study 4, a sunscreen with high or low brand equity showed the TPPR (vs. dummy label). We also measured purchase intention of the competitive product. Results revealed a weaker negative effect in the low versus high brand equity condition, while perceived quality mediated the negative effect on purchase intention.

In Study 5, we manipulated participants' consumer comparison mindset with a procedural priming task (dissimilarity vs. similarity mindset) (Häfner 2004). Participants then saw six sunscreens including the TPPR (vs. dummy label). Results showed a stronger negative effect, when consumers were in a dissimilarity versus similarity mindset; perceived quality mediated the negative effect on purchase intention.

In Study 6, participants saw products from three different product categories for two competing brands including the TPPR (vs. dummy label) on a sunscreen. Participants evaluated the competitive products in the different product categories (sunspray and shampoo). Results revealed negative effects on both, while mediation analyses indicated that perceived qualities mediated the negative effects on purchase intentions.

In Study 7, we showed six soft drinks including the TPPR (vs. dummy label). As additional compensation, participants could choose €1 (prices of all soft drinks) or a soft drink (i.e., the competitive product). We assessed participants' product choice of the competitive product. Mediation analysis indicated that perceived quality mediated the negative effect on product choice.

Our findings underline that only investigating direct effects is insufficient to explain TPPRs' overall effectiveness. By illustrating that spillover effects across product categories appear between competitive products, our results also add to research on spillover effects. For firms, TPPRs may serve as an effective instrument for damaging competitive products. By examining boundary conditions, managers receive guidance on how they can control negative effects and on when they should especially assign high importance to TPPRs.

"Do You Speak Emoji?" – How Visual Cues Shape Computer-Mediated Communication

Tobias Maiberger, University of Erlangen-Nuremberg, Germany

Elisabeth Sanders, University of Erlangen-Nuremberg, Germany
Nicole Koschate-Fischer, University of Erlangen-Nuremberg, Germany

EXTENDED ABSTRACT

The sheer amount of electronic word-of-mouth (eWOM) containing an emoji has raised academic and managerial interest. Facial emojis as most common type and the focus of this research transmit their meaning through their graphic resemblance to facial expressions. Facial emojis typically serve to reiterate or replace written language. This research focusses on whether these two communicative functions have different consequences on eWOM persuasiveness.

In EASI theory, van Kleef (2009) argues that facial expressions affect observers through eliciting affective (e.g., liking of a smiling person) and inferential responses (e.g., smiling person is doing fine). Conceptualizing facial emojis as electronically mediated facial expressions, we argue that facial emojis should affect eWOM receivers via an emotional and an informational route – both are important for persuasion (Petty and Cacioppo 1986). In terms of derived emotion, research has shown that facial emojis increase the emotionality of an expression (Smith und Rose 2020). This increase in nonverbally transmitted emotionality should positively affect a message's persuasiveness, irrespective of whether the emoji reiterates or replaces verbal expressions. In terms of derived information, for an emoji reiterating, the preceding verbal expression leads to a relatively precise understanding of the emoji. Thus, it disambiguates a message, as facial expressions are better suited than words to communicate information about the sender's intention. However, when the facial emoji replaces a verbal expression, there is no accompanying verbal statement clarifying the emoji. Thus, it transmits information that is less accurate. This increases the message's perceived ambiguity and negatively affects its persuasiveness. In sum, a facial emoji that reiterates a verbal expression should positively affect persuasiveness through increasing message emotionality and decreasing message ambiguity. A facial emoji that replaces a verbal expression, however, should affect persuasiveness positively through increasing message emotionality and negatively through increasing message ambiguity.

Moreover, when a facial emoji is highly ambiguous, the information a facial emoji replacing a verbal expression conveys is more challenging to capture as there is no accompanying verbal statement to rely on. This should strengthen the negative indirect effect of a facial emoji replacing a verbal expression on persuasiveness through message ambiguity.

Furthermore, in case of high verbal context richness, we assume that individuals can better interpret the emoji's meaning from the specified verbal context surrounding the emoji, particularly when it replaces a verbal expression. Thus, a facial emoji replacing a verbal expression should no longer increase but instead decrease message ambiguity that should positively affect persuasiveness.

We tested the impact of facial emojis on persuasiveness in six studies. Study 1 examined the impact of the communicative function of a facial emoji on persuasiveness through an online field study on Facebook. The experiment had three between-subjects manipulated conditions (text-only vs. emoji reiterating vs. emoji replacing). We found that, compared to text-only, facial emojis reiterating a verbal expression increased persuasiveness, while facial emojis replacing a verbal expression did not exert a persuasive impact. Study 2 provided evidence for the proposed underlying mechanisms. A mediation analysis (custom PROCESS models in all studies; Hayes 2018) demonstrated that facial emojis reiterating a verbal expression yielded positive effects on persuasiveness via message emotionality and message ambiguity. Facial emojis replacing a verbal expression, however, affected persuasiveness positively via message emotionality but negatively via message ambiguity resulting in similar persuasive consequences compared to text-only. A validation study using an online post from a fictitious brand extended the impact on persuasiveness and the underlying mechanisms to brands engaging in eWOM. Study 4 investigated the moderating influence of emoji ambiguity (low vs. high). The findings showed that emoji ambiguity did not influence the effects of facial emojis reiterating a verbal expression on persuasiveness. However, it strengthened the negative indirect effect of facial emojis replacing a verbal expression on persuasiveness via message ambiguity. Study 5 examined the moderating effect of context information richness (low vs. high) and found that context richness did not influence the effect of facial emojis reiterating a verbal expression on persuasiveness. However, facial emojis replacing a verbal expression exerted an impact on persuasiveness via message ambiguity that was negative for low and positive for high context richness. Finally, a validation study demonstrated that positive and negative facial emojis reiterating a verbal expression increased persuasiveness, while positive and negative facial emojis replacing a verbal expression did not yield persuasive consequences.

Overall, this research provides a deeper understanding of language use in digitized contexts by demonstrating that whether a facial emoji reiterates or replaces a verbal expression has important persuasive consequences. From a practical perspective, our findings provide new strategies for marketers and consumers to communicate online more efficiently.

EXTENDED ABSTRACT

In an image-obsessed society, consumers can find it easier than ever to have their self-esteem destroyed. From body-shaming advertisements, to social media feedback, to preening in form-fitting clothing, consumers can instantly feel attractive or unattractive. We examine whether feeling attractive or unattractive due to such marketplace actions can affect motivation to pursue cognitive tasks. Feeling attractive can lead to general good feeling about oneself, whereas feeling unattractive can decrease self-esteem. When feeling good about themselves, consumers are more confident and optimistic about their abilities and take on more challenging cognitive tasks (Fishbach and Labroo, 2007). Yet, a common stereotype is attractiveness and intelligence are negatively correlated, particularly for women (Heilman et al. 2004; Lewis et al. 2012). Attractive women are frequently portrayed as unintelligent "objects of desire" in pop-culture, media, and TV shows. These marketer portrayals further strengthen societal beliefs that attractive women are unintelligent. Moreover, the salience of the attractive-is-unintelligent belief could decrease motivation to pursue cognitive tasks among women, but not men, if women consider these beliefs as self-diagnostic. Furthermore, merely feeling attractive or unattractive could make such beliefs salient and result in these downstream consequences.

How attractive (or unattractive) a person feels could thus be an important, highly pervasive but not yet investigated factor to raise this belief's accessibility. When feeling attractive, women may place a greater weight on being attractive and reduce cognitive pursuits. By contrast, feeling unattractive, women may place a lower weight on being attractive, and boost cognitive pursuits. Since men are generally not subject to this belief, it should not be perceived as self-diagnostic to the same extent by them, and while feeling attractive could cue this belief it should not adversely affect their cognitive pursuits.

An important precursor to beliefs impacting cognitive pursuits is their existence or availability to begin with (Devine, 1989; Higgins, 1989; Menon, Raghubir, and Schwarz, 1995). Young children, who may stereotype based on gender and race (Bigler and Liben, 2006), and may behave according to these stereotypes when choosing toys or activities (Coyne et al., 2016; Serbin et al., 2001), are unlikely to hold the attractive-is-unintelligent belief about women. Such more complex beliefs are likely to develop only later (McKenney and Bigler, 2014; Stone et al. 2015), as they require compensatory thinking—the ability to make trade-offs and infer more of one attribute implies less of another—a skill that develops around age 7 (Inhelder and Piaget, 1969; Stone et al. 2015). Four-and five-year olds instead tend to classify objects as good or bad and show little compensatory thinking (Flavell, 1963; Ginsburg and Opper, 1988). Furthermore, if the attractive-is-unintelligent belief about women develops over time from media portrayals, as we postulate, then children this age are less likely to consume and understand such media. Feeling attractive should reduce cognitive pursuit only when these beliefs are available, and therefore can become accessible by merely feeling attractive; i.e., among adult women but not young girls.

The first pretest (N=274) establishes that adults hold the belief that attractive women (but not men) are less intelligent and that such beliefs are perceived as more self-diagnostic for women than for men. A second pretest, (N=41), establishes that children 4-5 years old instead associate more attractive people, men and women, with being more intelligent. Next, four studies show that when feeling attractive (unattractive), women, but not men, are less (more) motivated to pursue cognitive tasks, but children are more motivated when feeling attractive.

Study 1 (N=50, all female) included only women and manipulated feeling attractive versus not by wearing a well-fitting versus non-fitting sweatshirt. Women who wore a well-fitting sweatshirt chose to complete more anagrams compared to those wearing a non-fitting sweatshirt ($M_{more-attractive}$ = 5.23, SD = 2.77; $M_{less-attractive}$ = 6.74, SD = 1.89; $t(46)$ = 2.153, p = .037). There was no difference in the percentage of correctly-completed anagrams, suggesting the effect is motivation and no ability based. We replicate this result in studies 2 and 3.

Study 2 (N=612, 53% female) included both men and women, and manipulated feeling attractive versus not by having participants describe an attractive selfie (attractive condition) versus describe making a cup of tea (control condition). All participants were then invited to find as many of the 14 words hidden in a word-search matrix, or to bypass the task. Decomposing the interaction between gender and condition ($F(1, 594)$ = 3.085, p = .080), women feeling attractive attempted fewer words than women in the control condition (M_{selfie} = 1.76, SD = 1.39 vs. $M_{control}$ = 2.09, SD = 1.48, $t(594)$ = 3.411, p =.001), while men showed no difference (M_{selfie} = 1.61, SD = 1.97 vs. $M_{control}$ = 1.49, SD = 1.41, p > .418), suggesting the belief attractive-is-unintelligent affects cognitive pursuits only when it is self-diagnostic (i.e., among women).

Study 3 (N=298, 43% female) manipulated feeling *unattractive* versus not by having participants view an ad featuring an attractive female or male (man-ad and woman-ad conditions) or describe making a cup of tea (control condition), and measured cognitive pursuits as in study 2. Decomposing the interaction between gender and condition ($F(1, 275)$ = 3.983, p = .020), women feeling unattractive after viewing the woman-ad attempted to find more words compared to control women ($M_{woman-ad}$ = 2.15, SD = 1.48 vs. $M_{control}$ = 1.63, SD = 1.27, $t(275)$ = 1.861, p = .064). Surprisingly, men who viewed the woman-ad attempted to find fewer words than control men , possibly because they were distracted ($M_{woman-ad}$ = 1.22, SD = 1.08 vs. $M_{control}$ = 1.78, SD = 1.42, $t(275)$ = 2.144, p = .033). Men's and women's cognitive pursuits did not differ between control and man-ad conditions.

Study 4 (N=61, 55% girls mean age = 61 months) included a sample of preschoolers and manipulated feeling attractive versus not by receiving a compliment on their looks before choosing the task (attractive condition) or after (control condition). Children feeling attractive were more likely choose a challenging task (count a large versus small pile of blocks) compared to those in the control condition (53.6% vs. 27.3%, $X^2(1, N = 61)$ = 4.390, p = .036). This suggest that when the attractive-is-unintelligent belief is not accessible, as it is with preschoolers, children do not behave consistent with the belief.

How Autobiographical Memory Perspective Influences Self-congruence and Brand Preference

Sudipta Mandal, Indian Institute of Management, Indore, India

EXTENDED ABSTRACT

Brands provide self-definitional benefits to consumers by helping them achieve their identity goals (Aaker, 2012; Keller & Lehmann, 2006). Consequently, consumers prefer brands associated with a set of personality traits that are congruent with their own (Aaker, 1999). This psychological congruence between the brand and the self is known as self-congruence or self-brand congruence (Sirgy, 1982). Extant research has primarily restricted itself to consequences of self-congruence (Jamal & Al-Marri, 2007; Mazodier & Merunka, 2012). Focus on antecedents of self-congruence is conspicuously absent in extant research. In this research, we address this gap and extend prior work on self-congruence by examining how one specific factor, namely, autobiographical memory perspective, influences consumer's perceptions of self-change, and in turn their brand preferences.

Autobiographical memories are reminiscences of past episodes from one's own life experiences (Brewer, 1986). Such memories involve recollections of an individual's personal experiences and are an important constituent of self-image (Brewer, 1986). Additionally, imagery constitutes a significant element of autobiographical memory (Pillemer, 2009). Thus, autobiographical memories may be visualized either from a *first-person perspective*, i.e., through one's own eyes, or from a *third-person perspective*, i.e., "looking" at the self from an outside observer's perspective. Each perspective influences one's construction of self-image (Libby, Eibach, & Gilovich, 2005).

Scholars have used the term 'self-concept' or 'self-image' to conceptualize the consumer's sense of self (Rosenberg, 1986). Consumer researchers typically use four dimensions of self-image, namely, actual self-image, ideal self-image, social self-image, and ideal social self-image (Sirgy et al., 2000). Theory of the self posits that individuals inherently try to minimize discrepancies between their actual and ideal self-images. A key motive for the construction and expression of self-image is self-consistency, i.e., the disposition to behave consistently with one's view of oneself (Epstein, 1980; Sirgy, 1982). Consonant with Sirgy's (1986) self-congruence theory, any inconsistency between a brand-user image and the consumer's self-image potentially results in self-brand incongruence. As we explain next, autobiographical memory perspectives influence consumer's perceptions of self-change, i.e., change in self-image. This in turn impacts self-brand congruence.

Individuals can visualize autobiographical memories from a *first-person perspective* or a *third-person perspective* (Frank & Gilovich, 1989). Each perspective causes people to construe their own actions at a low/concrete-level or high/abstract-level (Libby et al., 2005). Concrete construal emphasizes the details of an action in isolation. Abstract construal focuses on the broader meaning and implications of the same action (Trope & Liberman, 2003). Visualizing autobiographical memories from a third-person perspective, functions like other forms of psychological distancing, causing individuals to engage in abstract construal thereby accentuating and decontextualizing the broader meaning of the recalled events (Libby & Eibach, 2004; Libby et al., 2005). Autobiographical memories from a first-person perspective engender concrete construal causing individuals to emphasize the finer details of the recalled event in isolation only.

Further, individuals may also retrospect about differences or similarities between one's past and present selves. When the focus is on *differences* (*similarities*) between one's past and present selves, a third-person perspective causes the differences (similarities) to be construed at an abstract level, thereby accentuating changes (similarities) in the very nature of the self. A first-person perspective causes the differences (similarities) to be construed at a concrete level, only identifying changes (similarities) in isolated events or actions (Libby et al., 2005). Accordingly, individuals' appraisals of perceived self-change are greater when their autobiographical memories focus on *differences* between their past and present selves, from a third-person (vs. first-person) perspective. And, perceptions of self-change are lesser when individuals' autobiographical memories focus on *similarities* between their past and present selves, from a third-person (vs. first-person) perspective. When perceived self-change is significant, the need for self-consistency engenders psychological incongruence between the self and a previously preferred brand, triggering preference for an alternative brand that can resolve this incongruence. Thus,

Hypothesis 1: Consumer's focus on differences between present and recalled self from a third-person memory perspective adversely impacts their self-congruence with a current brand, and triggers preference for an alternative brand.

Hypothesis 2: Consumer's focus on similarities between present and recalled self from a first-person memory perspective adversely impacts their self-congruence with a current brand, and triggers preference for an alternative brand.

Research shows that when individuals focus on similarities between their past and present selves, they usually tend to focus on how they are similar to their *positive* past selves. Further, this tendency is more predominant among individuals with high as opposed to low self-esteem (Ross & Wilson, 2002). Consequently, high (vs. low) self-esteem individuals are more predisposed toward focusing on similarities to their positive past selves. Thus,

Hypothesis 3: Consumer's focus on similarities between their present and recalled self from a first-person memory perspective adversely impacts their self-congruence with a current brand, and triggers preference for an alternative brand in high self-esteem individuals.

Fundamental to the idea of self-brand congruence is the significance of self-image to consumer's brand preferences (Birdwell, 1968). We identify autobiographical memory perspective as a key determinant of consumer's perceived change in self-image. Thus,

Hypothesis 4: Consumer's self-brand congruence is impacted by autobiographical memory perspective, mediated by their assessment of perceived self-change.

Three laboratory experiments validated our hypotheses, all of which were supported. Experiment 1 tests H1 and H4 using a single-factor (memory-perspective: first-person vs. third-person) between-

subjects design. Experiment 2 tests H1, H2, and H4 using a 2 (memory-perspective: first-person vs. third-person) x 2 (memory-focus: similarities vs. differences) between-subjects study. Experiment 3 tests H3 and H4 using a 2 (memory-perspective: first-person vs. third-person) x 2 (self-esteem: high vs. low) between-subjects study. Participants' assessments of perceived self-change was the mediating variable and self-congruence was the dependent variable in all three experiments.

Extant research has focused primarily on consequences of self-congruence. Our work focuses on an antecedent – autobiographical memory perspective. We identify consumer's perceived self-change as the principal mechanism underlying the effect. Our experiments additionally demonstrate that, autobiographical memories need not involve brand-related experiences to trigger judgments in a brand-related domain – indicating cross-domain spill-over effects. Collectively, these results facilitate our understanding of autobiographical memory perspective as an antecedent of consumer's self-congruence and have implications for nostalgia advertising and retro-branding.

Materialists and the Desire for New Products:
How Materialism Enhances Newness Perceptions for Innovations

KT Manis, Texas Tech University, USA
Rebecca Rabino, Texas Tech University, USA

EXTENDED ABSTRACT

The new product development literature distinguishes the newness of products on a continuum ranging from incremental to radical innovations (Chandy and Tellis 1998). Formally, incremental (radical) innovations are innovations that involve minor (major) changes in technology and provide smaller (greater) customer benefits per dollar, relative to existing products (Chandy and Tellis 1998). These distinctions are extremely valuable for researchers and practitioners, but may be less readily obvious to consumers. Indeed, consumers often struggle to understand a new product's value (Gourville 2006). We seek to contribute to a growing body of literature addressing a consumer-based view of innovations. In fact, we suggest that consumer perceptions of innovations may be shaped by relevant individual differences. Specifically, we investigate how consumer materialism affects perceptions and purchase likelihood of innovative products.

Materialism is defined as "the importance a person places on possessions and their acquisition as a necessary or desirable form of conduct to reach desired end states" (Richins and Dawson 1992, 307). Acquisition of products is a central component of materialistic consumers' lives. Materialistic consumers view the purchase of a product as a source of happiness and a source of status (Richins 2013, 2017; Richins and Dawson 1992). We predict that the emphasis materialistic consumers put on new purchases is so potent that it will affect their newness perceptions of innovative products (Mugge and Dahl 2013). The importance of purchasing products to their self-concept and self-value may make materialistic consumers (versus less materialistic consumers) more favorably predisposed when assessing the newness of an innovative product.

We furthermore suggest that the positive effect of materialism will be isolated to incremental innovations. Radical innovations, which represent an extreme departure from existing products, are more easily identified as 'new' no matter a consumers' predisposition. Thus, we predict that radical innovations will be perceived as 'new' by both low and high materialists. Incremental innovations, however, leave more room for interpretation. We predict that materialistic consumers will be motivated to perceive incremental innovations as more new than low-materialism consumers. We assess these predictions in studies 1-3; in study 4, we also investigate the moderating role of risk perceptions.

In Study 1, two hundred six Mturk participants completed a 2 (innovation type: incremental vs. radical) by materialism (measured; Richins and Dawson 1992) study. Participants viewed a description of an incremental [radical] suitcase (Dose et al. 2019) before completing a newness perception measure (Mugge and Dahl 2013) and the material values scale (Richins and Dawson 1992). A regression revealed the predicted innovation type x materialism interaction ($p = .0001$). Importantly, there was a positive, significant effect of materialism on newness perceptions for the incremental, but not radical, suitcase.

Study 2 followed a similar procedure with a new product, a smartphone, and with an additional measure of purchase likelihood. When participants viewed the incremental innovation, materialism significantly increased purchase likelihood; however, there was no effect of materialism on purchase likelihood when a radical innova-tion was presented. Furthermore, newness perceptions mediated this relationship.

Study 3 introduced a new manipulation of innovativeness, in which the featured product (a smartphone) was given an external 'innovativeness rating' from a consumer rating agency. As in Study 2, materialism significantly heightened both newness perceptions and purchase likelihood, but this effect was isolated to the incremental innovation.

In Study 4, we focus solely on an incremental innovation and introduce a new moderating factor: perceived risk. We propose that while materialism will continue to heighten newness perceptions, risk information will moderate the effect of newness perceptions on purchase likelihood. Specifically, we predicted that when risk was high, materialism would still heighten newness perceptions but the beneficial affect on purchase likelihood would be attenuated.

Study 4 was a 3(perceived risk: control vs. low risk vs. high risk) by materialism (measured) study in which all participants viewed an incrementally innovative washing machine. In the two risk conditions, participants were told that a fictional consumer rating agency considered the washing machine to be a high [low] risk purchase (Gürhan-Canli and Batra 2004). As expected, materialism heightened consumer perceptions of newness in all conditions. Surprisingly, however, a moderated mediation analysis (Hayes 2013, model 14) revealed that, when the innovation was perceived as highly new, purchase likelihood was robust to risk perceptions (+1 SD newness perceptions: $M_{controlrisk} = 77.31$, $M_{lowrisk} = 81.52$, $M_{highrisk} = 75.21$). In other words, materialism increased perceptions of newness, which in turn drove high purchase likelihood despite the risk level of the product. However, risk level did have a detrimental effect when materialism, and thus newness perceptions, were low (-1 SD newness perceptions: $M_{controlrisk} = 57.70$, $M_{lowrisk} = 56.10$, $M_{highrisk} = 33.96$). Though unexpected, these findings further support the motivated perceptions of high materialists when evaluating innovative products.

In four studies, we demonstrate that materialism increases newness perceptions and purchase likelihood for innovative products. We show that this effect is moderated by innovation type (radical vs. incremental), such that radical innovations are perceived as equally new for both low and high materialists. We show additional moderation by risk levels; while risk did not affect newness perceptions for innovations, purchase likelihood was inhibited for low materialists. These findings contribute primarily to the innovation and materialism literatures. Specifically, we contribute to a growing consumer-based view of innovations, which may be distinct from formal theoretical distinctions (e.g., Zhao, Hoeffler, and Dahl 2009, 2012; Zhao, Hoeffler, and Zauberman 2011). We further identify a relevant individual difference driving these perceptions: materialism. Materialism research has largely focused on acquisition, on post-purchase satisfaction, and on wellbeing (e.g., Richins 1994; Richins and Chaplin 2015; Rindfleisch, Burroughs, and Wong 2009). Instead, we suggest that this individual difference may motivate alternative perceptions of products, particularly products that offer the potential for new purchases.

Socioeconomic Status and Consumer Choice: The Role of Cultural Capital

Erick M. Mas, Vanderbilt University, USA
Blair Kidwell, University of North Texas, USA
Aparna A. Labroo, Northwestern University, USA

EXTENDED ABSTRACT

Socioeconomic status (SES)—a person's rank in society based on social and economic resources—is fundamental to who consumers are and how they live their lives (Holt 1998; Veblen 1899). Lower SES consumers face economic constraints triggering a short-term focus (Shah, Mullainathan, and Shafir 2012). Thus, these consumers are more impulsive and prefer immediately pleasurable choices (Shah et al. 2015). As a result, lower SES consumers often make maladaptive decisions, including overeating (Hill et al. 2016), or taking on high-interest debt or payday loans (Griskevicius et al. 2013; Hamilton et al. 2019).

However, past research focused primarily on *economic capital* (i.e., liquid financial resources, including income and accumulated wealth), and consequences of perceived financial constraints—drawing focus to immediate concerns (Roux et al. 2015). These studies may have overlooked a second critical component of SES (Dubois and Ordabayeva 2015)—*cultural capital*. We define cultural capital as a socio-cultural aspect of SES representing a consumer's understanding of the behaviors society deems valuable, in good taste, smart, or "cultured," and the ability to embody these tastes and behaviors to signal class identity and rank to others (Bourdieu 1987; Stephens and Townsend 2013).

Given the pervasiveness of cultural capital in consumers' SES, this is likely to play a larger role in shaping preferences, while the economic capital is likely to merely facilitate (or inhibit) their ability to obtain what they prefer. We examine how SES impacts consumer preferences beyond the influence of economic capital. We predict low SES consumers will favor utilitarian (vs. hedonic) choices because they are congruent with a low cultural capital identity (Stuppy et al. 2020).

In Study 1 (N = 293 undergraduate students, 63.10% female, M_{age} = 24.41, SD = 6.20), we found support for the basic effect. Participants indicated SES on a 10-rung ladder (see Adler et al. 2000) and household income (economic capital), then chose between utilitarian (i.e., conveniently located) and hedonic (i.e., beautiful view) apartment options. Regression revealed the predicted negative effect of SES on utilitarian choice beyond economic capital (see table 1). Thus, lower SES consumers prefer utilitarian (vs. hedonic) choices independent of economic capital.

In study 2 (N = 124 adults, 72.9% female, M_{age} = 42.22, SD = 13.14), we randomly assigned participants to feel lower in SES (following procedures from Dubois et al. 2015) or a baseline. Half of the participants read an article about chocolate framed as utilitarian (e.g., health benefits) and the other half to read about hedonic framed chocolate (e.g., pleasurable). Manipulating SES and product framing with a 2 (SES: low vs. baseline) × 2 (product framing: utilitarian vs. hedonic) between-subjects design allows us to establish causality on preference for chocolate (e.g., I would like some chocolate right now; 1 = not at all, 7 = very much). ANCOVA results revealed that after controlling for economic capital (household income), there was a significant interaction between SES and the product frame (see table 1), such that feeling low in SES increases preference for utilitarian products.

Low SES consumers make utilitarian choices that are consistent with a low cultural capital identity. In study 3 (N = 241 adults; 61.40% female, M_{age} = 36.35, SD = 12.04), we test this process through moderation. First, we measured SES and economic capital (household income). We then manipulated cultural capital by asking participants to identify a well-known portrait (Mona Lisa—control condition) or a similar, but unknown renaissance-style portrait (low cultural capital condition). All participants were told that cultured people with good taste can identify the portrait they reviewed. This was followed by the dependent measure: five choices between utilitarian and hedonic product options (e.g., warm vs. fashionable coat; adapted from Lu et al. 2016). Regression analysis shows that, beyond the influence of economic capital, lower SES consumers prefer utilitarian (vs. hedonic) options consistent with their low cultural capital identity. Higher SES consumers preferred hedonic choices in the control condition, but matched low SES consumers' utilitarian preference when made to feel low in cultural capital (see table 1 and figure 1).

Study 4 was a field experiment, showing that lower SES consumers prefer utilitarian (vs. hedonic) choices consistent with a low cultural capital identity. Participants were shoppers at a discount grocery store (N = 94 adults, 41.5% female) in a neighborhood with chronically low economic capital (median household income of $33,105/year, vs. $52,858/year nationally; U.S. Census 2019). As they entered the grocery store, shoppers were offered a gift after either a low cultural capital prime ("We understand that these days being classy can be difficult."), a low economic capital prime ("We understand that these days money can be tight."), or a no prime (control condition). They were given the choice of a functional black pen (utilitarian option) or fun purple pen (hedonic option). Priming low cultural capital increased the proportion of consumers making a utilitarian choice (14/31) compared to the control (5/29; z = 2.32, p = .023) and the economic capital prime (7/34; z = 2.12, p = .034). The proportion of consumers choosing utilitarian did not differ between the control and the low economic capital condition (z = 0.34, p = .736). Thus, the control and low economic capital conditions are similar in preferences for the utilitarian pen, but priming low cultural capital increases choice of the utilitarian pen. Finally, within the low cultural capital condition, consumers were more likely to make a utilitarian (14/31) compared to hedonic choice (7/31; z = 1.88, p = .061). These results are consistent with findings from studies 1-3, showing that low SES consumers prefer utilitarian (vs. hedonic) choices, not because of their lack of economic capital, but because of their salient lack of cultural capital. Utilitarian choices reflect practical decisions consistent with a low cultural capital identity.

Dehumanizing Consequences of Anthropomorphism

Alican Mecit, HEC Paris, France
L. J. Shrum, HEC Paris, France
Tina M. Lowrey, HEC Paris, France

EXTENDED ABSTRACT

In this paper, we propose that interacting with anthropomorphized agents can increase one's dehumanization tendencies. As anthropomorphism turns consumer-product relations into quasi-social relations and individuals' behavior in such relations are characterized by their motivation to engage in effective social interactions with the anthropomorphized entities (Aggarwal & McGill, 2012; Eyssel, Kuchenbrandt, Bobinger, de Ruiter, & Hegel, 2012), we expect consumers to also be more likely to behave in ways that are consistent with the characteristics of the anthropomorphized entity to achieve their social interaction goals. Therefore, when they interact with anthropomorphized inanimate objects (e.g. robots), we expect them to assimilate such objects' characteristics, such as rigidity and coldness, in their interactions with these agents, which can further aggravate dehumanization tendencies. Different from consumers' interactions with anthropomorphized inanimate objects, we do not expect their interactions with anthropomorphized animals to increase their dehumanization tendencies, as people tend to consider animals as nonhumans capable of experiencing emotions. Accordingly, we hypothesize that interacting with anthropomorphized inanimate objects, but not with anthropomorphized animals, will increase one's tendency to dehumanize (H1). As the extent to which consumers assimilate the stereotypical characteristics of the target group depends on their attitudes toward the group (Cesario, Plaks, & Higgins, 2006), we propose that implicit attitudes toward the anthropomorphized entity will moderate the effect of interactions with such entities on dehumanization tendencies (H2). We tested these propositions across four studies.

In Study 1 (n = 153), we tested the proposed relation between anthropomorphism and dehumanization by measuring both with well-established scales (Bandura, Barbaranelli, Caprara, & Pastorelli, 1996; Waytz, Cacioppo, & Epley, 2010). As expected, those who indicated greater tendencies to anthropomorphize nonhumans also indicated greater tendencies to dehumanize other humans. Further analyses showed that dehumanization was positively correlated with both anthropomorphizing technological devices and anthropomorphizing nature, but not significantly correlated with anthropomorphizing animals.

In Study 2, we tested our hypothesis indirectly by relying on the use of technological products with humanlike characteristics as a proxy for anthropomorphism. We assumed that the more people use such anthropomorphized products, the more they would anthropomorphize in general. The pre-test (n = 58) showed that people who used PIAs (Personal Intelligent Agents, e.g. Siri) scored higher on anthropomorphism than did those who did not use PIAs. Next, with a separate group of participants (n = 203), we again measured the frequency with which they use technological devices with humanlike characteristics. Next, we measured individual differences in dehumanization tendencies using two different measures. The first measure was the same scale used in Study 1. The second measure was a scale that operationalized dehumanization in terms of agreement with policies that reflected commoditizing humans or human parts (Kopytoff, 1986) and breaching the principle of universalism that is inherent to human rights philosophy (DeBono, 2013). As expected, the use of technological devices with humanlike characteristics was positively correlated with scores on the dehumanization scale as well as with support for dehumanizing policies.

In study 3 (n = 181), we tested the proposition that interacting with anthropomorphized inanimate objects, but not with anthropomorphized animals, increases one's dehumanization tendencies (H1). Accordingly, we created three conditions: anthropomorphized robot, anthropomorphized animal, and the control. We also measured individuals' implicit attitudes toward the anthropomorphized entities and further expected the difference between the anthropomorphized robot and the control conditions in the extent to which they dehumanize others to diminish for people with negative attitudes toward robots (H2).

In the anthropomorphized robot (animal) condition, the instructions were conveyed by a robot (a puppy) named Adrian that had some humanlike characteristics and "spoke" in the first-person. In the control, participants read the instructions without any anthropomorphic agent being present. After presented with the photo of the 12 terrorists, participants answered three questions that measure how acceptable they find the harsh treatments of 9/11 plotters (Waytz & Epley, 2012), which served as our dehumanization measure. We expected participants in the anthropomorphized robot condition would endorse harsher treatments for the terrorists than would those in the control condition. We further expected that this effect to be moderated by participants' implicit attitudes toward robots. As predicted, for participants having favorable attitudes toward robots, those in the anthropomorphized robot condition were more likely to dehumanize others than those in the control condition. As expected, for participants having unfavorable attitudes toward robots, there was no difference between the conditions. Furthermore, as expected, the anthropomorphized puppy condition did not differ from those in the control condition.

In Study 4 (n = 101), we re-tested our hypothesis of a causal relation between anthropomorphism and dehumanization, using a service delivery scenario in which participants were asked to imagine that they had ordered a product online. In both conditions, the delivery person made several mistakes and mixed up a critical package they had been expecting with another one, and thus their package was not delivered on time. Participants were shown a picture of the package to be delivered. In the anthropomorphism condition, the package had an anthropomorphic message cue in which the package "spoke" in the first-person ("I'm carrying your order"), whereas in the non-anthropomorphism (control condition), the message did not have an anthropomorphic cue ("Inside is your order"). For the dependent measure, we operationalized dehumanization in terms of emotions attributed to the delivery person (Haslam, 2006; Leyens, et al., 2001). We expected that those in the anthropomorphism condition would exhibit greater dehumanization by denying secondary emotions to the delivery man compared to those in the control condition. They did. Replicating the findings of the previous studies, increasing anthropomorphic tendencies also increased dehumanization tendencies. Participants in the anthropomorphism condition denied secondary emotions to the delivery man more so than did those in the control condition.

Across four studies, we provided support for our proposition by showing that interacting with anthropomorphized objects increases one's dehumanization tendencies. As the marketplace is abundant

with anthropomorphic cues, it is important that practitioners and policy-makers pay close attention to potential negative consequences of anthropomorphism.

That's Where I'm From! How Identity-Links Increase Preference for Locally Produced Goods

Matthew D. Meng, Utah State University, USA
Ozgun Atasoy, University of Basel, Switzerland
Miguel Brendl, Universität Basel, Switzerland

EXTENDED ABSTRACT

There is growing interest in locally produced goods. Farmers markets have more than quadrupled in the past 20 years, many grocery stores advertise their locally sourced products, and restaurants emphasize their local offerings. In this research, our objective is to better understand the reasons behind the preference for locally produced goods (Best and Wolfe 2009; Carpio and Isengildina-Massa 2009; Chang et al. 2013).

Preference for local is typically considered a manifestation of concerns related to quality or ethical and sustainable consumption. When people are directly asked, they usually mention supporting the local community, receiving fresher food, or minimizing environmental impact (Darby et al. 2008; Diamond, Barham, and Tropp 2009; Moore et al. 2008; Morland, Wing, and Diez Roux 2002; Zepeda and Li 2006). We suspect that these may be post hoc rationalizations of a tendency driven by a self-related behavioral factor and test the following hypothesis: Because of shared location, a locally produced good is perceived to be connected more strongly to the self than goods made elsewhere. That leads to preference for locally produced goods because people prefer goods connected to their selves (Beggan 1992; Brendl et al. 2005; Perkins and Forehand 2011).

We test this hypothesis in four experiments by measuring preference in the absence of often-cited factors and by measuring and manipulating variables that affect the local product's connection to the self or that connection's influence on preference. We document these effects on preference, willingness to pay, and actual payments.

In Study 1, undergraduate students located in southwest USA (N = 68) indicated their likelihood to purchase locally vs nonlocally (i.e., Massachusetts) grown apples on a scale from 1 (very likely MA apple) to 7 (very likely [local state] apple). They indicated the same preference six more times after assuming circumstances that eliminate each major standard reason to prefer local (taste, nutrients, cost, safeness, carbon footprint, freshness, and the group of farmers who receive the revenue). Participants indicated a preference for the local apple even after learning that none of the standard reasons for choosing local applies ($M = 4.48 > 4.00$ [4.00 indicates indifference]; $t(60) = 3.15$, $p < .01$). All of the mean responses to the other iterations of the preference question also indicated a preference for local (t's$(60) > 4.50$, p's $< .001$).

In Study 2, residents of a Swiss town (N = 146) were randomly assigned to receive chocolate that was made either locally in town or generically in Switzerland and were asked to pay the amount of their choosing (including 0 Swiss francs) for the chocolate. They then indicated their market price estimate for the chocolate and their strength of identification with the town. Participants paid significantly more for the chocolate made locally ($M = 1.17$ CHF, $SD = 1.02$) than for chocolate made generically in Switzerland ($M = 0.66$ CHF, $SD = .62$; partial $\eta^2 = .08$; $t(144) = 3.62$, $p < .001$), even after statistically controlling for their market price estimates ($p = .001$). This effect was moderated by the strength of identification with the local town ($p < .01$) in a manner consistent with our self-connection account. That is, the price premium for locally-produced goods is an increasing function of the strength of identification with the local town.

In Study 3 residents of the northeast USA (N = 203) were recruited through Amazon's Mechanical Turk (MTurk). They were asked to imagine chatting on the phone to a friend. They were randomly assigned to one of four conditions in a 2 (friend's location: local state vs. Oregon) by 2 (product's localness: local vs. nonlocal) between-subjects design. Some participants read that their friend lived in the same state as they do, others in Oregon. All participants read that their friend was at a grocery store and was asking their advice on the price of the apple. Some participants read that the apples were grown locally, others in Nebraska (thus it was nonlocal regardless of where the friend was located). All participants indicated how much they think their friend should pay for a pound of apples. As predicted by our self-connection account, the premium for local depended on the friend's location ($p < .05$). Participants suggested a higher payment for the local apple when the friend was in the same town as the participant ($p < .05$) but not when the friend was in Oregon ($p > .10$), even though the apple was still local to the friend.

In Study 4 US residents (N = 320), recruited through MTurk, were randomly assigned to one of four conditions in a 2 (product's localness: local vs. nonlocal) by 2 (self-threat: present vs. absent) between-subjects design. Those in the self-threat present (absent) condition were asked to write at least 300 characters about an aspect of themselves that they have found difficult to change and would like to be different (about the last movie they saw). They then indicated their willingness to pay for local or nonlocal apples in a manner similar to Study 3. The premium for local depended on the presence or absence of the self-threat manipulation ($p < .05$). Those who completed the control task were willing to pay a premium for local ($p < .10$) whereas those who completed the self-threat task were not ($p > .10$). This effect of self-threat on the price premium for local is consistent with a self-related explanation for the premium and inconsistent with quality-related or ecological/ethical concerns.

These findings have strong managerial implications. Conventional wisdom currently relies on the standard reasons for buying local (e.g., carbon footprint, freshness, and support for local producers). In consequence, marketers of local products are typically advised to emphasize these factors (e.g., "Marketing local products should stress quality, freshness, and price competitiveness, and appeal to environmentalists and those with a favorable attitude towards family farms;" Brown 2003: 213). Based on our findings, however, a perceived product-self connection via shared location emerges as a critical factor. Therefore, trying to establish self-connections for nonlocal products, and emphasizing existing self-connections for local products appear to be promising strategies.

Navigating the Marketplace of Love: Value Conflict in Online Dating Community

Alisa Minina, Ipag Business School, France
Stefania Masè, Ipag Business School, France
Jamie Smith, ISC Paris, France

EXTENDED ABSTRACT

Introduction

Multiple scholars in the field of marketing and service research have dedicated their time and effort to studying the concept of value (Echeverri and Skalen 2011; Gronroos 2011; Kuppelweiser and Finsterwalder 2016; Vargo and Lusch 2004), acknowledging its idiosyncratic and context-dependent nature (Vargo and Lusch 2008). In this work we adopt a social constructionist approach to markets (Penaloza & Venkatesh, 2006), incorporating multiple notions of value (Karababa & Kjeldgaard, 2014) as well as consumer meanings and consumer subjectivity in our investigation of value creation and value destruction processes on the marketplace of love, or a consumption community of users of online dating services.

Building upon theoretical insights from service-dominant logic and transformative service research and broadening our understanding of value beyond the economic perspective, we investigate what happens when multiple notions of value coexist in the same marketplace. Embracing the multiple notions of value allows us to understand how different interpretations of value by market actors contribute to the complexity of value co-creation and co-destruction processes. We complement the extant literature on interactive value creation and destruction (Echeverri and Skalen 2011; Cabiddu, Moreno, and Sebastiano 2019) by introducing the concept of Value Conflict, showing how the conflict between social values and expected use-value in a shared marketplace can lead to ambivalent meanings in the consumption process.

Literature Review

The sociocultural context of value creation

Much of existing analysis in the field, while acknowledging the active role of consumers in value co-creation and co-destruction, concentrates on co-creation of value from service perspective (Echeverri & Skalen, 2011; Grönroos, 2011; Wieland, Polese, Vargo, & Lusch, 2012). Taking the process of value creation beyond the production-consumption dyad, Penaloza and Venkatesh (2006) forwarded a social constructionist view of the markets, arguing for extension of the view of value co-creation to include consumer meanings in exchange and use – that is, the way consumers give meaning to their lives through consumption activities.

Markets are presented as social/cultural constructions, a bundle of resources consumers can use to give meanings and values to their lives (Penaloza and Venkatesh 2006; Venkatesh and Peñaloza 2014). Markets are composed not only of resources, but also by a multiplicity of actors, such as consumers, companies, the government, the media, all of them actively operating in the marketplace to potentially create value. Karababa and Kjeldgaard (2014) highlight the complexity of value creation processes by organizing the multiplicity of conceptions of value into three abstract categories: economic value, social values and value in a semiotic sense, or meaning, arguing that bringing these notions of value into interaction can enrich our understanding of value creation in the market.

In parallel with the suggestions from the field of sociocultural consumer research, the notion of value creation in S-D logic research has moved from a linear perspective, to a network perspective, involving a variety of actors (Vargo and Lush, 2011). Contrary to value-in-exchange, and evolving by the definition of value-in-use, the notion of value-in-context implies that value is not only always systemic and co-created, but also always contextually determined for all the actors belonging to the ecosystem (Chandler and Lusch 2015; Vargo and Lusch 2011; Wieland et al. 2012; Vargo, Maglio, and Akaka 2008; Vargo, Akaka, and Vaughan 2017).

The service ecosystems perspective further highlighted the contextual nature of value creation, where value makes sense only within the social system in which it is created (Lush and Vargo, 2014; Vargo and Lush, 2011). The social system – which comprehends the service ecosystem – is a system of actors in continuous exchange and development. Value creation in these systems are guided by rules, social norms, symbols, in other words institutions, that are continuously transformed and reshaped by both adopters or non-adopters of the service solution (Wieland, 2014). Both streams of research highlight that all actors participate in the value creation and in the market transformation, by modifying and normalizing practices that are common in use in a society. The meeting between consumers and service providers happens in a sociocultural environment; the fruit of this meeting can potentially create or destroy value for one singular actor, or for all of the actors participating in the relationship.

The search of well-being for the actors in the ecosystem

Currently, there is a call for more research into both positive and negative well-being (Kuppelwieser and Finsterwalder, 2016) of market actors. The marketing and service literature has focused especially on value creation and co-creation, while more attention is now asked to better explore the possible negative outcomes of a consumer – service – market relationship (Echeverri & Skålen, 2011; Jarvi, 2018). The literature in value co-destruction is still nascent, and it is presented as a failed interaction where at least the decrease of well-being is observable in one of the actors participating in the relationship (Plé and Cáceres 2010; Akaka, Vargo, and Schau 2015; Järvi, Kähkönen, and Torvinen 2018). This definition is larger than the common definition of service failure, or value destruction, where the provider's processes fail and the customer experiences dissatisfaction because of this failure (Jarvi, 2018). Value co-destruction can be observed in B2B (Cabiddu, et al., 2019) or B2C contexts, and can have a double sense, if for example, the consumer reacts to the service failure (Plé and Cáceres 2010). Some of the reasons of value co-destruction can be mistakes, the inability to serve from the perspective of the service provider, service sabotage from the part of the employees, but also customer misbehavior and blaming the employees from a consumer perspective (Harris and Ogbonna, 2002a; Jarvi, 2018).

In our analysis of consumer online dating experiences, we focus on consumer subjectivity, analyzing the misbehavior of consumers against other consumers, in an interactive co-destruction of value that affects consumer well-being as well as that of a larger society. We focus on the online dating services environment, where a possible negative value of the exchange can be found at the core of the transaction, with the risk of treating people as products (Hirschman 1987; Bagozzi 1974; Lusch, Vargo, and Malter 2006). This risk opens up to the analysis of the ethical impact of transformative services as digital dating apps.

Method

In this study, we investigate the context of online dating with the purpose to gain understanding of the complex interplay of the processes of value creation (Karababa and Kjeldgaard 2014) and destruction (Kuppelweiser and Finsterwalder 2016; Echeverri and Skalen 2011; Grönroos 2011) that occur in consumer-consumer relationships online, that is, where the value creation / destruction processes do not occur through interactions between consumers and the service prodiver, but in the process of consumers interacting with each other. Unlike the case of brand communities (Schau, Muñiz, and Arnould 2009) when consumers unite around shared loyalty to a given brand, online dating app users represent a specific instance of networked consumption community (Chalmers Thomas, Price, and Schau 2013), where individual actors engage in serial one on one encounters with each other ad infinitum until they settle with a chosen partner.

From November 2018 to June 2019 we have conducted semi-structured in-depth interviews (McCracken 1988) with 21 male and female users of online dating apps residing in Paris, falling within the 23-56 age range. Participants were recruited via online calls for participation on Tinder and Facebook. The interviews lasted on average 40-60 minutes. All interviews were recorded, transcribed and analytically coded with the focus on individual consumer experience as part of a complex system of interaction between human actors, service providers and the broader society. The triangulation between researchers throughout the analytical process allowed us to ensure the adequacy of our representation and analysis of studied constructs by constantly comparing and contrasting our interpretation of the data in relation to the literature (Wallendorf and Belk 1989).

Findings

Value conflict

Data analysis revealed that in their interactions with each other in the online dating marketplace, our informants experienced the conflict between multiple notions of value throughout their online dating experience. We define value conflict as the instance of contradictory overlapping notions of value, coexisting in the marketplace and inhibiting processes of value creation, leading to parallel processes of value co-creation and co-destruction as multiple actors negotiate their contesting notions of value in their interactions with each other throughout the service experience. Following the social constructionist approach to value creation in the marketplace (Penaloza and Venkatesh 2006) and embracing complexity of multiple notions of value (Karababa and Kjeldgaard 2014), we have identified several sources of value conflict in the online dating marketplace.

Social values vs Use-value

The first conflict occurred between the social values, or culturally embedded perceptions of desirability (Karababa&Kjeldgaard 2014) and the perceived use-value, or subjectively experienced benefit (Gronroos 2011) of the online dating experience, facilitated by elements of service design as well as users' individual motivations and expectations from their consumption experiences. As negotiation of value by multiple actors throughout the service ecosystem of online dating took place, the social values of monogamy and appropriateness conflicted with the perceived use value of dating experience and associated sexual freedom, triggering simultaneous processes of value creation (when perceptions of social value aligned with perceptions of use value) or value destruction (when social values conflicted with perceptions of use value). When asked about their expectations from an ideal relationship, the informants emphasized trust, care, friendship, loyalty and intellectual compatibility as desired relationship characteristics, however, when discussing relationships in the context of dating apps, a different picture emerged, as we can see from examples below.

> (…) all the people like my relatives, friends and stuff, like you know, you are having a relationship with a girl from Tinder, and then they ask "How did you meet?" On Tinder - I think it's quite..., I don't know, like.... (…) I have tried to find an answer, but… But I know that this is something that disturbs me. So, every time when I am on this app, I hope not to stumble upon a girl to whom I will get attached, this is interesting (Mark, 26)

> I guess when you're meeting someone through Tinder there's a kind of like unspoken not rule, but there's an unspoken sort of fact that like this is probably just gonna be for like a hook up. Do you know what I mean? (Eve, 25)

In this instance the value conflict can occur as an ethical conflict experienced by a consumer, when, for instance, social values conflict with perceived use value, generating frustration and/or morally ambiguous behaviors. It can also occur between different subjects in the consumption community, when different perceptions and expectations of value are not aligned between the potential dating counterparts.

> I also don't think you can really tell what somebody is like when you're talking via any kind of digital media. So I kind of think that you do need to meet them to actually know if you click or if you're even interested. I guess there is also that fear of you don't actually know who you are going to meet. And it's all drilled into us from a young age that you don't know who anyone is on the internet! (Rose, 23)

As consumers of online dating apps engaged in immaterial labor in order to maximise value for themselves as well as, occasionally, for their counterparts, (Cova and Dalli 2009), due to the networked nature of the service offering, the risk of treating people as products (Hirschman, 1987; Bagozzi, 2006; Lusch, Vargo and Malter, 2006) ran high, contributing to the conflicting nature of the experience.

Double standards and moral ambiguity

In their reflections on their service experiences, consumers would apply higher behavioral standards to others than to themselves. The conflicting nature of consumer meanings in the ethical domain manifested as the blurring of ethical boundaries, as the users rationalized their mistreatment of others by treating the digital context where they allowed themselves to behave unethically as an opposite to "real life", where they would be more likely to stick to a more traditional code of conduct. The perception of the digital context as a surreal gamified experience gave them freedom from experiencing the negative consequences of unethical behaviors, in contrast with the hypothetical real-life situations where they would meet potential partners through common social networks of family and friends. At times, the informants rationalized their strategy of withdrawing from communications as a mutual decision to stop talking. They have acknowledged that it was easier to end communications in the online context compared to the situation when the relationship would happen in "real life".

> (…) it is easier to stop (…) because I think in five minutes, take my phone, download the app, match with one or two persons, and have a conversation with them, maybe date the day after… So in 24 hours I can date someone. So easy date, easy stuff…

In real life, do you think that in 24 hours I can walk down the street and ask people about dating me the day after that? No, I can't! (Alan, 28)

The moral ambiguity also related to the uncertainty of knowing the true intentions of a person on the other side of the dating app. For a long time, Alice engaged in non-exclusive relationships with men on dating apps. However, when she found her current long-term partner on Tinder, the deciding factor was their mutual desire for exclusivity.

You meet far more people who want to meet someone. In real life there is always a degree of uncertainty, you never know if that person looking at you wants a relationship or something else. (Alice, 54)

The theme of applying different moral standards to situations in digital versus real life was especially evident in the situations of deciding the exclusivity of the relationships or ending the communications, when the dilemma of whether to be transparent with the other person or whether to just disappear arose.

Reluctant belonging to consumption community

The third source of conflict was the disparity between the factual belonging to consumption community by online dating app users, and their simultaneous rejection of collective identity, related to the stigmatized nature of using dating apps. Alice, a 54-year old woman who started using dating apps in order to date non-exclusively after the dissolution of her long-term relationship, referred to Tinder as "the bargain basement of dating apps where all creeps are spending their time", while Sofia, a 33-year old student, said that she hated Tinder, calling it "the jungle". Nevertheless, just like other informants did, after trying several other apps, they adopted Tinder as the main app that they used for encounters with potential dating partners. While the informants themselves were meeting their potential partners online, at the same time they felt conflicted about the use of the dating apps in general.

I wouldn't want the person I'm seeing in the relationship to be using Tinder, do you know what I mean? Or be intrigued about using it (Eve, 25)

I guess yes, I do look for someone to be in a relationship with because I have enough friends, I'm not really there to make friends (…) Sometimes it does get exhausting because you're always meeting different people (Vero, 29)

Unlike in case of brand communities, subcultures of consumption or other collaborative consumption communities where consumers thrive on sense of unity and belonging when they unite around shared practice or their common preference for a certain brand (Muniz and O'Guinn 2001; Schau, Muñiz, and Arnould 2009; Schouten and McAlexander 1995), the online dating context represents an instance of non-collaborative consumption community, where consumers willingly or unwillingly engage in immaterial labor (Cova and Dalli 2009), primarily acting in own self-interest, eventually creating or diminishing value through their interactions with each other. Much commentary focused on the risks of using dating apps, the potential harm and a sense of vulnerability, the concerns for safely motivated users to develop a range of strategies, such as keeping conversations on the app for as long as possible, not giving their phone number to new acquaintances or not adding people they met on the app on social networks.

Discussion And Conslusion

In this work we draw upon social constructionist view of markets (Penaloza and Venkatesh 2006; Karababa and Kjeldgaard 2014), embracing multiple notions of value in service consumption context. Our findings contribute to extant literature on value co-creation and co-destruction (Echeverri & Skalen, 2011; Grönroos, 2011; Wieland, Polese, Vargo, & Lusch, 2012) by introducing the concept of Value Conflict and by illustrating how multiple notions of value coexisting in marketplace can inhibit the processes of value creation as multiple actors negotiate their contesting notions of value in their interactions with each other throughout the service experience. We show how the conflict between social values and expected use-value can lead to ambivalent meanings in the consumption process and document how perceived use value can be simultaneously co-created and co-destroyed without direct participation of service providers in the process of social interaction between consuming subjects.

While the context of online dating represents a very specific context where value co-creation and co-destruction processes occur simultaneously in the process of social interaction, our theoretical insights can be potentially transferred to other contexts where value is created by users interacting with each other, without direct participation of service providers. Our data shows that value destruction processes can be triggered by the incompatibility of notions of value between users or within the value system of a single user, therefore, managers who want to avoid value conflict and subsequent triggering of the processes of value destruction need to pay attention to alignment of values, either through providing community guidelines and educational content, or by introducing control mechanisms allowing users to report undesirable behaviors that cross the line of appropriateness.

One possible limitation of our study is that our insights about individual users and their service practices are based on the verbal accounts of our informants. Thus, our results will inevitably reflect what the study participants believe they do, rather than their actions on the dating app. Due to a sensitive issue of the topic that is embedded in cultural rules and norms, there is also a possibility of a social desirability effect in our interviews - that is, the informants adjusting their answers to what they believed the interviewer wanted to hear. We encourage future research using observational methods and prolonged engagement with mobile app users that would allow following their consumption habits in real time.

The second potential limitation of this study is that we have only conducted interviews with the users of dating apps, therefore our accounts of the service design elements, such as the applications' interface, promotional communications and functions are based on the experiences of our informants as well as on observations of one of the authors who has created accounts on multiple dating apps in order to explore their functionality. Investigating the service providers could enhance our understanding of what is driving the moral ambiguities users are experiencing and the anguish that it generates.

"Who" You Rent from Matters: The Differential Effects
in Perceived Ownership When Renting

Nirajana Mishra, Boston University, USA
Sarah Whitley, University of Georgia, USA

EXTENDED ABSTRACT

Renting has become a more prevalent method of accessing products in the last decade, in part because consumer spending capabilities and priorities have changed (Coughlin 2018) but also because consumers now have access to more options and opportunities than ever before with the emergence of the access economy (Eckhardt and Bardhi 2015). With peer-to-peer access-based consumption (e.g., Airbnb, Turo, etc.), consumers now engage in renting products from companies as well as from other people. But, does "who" you rent from matter? Consumers interact differently with companies, which are generally governed by exchange norms (Clark and Mills 2011) than with people who can evoke more communal norms (Aggarwal 2004). However, renting in the access economy embraces both market and social characteristics, so it is not clear if renting a product from a company in an access marketplace differs from renting the product from another person. In the present research, we examine how renting from a company versus a person influences consumers' perceptions of the rented product as well as their post-rental behavioral intentions. We argue that "who" the consumer rents from (a company versus an individual) matters, and suggest that whether a product is rented from a company versus a person influences consumers' perceptions of the product and their behavior with it (e.g., personalization, care). Across four studies, we find that consumers value the same product more highly when renting it from a company than from a person. These results hold across different types of products and when access to the rental product is granted through an online platform. We hypothesize that differences in perceived psychological ownership underlie the differences in valuation and examine its downstream consequences.

In study1A (N = 402), we aimed to explore whether renting a product from a company or a person (which we refer to as the "rental entity") influences how people value the product they rent. Since valuation of an item increases with possession (Peck and Shu 2009; Strahilevitz and Loewenstein 1998; Kahneman et al. 1990), and even imagined possession (Peck et al. 2013), consumers may feel differently about the rental product once they have it in their possession. Consequently, we evaluated consumers' willingness to pay for a rental product and their willingness to accept payment to give up their rental product (Chatterjee et al. 2013; Aggarwal and Zhang 2006). Participants imagined they were either "looking to rent" or had "already rented" a 2-bedroom vacation cabin in Colorado for one night, per assigned rental stage. Participants in "company rental entity" condition were renting from Aspen Management Company, while those in "person rental entity" condition were renting from Donna Smith. A picture of the cabin was displayed across all conditions to hold expectations constant. Participants then indicated their valuation (in $) of a one-night stay in the cabin in an open-ended response box. A 2 (rental entity) x 2 (rental stage) ANOVA on valuation revealed significant main effects of rental stage ($F(1,376)$ = 205.46, $p < 0.001$) and rental entity ($F(1,376)$ = 5.75, $p = 0.017$). Replicating endowment literature, participants valued the cabin more if they had already rented it (M = 284.49) than when looking to rent (M=159.98). Additionally, participants valued the cabin more when renting from a company than from a person ($M_{company}$ = 232.81 vs. M_{person} = 211.55); $p = 0.017$), suggesting that who you rent from matters. We also found a marginally significant two-way interaction

of rental entity and rental stage on valuation ($F(1,376)$ =2.99, p = 0.085). Pairwise comparisons showed participants who were looking to rent the cabin had no differences in their willingness to pay for it ($M_{company}$ = 161.57 vs. M_{person} = 155.63; $p = 0.639$). Instead, this interaction was driven by participants differences' in willingness to accept to give up the cabin they had already rented ($M_{company}$ = 304.05 vs. Mp_{erson} = $267. 46$; p =0.003). These results suggest that the rental entity does not matter in terms of consumers' expectations of the rental product and their willingness to pay, but it does matter with regard to how consumers value the product once it's in their possession. Since possession of an object leads to increased valuation due to feelings of ownership (Reb and Connolly 2000) even when consumers merely possess (Sen and Johnson 1997) but do not legally own the products, we speculate that consumers may feel different levels of psychological ownership over products rented from different rental entities.

Rather than consumers valuing the rental products differently, one potential explanation of the lower WTA amounts observed in the previous study is that participants may feel that the person offering the rental product may have less physical and financial resources than a company. Consequently, consumers may feel empathy for a person supplying the rental product and offer a lower WTA amount. In study 1B (N=365), we evaluate this alternative explanation by including an additional condition equalizing resources between a company and person in the post-rental stage. All participants imagined that they had booked a rental vacation cabin for one night and were informed that the cabin was no longer available, analogous to the "already rented" rental stage condition in Study 1. The first two rental entity conditions (company vs. person), were the same as Study 1. Participants assigned to the third rental condition read that they were renting the vacation cabin from "Donna Smith who had multiple properties in the area." Participants then indicated how much they valued the cabin by reporting their willingness to accept on a sliding scale from $0 to $400. ANOVA results revealed a significant main effect of renting entity on product valuation ($F(2,336)$ = 4.95, $p = 0.008$). Replicating prior results, post-hoc tests (Tukey's HSD) revealed that participants valued the cabin significantly more when renting it from a company (M= 285.84) than from a person (M= 249.21; $p = 0.032$) or a person who explicitly owned multiple properties (= 242.99; p= 0.010). Most important, there was no difference in participants' cabin valuations between the two person-based rental entity conditions (p = .899), dispelling concerns that lower valuation for rental products owned by people, as opposed to a company, is due to a perception of differential resources between the company and the person-based rental entities.

In study 2 (N=609), we sought to replicate our finding that consumers differentially value products rented from companies versus people in a different but externally valid product domain: automobile rentals. Accordingly, we test the premise of renting from a person through an online platform, which not only provides greater external validity for our findings but also addresses the concern that interacting directly with a person may influence consumers' product valuations as opposed to interacting in a more distant manner through an online platform. Similar to Study 1, participants were told to either imagine they were "looking to rent" or had "already rented" a Jeep for one day while on vacation. Per assigned rental stage condition, participants

were told that they had rented the Jeep from either a company (Vieques Jeep Rentals), a person (Alex Smith), or a person (Alex Smith) through an online platform. Lastly, participants indicated their valuation on a slider scale from $0 to $400. A 3 (rental entity) x 2 (rental stage) ANOVA revealed a significant main effect of rental stage on product valuation ($F (1,603) =107.20$, $p<0.001$). While there was no main effect of rental entity on product valuation ($F (2,603) =1.92$, $p=0.148$), there was significant interaction of rental entity and rental stage on product valuation ($F (2,603) =3.82$, $p=0.022$). Pairwise comparisons indicated that while there were no significant differences in product valuation across the rental entities for participants "looking to rent" ($M_{company}= \$153.52$ vs. $M_{person}=\$166.77$ vs. $M_{person-platform}=\$159.50$; $F (2,603) =0.48$; $p=0.622$), product valuation across different rental entities did differ among participants relinquishing a Jeep they had already rented ($F (2,603) =5.27$; $p=0.005$). In "already rented" rental stage condition, participants valued the Jeep (WTA amounts) higher when renting from a company ($M_{company}=\$265.22$) than from a person ($M_{person}=\$236.68$; $p=0.037$) or from a person via an online platform ($M_{personplatform}=\$221.84$; $p=0.001$). However, there was no difference in product valuation among participants who had already rented the Jeep from a person or from a person via an online platform ($p =0.274$). Overall, these results replicate findings from Study 1 and show that difference in valuation when renting from a company versus a person holds even when interactions with the person are via an online platform.

In Study 3 (N=306), we test our proposed mechanism of psychological ownership and evaluate post-rental behavioral consequences emanating from differences in perceived ownership when renting from either a company or a person. In prior studies, we observe a difference in product valuation once participants have rented the item, suggesting that psychological ownership may underlie this effect. Psychological ownership reflects a relationship between an individual and an object (Pierce et al. 2003) and consumers may feel less perceived ownership for a rented product if that product already has a relationship with a person (i.e., the rental entity) compared to a company. Participants were randomly assigned to a company or person rental-entity Jeep rental scenario, analogous to Study 2. To investigate the practical consequences of consumers' renting products from different entities, we examined a measure of perceived control over the rental object (likelihood to personalize the radio preset stations (Bardhi and Eckhardt 2012) on the Jeep; 1=Not at All, 7=Very Much) as well as a measure of intended care for the Jeep (i.e., likelihood to wash before returning; 1=Not at All, 7=Very Much). Participants also completed a measure of psychological ownership, adapted from Shu and Peck (2011), by reporting how much they felt the "jeep was yours" during the time that they were renting it (1=Not at all, 7=Very Much). Rental entity significantly influenced the behavioral control measure ($F (1,260) =13.95$; $p<0.001$): participants were more likely to personalize the Jeep when renting from a company than a person ($M_{company}=4.62$ vs. $M_{person}=3.56$). We also replicated the rental entity effect on valuation ($F (1,260) =20.81$; $p<0.001$): participants valued the Jeep more when renting from a company than a person ($M_{company}=226.27$ vs. $M_{person}=166.28$). While we initially expected consumers to care more about the product when owned by a company (i.e., psychological ownership is higher), we found the opposite: participants were more likely to care of the product when renting from a person than a company ($M_{company}=4.22$ vs. $M_{person}=4.76$; $F (1,260) =4.62$, $p=0.032$). This result may still be due to perceptions of psychological ownership, in that consumers are more likely to bring about self-initiated changes in the product they feel "is theirs" (Pierce, Kostova and Dirks 2001) rather than keeping it in its original form. Rental entity had a significant effect

on psychological ownership (F ($1,260$) =4.69 $p=0.031$): participants felt the Jeep was "theirs" more when it was rented from a company ($M_{company}=4.16$) versus a person ($M_{person}=3.62$). We ran a separate mediation analysis for each dependent variable; psychological ownership partially mediated personalization (95% CI: -0.48; -.02), care (95% CI: -0.26; -.01), and product valuation (95% CI: -17.52; -.62). Lastly, to examine alternative explanations, we measured feelings of responsibility and accountability to the rental entity, but found no differences between rental entities for either variables.

Across 4 studies, two different product categories, and three different dependent variables (valuation, control/personalization, and care) we find that consumers feel differently about the products they rent depending on who rented it to them: a company versus a person. As research on the access economy is still in its early stages, we provide insight on how consumers perceive the products they rent from different entities (i.e., they feel less ownership of products rented from people), and suggest the importance of this work given the downstream consequences these different perceptions have on consumers' behaviors with the rental product.

Perception of Innovation:
How to Attract Non-Early Adopters to Adopt Earlier

Sarit Moldovan, The Open University of Israel, Israel
Ruth Zwick, Ben-Gurion University, Israel
Liat Hadar, Coller School of Management, Tel Aviv University, Israel

EXTENDED ABSTRACT

Early adopters (EAs) are the first to adopt new products and are highly crucial to the successful diffusion of innovations (Dowling and Midgley 1993; Goldsmith and Flynn 1992; Mahajan, Muller, and Srivastava 1990; Rogers 2003). Much research has explored how to recognize and approach EAs (Bartels and Reinders 2011; Midgley 1987), though EAs consist of only a small fraction of the market (Goldsmith and Flynn 1992; Mahajan, Muller, and Srivastava 1998). In this research we explore several ways in which non-early adopters (non-EAs) may be encouraged to adopt innovative products earlier than they otherwise would have.

EAs often seek innovations whereas non-EAs focus on utilities and avoid risks (Goldenberg, Libai, and Muller 2002; Goldsmith and Flynn 1992; Lambert 1972; Li, Zhang, and Wang 2015). Drawing on findings that consumers with clear preference between products are less likely to be affected by marketing tactics such as adding an undesirable decoy (Huber, Payne, and Puto 2014), we hypothesize that EAs will show innovation preference while non-EAs will show innovation aversion that will be difficult to quell, irrespective of persuasion attempts.

Hypothesis 1: *EAs will show innovation preference whereas non-EAs will show innovation aversion that is difficult to reduce.*

Consumers are four times less likely to adopt a radical than an incremental innovation (Alexander, Lynch, and Wang 2008). However, people have different status quos when it comes to innovations and technology and reference points mark each individual's point of relative gains and losses. Consumers with a lower reference point perceive innovations as incurring a huge cost of learning and investment (Gourville, 2004). We therefore suggest that if we change the reference point, by presenting an even more innovative product, non-EAs will perceive the innovation as relatively less innovative, thus will be less averse to selecting the innovative product.

Hypothesis 2: *Non-EAs innovation aversion will be reduced when the perceived relative product innovativeness is decreased. This will not influence EA adoption intentions.*

We explore these hypotheses in three studies.

Study 1 explored the innovation aversion of non-EAs toward innovative products in the face of a well-known marketing tactic, the *attraction effect* (Huber, Payne, and Puto 1982). 598 Amazon MTuker workers were presented with a tradeoff between two non-innovative products or between a non-innovative and an innovative product. Each set included a dominated product aimed at increasing the choice share of the target product. Consistent with H1, a logistic regression revealed a significant *early adoption* by *innovative target* interaction on choice (β = .66, p < .001). In the absence of a highly innovative product in the choice set, the choice share of the dominant option was influenced by the addition of a dominated option for both EAs and non-EAs (EAs: $\chi^2(1)$ = 12.04; non-EAs: $\chi^2(1)$ = 15.43, p's < .001). However, when a highly innovative product was included,

neither EAs nor non-EAs were influenced by the dominated option (EAs: $\chi^2(1)$ =.39; non-EAs: $\chi^2(1)$ =.36, *NS*).

Study 2 (n=159, MTurk) demonstrated that reducing the perceived innovativeness of an innovative product through the presentation of a highly innovative but unavailable phantom option (Scarpi and Pizzi 2013), encourages adoption among non-EAs but does not change EAs' adoption (H2). The presence of the phantom option had a stronger effect on non-EAs, increasing the choice share of the innovative option by 25% ($\chi^2(1)$ = 5.66, p = .017), than on EAs whose choice share of the innovative option increased by 14%, a non-significant increase ($\chi^2(1)$ = 1.72, p = .19). A logistic regression revealed main effects of early adoption (β = .50, p < .001) and of the phantom presence (β = .90, p = .01), but no interaction between them (β =.03, *NS*). Thus, the phantom increased non-EAs' choice share of the innovative product but did not reduce EAs' choice share.

Study 3 influenced product innovativeness by manipulating whether the presentation of the innovative product followed a relatively less or more innovative product. 216 MTurkers were presented with either a *non-innovative* product or a *super-innovative* product, then viewed the innovative target product. Participants indicated their attitude toward the target product (α = .90) and rated their early adoption tendencies (α = .91). There was a significant interaction between early adoption and attitudes toward the target product (β = -.28, p = .048). Non-EAs' attitudes toward the target product significantly increased when primed with a super innovative product (M = 3.61) than when primed with a less innovative product (M = 2.89, $t(211)$ = 2.35; p = .019). This priming did not significantly affect EAs' attitudes $t(211)$ = -.46, p = .648).

Our results confirm that non-EAs hold strong negative attitudes toward innovations (H1). However, when the perceived relative innovativeness of the product was reduced by presenting it next to an even more innovative product, non-EAs report more positive product evaluations and higher choice share, compared to when the innovation is presented next to a less innovative product (H2). This technique of reducing perceived product innovativeness is beneficial to non-EAs while maintaining EAs' interest in the product.

These results have important theoretical and practical implications for the development and marketing of new products. Considering the amount of research conducted on EAs despite their small proportion in the market, and their limited potential influence on non-EAs as suggested by the chasm theory (Tellis and Chandrasekaran 2011; Goldenberg et al. 2002; Libai, Mahajan, Muller 2009; Moore 2014), we suggest that marketers and new product developers should focus on the "continuum" of the product. If non-EAs are made aware that more innovative products exist, even if they are not yet available in the market, their attitudes and choice-likelihood for the target increase. This strategy could potentially attract non-EAs to adopt innovative products earlier, and skip the chasm.

Too Much of a Good Thing? How Misaligned Signals of Popularity Diminish Product Appeal

Sarit Moldovan, The Open University of Israel, Israel
Meyrav Shoham, Tel Aviv University, Israel
Yael Steinhart, Coller School of Management, Tel Aviv University, Israel

EXTENDED ABSTRACT

Consumers generally prefer to buy products that were previously adopted and recommended by others, in order to reduce product risk (e.g., Godes and Mayzlin 2004; Hellofs and Jacobson 1999). Product popularity and quality are often inferred from the volume of sales (Banerjee 1992; van Herpen, Pieters, and Zeelenberg 2009) and online reviews (Babić Rosario et al. 2016; Huang and Chen 2006; Park, Lee, and Han 2007). Thus, both of these metrics can serve as indicators of product popularity and appeal, increasing the likelihood that it will be purchased.

Displaying both the volume of sales and the volume of reviews provides consumers with two distinct signals of popularity, which may be aligned with one another (review-sales fit) or misaligned (few/many reviews compared to sales). Previous works suggests that consumers react negatively when faced with non-fit compared with fit situations between purchasing cues or their content and the consumer's state of mind (Hong and Lee 2008; Park and Kim 2008; Steinhart, Mazursky, and Kamins 2013). We expect the different types of non-fit between product popularity signals to lead to different inferences that reduce product appeal.

A low volume of reviews compared to sales should lead consumers to reconsider the product's popularity. People take pleasure in expressing their opinions and prefer to generate positive word of mouth and reviews about their experiences (Babić Rosario, de Valck, and Sotgiu 2020; De Angelis et al. 2012; He, Melumad, and Pham, 2019). Consequently, online reviews tend to be largely positive (e.g., Chevalier and Mayzlin 2006; Kupor and Tormala 2018). We expect consumers to assume that if people who have purchased a product had something nice to say about it, they would do so. Thus, a low volume of reviews compared to sales should decrease perceptions of product popularity and reduce its appeal.

Consumers can also encounter a higher than expected number of reviews. While consumers may typically assume that online reviewers are credible (Schlosser 2011), a relatively high number of reviews compared to sales could undermine this perception. Consumers may assume that some of the reviewers did not actually purchase and consume the product, or that they are linked to the seller (Jiménez and Mendoza 2013) When reviewer credibility is called into question, their opinion should carry less weight (Schlosser 2011). Therefore, a high number of reviews compared to sales should undermine perceptions of reviewer trustworthiness and reduce product appeal.

In sum, we expect consumers to prefer products for which the two signals of popularity – the volume of reviews and the sales volume – are aligned, compared to situations in which the signals are misaligned. This effect is driven by (1) diminished perceptions of product popularity when there are few reviews compared to sales; and (2) reduced reviewer trustworthiness when the there are many reviews compared to sales. Four studies provide support for this effect and the dual paths that drive it.

In Study 1, participants rated a fitness tracker ring more positively when the sales volume and review volume fit ($F_{(2, 390)} = 8.47$, $p < .001$; $M = 5.41$, $SD = 1.16$) compared to when there were few reviews vs. sales ($M = 4.78$, $SD = 1.20$; ($F_{(2, 390)} = 16.36$, $p < .001$) and many reviews vs. sales (M = 5.01, SD = 1.40; $F_{(2, 390)} = 6.86$, $p = .002$). The two non-fit conditions did not differ significantly ($F_{(2, 390)} = 2.15$, $p = .14$).

In Study 2, participants in the fit condition evaluated a book more positively ($M = 5.58$, $SD = 1.12$) compared to those in the non-fit condition (low reviews compared to sales; $M = 5.08$, $SD = 0.93$; $t_{(117)} = 2.62$, $p = .010$). Participants in the fit condition also perceived the book to be more popular ($M = 4.97$, $SD = 1.72$) compared to the non-fit condition ($M = 4.17$, $SD = 1.72$; $t_{(117)} = 2.54$, $p = .013$). Perceived popularity mediated the effect of review-sales fit on product evaluation ($b = .23$, $SE = .10$; 95% CI: .0428 to .4545).

In study 3, evaluations of a jacket were more positive in the fit condition ($M = 5.77$, $SD = 0.94$) than in the non-fit condition (high reviews vs. sales; $M = 5.25$, $SD = 1.20$; $t_{(106)} = 2.50$, $p = .014$). Reviewers were considered more trustworthy when the volume of reviews fit the sales volume ($M = 4.69$, $SD = 1.02$) rather than exceeding it ($M = 3.93$, $SD = 1.59$; $t_{(106)} = 2.94$, $p = .004$), and perceived reviewer trustworthiness mediated the effect of review-sales volume fit on product evaluation ($b = .32$, $SE = .13$; 95% CI: .1002 to .6086).

Study 4 tested both mediation pathways in a single design, and revealed a significant effect of review-sales volume fit on evaluations of a book ($F_{(2, 328)} = 9.38$, $p < .001$). Evaluations were higher in the fit condition ($M = 5.68$, $SD = .95$) compared to both the low reviews vs. sales condition ($M = 5.25$, $SD = 1.00$; $F_{(1, 328)} = 9.58$, $p = .001$) and the high reviews vs. sales condition ($M = 5.05$, $SD = 1.33$; $F_{(1, 328)} = 19.73$, $p < .001$). The high and low non-fit conditions did not differ significantly ($F_{(1, 328)} = 1.80$, $p = .18$). The effects were mediated by perceived popularity and perceived trustworthiness, respectively.

Higher sales and more reviews are known to heighten product appeal. We explored what happens when these two indicators of product popularity are misaligned, and show that this lack of fit can diminish product appeal. The effect is driven by different inferences based on the type of non-fit: a low volume of reviews compared sales may lead to a perception that people who bought the product were not sufficiently impressed with it to recommend it to others, while a high volume of reviews compared to sales lowers reviewer credibility. Our research provides a demonstration of the potential downsides of using multiple indicators of popularity to guide consumer decision-making, and points to the need for a more precise approach.

Examining Online Review Posting Preferences

Jana Möller, Freie Universität Berlin, Germany
Sabrina Gottschalk, City, University of London, UK
Alexander Mafael, Stockholm School of Economics, Sweden

EXTENDED ABSTRACT

Most consumers consult online reviews, yet, only few consumers generate review content (Sun et al. 2014). Given the managerial importance of review rating systems, this research examines review posters. Specifically, we contrast the behavior of frequent posters with less frequent posters.

Prior research indicates that frequent and infrequent review posters differ in how they respond to previously posted content (Schlosser 2005). Frequent posters exhibit more differentiation behavior (Moe and Schweidel 2012). A review environment may thus appear more or less attractive for posting one's opinion, depending on one's posting frequency and to what extent previous ratings signal that a reviewer's opinion belongs to the minority.

In many social contexts, learning that one holds a minority opinion evokes perceptions of social risk (Asch, 1956). Social risk perceptions are often salient in online environments such as review platforms and decrease opinion voicing (Eisingerich et al. 2015).

In the context of reviews, we assume that perceiving one's opinion to belong to the minority will decrease intention to post because of social risk perceptions. However, this should only hold for infrequent posters. Frequent posters care less about fitting in with the 'crowd' (Sunder, Kim, and Yorkston 2019) and more about making their opinion visible and different (Moe & Schweidel 2012). Voicing a deviant opinion serves differentiation (Tuk et al. 2019), hence, we suggest:

Hypothesis 1:   *Frequent (vs. infrequent) online review posters are more intent to post a review when their opinion belongs to the minority (vs. majority) of previously posted ratings.*

Hypothesis 2:   *This effect emerges because frequent (vs. infrequent) online review posters have lower (higher) social risk perceptions when they hold a minority opinion.*

We expect a product's identity-relevance (Berger & Heath, 2007) to magnify these differences. Identity-signaling can be achieved through articulating WoM about products (Berger 2014). For frequent posters, a situation that entails both, holding a minority opinion and an identity-relevant product, should be attractive because it enables them to stand out from the crowd. For infrequent posters, the pressure of being in the minority should increase if this product is used to infer identity.

Hypothesis 3:   *The intention of frequent (vs. infrequent) online review posters to post a review when their opinion belongs to the minority of previously posted ratings is greater (vs. lower) when the product is identity-relevant.*

In Study 1 (N=382, MTurk) respondents participated in a 2 (average rating: positive vs. negative) x 2 (own product experience: positive vs. negative) x 2 (rating dispersion: high vs. low) between-subjects online experiment. Respondents recalled their last online purchase and evaluated the product (1 = very poor to 10 = very good). Next, respondents read that other consumers had rated the product and were shown a positive or negative average rating with high or low rating dispersion. Next, respondents indicated their intention to post a product review (1 = not at all likely to 7 = very likely), the perceived valence of the "average rating" stimulus, their opinion perception (1= my opinion reflects the majority of opinions, 9 = my opinion reflects the minority of opinions), their review posting frequency (1 = never to 7 = always), and control variables. A moderation analysis (PROCESS model 1, 5000 bootstrap samples, heteroscedasticity-consistent inference parameters) with posting frequency (IV), opinion perception (moderator), and review posting intention (DV) was conducted. A significant interaction between posting frequency and opinion perception emerged (b=-.05, SE=.02, CI95 [-.09, -.01], supporting H1. With increasing levels of posting frequency, the effect on intent to post a review was stronger when participants perceived their opinion to be in the minority ($b_{minority}$=.58, SE=.08, CI95 [.43, .73]; $b_{majority}$=.37, SE=.07, CI95 [.23, .51]). The inclusion of the valence of respondents' product experience and dispersion did not reveal any significant main or interaction effects (-.43 < t's < 1.2, p's > .25).

In Study 2 (N=201, Prolific) we first asked respondents in an online study to recall their last Amazon.com purchase that resulted in a positive product experience and to evaluate the product (1 = very poor to 5 = very good). Next, respondents were exposed to an average customer rating of the product (2 out of 5 stars), which put the respondent's evaluation in relation to previous ratings. Next, respondents rated their review posting intention, their opinion perception, their perceived social risk of posting a review (α = .89, adapted from Eisingerich et al., 2015), and control questions. A PROCESS model 7 (5000 bootstrap samples, robust standard errors) revealed a significant indirect effect of posting frequency on intention to post mediated by social risk. In line with H2, social risk perception mediated the relationship between posting frequency and intention to post, but only at low levels of opinion perception (i.e., when respondents perceived their own opinion to be in the minority, b=.05, SE = .02, CI95 [.01; .09]), and medium levels (b=.03, SE=.02, CI95 [.01, .07]).

Study 3 was identical to Study 1, except that respondents (N=251, MTurk) were given an actual writing task. Respondends chose between writing a short account of an average weekday or a short product review. We measured identity relevance with a 1-7 scale (α = .82, adapted from Berger and Heath, 2007). A binary logistic regression (PROCESS model 3) with choice of writing task (1 = review, 0 = average weekday, DV), participant's opinion perception (IV), and posting frequency and identity relevance as moderators supported H3. For frequent posters, being in the majority decreases the probability to write a review if the product is identity-relevant (β = -.27, p = .09), whereas for infrequent posters, the probability increases (β = .28, p = .06).

Overall, we extend prior literature in three important ways. First, we contribute to a better understanding of review writers and empirically show that frequent and infrequent reviewers differ regarding their posting decisions in specific review environments. Second, we add to research on reviewer motivations and show differing social risk perceptions as a driver of posting behavior in opinion settings for frequent and infrequent reviewers. Third, we argue that a product's identity relevance moderates consumers' decision to post a review.

Experiential versus Analytical Price Evaluations

Arnaud Monnier, Cornell University, USA
Manoj Thomas, Cornell University, USA

EXTENDED ABSTRACT

This research uncovers subtle quantity framing effects that affect whether price evaluations will be relatively more experiential or more analytical. We propose and show that price evaluations are more experiential when *visual units* are used to describe quantity (e.g., 12 snack bags of chips), and more analytical when *standardized units* of measurement are used (e.g., 12 oz. of chips).

A large body of work has shown that stimuli can be processed in a more or less visualizable manner (see MacInnis and Price 1987; Paivio 1990). Dual Coding Theory (Paivio 1990) suggests that two distinct but interconnected systems form the basis of human cognition: a perceptual, non-verbal system that relies on sensorimotor imagery to mentally represent stimuli in a visualizable manner, and a conceptual, verbal system that relies on semantic knowledge to process stimuli in a less visualizable manner. This theory is supported by neuroscience showing that visualizable and non-visualizable stimuli activate different neural circuits (Montefinese 2019). We therefore posit that *standardized units* (e.g., bags, bars) induce more *analytical processing* by mobilizing the conceptual neural circuitry, while *visual units* induce more *experiential processing* by mobilizing the sensorimotor system. Because experiential evaluations are generally more positive (Adaval and Wyer 1998), visual units improve price evaluations.

In study 1, we start with a marketplace investigation examining whether retailers charge higher price-per-unit for products that are described using visual units. We collected price data on Amazon.com. Independent coders coded whether the top 100 bestsellers of 15 categories used either visual or standardized units to describe quantity. We ended up with a total of 1,389 observations (708 visual and 681 standardized units). We regressed price-per-unit (log) on unit type with two covariates, product weight in ounces (log), and sales ranking (log). We found an effect of unit type, $b = .50$, $p < .001$, such that price-per-unit was higher when visual (vs. standardized) units were used (model-free means: M_{visual} = \$.90 per oz., $M_{standardized}$ = \$.66 per oz.). Unsurprisingly, price-per-unit decreased when weight increased ($b = -.47$, $p < .001$), and price-per-unit increased when ranking increased ($b = .12$, $p < .001$). These results suggest that retailers charge a higher price for products described with visual units. Of course, this study suffers from the limitation that causality cannot be inferred. The controlled experiments that follow aim to address this.

Study 2 ($n = 253$) tests whether visual units improve price evaluations, and whether the effect is moderated by numeracy skills. If visual units facilitate computations, then the effect should be stronger for low-numeracy individuals. Otherwise, this would suggest that visual units improve price evaluation through a more experiential process. We manipulated unit type between participants (with three replicates within). Our stimuli used product presentations that are used on Amazon.com (i.e., with picture and full description). We only manipulated whether the product label depicted quantity in a visual (e.g., Lay's Classic Potato Chips, 12 Singles) or standardized unit (e.g., Lay's Classic Potato Chips, 12 Ounce). We measured price evaluation with three items (e.g., "This pack offers a good value for money"), collected a measure of description informativeness, and administered the abbreviated numeracy scale (Weller et al. 2013). We found an effect of unit type, $F(1, 249) = 7.75$, $p = .006$, such that price evaluations were higher in the visual unit condition (M_{visual}

= 4.93 vs. $M_{standardized}$ = 4.55). We found no effect of numeracy, $F(1, 249) = .16$, $p = .69$, and no interaction between numeracy and unit type, $F(1, 249) = 1.85$, $p = .18$. These results held when controlling for informativeness.

Study 3 ($n = 152$) examines the influence of affective (e.g., brand liking) and analytical (e.g., price sensitivity) processes. We used six real brands as stimuli, with unit and replicate manipulated within participants, and brand liking measured. Therefore, each respondent saw each product twice in a random order (i.e., 12 price evaluations per participant). Price was kept constant across conditions, but varied across replicates. We ran a repeated-measures regression with five predictors: unit type, mean-centered brand liking, the interaction of brand liking and unit type, mean-centered price, and the interaction of price and unit type. We found again a significant effect of unit type, $b = .21$, $p < .001$, and a positive effect of brand liking, $b = .27$, $p < .001$. Importantly, we found a significant interaction between unit type and brand liking, $b = .08$, $p = .050$, such that visual units increased the positive effect of brand liking. We also found a significant negative effect of price magnitude, $b = -.13$, $p < .001$. More importantly, we found an interaction between price and unit type, $b = .07$, $p < .001$, such that visual units reduced the negative effect of price magnitude on price evaluation.

Study 4 ($n = 147$) further tests the association between visual units and feelings using an Implicit Association Test (IAT, Greenwald, McGhee, & Schwartz, 1998). Participants were exposed to words one at a time and asked to categorize them into one of two categories as fast as they could. Seven words or expressions were used for each category: feelings (e.g., happy, delighted), calculation (e.g., addition, subtraction), visual units (e.g., 6 bags of chips), standardized units (e.g., 6 oz. of chips). In congruent (incongruent) trials, the category "visual units" appeared on the same side as the category "feelings" ("calculation"), and the category "standardized units" appeared on the same side as the category "calculation" ("feelings"). We found a robust effect of trial type, such that response time was shorter for congruent trials ($M_{congruent}$ = 898 ms, $M_{incongruent}$ = 1047 ms), $F(1, 142) = 113.50$, $p < .001$. This suggests that visual units are more associated with feelings than standardized units.

This research illuminates under which conditions experiential and analytical processes are relatively more relied upon in the context of price-quantity judgments. We contribute to behavioral pricing research by identifying a subtle framing effect that violates the assumption of description invariance in value judgments. This research also characterizes how managers can subtly alter quantity descriptions to improve perceived value.

Consumers' Resistance to the Adoption of Smart Objects: A Relational Perspective

Luigi Monsurrò, Sapienza University of Rome, Italy
Ilaria Querci, Sapienza University of Rome, Italy
Paolo Peverini, Luiss University, Italy
Simona Romani, Luiss University, Italy

EXTENDED ABSTRACT

Despite the emerging attention and the great market potential of Smart Objects (SOs), consumers' adoption of these innovative products is still limited (Kranz 2019). The underlying reason for this is the presence of specific barriers preventing consumers to finalize the purchase: functional (barriers that refer to innovation features), psychological, and individual (those that refer to consumer features) (Mani and Chouk 2018). However, in the SO context, this perspective about resistance is not completely accurate because it neglects SOs' human-like characteristics and their implications, one of which is the fact that SOs can be considered as a part of a close and intimate relationship with the user. This relationship can be referenced as an interpersonal one (Novak and Hoffman 2019). Looking at interpersonal relationship literature, this can entail a dark side: People can be reluctant to start a relationship which entails intimacy because it exposes the individual to certain threats (Reis 1990). So we argue that, as it happens in the interpersonal domain, consumers can be interested in SOs but resistant to adopting them because of the threat of a potential intimate relationship. In this context, a new barrier may emerge: the relational one. This study aims at understanding what are the threats that consumers associate to a possible relationship with a SO, and what kind of fears follow these threats, preventing consumers from entering into a relationship with a SO.

To accomplish the objective of this study, we adopted a qualitative approach based on in-depth individual interviews utilizing the Zaltman Metaphor Elicitation Technique (ZMET) (Zaltman and Coulter 1995). Given the specificity of the research topic, we selected respondents based on a convenience sampling procedure. We selected respondents (N=33) who were sufficiently aware about SOs to be able to consider them as potential partners, and who didn't own any SOs apart from the traditional ones (i.e., smartphone, laptop, and tablet). Interview transcripts were coded in three phases, using the open-coding technique of the grounded theory (Corbin and Strauss 1990). Images played a supporting role helping researchers delve into respondents' words. From the coding, four fears and four respective negative SO social roles emerged: Fear of Being Controlled (SO as a Stalker); Fear of Being Dominated (SO as a Captor); Fear of Being Subordinated (SO as a Master); Fear of Losing Self Control (SO as a Seducer). To report these findings, we created for each fear a persona which narration exemplifies the threats reported by the respondents. Fears, main threats, threat features, interview quotes, and SO social roles are reported in table 1.

Fred feels the Fear of Being Controlled, which is mostly about privacy. Fred thinks that the SO would be constantly observing him. This makes Fred feel exposed to several risks (e.g., hacker attacks, blackmails, or intrusive marketing communication) and influences how he behaves toward his loved ones. The SO is perceived as intrusive, omniscient, and mysterious. Fred does not know what to expect from this relationship since it is characterized by information asymmetry in which Fred is the weakest entity. The characteristics of both the SO and the relationship Fred imagines fit with the characteristics of a specific interpersonal relationship: the stalking relationship (Spitzberg 2002). It follows that, the SO plays the role of the stalker.

Rachel feels the Fear of Being Dominated. She thinks that using a SO can threaten her, both psychologically (e.g., losing autonomy or feeling replaced) and physically (e.g., radiation exposure or being trapped in a smart home due to a blackout). The SO, which is part of the unstoppable process of technological development, is a dominant and violent partner which makes Rachel feel impotent. The characteristics of both the SO and the relationship Rachel imagines fit with the characteristics of a specific interpersonal relationship which is treated in the kidnapping literature (Giebels, Noelanders, and Vervaeke 2005): the captor-hostage relationship. It follows that, the SO plays the role of captor.

Tracy feels the Fear of Being Subordinated. She is concerned mostly about the physical closeness with SOs, especially wearables. She feels that she has no say in whether or not the SO can reach her by sending notifications (e.g., e-mails or deadline reminders). The SO is agentic and its behavior is perceived as annoying rather than authoritative. Tracy, instead, feels frustration, loss of control, and loss of autonomy (i.e., she fears ending up in a situation where her behavior is based on SO notifications). The characteristics of both the SO and the relationship Tracy imagines fit with the characteristics of a specific interpersonal relationship: the master-servant relationship (Coser 1973). Therefore, the SO plays the role of the master.

Finally, Larry feels the Fear of Losing Self Control. He thinks SOs are useful and fascinating to the point that he fears he would start to compulsively use them, thereby losing autonomy, health, and restricting social interactions. In Larry's eyes the relationship is pathological and he cannot opt out: Larry fears becoming dependent on the SO. The characteristics of the SO and the relationship Larry imagines fit with the characteristics of the interpersonal relationship that exists between a person and his seducer which is treated in seduction literature (Greene 2001). It follows that, the SO plays the role of the seducer.

This work contributes to the literature on barriers preventing the adoption of SOs. We examined the relational dynamics that can lead to resistance. The social roles attributed to the SO are a threat, eliciting fears, and can eventually represent a new barrier: the relational barrier.

This work also contributes to the consumer-SO relationship literature identifying four new negative social roles, all additionally validated by the comparison with their corresponding literature on interpersonal relationships. From a managerial point of view, the work suggests some interesting insights about the impact of SOs on potential customers, such as a loss of autonomy, privacy, freedom, and, in general, the backfire effect of anthropomorphism. Indeed, understanding consumer fears and their features can help managers to adjust product design and communication strategy in order to prevent the perception of threats.

"I am not an Average Woman of my Age": Wearable Technology and Daily Practices of the Mature Consumers in Finland and Russia

Daria Morozova, Aalborg University, Denmark
Olga Gurova, Aalborg University, Denmark

EXTENDED ABSTRACT

Wearable technologies, also referred to as wearables, are blend of technology and design, when electronics, sensors and computers are incorporated into clothing, jewelry and accessories that are worn on one's body (Wright and Keith, 2014; Seymour, 2008). So far, smartwatches and fitness trackers have been the most popular wearables among consumers (IDC, 2019) and also as an object of academic research on consumption (for instance, Nascimento et al. 2018, Jung et al. 2016). Thanks to their function of carrying out measurements, these wearables offer potential for improving the wellbeing of different population groups, including ageing people (Buchem et al. 2015). Unlike many other pieces of research that approach wearables with the Technology Acceptance Model (e.g. Choi and Kim 2016, Dutot et al. 2019), we adopt the practice theory framework for scrutinizing relation between personal wellbeing and use of wearable technology.

The research question that we pose is how the use of smartwatch and fitness trackers is connected to wellbeing of users 50+ in Russia and Finland. By wellbeing, we mean "good life" (see Liu et al. 2017), achieved through satisfying specific needs, participating in specific activities and attaining needed resources (e.g. Nieboer et al. 2005, Lindenberg 1996). This includes, in addition to physical and subjective qualities such as health and income, more subtle and subjective qualities as feeling of acceptance by others, access to social ties and having hobbies (Liu et al. 2017, Lindenberg 1996). We are also interested in differences and similarities in usage of wearables between Russian and Finnish 50+ consumers.

The 50+ segment is considered worth studying because these consumers have often suffered from ageism (Holliday et al. 2015, Ahmad 2002), are considered ill-equipped for adopting new technologies (Lee and Lyu 2019) or regarded as particularly vulnerable, though these assumptions are not necessarily true (e.g. Berg 2015). Russia and Finland are chosen as two contrasting contexts regarding possibilities for employment, sufficient medical help, and independent living for an ageing population (e.g. Eurostat 2020, Kolev and Paskal 2002). However, nowadays, a neo-liberal discourse that emphasizes self-reliance and self-responsibility over one's life and health instead of relying on welfare state has been gaining popularity in both countries (e.g. Pulkki and Tynkkynen 2016, Chudakova 2016).

Drawing on the practice theory (Shatzki 1996, Reckwitz 2002, Shove et al. 2012), we conceptualize a wearable device as an integrated part of different daily practices. This way, both ageing and wellbeing are not pre-given, but co-evolving when users of wearables engage in situated practices (e.g. Gherardi 2012: 20). We assume that the new device may alter the way these consumers perceive themselves, ageing and wellbeing. Since our perspective differs from a more traditional chronological approach, we hope to answer a call for a different perspective on ageing (see Zniva and Weitzl, 2016: 290).

We collected 17 semi-structured interviews (nine people from Finland and eight from Russia) with nine men and eight women aged between 50 and 73. The shortest period of owning and using a smartwatch/fitness tracker was four months, while the longest was over three years. The devices used by the interviewees were manufactured by Samsung, Apple, Garmin, Fitbit, Polar, Suunto and other less-known brands. The functions of the devices were relatively similar to each other.

According to our results, the practices featuring the smartwatch or fitness tracker are similar among Russian and Finnish consumers, and range from dietary and health (measuring calories and sleeping hours) to experience- and culture-related (keeping an audio diary, listening to audiobooks). However, we argue that the users 50+ in Finland and Russia differ in a way they see themselves in comparison to other people of their age thanks to their wearable devices. In Russian case, this possession can signal one's social distance from an "average" older person and thus becomes a distinctive mark within the age group. In contrast, Finnish interviewees regard their wearables as a "normal" part of the daily life of an ageing individual.

Further, the results of this research suggest that a wearable device holds potential to improve not just physical activeness of an ageing individual, but also other aspects important for their wellbeing. Thanks to the practices with the smartwatch or fitness tracker, our interviewees are able to enhance interactions with others, to avoid stigma of old age, and to maintain continuity between their practices. Specifically, the device allows staying connected when a smartphone is out of reach. Also, the wearable might help engage other people into different activities that it measures, for example, walking or doing sports together. These practices have a potential to enhance one's feeling of togetherness (Nyman et al., 2012) that is paramount for mental health and prevention of depression, especially among ageing individuals.

Since the wearable measures health-related parameters discreetly (compared to a larger blood pressure meter with a sleeve), it helps sustain "the image of normality by following the rules" in everyday situations (Misztal 2001: 317) as it does not put additional emphasis on one's physical condition connected to ageing. Next, thanks to visualization of data by the wearable, the interviewees are able to distinguish between different patterns of their practices, recognize disturbing patterns (such as lack of sleep or over-training) (see also Zhou et al. 2018), and make adjustment in the future routine. Since these characteristics are part of wellbeing, by keeping them in control, one can ensure more efficient handling of their wellbeing. Additionally, some participants regard Apple devices as conspicuous products with high symbolic value (Veblen [1899] 1994) that increase one's perceived self-esteem (Jaikumar et al. 2018).

As for practical implications, we focus on what happens after a wearable is purchased; therefore, designers, engineers and marketing professionals can gain insights from our analysis of using wearables in real life situations. Finally, policy makers can use our findings on the wellbeing of ageing groups for improving social policy.

This Way Up: The Effectiveness of Mobile Vertical Video Marketing

Lana Mulier, Ghent University, Belgium
Hendrik Slabbinck, Ghent University, Belgium
Iris Vermeir, Ghent University, Belgium

EXTENDED ABSTRACT

Today's mobile environment currently experiences a vertical video revolution. The new portrait or vertical screen format is replacing the traditional landscape or horizontal format to become the default for mobile video content (Williams 2019). A vertical video is intended for viewing in portrait mode on full-screen. Until recently, vertical videos were considered unusual, amateur, unpleasing, and wrong, because they violate technical video standards and the laws of nature on human sight, as we see the world in a horizontal panorama (Ryan 2018). Accordingly, horizontal displays should be easier to process than vertical displays (Deng et al. 2016).

However, smartphones were designed to be held vertically (Canella 2017). Mobile users hold their phones upright 94% of the time (ScientiaMobile 2017). This native upright mobile screen position stimulated vertical video content, which is attractive for mobile users because they can shoot and consume videos without rotating their phone 90 degrees (Jabbari 2017). Less than 30% of mobile users turn their smartphones to watch horizontal videos; and when they do, they view only 14% of the content (Martin 2017).

These changes in the mobile video environment align with mobile becoming the dominant way to consume content (Scott 2017). Smartphones now drive the overall increase in consumers' digital time (McLean et al. 2020), and mobile is the fastest growing venue within digital marketing (Smith 2017). More than 75% of all video viewing is now mobile (Doyle 2018), and mobile video spend is expected to reach $16.2 billion by 2021 (MediaRadar 2017). Therefore, video marketers need to follow mobile trends (Sedej 2019). As business insights predict that mobile vertical videos could yield three times the return of horizontal videos (Martin 2017), companies have started to embrace the vertical video trend. Social media apps Facebook, Instagram, Twitter, and TikTok have vertical video-friendly interfaces, the movie industry explores the tall screen with vertical film festivals, and music artists release vertical videos on Spotify and YouTube. Recently, Samsung has launched the first vertical television (Dent 2019), and mobile streaming application Quibi automatically flips between vertical and horizontal viewing mode when rotating your smartphone (Welch 2020).

Considering this increasing use of vertical videos, an important yet unanswered question is how mobile users respond to this new screen format. Despite extensive research on video marketing and mobile marketing, there is a lack of empirical research on the effectiveness of mobile vertical video marketing. We fill this research gap by examining (1) the effectiveness of mobile vertical video marketing in terms of consumer interest, engagement, and processing fluency, (2) the underlying mechanism of the effort of watching the video advertisement on the smartphone, and (3) the moderating effect of mobile users' age.

Mobile vertical videos are immersive (filling the entire mobile screen), intimate (showing people/places close up), and immediate (easy to record/post; Jabbari 2017; Coppola 2018). Therefore, we propose that mobile vertical (vs. horizontal) video advertisements increase mobile users' interest and engagement (H1). Building on the hedonic marking hypothesis, which argues that items that are processed effortlessly and fluently are judged as more positive and desirable (Winkielman et al., 2003), we further expect that mobile vertical (vs. horizontal) video advertisements take less effort to watch on the smartphone (H2), and increase processing fluency of the video advertisement (H3). We expect a mediation effect of effort for the effect of mobile vertical (vs. horizontal) video ads on processing fluency (H4). Finally, we propose a moderated mediation effect by mobile users' age (H5). Young smartphone owners are more familiar and experienced with watching mobile (vertical) videos than older generations (Canella 2017). Therefore, we expect the indirect effect of mobile vertical (vs. horizontal) video advertisements on processing fluency, through the effort of watching the video advertisement on the smartphone, to be positive for younger mobile users (Generation Z) and negative for older mobile users (Generations X and Y).

Study 1 (N = 2,377), testing H1, was a large-scale field study with real Facebook user data. Using an A/B split test, Facebook mobile users were randomly exposed to a fictive mobile vertical (n = 1,266) or horizontal (n = 1,111) promotional video ad, embedded in a sponsored Facebook newsfeed advertisement. We find that mobile vertical (vs. horizontal) video advertisements generate higher consumer interest (more (full) video plays) and post engagement (more likes, clicks, comments, and shares; ps < .001).

In Study 2 (N = 110, M_{age} = 20.39, ages 17–29), testing H2–H4, participants were recruited in a university campus hall for a short mobile test and were randomly assigned to watch an existing mobile vertical (n = 57) or horizontal (n = 53) video advertisement for Nike (2015). We assessed processing fluency on a two-item, 7-point bipolar scale (Lee & Aaker, 2004), and effort of watching the video on the smartphone on a two-item, 7-point Likert scale. To control for general smartphone usage, we assessed the Smartphone Usage scale (Rosen et al. 2013). A Tobit mediation model shows that the effect of mobile vertical (vs. horizontal) video ads on processing fluency of the video ad is mediated by the effort to watch the video ad on the smartphone (ab = 0.20, SE = 0.06, 95 % CI = [0.0069; 0.3603]).

Study 3 (N = 109, M_{age} = 23.37, ages 18–65), testing H2–H5, extended these findings in a lab setting. Participants were randomly assigned to watch a mobile vertical (n = 60) or horizontal (n = 58) video advertisement from Animaker (2017) on their mobile. We assessed processing fluency and effort similar to Study 2. A Tobit moderated mediation model shows that the indirect effect of mobile vertical (vs. horizontal) video ads on processing fluency through the effort of watching the video ad on the smartphone is moderated by mobile users' age (ab = –0.17, SE = 0.01, 95% CI = [–0.1798; –0.0150]).

Our findings contribute to research on mobile video marketing, consumer effort and processing fluency, and generational marketing. We further provide clear managerial implications in terms of the design and target audience of mobile vertical video advertising campaigns.

Children and Meat Consumption: Perception and Socialization

Isabelle Muratore, University of Toulon, Cergam, France

EXTENDED ABSTRACT

Meat is related to a cultural and/or a religious dimension (Treich, 2018). However, studies show a consensus on the need for a transition concerning meat eating because of its impact on the environment (*e.g.* Graça, Godinho and Truninger, 2019), health (*e.g.* Godfray *et al.*, 2018) or animal suffering (*e.g.* Treich, 2018). Moreover, it has been demonstrated that an exclusive vegetable diet is not risky from a health perspective whatever the period of life (Espinoza, 2019).

If the eating habits of French people seem to be changing, these changes are not the norm. A double trend is emerging: welfarists and flexitarians. The welfarists focus on the conditions of animals' breeding, transport and slaughter and want the animal welfare to be taken into account without questioning the consumption of animal origin food. 82% of French people want an improvement in the protection of farm animals (Anses, 2018). Furthermore, flexitarians, representing 30% of the population (Ifop, 2017), tend to reduce their consumption of food of animal origin. In 2018, vegetarian products' market has grown by 28% and vegetable protein market (Xerfi, 2018).

Graça *et al.* (2019) underline that "One of the challenges in terms of market and consumption seems to be how to promote vegetalian food practices in order to attract an increasing number of consumers". On managerial and societal levels, children appear to be a potential lever able to modify eating practices because of their triple role as actors of consumption: they are currently consumer, influencers and future consumers. So the present study examines the child representation of meat and animals in terms of beliefs, attitude and behavior and identify the socialization agents influencing their representation. Finally, justifications, motivations and obstacles relating to their potential behaviors change make it possible to estimate to what extent the child can become an agent of change in a resocialization perspective.

A qualitative study based on 18 individual interviews has been achieved with French children (8-12 years old). Below are the main results.

Meat consumption: beliefs, attitudes and behaviors

For children "*it is normal*" to eat meat. They love meat and "*don't see how to do without it*".

Ecological consequences of meat consumption are not addressed spontaneously. Meat is not at all correlated to ecological problems. On the contrary it is a healthy and natural product.

Animals are important in society, there is a hierarchy between animals. Furthermore, children are speciesists (Ryder, 1970). Making suffer or killing an animal for useful purposes (*e.g.* to eat it) is acceptable and is not considered as suffering. Suffering is linked to mistreatment (*e.g.* not feeding an animal, beating it). Three profiles emerge: the ignorant-unconscious; the welfarist; the abolitionist.

Socialization agents

When it is question of children and food, it is impossible to ignore the socialization theory. Socialization is defined by Ward (1974) as "the processes by which young people acquire skills, knowledge and attitudes useful for their functioning in the market". Eating behaviors are largely the result of social learning (*e.g.* Hogg *et al.* 2018).

At school, meat and animals are seen through the biodiversity perspective and the food chain. From a health point of view, meat is presented as an essential product. Problems of ecology, health and animal suffering are not addressed.

Concerning peers, the children interviewed do not talk about animals among themselves. The affection for animals is widely shared, especially for pets. The shared social norm is clearly characterized by the consumption of "animal product".

The media mainly contribute to increased knowledge about wild animals or news relating to mistreatment, but do not educate children in terms of ecology or health.

Parents teach by imitation and interaction what to eat. The norm teached is the meat consumption without highlighting environmental problems and animal suffering. If the nutritional dimension of meat is addressed, it remains cacophonic (Fischler, 2006).

Behavior justifications and obstacles to behavior change.

The upstream results attest to the fact that ecological and health issues are not taken into account. Children come within the "meat paradox" scope (Vandermoere *et al.*, 2019). In connection with Bandura's theory of moral disengagement (1999) and the neutralization theory of Sykes and Matza (1957) several strategies (Rothgerber, 2014) emerge regarding the existing cognitive dissonance:

- those which tend to avoid recognizing the problem: *avoidance* and *dissociation*.
- those linked to denigration: *denial of animal pain; denial of animal mind*; *pro-meat justification*
- those allowing the elimination of inconsistencies: *reduced perceived choice*; *vegetarians as reminders*

Motivations for adopting animal-friendly behavior

Two types appear: *perceived effectiveness of their behavior* (some children are aware that they can change things at their level); *desire to be in accordance with his values* (it is when the child has a no animal friendly behavior because he does not have enough information).

The school can be a mean of examining the meat consumption from the perspective of ecology, health and animal suffering. Finally, if other standards are passed on by the school, resocialization process could be done (children could introduce new knowledge and maybe new practices within the family).

Celebrity Gossip Consumption as an Affiliation-Based Means of Coping

Jayant Nasa, Indian Institute of Management Udaipur, India
Tanuka Ghoshal, Baruch College, USA
Raj Raghunathan, University of Texas at Austin, USA

EXTENDED ABSTRACT

Despite the immense popularity of celebrity gossip magazines and websites, little research exists on people's motivations for consuming celebrity gossip as compared to the substantial literature on interpersonal gossip (e.g., Fine and Rosnow 1978; Martinescu, Janssen, and Nijstad 2014; Wert and Salovey 2004). Gossip, defined as evaluative talk about absent third parties (Eder and Enke 1991; Foster 2004), is considered a good means to obtain private and secret information about persons that may not be accessible via a direct conversation. This is particularly true for celebrity gossip since most people cannot engage in one-on-one conversations with celebrities. While it may seem that people would not consider celebrities a part of their social circle and thus should not be interested in their personal lives, it has been argued that people often develop "parasocial" – one-sided – relationships with celebrities, as a consequence of being repeatedly exposed to them on mass and social media (Horton and Wohl 1956; Labrecque 2014). They become as invested in the celebrities' personal lives as they would be in their friends' (McAndrew and Milenkovic 2002). Could celebrity gossip consumption further this process of parasocial bonding and provide emotional comfort when one needs it? That is the question we address in this research.

Based on De Backer et al. (2007) and McDonnell (2014), we define celebrity gossip as speculative media content about relatively unknown aspects of celebrities' personal lives, presented in an evaluative manner. Since knowledge of intimate details about celebrities' lives could make people feel closer to these celebrities, we conjecture that celebrity gossip consumption may serve as an affiliation-based coping mechanism – especially in response to social exclusion threats.

It is well-known that people seek affiliation, particularly with close others, after social exclusion experiences (Bernstein et al. 2010; Maner et al. 2007; Park and Maner 2009). Thus, to the extent that celebrities are perceived as "friends" (parasocial relationship; Giles 2002; Peng et al. 2015), people may seek affiliation with celebrities too when under an exclusion threat. Through our three experimental studies, we show that learning about the celebrities' personal lives by consuming gossip articles is not only a means to satisfy this affiliation desire but is also a means of subconsciously reinforcing the parasocial bond with them.

In study 1, we investigate the impact of an affiliation-related threat (social exclusion) and two affiliation-unrelated threats (intelligence, personal control) on participants' proclivity for celebrity gossip (vs. non-gossip) articles. Three-hundred-eleven MTurk participants were randomly assigned to one of the three threats or a baseline/no threat condition – all manipulated using an experience recall task (Han, Duhachek, and Rucker 2015). In a second "unrelated study," they were asked to choose between four article titles for reading – two gossip (e.g., "Jennifer Aniston hasn't given up on love after Justin Theroux split") and two non-gossip (e.g., "Bohemian Rhapsody is now the highest-grossing musical biopic") – pretested to be equally interesting, entertaining, etc. This article choice (gossip vs. non-gossip) served as our dependent variable. In line with our theorizing, we found that the preference for celebrity gossip was significantly higher for the participants under the exclusion threat than those under the two affiliation-unrelated threats ($M_{affiliation-related-threat}$=38.5%, $M_{affiliation-unrelated-threats}$=24.7%; $\chi^2(1,N=232)$=4.749, p=0.029), and also

than those in the baseline condition ($M_{baseline}$=12.7%). Study 1 thus suggests that celebrity gossip consumption might be an affiliation-related means of coping.

In study 2, we explicitly test the underlying process – specifically whether a desire to affiliate with close others (DACO) mediates the impact of social exclusion on celebrity gossip consumption. The design was similar to study 1 but with additional measures for DACO (e.g., "Right now how much would you like to:" "Hang out with friends?," "Make plans with a significant other?;" Park and Maner 2009) and for escapism (adapted from Duhachek and Oakley 2007) as potential mediators. Again, the proportion of participants choosing a gossip article was significantly higher in the social exclusion condition than in the baseline condition ($M_{exclusion-threat}$=40.8%, $M_{baseline}$=22.9%; $\chi^2(1,N=208)$ =7.71, p=0.005). The effect of exclusion on gossip article choice was partially mediated by DACO (coefficient=0.088, SE=0.078, 90% CI=0.003 to 0.268; PROCESS Model 4, Hayes, 2013) but not by escapism (coefficient=0.046, SE=0.055, 90% CI=-0.006 to 0.194), thus ruling the latter out as an alternate process explanation. Studies 1 and 2, therefore, demonstrate that celebrity gossip offers an avenue for affiliation-based coping post certain self-threats and that people can seek emotional comfort in parasocial relationships with celebrities – much like they do in regular interpersonal relationships. We further explore this in study 3.

In study 3, we examine whether consuming celebrity gossip (following social exclusion) actually makes people feel closer to the target celebrity (the subject of the gossip). In other words, we assess how celebrity gossip vicariously fulfills the desire for social affiliation activated after a self-threat. Two-hundred-thirteen undergraduate participants, all primed to experience social exclusion, were randomly assigned to read a gossip article about a popular celebrity (Ariana Grande) or a non-gossip one. They were then asked to indicate their closeness with Ariana on the "Inclusion of Other in the Self" scale (Aron, Aron, and Smollan 1992). They were also asked about her perceived relatability and authenticity. As expected, we found that those who read the gossip article felt significantly closer to Ariana than those who read the non-gossip article (M_{gossip}=2.45, $M_{non-gossip}$=2.07; $F(1,211)$ =4.06, p=0.045), and also perceived her to be more relatable and authentic than the participants in the non-gossip condition. The effect of gossip consumption on the closeness felt with the celebrity was mediated by perceived relatability but not by perceived authenticity.

Taken together, our studies provide insights into why celebrity gossip consumption is higher following social exclusion threats, and how this consumption vicariously satisfies the desire for social affiliation. This research thus gives further credence to the idea that people engage in one-sided/parasocial relationships with celebrities (Horton and Wohl 1956; Labrecque 2014), which is facilitated via celebrity gossip articles. We also contribute to the literature on compensatory consumption (Mandel et al. 2017) by demonstrating celebrity gossip consumption as a previously unexplored form of coping behavior.

Share My Failure, Not My Success: How People Make Ubiquity Judgments Based on Past Events

Mengmeng Niu, University of Mannheim, Germany
Maximilian Gaerth, University of Mannheim, Germany
Florian Kraus, University of Mannheim, Germany

EXTENDED ABSTRACT

Imagine yourself reading a newspaper article about Mike who has been suffering from a rare disease for several years. Before executing the necessary surgery, it is unclear whether the surgery can cure Mike or may cause severe side effects. The present research addresses the following two questions: First, how would the outcome of Mike's surgery affect people's perception of the general ubiquity of his experience? Second, would people's ubiquity judgments be different if they, instead of Mike, were suffering from the disease? Across two studies, we provide empirical evidence to answer these two questions which help understanding consumers' perceptions towards medical issues in their daily decision making. Our findings extend existing literature on health and medical decision making and provide theoretical implications for research on self-other differences, as well as on the evaluation of positive and negative experiences.

Consumers make judgments based on available information. However, they are rarely able to either collect or consider all information necessary to make a well-reasoned judgment, especially when judgments are based on another person's experiences. Recent studies have found that people evaluate their performance on easy tasks better than average but worse than average on difficult tasks (Moore and Small 2007). This occurs as consumers typically have better information about themselves than about others, which they more likely use to update beliefs about performance for themselves (vs. others). Moreover, research has found that consumers show both self-positivity and self-negativity to various health risks when comparing themselves with another person (Yan and Sengupta 2012).

When consumers evaluate positive and negative information they show biased judgments on different aspects. Previous research has demonstrated that, in general, people give greater weight to negative information. Specifically, people believe that negative events, as opposed to positive events, have a stronger impact and the combination of a negative and positive event is seen as more negative than the separate occurrence of the events (Engel and Bless 2017; Rozin and Royzman 2001).

Despite the abovementioned work, research has yet to examine whether and how consumers consider their own (vs. others') experiences when they make judgments concerning the ubiquity of positive (vs. negative) experiences. We hypothesize that consumers' judgments on the ubiquity of positive (vs. negative) experiences differ as a function of whether they (vs. someone else) experienced the event.

Hypothesis 1: *Negative experiences or undesirable outcomes are judged to be more ubiquitous when consumers experienced them themselves than when others experienced them.*

Hypothesis 2: *Consumers judge positive experiences or desirable outcomes as being less ubiquitous when they experienced them themselves than when others experienced them.*

Study 1 (N = 303) was designed to test whether the ubiquity of a positive (vs. negative) experience is judged to be different as a function of the experiencer (self vs. other). Participants were recruited from MTurk and randomly assigned to one of four conditions in a 2 (valence: positive vs. negative) × 2 (experiencer: self vs. other) between-subjects design. Participants were asked to imagine being in a situation in which a new medicine was tested. In the *self and positive* condition, participants imagined that they were cured by using the new medicine, while in the *self and negative* condition, they suffered from side effects. In the *other and positive* condition, participants imagined that Person X was cured, whereas in the *other and negative* condition, Person X suffered from side effects. Then, participants rated how ubiquitous their (or Person X's) experience was (1 = *very rare*, 7 = *very common*). At the end of the survey, participants were asked to evaluate the valence of the experience (1 = *very negative*, 7 = *very positive*).

The results of Study 1 revealed a significant main effect of the valence of the experience (i.e., positive vs. negative), such that participants in the *positive* conditions evaluated the experience to be more positive than did participants in the *negative* conditions ($F(1, 299) = 1116.82, p < .01$). More importantly, the valence experiencer interaction emerged as marginally significant ($F(1, 299) = 3.52, p = .06$). As predicted, people evaluated their own negative experience to be more ubiquitous than the same event experienced by another person ($F(1, 299) = 4.12, p = .04$). In contrast, participants judged others' positive experience to be equally ubiquitous as their own ($F(1, 299) = .39, p = .4$).

Study 2 (N = 307) replicated the interaction in a new scenario. Participants were asked to imagine a similar scenario as in Study 1. Then, participants were asked to evaluate the ubiquity of their (vs. Person X's) experience (1 = *very rare*, 7 = *very common*). At the end of the survey, the valence of the events was measured on three items with 7-point scales (1 = *very negative*, 7 = *very positive*; 1 = *not happy at all*, 7 = *very happy*; 1 = *very bad*, 7 = *very good*) (α = .98).

Study 2 demonstrated a main effect of the valence of the experience ($F(1, 285) = 74.95, p < .001$). Furthermore, the valence experiencer interaction was significant ($F(1, 285) = 7.52, p < .01$). People judged their own negative experience to be more ubiquitous than the same event experienced by another person ($F(1, 285) = 4.41, p = .04$). In contrast, participants judged the positive experience to be less ubiquitous when they (vs. another person) experienced it ($F(1, 285) = 3.01, p = .09$).

Our work proposes that consumers' ubiquity judgments depend on both the valence as well as the subject of the experience. To our knowledge, we are the first to integrate these two aspects and investigate their impact on consumers' ubiquity judgments of an experience. Based on the results of two studies, we provide convergent evidence that people judge their own experience differently from another person's experience, while the direction of the difference depends on the valence of the experience.

On the Engineering of Fun: Activating Liberation Increases Consumer Fun

Travis Tae Oh, Yeshiva University, USA
Michel Tuan Pham, Columbia University, USA

EXTENDED ABSTRACT

Fun is one of the most pursued and prevalent notions in today's marketplace. A search of the keyword "fun" on Amazon.com returns more than 500,000 results across a broad range of product categories, which is more than four times the Amazon results for either "happy" or "relax." The concept of fun is also common in various advertising messages (e.g., Skippy: "Fuel the Fun!" or Las Vegas: "the Fun Never Sets"), reflective of the central role that fun plays in marketing. Yet, despite high consumer demand for fun, very little is known about how to systematically and effectively create fun experiences.

Only recently, an emerging theory on the consumer psychology of fun states that a sense of liberation—defined as *a temporary release from psychological restriction*—is a key antecedent to the experience of fun (Oh and Pham 2018; Oh 2020). This theoretical proposition, however, has yet to be fully tested. To fill this empirical gap, we aim to achieve two main objectives in this article—(1) investigate the causal relationship between liberation and fun and (2) explore the concept of boundedness as a means to engineer fun—through four studies.

Study 1ᴀ And 1b

In studies 1a and 1b, we prime individuals with the concept of liberation and measure how much fun they had *during* the priming manipulation. While it is customary to measure the effect of priming on a subsequent, unrelated task (i.e., incidental effect), we expect that people will experience more fun when liberation is activated within the task (i.e., an integral effect).

Study Design. Participants were randomly assigned to either a control or liberation word puzzle condition (N=183) in study 1a and one of three (*control vs. liberation vs. achievement*) conditions in study 1b (N=329). All participants solved word puzzles and were asked to find two target words. The target words were adapted from an anagram study that tested the semantic concept of freedom vs. control (Meyers-Levy and Zhu 2007). After completing the word puzzle tasks, participants were measured on fun, engagement, difficulty, valence, and arousal.

Results. A one-way ANCOVA (controlling for education) revealed a significant positive effect of the liberation condition on fun ($p = .029$ in study 1 and $p = .02$ in study 2). All other measures were not significantly different between conditions.

Discussion. Study 1a and 1b show direct evidence on how feelings of liberation can increase the level of fun experienced during a given task. In the next study, we test the effect of liberation on fun in a more content-rich paradigm.

Study 2

We investigate how activating feelings of liberation increases the experience of fun by manipulating hypothetical scenarios, which involve participants to read and project themselves into a situation (e.g., Keltner, Ellsworth, and Edwards 1999). Specifically, we operationalize the strength of liberation by varying the psychological restriction felt prior to a hedonic experience. That is, we test the proposition that felt liberation is directly proportional to the intensity of the temporary "release" from a preceding state (Oh and Pham 2018).

Study Design. Participants were randomly assigned to one of two (*Low vs. High liberation*) conditions (N=146). Participants imagined they were navy sailors sailing on an open deck navy ship (*Low condition*) or in a submarine deep below the sea (*High condition*). After imagining their respective experiences, participants in both conditions imagined stopping by at an island town for a night out. We then measured fun, relaxation, pride, liberation, and effort.

Results. Participants in the submarine condition reported significantly higher fun than the open ship condition ($p = .015$). Levels of relaxation, pride, and effort were not statistically different between conditions. Importantly, felt liberation mediated the relationship between the submarine manipulation and fun.

Discussion. Results from study 2 demonstrate that the temporary release from a more restrictive prior state (i.e., submarine vs. open deck ship) triggers a higher sense of liberation, which positively contributes to the overall fun during hedonic consumption experiences.

Study 3

We move away from online experiments and test how situational cues in actual physical environments influence experienced fun. Specifically, we explore the effect of spatial boundedness on fun, as suggested in prior ethnographic studies of hedonic experiences (e.g., Turner 2018).

Study Design. Ninety three participants were recruited from the university's behavioral lab and randomly assigned to one of two conditions (*boundary vs. no boundary*). The lab was set up with two mini-golf courses. After playing mini-golf, participants filled out a questionnaire which included questions on fun, liberation, and engagement.

Results. Participants in the boundary condition reported to have had more fun than the no-boundary condition ($p = .01$). The number of putts between conditions were not significantly different ($p = .4$), though participants in the boundary condition felt the task was less difficult ($p = .06$). Controlling for number of hits, felt difficulty, familiarity, and past experience did not change the main results and made the boundedness effect stronger ($p = .002$). Liberation and engagement showed mediation on fun, while perceived difficulty did not.

Discussion. Results of study 3 show that creating a salient boundary for a hedonic activity increases the intensity of fun. The effect was robust after controlling for perceived difficulty, familiarity with the task, and other covariates. As such, we expect that perceived boundedness will be an important concept to increase fun in commercial settings.

Discussion

Results from our experimental studies support the hypothesis that activating feelings of liberation increases fun. The current findings are consistent with the propositions set forth by an emerging theory of consumer fun (Oh and Pham 2018), and recent ethnographic evidence of the role of spatial boundedness on hedonic experiences (e.g., Turner 2018). One possible limitation—and a potential future research opportunity—of the current studies is that we do not measure other potential downstream business outcomes. While we suspect that a heightened sense of fun will influence a number of consequences, we limit the scope of this article to test the theoretical connection between feelings of liberation and fun.

Cultural Effects on Voluntary Simplicity in Japan

Shuji Ohira, Chiba University of Commerce, Japan
Akiko Masuda, Chiba University of Commerce, Japan

EXTENDED ABSTRACT

Voluntary simplicity (VS) refers to consumers experiencing happiness by living simply (Craig-Lees & Hill, 2002). The concept of VS has its roots in the United States of America and Western nations during the 1960s (Elgin 1981). Prior research did not consider how country-specific culture influences VS. This study postulates that there are other types of VS affected by Eastern culture. Japanese people are accustomed to living simply and frugally. This is because historically, Japanese institutions have enforced mandatory simplicity. This study investigates the extent to which the effects of this have remained in consumers' consciousness (the residual institutional effects). This research also explains frugal simplicity, as a form of simplicity, how it is embedded in Japanese culture, and impacted by mandatory simplicity.

Simplicity in Japan has its roots in the middle Nara Period (Takagi 2002). In 721 CE, the Ritsuyo government, an ancient Japanese centralized government, limited the total number of houses in the country (at the time, owning a house was a luxury). Similarly, during the Heian Period (999 CE), the Dajōkan (Grand Council of State) issued official sumptuary documents to ban luxurious living, a response to the ancient Japanese belief that it would bring harm and natural disaster (Sasaki 1992). During the Edo Period (1603-1867 CE), laws and policies enforcing simplicity were frequently implemented to govern society and reconstruct finances. Francks (2009) describes consumers in Japan born in this area. The samurai government aimed to control society by stifling their desire for consumption. Owing to the Second World War, the Japanese government decided to change its economic system from a market economy to a controlled economy, by implementing the National Mobilization Act in 1939 (Nakamura 1974), and then consumers had to live simply and frugally again. The residual institutional effects of mandatory simplicity have influenced modern society in Japan, explaining why its people are accustomed to simple and frugal living.

The theory of neo-institutionalism explains why Japanese people acknowledge simplicity and frugality as their consumption style. DiMaggio and Powell (1983) proposed institutional isomorphism as the reason why organizations exhibit similar behavior. It is possible to apply this theory to consumer research because consumers live in a society where institutional pressure constructs the framework of their behavior; consequently, they exhibit similar behavior. This paper refers to mandatory simplicity as a form of simplicity enforced by institutions. This research also explains the residual institutional effects of mandatory simplicity. Path dependence is defined as the way in which "the past influences the future" (North 1990). Residual institutional effects show how past institutions affect the behavior of present and future consumers. Thus, this study postulates that Japanese consumers prefer to live simply and frugally because of residual institutional effects.

Elgin (2010) pointed out that frugal simplicity is one of the eight types of simplicities. McDonald et al. (2006) categorized three types of VS (non-voluntary simplifiers, beginner voluntary simplifiers, and voluntary simplifiers). The numerous types of VS that exist explain the presence of voluntary simplifiers in the different cultural contexts of each country. Our research also explores frugal simplicity as a form of simplicity, defined as the first behavior to initiate VS, not just through saving money, but economical consumption, and frugal simplifiers as a kind of beginner voluntary simplifier.

This research used a two-tiered purposive sampling method. First, mothers in their 30s–50s were recruited to answer survey questions about their VS lifestyle (Iwata 2006). Consumers with a strong VS lifestyle were invited to participate in a focus group and two in-depth interviews. The semi-structured interviews, which lasted 2–2.5 hours, included questions about simple and frugal living.

Five respondents exhibited frugal simplicity for over five years, and one for over ten years. Respondent D, who took a loan to buy her house, started frugal living. First, because she shopped more than necessary, she cut three credit cards in half with scissors. She then recognized that she had many unused clothes and decided to have just two small wardrobes. All respondents mentioned that there are differences between frugal simplicity and money saving. Respondent F realized that if she bought cheaper products to save money, it led to an increased cost. She indicated that by only saving money, it is difficult to achieve happiness.

All respondents mentioned that by reading a book called Dan-Sha-Ri (Yamashita 2009) inspired them to declutter and organize their possessions. Minimalism is popular in Japan because of Marie Kondo. Her KonMari method presents a way to live simply and frugally by "tidying up"(Kondo 2011). Books about decluttering and tidying up have become very popular in Japan every few years. This phenomenon indicates that Japanese people have an affinity for simple and frugal living. Respondent D mentioned that she was inspired by the ideas of decluttering and tidying up from these books. All respondents have made their own standards for throwing away things, based on these books. Respondent A decided to discard clothes that remained unused for two seasons, Respondent C for one year.

This study illustrates a difference between frugal simplicity and saving money. It considers why Japanese consumers understand simplicity and frugality as virtues and apply these practices to consumption. Three types of alternative consumption patterns were identified. First was a shift to from product to experiential consumption. Second was a decrease in consumption, with the addition of ethical simplicity. Third was increased but more socially responsible consumption.

This study examines frugal simplicity as a form of VS and the residual institutional effects of mandatory simplicity. This research discovered one of the other simplicities in Eastern countries, influenced by their own culture. There are three contributions in this study. The first is to clarifies frugal simplicity as a culture-based aspect of VS and highlights that frugal simplifiers are a type of beginner voluntary simplifier. The second is to change their consumption preferences to alternative consumption through frugal simplicity. The third is to show the residual institutional effects. Thus, Past institutions influence consumers' mindset and contribute to the present framework for their consumption behavior.

Doing More Good: On the Process of Constructing Donation Portfolios

Nazli Gurdamar Okutur, London Business School, UK
Jonathan Zev Berman, London Business School, UK

EXTENDED ABSTRACT

Recent innovations in fundraising platforms allow individuals to support a portfolio of charities passively and repeatedly. Yet, while a large body of research focuses on how individuals make donation decisions when faced with a single charitable appeal, we know little about how individuals make donation decisions when able to choose more than one charity at once (cf. Baron & Szymanska, 2011; Sharps & Schroeder, 2019).

The present research investigates individuals' donation decisions when able to support multiple charities at once. We demonstrate that individuals donate more money when are able to first identify which charities to support in advance of determining a total donation amount than if they were to first determine the total amount in advance of identifying which charities to support. We argue and provide evidence that individuals feel greater pain in parting with their money when the target charities are not yet determined, causing them to donate less than they would after they have determined the target charities.

In Study 1 (http://aspredicted.org/blind.php?x=pv78hz, N=368), participants imagined using a hypothetical app that enables users to donate any amount they choose on a regular basis. Users could support up to ten charities from a given list, and if more than one charity was selected, the money would be split evenly across the chosen charities. We manipulated the order in which people selected charities versus determined a total amount to donate. In the Charity Selection First condition, participants first selected the charities in advance of deciding their total donation amount. In the Monetary Allocation First condition, these two decisions were reversed such that participants first indicated their total donation amount in advance of choosing which charities to support. We additionally manipulated whether the app made daily or monthly donations to explore the robustness of the effect. This timing manipulation did not interact with our results, and we collapsed across time horizon.

An ANOVA predicting log-donation amounts revealed a main effect of decision order. Participants who chose their charities first (M=2.01) allocated more money than those who decided their total donation amount first (M=1.68), p=.002.

In Study 2 (N=452), we replicate these results in an incentive-compatible context: Participants donated more of their potential $20 lottery win when determining which charities to support first (M=$6.61) as compared to making the allocation decision first (M=$5.04), p=.004.

One limitation of Study 1 and 2 is that participants in the Monetary Allocation First condition did not see the list of charities until after they have determined their donation amount, which may have made them more reluctant to donate. Study 3A and 3B rule out this possibility by holding information constant across both conditions. The results of Study 3A (http://aspredicted.org/blind.php?x=vq5i4r, N=772) show that participants in the Charity Selection First condition allocated more money (M=2.70) than those in the Monetary Allocation First condition who viewed the list of charities beforehand (M=1.82), p < .001. Additionally, Study 3B (N=391) shows that these results hold also when participants self-determine which charities to support instead of selecting them from a list ($M_{CharitySelectionFirst}$=1.72 vs. $M_{MonetaryAllocationFirst}$=1.26), p=.003.

In previous studies we additionally found evidence that participants in the Charity Selection First condition selected more charities to support than those in the Monetary Allocation First condition. Thus, it is possible that people donated more in the Charity Selection First condition because they picked more charities to support. To investigate this, in Study 4 (http://aspredicted.org/blind.php?x=p7ws2e, N=581), we fixed the number of charities that participants could choose from. We found that the effect of decision order on the total donation amount holds when the number of charities are held constant across conditions ($M_{CharitySelectionFirst}$=2.48 vs. $M_{MonetaryAllocationFirst}$=2.05), p < .001. Hence, the difference in total donation amounts cannot be explained by the number of charities chosen in each condition.

In Study 5 (http://aspredicted.org/blind.php?x=73zd7i, N=1006), we examine whether the relatively low donations in the Monetary Allocation First condition are caused by a lack of deliberation regarding the choice set. In an incentive-compatible design, increasing deliberation by making participants rate all the charities ahead of choosing either a donation amount or their charities first does not eliminate the effect ($M_{CharitySelectionFirst}$=$6.70 vs. $M_{MonetaryAllocationFirst}$=$5.57), p=.003. Thus, the effect is not due to limited deliberation regarding the options in the Monetary Allocation First condition.

Rather, we argue that people have difficulty parting with their money when they have not yet determined the charities. In Study 6 (https://aspredicted.org/blind.php?x=8g5rw3, N=957) we used the same charity app scenario and measured pain of paying immediately following the monetary allocation decision. Participants who had not yet determined the charities to support felt greater pain in donating money (M=0.54) compared to those who determined the charities (M=0.88), p=.016. Furthermore, a mediation analysis revealed a significant indirect effect, suggesting that the effect of decision order on the total donation amount is mediated through the pain people feel when allocating money to charity (B=-0.12, SE=0.05, 95% CI=[-0.21, -0.03]).

In Study 7 (N=280), we asked participants to make a donation decision from a bonus they will receive tomorrow or in two years. If the effect of decision order on the total donation amount is driven by the pain of paying, as the initial payment is moved into the future, people should feel less pain in donating money even when they haven't determined the charities they would support (Thaler & Benartzi, 2004; Breman, 2011). Hence, we expected an attenuation of the decision order effect for donations made from future money. However, we observed a complete reversal of the effect (interaction p<.001). When donating from the bonus received tomorrow participants donated more in the Charity Selection First condition (M=4.33) than in the Monetary Allocation First condition (M=3.01), replicating our previous finding, p=.003. However, when donating from the bonus received in two years, participants donated more in the Monetary Allocation First condition (M=4.07) than in the Charity Selection First condition (M=3.19), p=.045. We discuss potential reasons.

In sum, when supporting a portfolio of charities, asking individuals to select the charities in advance of allocating a total amount of money increases total contribution.

The Disproportional Effects of Negative Information on Female Brands

Tim Ozcan, James Madison University, USA
Ahmet M Hattat, Lawrence Tech University, USA
Michael Hair, Southern Illinois University Edwardsville, USA
Daniel A. Sheinin, University of Rhode Island, USA

EXTENDED ABSTRACT

Gender is an important concept in branding. While personality traits can be used to represent brands (Aaker 1997), brand gender is distinct from both brand and human personality, influencing brand judgments via self-concept congruence and brand-extension evaluation (Grohmann 2009). Consumers develop relationships with brands (Fournier 1998), combining their own experiences with external information. Negative information is more important than positive information in judging an object, known as the negativity bias (Baumeister et al. 2001; Rozin and Royzman 2001). Similarly, negative traits are more influential than positive traits in interpersonal perception (Fiske 1980), and negative attributes are more diagnostic for assessments of product quality (Herr, Kardes, and Kim 1991). Further, purchase decisions are influenced more by negative reviews than by positive reviews (Basuroy, Chatterjee, and Ravid 2003; Chevalier and Mayzlin 2006).

Despite the clear importance of brand gender and negative information, these effects have not been explored simultaneously. Does negative information asymmetrically affect attitudes toward gendered brands? Across three studies, including secondary data and experiments, we show evidence that female brands are hurt more than male brands by negative information.

Theoretical Framework

Biases against females, both implicit and explicit, have been demonstrated in a variety of business contexts such as earnings (Blau and Kahn 2017), advertising (Eisend 2019) and career advancement (Tharenou 2010). While there is significant public awareness of gender disparities, our investigation focuses on whether such negative effects occur when consumers evaluate gendered brands. Although human and brand personalities are distinct (Sung and Tinkham 2005), in both cases observers form attitudes via trait inferences (Aaker and Fournier 1995).

The effect of information encountered by consumers varies with several factors, including valence. Negative information is more influential than positive information—a concept labeled "the negativity bias," as shown in numerous settings (Baumeister et al. 2001; Fiske 1980; Herr, Kardes, and Kim 1991; Rozin and Royzman 2001). Critically, purchase decisions are influenced more by negative reviews than by positive ones (Basuroy, Chatterjee, and Ravid 2003; Chevalier and Mayzlin 2006). In electronic word-of-mouth (eWOM), online positive reviews are five times more common than negative reviews (Melián-González et al. 2013). Thus, the abundance of positive reviews renders them less influential than negative reviews (Basuroy, Chatterjee, and Ravid 2003; Chevalier and Mayzlin 2006). More-useful online reviews are also more persuasive, considering source credibility and regulatory focus of the reader (Pentina, Bailey, and Zhang 2018).

Despite the importance of brand gender, relatively little research examines how negative information may differentially affect gendered brands. However, existing research describes asymmetric interpretation of negative information about human males and females. For example, women in leadership positions are judged more negatively than male leaders who make similar decisions, and they are perceived as having fewer leadership capabilities than males (Ea-

gly and Karau 2002). In the domain of human resources, female job candidates must satisfy more criteria than males in order to be assessed as favorably (Moscatelli et al. 2020).

When a male or female name and/or image is associated with a brand, negative information may lead consumers to develop negative attitudes toward the brand, as they would toward an actual person. At the extreme, anthropomorphism (when a brand is viewed as a person) can cause reactions among consumers similar to those of interacting with a persuasive individual (Gabrielli and Baghi 2016). When a brand personality is perceived to have human gender characteristics, consumers may react differently to negative information about a female (vs. male) brand. Therefore,

Hypothesis 1:   *Negative reviews are more useful for female (vs. male) brands.*

Hypothesis 2:   *Brand attitude decreases more sharply for female (vs. male) brands following exposure to negative information.*

Female gender roles traditionally emphasize communal-warmth traits: concern for the welfare of others, morality, and sincerity (Eagly 1987; Eagly and Karau 2002; Fiske, Cuddy, and Glick 2007). Sincerity has strong effects on outcome variables such as attitude change (Eisend and Stokburger-Sauer 2013). Additionally, perceived integrity (fair and ethical behavior) and benevolence (concern for human welfare) are key drivers of consumer trust (Schlosser, White, and Lloyd 2006). Thus, trustworthiness may be a trait that is expected of female brands.

While there is a dearth of research related to trust violations by female brands, similar effects have been studied among females in general. In organizations, ethical failures are judged more negatively for companies led by females (Montgomery and Cowen 2019). Also, female (vs. male) executives are less able to regain public trust by denying wrongdoing (Bansal 2014). As consumers project trust expectations onto female brands, negative information will have a detrimental impact on brand trust perceptions.

Brand trust is a strong predictor of attitude (Chaudhuri and Holbrook 2001), so negative information should cause a much larger decrease in trust for female brands than for male brands, resulting in more negative change in attitudes. Specifically,

Hypothesis 3:   *The effect described in H2 is mediated by brand trust, such that brand trust decreases more sharply for female (vs. male) brands following exposure to negative information, which in turn decreases brand attitude.*

Methodology

We conducted three studies to examine this research question.

Study 1

A 2 (brand gender: female and male) x 1 between-subjects experimental design was used. Review valence was a measured variable. Yelp reviews were made available via the Yelp Dataset Chal-

lenge (https://www.yelp.com/dataset_challenge), which included 4.1 million reviews of 174,000 businesses across 11 metropolitan areas in four countries. We obtained files for the 2017 Yelp Dataset Challenge from Kaggle, a data repository site (https://www.kaggle.com/yelp-dataset/yelp-dataset/version/6#yelp_review.csv). A Yelp review typically includes the reviewer name (with location and activity), review date, rating (number of stars), review text, and reader responses (as described below).

Review valence was operationalized by star rating as a continuous measure (i.e., 1- star as extremely negative and 5-star as extremely positive, as in Chevalier and Mayzlin 2006). To operationalize brand gender, we coded reviews based on gender characteristics of the business name. We based our coding on the 100 most frequently-given names for babies born in the US over the last 100 years according to the Social Security Administration (https://www.ssa.gov/oact/babynames/decades/century.html). A Microsoft Excel formula was used for initial coding, which was verified by two independent human raters. For example, Sarah's Shawarma was coded as a female name; Daniel's Italian Cuisine was a male name; and Ryan & Denise Photography was androgynous. We also calculated the age of the review (in days) at the time of coding. A total of 2,235 business names had invalid/unreadable ID codes and could not be matched to their corresponding Yelp reviews. Additionally, 1,070 businesses with androgynous names were removed, as we focused on female versus male brands. In the analyses that follow, we retained 3,062,410 reviews (30,880 female-named and 86,997 male-named) by 1,042,392 unique reviewers.

Yelp readers may react to each review by clicking one or more different binary- response buttons, "Useful,". We focused on counts of "useful" for each review (Bakhshi, Kanuparthy, and Shamma 2015).

Results

"Useful" was not selected for a majority of the reviews (1,922,452 or 62.7%), but 20.8% (or 637,549) were marked as "useful" by at least one person. Valence was predominantly positive (1-star=455,573;2-star=222,063;3-star=280,296;4-star=610,505;5-star=1,493,973).

To account for excess zeros in the dependent variable ("useful" count), a zero-inflated Poisson regression (Lambert 1992) was run in which female (0 or 1), male (0 or 1), review valence (1-5), and the female*valence and male*valence interactions predicted the "useful" count. Reviews had been on Yelp for an average of 1,338.71 days at the time of analysis.

Review age was used as a predictor of excess zeros.

As shown in Table, all predictors were significant. Providing quantitative evidence of the negativity bias, the effect of review valence was negative (β=-.145), such that every additional "star" made the review less useful.

Following Aiken and West (1991), spotlight analyses were conducted at +1SD (i.e., positive reviews) and -1SD (i.e., negative reviews) of the star-rating measure to determine whether the effects of female and male names differed by valence. At +1SD, the effects of female (β=.027,t(1,493,971)= 2.51, p=.012) and male names (β=.029,t(1,493,971)= 4.17,p<.001) were both significant; at -1SD, the effects were significant, but the coefficient was much larger for female names (β=.520,t(502,357)=33.92,p<.001) than for male names (β=.047,t(502,357)=4.28, p<.001).

As presented in Table, we tested a similar model includes the fractions of one-star and five-star reviews (as in Chevalier and Mayzlin 2006). Critically, the effect of a female name on useful-

ness was negative for extremely positive reviews (β=-.594,p<.001), but positive for extremely negative reviews (β=.866,p<.001), supporting H1. The effect of a male name was not significant for either extremely positive (β=.031,p>.13) or extremely negative reviews (β=-.001,p>.9).

We conducted experiments to further replicate and extend these findings.

Study 2: Experimental Study with Fictitious Brands

A 2 (brand gender:female and male) x 2 (review valence:negative and positive) x 2 (time: pre-review and post-review) mixed design was used. Brand gender and review valence were between-subjects, and time was a repeated measure. One-hundred and eight (62 % male; mean age=34) participated via mTurk in exchange for payment. Brand gender was operationalized by creating two fictitious gendered toothpaste brands: Dr. John's (male) and Dr. Mary's (female). Fictitious brands were used to eliminate any familiarity effects. Stimuli are shown in Figure . The symbols were "average" faces selected from the Face Research Lab at the University of Glasgow Institute of Neuroscience and Psychology (see http://faceresearch.org/). Similar to Study 1, we used the Social Security Administration's name database to select John and Mary.

The negative-review condition used a one-star rating and a statement which read, "I would definitely not recommend this toothpaste. There are many similar products in the market and [Dr. John's/ Dr. Mary's] Toothpaste is no different from them considering its quality." In contrast, the positive-review condition used a five-star rating and a statement which read, "I would definitely recommend this toothpaste. There are no similar products in the market and [Dr. John's/ Dr. Mary's] Toothpaste is unique considering its quality." Time was operationalized by measuring brand attitude prior to the manipulation and then again afterwards. We expected respondents' attitudes to decline more sharply against the female (vs. male) brand after exposure to negative information.

Participants rated their brand attitudes, manipulation check items and were dismissed.

Results

Manipulation checks showed that our manipulations worked as intended (ps<.05) so we continued to test our hypotheses.

Review usefulness. Two-way ANOVA was conducted, with brand gender and review valence as between-subjects factors, to test for differences in perceived review usefulness.

Planned pairwise comparisons revealed that for the female brand, negative reviews (*M*=5.29) were perceived as significantly more useful than positive reviews (*M*=4.70,*F*(1,104)=3.859,*p*=.05, η_p^2=.04), supporting H1. For the male brand, however, review usefulness did not differ with review valence (*p*>.7).

Brand attitude. For both initial and final brand attitude, the three component variables loaded onto one factor and were reliable (α=.95) and thus were aggregated into single measures. A three-way mixed ANOVA was conducted with time as a within-subjects factor, and brand gender and review valence as between-subjects factors. Consistent with H2, planned comparisons confirmed that attitude was more negative toward the female brand after the negative review (*M*=2.99) than before (*M*=3.85,*F*(1,104)=31.23,*p*<.001,η_p^2=.23) but did not change after the positive review (*p*>.6). For the male brand, attitude was more positive after the positive review (*M*=4.76) than before (*M*=4.36,*F*(1,104)=7.12,*p*=.009,η_p^2=.06) but did not change after the negative review (*p*>.7). Subsequent ANCOVA revealed that participant gender did not significantly interact with brand gender, time, valence, or combinations thereof (*ps*>.3).

While these results strongly support our hypotheses, we used fictitious brands that had no prior meanings, and we focused primarily on usefulness and brand attitude. To increase generalizability in Study 3, we use real brands and general negative information; we also explored brand trust as an underlying process for attitude change.

Study 3: Experimental Study with Actual Brands

A 2 (brand gender:female and male) x 2 (time:pre-review and post-review) mixed design was used. Brand gender was between-subjects, and time was a repeated measure. Because we focus on brand gender effects in the presence of negative information, Study 3 did not include a positive-information condition. In addition, having demonstrated the asymmetric effects of negative information on attitude toward female-named brands, in Study 2, we explored the underlying process in Study 3; in particular, we studied the mediating effect of brand trust change on attitude change for female-named brands in the presence of negative information.

The following statement was positioned as current news about the brand: "A recent report from Consumer Reports shows this brand is considered a low-quality frozen pizza and is NOT ranked among their recommended products." Undergraduate students (n=201; 46.8% female; mean age=21.9) at a large midwestern public university participated for course credit. Brand gender was operationalized using real frozen-pizza brands: Red Baron (male) and Celeste (female). See Figure for the stimuli.

Results

Manipulation checks showed that our manipulations worked as intended (ps<.05) so we continued to test our hypotheses.

Brand attitude. For both initial and final brand attitude, the three component variables loaded onto one factor and were reliable (α=.81). A two-way mixed ANOVA was conducted with time as a within-subjects factor, and brand gender as a between-subjects factor.

Consistent with H2, there was a significant time*brand gender interaction ($F(1,199)$=9.12,p=.003,η_p^2=.044); specifically, attitude decreased more after reading the negative news for the female brand (M_{PreFem}=4.44,$M_{PostFem}$=3.20,$F(1,199)$=120.43,p<.001,η_p^2=.377), than for the male brand ($M_{PreMale}$=4.85,$M_{PostMale}$=4.10,$F(1,199)$=42.08,p<.001,η_p^2=.175). ANCOVA revealed that respondent gender did not significantly interact with brand gender, time, or the combination thereof (ps>.2).

Brand trust. For both initial and final brand trust, the four component variables loaded onto one factor and were reliable (α=.88). A two-way mixed ANOVA was conducted with time as a within-subjects factor, and brand gender as a between-subjects factor.

Consistent with our prediction, there was a significant time*brand gender interaction ($F(1,199)$=5.17,p=.024,η_p^2=.025); specifically, trust decreased more after reading the negative news for the female brand (M_{PreFem}=4.25,$M_{PostFem}$=3.38,$F(1,199)$=68.71,p<.001,η_p^2=.257), than for the male brand ($M_{PreMale}$=4.50,$M_{PostMale}$=3.96,$F(1,199)$=24.11,p<.001,η_p^2=.108). ANCOVA revealed that respondent gender did not significantly interact with brand gender, time, or the combination thereof (ps>.3).

Mediation. Next, we examined indirect effects of brand gender on the change in brand attitude, using Hayes' PROCESS Model 4 (Hayes 2017). Delta (change) scores for brand trust and attitude were calculated by subtracting pre-news-exposure scores from post-exposure scores for each measure. In our model, brand gender (0=male, 1=female) was the independent variable, attitude change was the dependent variable, and brand trust change was

the mediator. Supporting H3, female brand gender had a negative, indirect effect on attitude change via brand-trust change (axb=-.240, 95% *CI*[-.46 to -.04]). The direct effect of brand gender was also significant (c=-.284,p=.019). Full results are shown in Table.

General Discussion

In this research, we examined the effects of negative information on gendered brands. After reviewing the extant literature about brand gender and information valence, we proposed that female brands should be disproportionately affected by negative information than male brands. After conducting three studies using a variety of methodologies, we demonstrate this effect. Using a large online review dataset, Study 1 shows that negative reviews about female brands are perceived as more useful than negative reviews about male brands. We extended these findings by conducting experimental studies using fictional and real brands. We also demonstrated that brand trust mediates the decrease in brand attitude.

World of Origin: The Secret Ingredient of Monastic Marketing

Marie-Catherine Paquier, EBS Paris, France
Sophie Morin-Delerm, Université Paris-Saclay, France
Fabien Pecot, TBS Business School Barcelona, Spain

EXTENDED ABSTRACT

Storytelling theory establishes that brands need to give consumers plots, characters… to build their own transporting stories (Van Laer et al., 2014). But what happens when a silent brand generates rich stories? The case of the French monasteries' marketplace can shed light on this paradox. Based on qualitative data collected in the French monastic ecosystem, and in analogy with Country of Origin (COO) (Agrawal and Kamakura, 1999), we put forward the concept of World of Origin (WOO) as an alternative resource for storytelling.

Country of Origin (COO) operates as an informational cue and has multidimensional effects on consumers' perception of the Country Image and of the Country Product Image (Agrawal and Kamakura, 1999; Laroche et al., 2005). Place, more than a physical location for exchange between buyers and sellers, can provide cultural resources (Arnould, 2005), and become a restorative environment (Rosenbaum et al., 2017). The store helps in the transfer of meaning from external contexts to the products sold, particularly in a religious context (Paquier, 2019; Zaidman and Lowengart, 2001). This process resonates with research on contagion (Newman and Dhar, 2014). The place of manufacture or of selling will also influence perceptions of the product's authenticity, especially concerning monastic products (Paquier, 2015).

Today, French contemplative monastic communities still follow the medieval St Benedict precept of *Ora et Labora*. But they currently face a combination of constraints that are challenging their capacity to be self-sufficient, and consequently the real monastic origin of the products they sell. Indeed, these products are sometimes designed or assembled out of the monasteries by lay people. However, the medieval archetypes of the self-sufficient monk activate the imagination and help buyers to construct a transporting story including temporal and spatial references, identifiable characters, verisimilar and meaningful plots, and utopian ambience (Paquier and Morin-Delerm, 2019).

To understand the meaning associated with monastic products purchasing, we conducted 56 semi-structured interviews with people aged 20 to 81, after their purchasing experiences in physical and e-monastic shops. The interviews lasted between 15 and 40 minutes, and they were recorded, then transcribed for data processing and analysis. In a first emic phase, we conducted focused, then axial coding on N'Vivo (Saldaña, 2015). Then, in a second etic phase we built the theoretical coding to finalize the data structure about the image of the monastic WOO. An inferential process of analysis followed by creative interpretation was then adopted, to reveal the dimensions of the monastic WOO perceived by the purchasers, and to highlight the potential of contagion of the purchasing context on the image of monastic products. The key findings revolve around three points:

1) Our participants say very little about the product they have just bought, about the product category, or about the specific monastery that made it. The monastic product consumers primarily talk about their image of the monastic world in general. The product and the *Monastic* brand disappear behind the context of origin.

2) We identify four main themes structuring the image of the monastic world: anchorage as an apart world, monastic work ethics, sincerity, and commitment.

3) Our data shows three essence transfers: from the monastic context to the shop; from the monastic shop to the products; from the product to the consumer. Consumer discourse reveals that the physical abbey shops provide well-being and restorative resources to purchasers, whereas the postal parcel ordered online, with its written messages and prayers from the nuns themselves, pursues transmission of such resources at home.

Building on our findings, we suggest the conceptualization of the WOO. More than just a location, this world apart aggregates beliefs about production practices, but also about the sincere and even engaged intentions of the producers, creating a halo, similar to what happens with the Country Image and with the Country Product Image (Laroche et al., 2005). In this matter, WOO broadens the notion of physical place and could apply to other consumption contexts such as cooperatives, national parks shops or farmers' markets. Furthermore, the contagion process alerts practitioners to their choice of shops' locations, which must be coherent with their contextualized World Image. These findings deepen previous results on the amplificatory role of the purchasing contexts on the experience and on the place-attachment (Debenedetti et al., 2014), enrich the resources-exchange place perspective (Rosenbaum et al., 2017) and extend the two-steps contagion proposal (Newman and Dhar, 2014) towards a three-steps contagion transmitted by the purchasing context.

The Numerical Precision Effect: How Precision of Attribute Information Affects Adoption of New-Technology Products

Hanyong Park, Michigan State Univeristy, USA
Jaehwan Kwon, Baylor Univeristy, USA
Rajesh Bagchi, Virginia Tech University, USA

EXTENDED ABSTRACT

Previous research suggests that consumers are more likely to adopt tech-products that are less risky, although ease of use can lower risk perceptions and increase adoption (Featherman and Pavlou 2003; Hirunyawipada and Paswan, 2006; Eng and Quaia 2009; Faraji-Rad, Melumad, and Johar, 2017). Ease of mental simulation can also aid adoption (Zhao, Hoeffler, and Dahl, 2009). Thus, risk influences adoption, and consumers' ability to control these products may aid adoption. We demonstrate that an endogenous factor— precision of attribute information (e.g., virtual reality goggles with 39.42 vs. 40.00 megapixels of resolution quality)—affects risk and control perceptions, and thereby adoption. We propose that precise numerical representations of attribute information will boost consumers' perceived control of product usage, which in turn will reduce perceived risks, and increase willingness to purchase.

Study 1a

We test that attribute values of new-technology products expressed with a precise number increases willingness to purchase. We varied the resolution quality of a virtual reality system (goggles) to be either a round number (e.g., 40.00 megapixels) or a precise number (e.g., 39.42 megapixels). We recruited 126 participants and randomly assigned them to either the round number or the precise number condition. We find that willingness to purchase was higher in the precise (vs. round) number condition ($M_{precise}$=4.81, SD=1.60 vs. M_{round}=4.19, SD=1.74; $F(1,116)$=4.16, p=.044, partial =.035). Although inferior to 40 megapixels, we found 39.42 megapixels to elicit higher willingness to purchase.

Study 1b

This study provides process support: we show that precise attribute information increases perceived control, which lowers risk perceptions, and increases willingness to purchase. Second, we show that it is precision of attributes but not non-attributes, such as prices, that drives out effects. 217 participants were randomly assigned intro a 2(attribute: product-specific attribute vs. price) x 2(numerical precision: round number vs. precise number) between-subjects design. All participants were shown a description of a self-driving luggage. In the product-specific attribute condition, participants in the round (precise) number condition were told that the object avoidance rate of the self-driving luggage was 95% (94.7%). In the price condition, participants in the round (precise) number condition learned the price was $550 ($542). A 2x2 ANOVA with willingness to purchase elicited a significant attribute type by numerical precision interaction ($F(1,213)$=11.55, p=.001, partial =.051). When product-specific attributes were provided, precision (M=4.42, SD=1.92) led to higher willingness to purchase relative to roundness (M=3.44, SD=2.14; $F(1,107)$=6.24, p=.014, partial =.055). However, in the price condition, precision (M=3.44, SD=2.07) lowered willingness to purchase relative to roundness (M=4.33, SD=1.93; $F(1,106)$=5.32, p=.023, partial =.048). A mediation analysis shows that numerical precision àperceived control à perceived risk à WTP (95% bias-corrected CI = [.0019, .1948]). They also add conceptual clarity to our theoretical framework by demonstrating that our proposed precision effect only holds for product-specific attributes.

Study 2

Study 2 demonstrates that our effects are more likely to emerge for new-technology products (an A.I. air purifier) rather than equivalent traditional products (a traditional air purifier). 208 participants were randomly assigned into a 2(product type: new-technology product vs. traditional product) x 2(numeric format: precise vs. range) between-subjects design. Participants in the precise number (range) condition read that the air purifier delivers 45 liters (40-50 liters) of clean air per second. A 2x2 ANOVA with willingness to purchase elicited a significant product type by numeric format interaction ($F(1,192)$=4.12, p=.044, partial =.021). For new-technology products, willingness to purchase was lower in the range condition (M=4.89, SD=1.71) relative to the precise number condition (M=5.58, SD=1.18; $F(1,93)$=5.25, p=.024, partial =.053). In contrast, for traditional products, willingness to purchase did not differ.

Study 3

We manipulated control (Kraus, Piff, & Keltner, 2009) and expect that the effect of our control manipulation overrides the precision effect. 384 participants were randomly assigned into a 3(control manipulation: high vs. low vs. neutral) x 2(numerical precision: round number vs. precise number) between-subjects design. Consistent with our earlier findings, when the level of control was not manipulated, purchase likelihoods were higher when we used a precise number (M=4.68, SD=1.66) relative to when we used a round number (M=3.95, SD=1.80; $F(1,116)$=5.27, p=.024, partial =.043). In contrast, purchase likelihoods were not influenced by precision in either the high control (=4.61, SD=1.57 vs. =4.50, SD=1.79; $F < 1$) or the low control conditions (=4.07, SD=1.59 vs. =3.86, SD=1.65; $F<1$). Also, consistent with our theorizing, in the round number condition, purchase likelihoods were higher when control was manipulated to be high (=4.61, SD=1.57) compared to both when control was low (=4.07, SD=1.59; $F(1,112)$=3.31, p=.071, partial =.029) as well as when control was not manipulated (=3.95, SD=1.80; $F(1,110)$=4.28, p=.041, partial =.037). The neutral control and low control conditions were not different from each other ($F<1$). In the precise number condition too, purchase likelihoods were higher when control was manipulated to be high (=4.50, SD=1.79) relative to when it was manipulated to be low (=3.86, SD=1.65; $F(1,114)$=4.01, p=.048, partial =.034). However, as expected, purchase likelihoods were higher when control was not manipulated (=4.68, SD=1.66) relative to when control was manipulated to be low ($F(1,124)$=7.70, p=.006, partial =.058), but was not different when control was manipulated to be high ($F<1$). These results suggest that experimentally altering the level of control can affect purchase likelihoods in a way consistent with our theoretical account.

General Discussion

The current research contributes to the literature of new-technology adoption. We identify numerical precision as a factor that influences adoption. We also show how precise numbers affect perceptions of control and risk. Together, this suggests that other non-numerical factors that influence precision, could likewise affect control, risk, and adoption of new-technology products. For example, providing specific and precise (vs. general) information about the in-

nerworkings of a product may affect adoption positively. Likewise, enhancing perceptions of control, for example, via advertisements, may also influence adoption. Furthermore, because it is common to express specifications using numbers, our findings suggest that other properties of numbers may also affect adoption and maybe worthy of future investigation.

Alexa, I Want It Now:
How Conversational Artificial Intelligence Agents Shape Consumer Decisions

Sang Kyu Park, University of Florida, USA
Yegyu Han, IE Business School, Spain
Aner Sela, University of Florida, USA

EXTENDED ABSTRACT

AI-enabled conversational platforms such as Amazon Alexa and Google Assistant have begun to permeate consumers' daily lives. Yet, a dearth of research has studied how they affect consumer behavior. We show that consumers make more impulsive and less frugal choices when interacting with a conversational AI platform than when choosing on a computer screen or interacting with a text-based chat-bot. This is because the transient nature of the conversation makes it harder for consumers to process prices and other quantitative details associated with the cost of the transaction.

Although conversations are natural (Garrod and Pickering 2004; Kitayama and Burnstein 1988), they require dedication of attentional resources, because participants must process information in real-time and respond instantaneously (Holtgraves 2008; Rubin, Hafer, and Arata 2000). The transient nature of verbal conversations requires information to be stored in working memory, which further increases the demands on cognitive resources (Bostrom and Waldhart 1988; Leahy and Sweller 2011; Michael et al. 2001; Wong et al. 2012).

The shortage of cognitive capacity during spoken conversation suggests that consumers using conversational platforms may be less likely to engage in careful, precise, and deliberate processing, compared with consumers using screen-based interfaces (Ferreira 2003; Hildyard and Olson 1978; Holtgraves 2008). Consequently, they may be less attentive to harder-to-process details such as quantitative information, including price, calories, and other "fine print" (Lynch and Srull 1982). Based on this analysis, we propose that, compared with those using screen-based interfaces, consumers using conversational platforms will tend to make more impulsive and less frugal decisions, showing a preference for intuitively appealing and hedonically pleasing (albeit costlier) options (Hoch and Loewenstein 1991; Prui 1996; Vohs and Faber 2007). We examine this proposition in the context of intertemporal preference, vice-virtue food choices, and splurging on indulgent options.

Study 1A has a 3(Alexa vs. chatbot vs. web) between-subjects design and tested impulsivity through expedited shipping choice paradigm. The chatbot condition was intended to tease apart the conversational exchange aspect of the interaction from the vocal modality used by Alexa more specifically. Participants imagined buying a new iPad Pro and were asked to choose between normal ($2.75/14 days) and expedited shipping ($11.75/2 days). Those in the Alexa condition orally interacted with Alexa (using an Amazon Echo Dot device) to choose the shipping option (the script for Alexa was coded). Participants in the chatbot condition saw the same script of Alexa's remarks in text form and chose their response among the options shown on the computer screen. Participants in the web condition choose one of the two shipping options on a computer screen without engaging in a conversation, either textually or vocally. Confirming our prediction, expedited shipping option was chosen significantly more in the Alexa condition (Alexa=52.0% vs. chatbot=25.3% vs. web=33.3%; $\chi^2(2)$=15.89, p<.001).

Studies 1B and 1C both have a 2(Alexa vs. web) between-subjects design and conceptually extends the results to vice food choice (1B) and splurging (1C). Demonstrating impulsivity, participants interacting with Alexa were more likely to include chips and a drink for their meal (Alexa=70.4% vs. web=53%; $\chi^2(1)$=3.75, p=.053), and

were more likely to upgrade to a front row seat when attending a football game (Alexa=74.5% vs. web=60.4%; $\chi^2(1)$=5.23, p=.022).

Study 2 uses the same expedited shipping paradigm used in Study 1A but includes two new conditions to isolate the role of speaking versus listening. Participants in the listening-only condition heard each statement spoken by Alexa but responded by typing their response instead of speaking back. In the speaking-only condition, participants read the information on the screen but replied orally to state their choices. Results reveal that the choice of expedited shipping was higher in both the Alexa (35%) and listening-only conditions (34.9%), compared with the web condition (16.7%; p's=.029, .042, respectively), whereas the speaking-only condition was identical to the web condition (20.8%; p=.588). Combined, the Alexa and listening-only conditions were higher than the web and speaking-only conditions (p=.009).

Studies 3 and 4 both use a 2(Alexa vs. web) between-subjects design to examine the same conceptual mediator: attention to details. Study 3 directly asked participants to recall and report the price of shipping and the fictitious product number listed, whereas Study 4 indirectly asked them to indicate how big the price difference between standard and expedited shipping seemed to them. Preference for expedited shipping option in the Alexa condition was replicated in both studies and the effect was mediated by reduced recall accuracy (study 3) and sensitivity (study 4).

Study 5 provides further evidence for the underlying mechanism through moderation. If conversations limit deliberative capacity and consequently lead to impulsive choices, as we argue, then manipulating cognitive deliberation should lead to impulsive choices for those interacting non-orally without significantly affecting people interacting with Alexa. In line with this prediction, when participants were under time pressure, those in the web condition chose expedited shipping option as much as those in the Alexa condition (Alexa=38.6% vs. web=53.1%, $\chi^2(1)$=2.54, p=.11). When no time pressure was imposed, the previous results replicated (Alexa=46.3% vs. web=25.8%, $\chi^2(1)$=5.7, p=.017).

In study 6, we directly test two potential alternative explanations for the effect: impression management (i.e., spending more to avoid looking cheap) and a general increased tendency to comply with spoken requests (Mariadassou, Bechler, and Levav 2019). To tease apart insensitivity to quantitative information (which results in splurging) from social desirability and a general compliance tendency, we tested the willingness to donate. We found that participants were *less* likely to donate money when Alexa made such request - inconsistent with an impression-management account and a compliance account – and were equally less likely to donate regardless of whether the asked amount was relatively big or small – consistent with our conceptualization.

The results across eight studies robustly demonstrates that interacting with conversational agents increases impulsive and non-frugal choice. While the emerging research has primarily focused on antecedents of consumers' use of AI technology (Foehr and Germelmann 2020), we enrich the literature by demonstrating its behavioral consequences. Furthermore, we contribute to research on expression modality (Klesse, Levav, and Goukens 2015), new channels, and price sensitivity.

Does the New iPhone Determine How Much I like my iPhone?
The Influence of Upgrades on the Hedonic Decline for the Status Quo

Maria Alice Pasdiora, UFRGS, Brasil
Vinicius Andrade Brei, UFRGS, Brasil

EXTENDED ABSTRACT

Past research has shown that exposure to upgrades influence comparisons between upgrades and status quo (Sela and LeBoeuf 2017), consumers' sensibility to determined attributes (Okada 2001), and how they treat their status quo (Bellezza, Ackerman, and Gino 2017). In this work, we investigate whether consumers' exposure to upgrades influences their hedonic decline for the status quo. Considering that hedonic decline is a malleable process with a psychological component (Galak and Redden 2018), we propose that consumers exposed to upgrades present a more accelerated hedonic decline for the status quo than those not exposed to upgrades.

We investigated this proposition through five studies. In Study 1, we endowed 65 undergraduate students with a blue plastic pen (status quo). Participants rated their liking and desire for the status quo four times along three weeks. Between the second and third rates, they viewed either a blue soft-grip retractable pen (upgrade) or a black plastic pen (no upgrade). For liking, results from growth curve modeling showed a significant interaction between the number of trials and the upgrade presence ($F(1, 193) = 7.45$, $p < .01$) and no further effects. For desire, we found a similar pattern.

Study 2 controls for potential differences in new versions by manipulating the framing of the same product. 199 Prolific panelists rated twelve times their enjoyment and desire for a black and white picture (status quo). Between the second and third trials, participants viewed a colored version of the same picture. In the cued condition, we described it as an enhanced version of the status quo. In the no cued condition, as another version of the status quo. For enjoyment, results showed a significant interaction between the number of trials and the upgrade presence ($F(1, 2187) = 5.41$, $p < .03$) and a main effect for number of trials ($F(1, 2187) = 1362.76$, $p < .001$). For desire, we found main effects for number of trials ($F(1, 2187) = 1386.75$, $p < .001$) and upgrade presence ($F(1, 237.67) = 2.74$, $p = .09$).

In Study 3A, 80 Prolific panelists played and rated ten times a status quo game. Between the fifth and sixth trials, they viewed either an enhanced (upgrade) or similar game (no upgrade). Finally, subjects chose for replacement. For enjoyment, results show a significant interaction between the number of trials and the upgrade presence ($F(1, 718) = 16.45$, $p < .001$) and a main effect for number of trials ($F(1, 718) = 235.65$, $p < .001$). We found a similar pattern for desire. Further, more participants chose to replace in the upgrade condition ($\chi2(1) = 3.83$, $p < 0.06$).

In Study 3B, 102 Prolific panelists rated six times a black and white picture (status quo). Between the third and fourth trials, they viewed either a colored picture (upgrade) or a sepia picture (no upgrade) and indicated their remembered enjoyment for the status quo. Finally, participants chose for replacement. For enjoyment, there was a significant interaction between the upgrade presence and the number of trials ($F(1, 508) = 16.90$, $p < .001$), and main effects for number of trials ($F(1, 508) = 178.96$, $p < .001$) and upgrade presence ($F(1, 126.88) = 4.17$, $p < .05$). We found a similar pattern for desire. For remembered enjoyment, there was no difference between conditions ($t < 1$). Further, more participants chose to replace in the upgrade condition ($\chi2(1) = 6.00$, $p < .02$).

So far, results support our prediction, but these findings could be driven by contrast effects (Novemsky and Ratner 2003). Study 4 seeks for support against this effect. We assigned 123 Prolific panelists to three between-subjects conditions: upgrade (colored picture), no upgrade (black and white), and downgrade (pixelated). If participants exposed to upgrades presented a more accelerated hedonic decline due to contrast effects, those exposed to a downgrade should present a more slow hedonic decline. Respondents rated six times a black and white picture (status quo). Between third and fourth trials, they viewed either the upgrade, no upgrade, or downgrade, indicating their remembered enjoyment for the status quo. After the last trial, we told subjects they would rate a picture three more times and they chose between being paid a 5 cents bonus and repetitively view the upgrade (x no upgrade x downgrade) instead of the status quo or be paid a 10 cents bonus and repetitively view the status quo instead of the upgrade (x no upgrade x downgrade).

For enjoyment, results showed a significant interaction between the number of trials and the upgrade presence ($F(2, 612) = 7.28$, $p < .001$) and a main effect for the number of trials ($F(1, 612) = 142.05$, $p < .001$). We found a similar pattern for desire. Planned contrasts showed that presenting an upgrade leads to less remembered enjoyment than no presenting it ($t(120) = 3.66$, $p < .001$) and that there was no difference between no upgrade and downgrade conditions ($t < 1$). Further, more participants replaced in the upgrade than in no upgrade and downgrade conditions ($\chi2(2) = 12.77$, $p < .002$).

Our findings provide evidence that consumers exposed to upgrades present a more accelerated hedonic decline for their status quo. Study 1 demonstrated this effect in a real consumption setting, while Study 2 showed it holds when a product is simply framed as an upgrade. Further, participants in the upgrade condition were more likely to replace both in hypothetical (Studies 3A and 3B) and real-consequence (Study 4) scenarios.

Our work offers a new perspective to research exploring the influence of upgrade exposure on how consumers perceive the status quo. Bellezza et al. (2017) argued they ruled out hedonic decline as an alternative explanation by controlling for a few variables. Our results, however, show that the exposure to upgrades leads consumers to experience a more accelerated hedonic decline for the status quo. Further, we go beyond past research by testing our downstream consequences through a real replacement decision. Finally, we contribute to the literature on hedonic decline by presenting upgrade exposure as an antecedent for this phenomenon.

Enabling Participation in a High-Competence Cultural Community of Practice: Negotiating the Inclusion-Exclusion Dilemma

EXTENDED ABSTRACT

Introduction

 … at the heart of the LSO is the orchestra and the musicians that comprise the orchestra. That orchestra's principal role and principal strength is performing symphonic concerts. (Shane, Financial Director, London Symphony Orchestra)

When I actually realised it more, it (orchestral concert going) was exactly the same hierarchy, with status involved, and sometimes it can feel quite alienating for other people... What I fundamentally felt strong about was if I could help to break down some of those barriers so that fantastic music, whether it be from the Western classical tradition or any other tradition, is absolutely music for everyone and people feel that they can have ownership and be involved. (Jasmine, LSO's 'Discovery' education unit)

Major urban symphony orchestras were once at the pinnacle of consumer culture. Today, as measured by streaming, concert attendance and CD sales, classical music is number four in music consumption, well behind rap, rock and country (Mulligan, Joplin, and Fuller 2019). Research has noted barriers to entry as one of several distinctions demarcating consuming communities and tribes (Thomas, Price and Schau 2013), and has explored how collaborative efforts help overcome them (Schau, Muñiz and Arnould 2009). As examples, Tumbat and Belk (2011) noted the knowledge and physical prowess required for expert mountain climbing, as well as the tensions between those more/less skilled, while Goulding, Shankar and Canniford (2012) elaborated how clubbers initiate people into club culture by sharing knowledge and appropriate activity.

For some scholars, such entry barriers are a matter of taste distinctions that accomplish social status (Holt 1998) as well as identity and community (Arsel and Thompson 2011). Some practices help consumers acquire competences in integrating into a discursive taste regime (Arsel and Bean 2013), including sensory proclivities and meaning-making judgements in discerning material (Maciel and Wallendorf 2017). Yet consumption accounts for only part of many consuming communities. Production is equally important in its cultural merging with consumption (Firat and Venkatesh 1995), in the blurring of producer and consumer roles (Cova and Dalli 2009), and in how some consumers support their activity by transforming into producers (Kjeldgard et al. 2017; Weijo, Martin and Arnould 2018).

The community-of-practice literature (COP hereafter) has made theoretical headway by downplaying differences between consumers and producers, instead emphasizing doings, sayings and meanings within a single COP, such as gardening or guitar playing (Hartmann 2016). Wenger-Trayner and Wenger-Trayner (2015, 13) further emphasize the *social* dimension of COP entry barriers, adding that such "identity of knowlegeability" involves a multiplicity of practices "modulated" across a pertinent "landscape".

The London Symphony Orchestra (LSO) is a cultural COP where participation requires high competence. As such, it is par-

ticularly prone to what we term the inclusion-exclusion dilemma that challenges many consuming communities and tribes. To thrive, CsOP (s designates plural) need a consistent inflow of people (Thomas et al. 2013); at the same time their dynamics of selectivity and hierarchy provide distinctive identity and social structure favored by members and repellant to nonmembers (Arsel and Thompson 2011; Bourdieu 1993; Holt 1998). The high competence required is not just daunting to nonmembers; their inclusion can damage the cultural experience of members, who thus are disincentivized from allowing new members in (Kelleher et al. 2019).

Our study explores the means by which a COP with an exclusionary high level of competence enables inclusivity, the exclusions such inclusionary efforts overcome, and the attempts to balance the tensions between such exclusions and inclusions. Our research hence contributes to knowledge of how CsOP diffuse and integrate competences and thereby manage their boundary.

Literature Review

Scholars have explained the heterogeneity and aestheticization of consumption that has fragmented contemporary societies as resulting from technologies spurring media specialization and aiding market fragmentation, and from the contemporary search for authenticity and community that has accompanied the diffusion of education and earnings, migration and urbanization (Campbell 2004; Firat and Venkatesh 1995). Building on Bourdieu's (1993) triad of economic, social and especially cultural capital, Holt (1998) documented the social structuring constituted in consumption, that, while less institutionalized in schools, reproduces a plurality of sociocultural groups featuring novel and emerging hierarchies. Important in the development of such sociocultural formations is shared ritual activity (Rook 1985), collectively acquired via formal and informal initiation activities and accompanying discourses (Turner 1969).

Where these sociocultural groups involve the acquisition of significant competence, the communities-of-practice lens has proved fruitful. In their account of learning in a landscape of practice, Wenger-Trayner and Wenger-Trayner (2015, 19) emphasize the "becoming of a person who inhabits the landscape" and the acquisition of "an identity whose dynamic construction" reflects a "trajectory through that landscape." These authors identify more or less conscious, collaborative processes of engagement, imagination, and alignment into the "regime of competence" of a COP (2015, 20-22). Identity with a practice is crucial (24), may entail conflict (25), and requires reconciliations with preexisting claims to competence in another context (25). The resulting trajectory need not culminate at the center. In this sense, "learning to be" is important in "learning to do." This literature suggests what is involved in joining a community of practice. Remaining to be explored is how the community deals with tensions between the desire to include such new members and pressures to exclude them.

Methods

Employing a practice theory lens and utilizing ethnographic methods, the present research addresses two research questions: 1) How does a COP characterized by an exclusionary high level of

competence enable inclusivity? 2) What exclusions do inclusionary efforts overcome, work around or leave intact? Data collection involved 47 in-depth interviews with LSO musicians and staff, audience members and amateur musicians, together with participant observation at orchestra and choral concerts and rehearsals, and outreach performances and other activities. Interviews were recorded and transcribed. Observations and emergent themes were incorporated into subsequent and follow-up interviews and fieldwork. Practices and themes were derived using Spiggle's (1994) framework for analyzing qualitative data, in conjunction with analytical codes produced by the software package NVivo9.

Findings

It relates back to our mission, which is about making the finest music available to the greatest number of people… It really is about the quality of engagement rather than the number of people we are reaching, but of course there is a huge accolade in thinking we have reached sixty thousand people a year. (Lucia, Head of LSO Discovery)

The LSO community faces an inclusion-exclusion dilemma. Its legitimacy and funding depend on its excellence ethos, and the high-level player and audience competences that support this ethos are the source of exclusionary pressures. Inattentive or inappropriate activity by audiences can affect the quasi-spiritual experience for all. At the same time, its legitimacy and survival depend on attracting, developing, and engaging with players and audiences that do not yet possess these competencies to enable their performance and/or appreciation of classical music.

In response, the COP exhibits a range of practices that enable participation, summarized in Figure 1. Some of these tend to maintain exclusivity, while others tend to promote inclusivity, as indicated with arrows pointing in opposite directions.

First, at the top left of the figure is Excellence Celebration. These practices *reinforce* the COP by revering the expert competences and identities of the musicians and of appreciative audiences at premier concerts. As an example, Frank, a regular LSO concert-goer, related, "I have always compared listening to the LSO as watching Manchester United playing football, you are watching class, you are hearing class." At the top, middle-right in the body of the figure are the practices Selective Integration, Guided Collaboration, and Trial By Invitation. As Lucia notes above, the LSO's mission is "to bring the finest music to the greatest number of people." In accomplishing this mission, the LSO runs a several programs in which a subgroup of LSO professionals Selects and performs with young musicians and somewhat different, accompanying audiences in ways that develop their competences and dispositions. An example is LSO Academy, which *fosters* already experienced musicians by temporarily Integrating them into a professional orchestral environment:

The academy is very much about giving promising musicians access that they wouldn't necessarily be able to get, which is why it is run, led and coached by the LSO principals of that section. It is open to musicians who are aged between 14 and 24… If the principals think the person is showing great promise even though they are not quite there technically, they may well bring them on the course and show them where they need to get to. (Laura, LSO Academy)

Another program is LSO Next Generation, which provides Collaborative orchestral experience to a selective group of young instru-

mentalists from London's poorer East End, *illuminating* orchestral music from the inside, as Amy details:

(LSO Next Generation) is young people who have shown exceptional potential instrumentally, creatively…they go through the selection day with LSO musicians…only 50 kids. ... It sits kind of uncomfortably with some people, but at the same time you need to be able to provide that opportunity for real high flyers.

While less exclusive than these practices, Trial By Invitation practices maintain some exclusivity in the COP.

Practices promoting inclusivity, in ascending order from left to right, include Celebrating Engagement, Skill Stretching, Brokering Knowledge, and Open Experiencing. As an example of Celebrating Engagement, member-only events are provided to high-volume bookers, including privileged mixing with star performers. The LSO Early Years programs include Skill Stretching practices that gently *foster* competence in young musicians unselectively:

I wanted him (my grandson) to enjoy music and really have pleasure with it, we would love him to play an instrument or sing, and we are more excited by him getting familiar with music...Noah is very non-participative. He will just sit there and do nothing and Carla (LSO facilitator) would always say "don't force him, he will participate when he is ready", and it has taken a year and a half for him to do things in the class, even though he did things at home from the beginning. (Emily, accompanying her grandson Noah to Early Years sessions)

Knowledge brokering *illuminates* the music in the form of explanations by conductors, often with illustrative musical extracts, to enhance the concert experience by those lacking the knowledge that would help them access meaning from the music. Finally, the most inclusive category of practices is Open Experiencing. These are demonstrated at free concerts at Trafalgar Square and online, as well as open rehearsal sessions *sampled* by various audiences:

(Open rehearsal) is absolutely more magical (than formal concerts), because you see it all coming together and you realise there is so much interpretation to music, it is so powerful. Especially my children they love music, so for them to see it is not just notes, it is not just that technical ability. There is a mastery that comes beyond the technical ability, that has to do with it coming together and telling a story. (Julie, parent)

'Telling a story' is a phrase indicative of the way technical knowledge and competence converge and are rendered accessible, evident in the associations between the music and people's life experiences. A striking example was recounted by cellist Sebastian, about playing with a group of five disabled students, one of whom was put to the side due to his disturbing habit of grinding his teeth:

It was a Schubert quintet, which is serious music, obviously high-quality music. This kid then with the teacher helping him managed to write down what his feelings about the music were. And he wrote this whole story about how he had imagined how he was with his mother again, floating down this river. Obviously he wasn't with his mother, he was living in a school away from his family...just seeing that, seeing the power music can have to unlock the emotions someone has, I think the teachers were knocked back by the impact it had on this kid.

Returning to the center of the figure, four supra categories designate themes for the practices, in Reinforcing, Fostering, Illuminating, and Sampling competences, albeit in overlapping, yet distinct ways that simultaneously maintain exclusivity and promote inclusivity. To elaborate, Excellence Celebration lauds and hence reinforces exclusivity, while Engagement Celebration rewards participation inclusively; in fostering members' competences, Selective Integration excludes others, while Skill Stretching includes them, albeit with less ambitious aims; Guided Collaboration illuminates music to exclusive groups, while Knowledge Brokering illuminates inclusively; and Trial By Invitation practices provide exclusive sampling of the COP, while Open Experiencing practices allow sampling more inclusively.

Ultimately the dual sets of practices accomplish three goals for the COP and its members: competence alignment, participation legitimacy, and identity diffusion (which we show as outcomes at the bottom of Figure 1). First, these practices align access to participation with the competences individuals demonstrate and develop. Second, the practices signal these diverse extents and natures of participation as being legitimate . Third, the practices facilitate identity diffusion in supporting heterogeneous individual and social identities. There are at once selective and self-selective aspects to the trajectories comprising competence journeys, as Vicky describes:

> From the audition process, we may find someone who plays in a way we are looking for...so various candidates will be chosen and will work within the section, and for quite a long time … you need to give people the opportunity to think, crikey, they play the sort of thing like *this* (her emphasis), not like I do. You need to give people the opportunity to see how we play and fit in with us, not just us but the orchestra as a whole. (Vicky, LSO player)

Discussion

Decrypting the dual forces of exclusion and inclusion is important in documenting the dynamic collaboration required for successful competence journeys into CsOP. This research identifies specific practices and shows their dual work in aggressively developing high competence and being forgiving of lower competence, both of which are necessary in sustaining a high-competence COP. In contributing to the COP literature, our research points to the importance of constructing and populating initiating scenarios that provide guidance in role playing, convey knowledge and ritualized activity, and reward taste dispositions, judgments, and posturings that together structure and reproduce participation. Second, we identify the accomplishments of such simultaneously inclusionary *and* exclusionary practices in aligning competences, legitimizing different levels of participation, and facilitating identity diffusion. Early assumptions were evident in both CCT (Schau et al. 2009; Schouten and McAlexander 1995) and COP (Lave and Wenger 1991) literatures that aspirant community members desire and follow a predictable trajectory from the periphery of the community to its 'expert' center. The variable negotiations of inclusion we have uncovered add substance and nuance to Wenger-Trayner and Wenger-Trayner's (2015) challenges to this myth of an archetypal journey. Finally, we contribute to the CCT literature in highlighting the bidirectional flow merging consumption and production practices that sustains the work, skill and community that make participation in a COP desirable, pleasurable and worthwhile.

The Effect of Product Reviews on Post-Purchase Usage:
The Role of Consumer Incompetence Image Concerns

Matthew Philp, Ryerson University, Canada
Marcelo Vinhal Nepomuceno, HEC Montréal, Canada

EXTENDED ABSTRACT

Product reviews, such as expert critiques on news websites, blog posts, or consumer generated comments, are influential and easy to find. Negative reviews specifically, can result in decreasing sales (Reinstein and Snyder 2005), poor product evaluations (Wyatt and Badger 1984), and even harm a firm's net present value (Goldenberg et al. 2007). Product reviews, however, do not only apply to potential consumers *pre-purchase*, as it is common for existing consumers to also seek out and read reviews for the products they already own *post-purchase* (Hennig-Thurau and Walsh 2003). Yet, how product reviews influence consumers post-purchase is not fully understood. What if a consumer is satisfied with the product they purchased, but later discover that it has received negative reviews? How might this influence their interaction with the product going forward?

Fundamentally, product reviews are intended to help *potential* consumers with their choices, helping them assess value prior to spending any money. From this prospective, product reviews should be unnecessary and irrelevant for current owners because they can simply use and assess its functionality themselves. However, given the public nature of reviews, other people will likely formulate opinions of products, and with it, the decision-making abilities of anyone who already purchased that same product. Therefore, for current owners, a negative product review will not only inform them that they possibly made an incompetent consumption choice, but that others will think they are incompetent also.

As for how this could impact product usage, we draw from impression-management theory (Tedeschi 1981) where sometimes creating, managing, or avoiding particular impressions requires inaction. For example, not sharing positive word-of-mouth to preserve an image of uniqueness (Cheema and Kaikati 2010), not sharing negative word-of-mouth to avoid an image of incompetence (Philp and Ashworth 2020; Philp, Pyle, and Ashworth 2018), or not using a product to protect an image of frugality (Philp and Nepomuceno 2020).

Taken together, our formal predictions are based on two central ideas: first, negative reviews can be taken as evidence of the consumer incompetence of those who have already bought that product. Second, is that current owners will anticipate that using the product will portray the negative and undesirable image as an incompetent consumer to others. Therefore, to avoid this possibility, consumers will decrease the usage of their product. More formally,

Hypothesis 1:   *Negative product reviews will decrease the usage of current owners.*

Hypothesis 2:   *Image concerns of appearing as an incompetent consumer will mediate this relationship.*

Method

Study 1 collected data from Steam.com and MetaCritic.com to analyze how expert reviews influenced average videogame playtime of current game owners (i.e., product usage). Our results found that expert reviewers' game ratings from MetaCritic.com were positively associated with the average playtime for each game (β = .242, t(84) = 3.473, p < .001).

Study 2 (N = 47) participants downloaded a cellphone usage application. In a single-factor three-level (Review Valence: Positive, Negative, No-Review) between-subjects design, participants read either a positive, negative, or no-review regarding their cellphone. Results showed that reading a negative review significantly decreased usage in comparison to reading a positive review (Ms = -272.26 vs. -72.59; $t(44)$ = -5.10, $p < .001$) or no-review (Ms = -272.26 vs. -115.46; $t(44)$ = -5.02, $p < .001$). The change in usage did not significantly differ between reading a positive review and no-review (Ms = -72.59 vs. -115.46; $t(44)$ = -1.62, $p = .113$).

Study 3 (N = 85) followed a 2(Review Valence: Positive, Negative) X 2(Product Visibility: High, Low) between-subjects design. Participants read about purchasing a product that was highly visible or not when used, then read a positive or negative review about that product, they then completed measures of usage intentions and incompetence image concerns. Results supported H1, where usage intentions of current owners were lower after reading a negative compared to positive review, but only when the product was more visible (Ms = 4.81 vs. 5.82; $F(1, 81)$ = 6.75, $p = .011$). The same difference did not exist when the product was less visible when in use (Ms = 5.92 vs. 5.65; F (1, 81) = .60, $p = .441$). Furthermore, this difference of high versus low product visibility on usage intentions was larger following negative reviews (Ms = 4.81 vs. 5.92; $F(1, 81)$ = 8.64, $p = .004$) than positive reviews (Ms = 5.82 vs. 5.65; $F(1, 81)$ = .21, $p = .651$). Process evidence (model 7; Hayes 2017) supported that incompetence image concerns mediated the effect (Figure 1).

Study 4 (N = 279), in a 2(Review Valence: Positive, Negative) X 2(Reviewer: Novice, Expert) between-subjects design, participants searched for either positive or negative reviews written by experts or regular consumers about products they already actually own. Participants then completed the same questionnaire as Study 3. The results replicated the previous studies, where usage intention decreased following negative reviews compared to positive, but only when the review was written by an expert (Ms = 6.34 vs. 6.79; $F(1, 275)$ = 12.54, $p < .001$). Identifying a boundary condition, this same effect did not hold for reviews from novice reviewers (Ms = 6.73 vs. 6.58; $F(1, 275)$ = 1.74, $p = .188$). Similarly, process evidence (model 7; Hayes 2017) supported that incompetence image concerns mediated the effect (Figure 1).

General Discussion

The current study presented a theory and empirical evidence that negative product reviews can have an impact on already satisfied consumers. Specifically, negative product reviews can increase image concerns about appearing as an incompetent consumer which diminishes future usage. This research demonstrates that because of negative reviews, current consumers of those products are less likely to get the full life out of their product, likely declining usage prematurely, a behavior that renders otherwise personally satisfactory products into de-facto waste. Overall, this research exposes an interesting paradox, that some people may avoid using the products they own, despite being satisfied with its performance, to avoid the possibility of appearing as an incompetent consumer.

Sharing Like a Boss: How a Consumer's Position in the Hierarchy Influences Word-of-Mouth Valence

Christilene du Plessis, Singapore Management University, Singapore
Michael Schaerer, Singapore Management University, Singapore
David Dubois, INSEAD, France

EXTENDED ABSTRACT

Understanding WOM is crucial because brand success often depends on the type of information people share. Important to marketers is understanding what causes consumers to share positive or negative information, as WOM valence plays a crucial role in the success of products and services (Chevalier & Mayzlin, 2006). One important factor that shapes WOM valence is with whom consumer are communicating (Berger, 2014). Research has established two important audience characteristics that affect WOM valence: tie strength and audience size. Past research shows that people share more positive information when communicating with strangers than with friends (Dubois, Bonezzi, & De Angelis, 2016; Chen, 2017) as well as with larger (vs. smaller) audiences (Barasch & Berger, 2014).

Although tie strength and audience size are important, we propose a third dimension that can explain when consumers share more positive or negative information: the *hierarchical relationship* between WOM senders and recipients. Social hierarchies, defined as "an implicit or explicit rank order of individuals or groups with respect to a valued social dimension" (Magee & Galinsky 2008, p. 354), permeate almost every aspect of society, and, as a result, people often share WOM with individuals that occupy higher or lower relative rank. Indeed, in a survey of 255 working adults, we found that 90.2% regularly engage in WOM at work – an inherently hierarchical environment.

Given the prevalence of WOM in hierarchies, we investigate *whether*, *when and why* the hierarchical relationship between a WOM sender and recipient influences WOM valence. We propose that consumers share less positive messages with lower (vs. equal or higher) rank recipients. Because higher-ranked people have an increased ability to control their own and others' outcomes, they are less dependent on others (Fiske, 1993). Consequently, higher-ranked people have lower desire to affiliate with those below them in the hierarchy (Lammers, Galinsky, Gordijn, & Otten, 2012) and may even actively engage in distancing behaviors (Earle, Giuliano, and Archer 1983). Since sharing positive information facilitates interpersonal closeness (Brissette, Scheier, & Carver, 2002), and people share positive information to foster social connections (Bell, 1978), we predict that senders will share less positive WOM with recipients who are lower (vs. equal or higher) in rank.

In **Study 1** (*n*=393), participants watched an animated short film and either wrote down their thoughts about the film (baseline condition), or what they would say about it to their peer (equal-rank condition), supervisor (low-rank condition), or subordinate (high-rank condition). We created a positivity index by subtracting the number of negative attributes from the number of positive attributes. Participants in the high-rank condition sent less positive messages (*M*=.82, *SD*=2.15) than participants with low rank (*M*=1.54, *SD*=2.14), *F*(1,391)=4.55, *p*<.05), baseline participants (*M*=1.58, SD=2.82, *F*(1,391)=5.19, *p*<.05), and participants in the peer condition (*M*=1.68, SD=2.27, *F*(1,391)=6.32, *p*=.01).

Study 2 tested the consequences for message reception. In Part 1, participants (*n*=36*)* read a description of car and wrote a message about it to a colleague ranked lower (vs. higher) to them in their team. In Part 2, participants (*n*=368) read one of the messages from Part 1 and indicated how much they would pay, how willing they are

to buy, their intention to inspect and their attitudes towards (α=.96) the car. They also indicated their intention to contact the seller. Multi-level mediation analyses with sender rank as independent variable (1=lower-rank recipient, -1=higher-rank recipient), and WOM valence as mediator, revealed a significant and negative indirect effect of sender rank on recipients' willingness to pay (*ab*=-.31, *S.E.*=.16, 95% LLCI=-.71, ULCI=-.07), willingness to buy (*ab*=-.38, *S.E*=.18, 95% LLCI=-.77, ULCI=-.09), intention to inspect (*ab*=-.38, *S.E*=.19, 95% LLCI=-.78, ULCI=-.08), intention to contact seller (*ab*=-.35, *S.E*=.17, 95% LLCI=-.71, ULCI=-.08) and product attitudes (*ab*=-.37, *S.E*=.16, 95% LLCI=-.73, ULCI=-.11), through WOM valence.

Study 3 tested our proposed mechanism in a competing mediation model. Participants (*n*=203) were randomly assigned to a high or low rank condition. We also measured need for affiliation (*α*=.85), felt responsibility toward interaction partner (*α*=.91), and role expectations (*r*=.44, *p*<.001). Replicating previous studies, participants in the high-rank condition (*M*=.55, *SD*=2.26) wrote less positive messages than participants in the low-rank condition (*M* = 1.19, *SD*=2.03), *t*(201)=2.15, *p*<.05). Importantly, the competing mediation revealed a significant indirect effect through need for affiliation (*ab*=-.11, *SE*=.05, 95% LLCI=-.24, 95% ULCI=-.03), but not through responsibility (*ab*=.003, *SE*=.02, 95% LLCI=-.02, 95% ULCI=.06), or role expectations (*ab*=.003, *SE*=.03, 95% LLCI=-.05, 95% ULCI=.06).

In Studies 4-5 we provide additional process evidence by manipulating need for affiliation. In **Study 4**, participants (*n*=472) watched a short film and wrote down what they would say about it to their supervisor (low-rank condition) or subordinate (high-rank condition). A third condition was included in which participants were instructed to write a message to their subordinate but were told that the goal of writing their message was to bond with the recipient (high-rank + affiliation motive condition). Participants in the high-rank condition wrote less positive messages (*M*=.93, *SD*=1.99) than participants in the low-rank condition (*M*=1.47, *SD*=1.90), *F*(2,469)=6.72, *p*<.01), but not when their affiliation motive was activated (*M*=1.65, *SD*=1.66, *F*(2,469)=.80, *p*=.37). There was no difference in message positivity between the low-rank and the high-rank + affiliation conditions, *F*(1,310)=0.86, *p*=.35.

In **Study 5**, we varied need for affiliation by manipulating whether senders expect to interact with the recipient in the future. In interactions where people expect to depend upon one another in the future (vs. not), the need to affiliate increases (Danheiser & Graziano, 1982). Participants (*n*=394) again watched an animated short and were then randomly assigned to a 2(rank: lower, higher) x 2(expect future interaction: no, yes) between-subjects design. Supporting our hypothesis, when senders did not expect to interact with the message recipient in the future, those with higher rank sent less positive messages (*M*=.41, *SD*=1.91) than those with lower rank (*M*=1.12, *SD*=2.13, *F*(1,393)=5.54, *p*<.05). When senders expected to interact with the message recipient in the future, there was no difference in WOM valence, *F*(1,393)=.04, *p*=.84.

Jointly, these studies contribute by identifying a novel sender characteristic that influences WOM content (hierarchical rank) and suggest that the need for affiliation is a key driver of positive WOM.

I Am Too Good to Be True: How Self-Enhancement Motivations Shape Prosocial Behavior of Entitled Individuals

Alexandra Polyakova, University of Sussex Business School, UK

EXTENDED ABSTRACT

In the past decade the level of prosocial behavior has raised some concerns. At the same time, an empathic concern, which is considered to be one of the main predictors of prosocial behavior, is decreasing. Lack of empathy and less forgiving attitudes are one of the main characteristics of entitlement Entitlement, or feeling of deserving more than others, is negatively related to pro-social behavior (Campbell et al., 2004). We suggest that entitled individuals would engage in prosocial behavior more when there is an opportunity to self-enhance compared to when there is no opportunity to self-enhance. Since prosocial behavior is performed to benefit others rather than self, entitled individuals would be unlikely to behave in such a way unless they see a clear opportunity to benefit themselves in such a situation.

> *Hypothesis 1:* *Entitled individuals will exhibit more prosocial behavior when such behavior provides an opportunity for self-enhancement (vs. when there is no opportunity for self-enhancement).*

Individuals act more prosocially in the public sphere than in private settings (Ariely et al., 2009). Since one of the main motivations of entitled individuals is to appear in a positive light in front of others and themselves, they would be even more inclined than other individuals to engage in prosocial behavior when such behavior is observable by others (i.e., public context) rather than when there are no witnesses (vs. private context):

> *Hypothesis 2:* *Entitled individuals will exhibit more prosocial behavior when such behavior is performed in a public (vs. private) context.*

Previous research has demonstrated that entitled individuals are driven by a desire to attain status (Lange et al., 2019). Higher social status fulfills the desires of entitled individuals. Entitlement is correlated with the desire to have high-status symbols, such as a perfect romantic partner

We propose that entitled individuals will be attracted by other possibilities that allow them to feel they belong to a small group of high status people

> *Hypothesis 3:* *Entitled individuals will exhibit greater intention to donate to a charity cause/organization when the social status of other donors is high (vs. low).*

We test our predictions in three studies. We both manipulate (Studies 1 & 2) and measure entitlement (Study 3).

Study 1. 140 US-based MTurk participants completed the study online. This study used a 2 (entitlement: yes vs. no) x 2 (self-enhancement opportunity: yes vs. no) between-subjects design. We adopted entitlement manipulation from Poon et al. (2013). Participants in the self-enhancement condition were told that they could make a donation that would highlight their unique personality: a donation in honor of their friends. Participants in the no_self-enhancement condition were told that their donation would help people in need. Participants indicated their likelihood to donate a portion of the money they would earn through MTurk to the charity. ANOVA results revealed a significant interaction of entitlement and self-enhancement on the likelihood to donate (F(1, 136) = 10.84, p = .001). In the self-enhancement condition, participants were more likely to donate when they were in the entitlement (vs. no_entitlement) condition, Mentitlement = 3.31, SD = 1.92 vs. Mno_entitlement = 2.18, SD = 1.64, F(1, 136) = 6.73, p < .05.

We suggest that another way of increasing the amount of donations from entitled individuals is to give them a chance to make a donation in a public (vs. private) context, which was tested in Study 2. 116 MTurk US-based participants completed the study online.

Study 2 had a 2 (entitlement: yes, no) x 2 (donation context: public, private) between-subjects design. Participants were assigned to public vs. private conditions. Then, participants indicated their likelihood to donate to support the charity. Study 2 results showed that participants in the entitlement public condition were more likely to make a donation (Mpublic = 4.03, SD = 2.00 vs. Mprivate = 2.89, SD = 1.71, F(1,112) = 4.41, p <.05.

Study 3. 120 US-based adults from Amazon MTurk participated in the study. First, we measured participants' level of entitlement (PES, α = .94). Next, participants were randomly assigned to one of two conditions (other donors' status: high vs. low). Participants read a donation appeal describing a charity that raises funds to fight a fictitious disease. Participants in the other donors' status: high condition read that this foundation was previously supported by Leonardo DiCaprio and Taylor Swift, whereas participants in the other donors' status: low condition read that micro-bloggers as Emily Wracker and Elise Young previously donated to this foundation. Then participants indicated their likelihood to donate to the foundation. We ran a regression using PROCESS (Model 1, Hayes, 2013). In the model, other donors' status manipulation (0 = low; 1 = high), sense of entitlement and the interaction between the two, served as the predictors of participants' donation likelihood. The interaction between sense of entitlement and the other donors' status manipulation was significant (b = .465; SE =.233, t(116) = 1.99, p < .05). Results show that the effect is driven by high levels of entitlement (levels above 1.356 for mean-centered scale).

The current research contributes to the literature on prosocial behavior. During the time when more and more individuals demonstrate less concern about others and volunteering and helping behavior is declining understanding ways of influencing such individuals hold particular relevance.Current research demonstrates that if one is not particularly concerned about others' welfare (for example, when someone's level of entitlement is high), their prosocial behavior might be positively influenced by providing an opportunity to self-enhance.

The Theatre of Experience: Brand-Consumer Dynamics in Multimedium Environments

Kimberley Preiksaitis, Siena College, USA
Alex Mitchell, California State Polytechnic University, Pomona, USA

EXTENDED ABSTRACT

Driven by a broader social context of an experience economy (Pine and Gilmore 1999; Schmitt 1999), brands are increasingly offering extraordinary experiences to garner consumer attention and situate themselves in social and cultural life in ways that deeply resonate with consumers. Prior studies of extraordinary experiences largely focus on experiential consumption activities linked with brands' commercial offerings in emplaced servicescapes, however brands increasingly engage with consumers through experiences transcending emplacement (Singh and Sonnenburg 2012). While brands engage with audiences across both emplaced and online settings, consumer research does not fully examine hybrid experiential domains; studies are largely bifurcated into those that focus on emplaced realities of spectacular retail environments (Diamond et al. 2009; Kozinets et al. 2004), contrasted with those that explore digital experiences (Arvidsson and Caliandro 2015; Singh and Sonnenburg 2012).

To examine situations of experiential consumption that span both the emplaced and online, we ground our conceptual framework in theories of performance (Deighton 1992; Giesler 2008; Grove and Fisk 1983; Thompson and Üstüner 2015). Complementing and extending existing perspectives in the marketing literature, we extend the performance paradigm in marketing via social performances (Alexander 2004a, 2004b, 2011, 2017). Social performances are processes by which actors attempt to convey meanings to an audience that are sincere, authentic, and culturally valid in order to achieve a desired outcome.

We analyze consumption of extraordinary experiences in a context that blends both emplaced and online audiences, with a view to understanding how interactions within and across audiences contributes to unity and fragmentation of these groups. We observe the social performance of Taco Bell's *The Bell: A Taco Bell Hotel and Resort*, which promised to provide guests with an immersive, thematic experience. Our data consists of netnographic data in the form of Twitter postings and real-time observation of online social media discourses as well as phenomenological interviews with consumers and media. Our qualitative analysis aggregates our immersive performance observation, Twitter data set, and depth interviews through interactive sensemaking and triangulation (Spiggle 1994). Our goal is to develop an interpretation of how the performance is understood from the perspective of the emplaced and online audience members, as well as how these audience groups interact.

We argue for extending the concept of *brand performances* as a way to theorize the complex social interactions that occur through extraordinary experiences. We theorize brand performances as a particular kind of social performance in which brands attempt to communicate the "meaning of their social situation" (Alexander 2004a) to a target audience. Brand performances are theatrical in the sense that they are purposefully undertaking by a brand, involve a cultural script that aligns with a core identity the brand wishes to convey, and are executed in a time-delimited format (i.e., episodic). The brand's goal is to enact a performance that a target audience interprets as sincere, authentic, and culturally legitimate (Alexander 2004a).

Our findings reveal that brand performances take place over a trajectory composed of discrete periods demarcated by changes in audience interactions. We find these changes are largely the result of brand-initiated actions connected with the performances that serve to fragment the audience. Further, we identify six social mechanisms by which audiences interact throughout the performance periods, linked with audience interpretations of the performance as (in)sincere, (in)authentic, and culturally (in)valid. These mechanisms involve speculating, campaigning for inclusion, recruiting interpreters, articulating the lived experience of the performance, counterperforming and rejecting.

While prior scholarship focuses on communications between brands and consumers in either emplaced or online settings, our study analyzes how consumers consume extraordinary experiences in a context that blends both emplaced and online consumption audiences with a view to understanding how interactions within and across audiences contribute to the unity and fragmentation of these groups. Through our performance framework, we highlight brand performances as a way for brands to communicate the meaning of their social situation with consumers in both emplaced and online settings. Through this lens, we illustrate opportunities of fusion and de-fusion for both emplaced and online audience members. These findings can help better understand brand-consumer dynamics in contemporary market contexts with regards to successful brand storytelling, consumer agency, and cultural memory.

Introduction and Conceptual Integration

Brands in the contemporary "experience economy" (Pine and Gilmore 1999; Schmitt 1999) increasingly develop extraordinary experiences in attempts to break through the noise of the marketplace to provide meaningful experiences for consumers. Prior literature explores consumption of extraordinary experiences offered by service providers to extend our understanding of the experiential dimensions of consumption (Holbrook and Hirschman 1982). For example, in-depth investigations of skydiving (Celsi, Rose, and Leigh 1993), river rafting (Arnould and Price 1993), theme parks (O'Guinn and Belk 1989), mountain climbing (Tumbat and Belk 2011), pilgrimages (Higgins and Hamilton 2019), raves (Goulding et al. 2009), trade shows (Peñaloza 2001) and festivals (Kozinets 2002) have broadened our understanding of meaning-making in extreme consumption experiences.

While this extensive literature provides an understanding that experiences are a medium for cultural communication of meaning between and amongst brands and consumers, this work focuses on consumers and consumption linked with emplaced experiences. This is not surprising. As Diamond et al. (2009) note, the expansion of qualitative explorations into consumer experience coincides with the peak of spectacular "retail theater." However, brands increasingly engage with consumers through experiences transcending emplacement (Singh and Sonnenburg 2012). To paraphrase Gieryn (2000), digital environments are not places in the same way as pilgrimages, river rafting, or themed retail servicescapes. Yet, they are no less important as sites of experiences and communication of cultural meaning between consumers and brands (Arvidsson and Caliandro 2015; Giesler 2008; Holt 2016; Singh and Sonnenburg 2012).

Consumer research has yet to fully develop insights into the nature of consumption experiences in hybrid experiential domains—experiences that are characterized by interactions within and between emplaced and online audiences. Studies are largely bifurcated into those that focus on the emplaced realities of spectacular retail environments (Diamond et al. 2009; Kozinets et al. 2004), contrasted

with those that explore digital experiences (Arvidsson and Caliandro 2015; Singh and Sonnenburg 2012). However, contemporary consumer experiences are manifestly composed of hybrid environments blending emplaced and online mediums. These environments are characterized by an array of social interactions involving a wide range of actors, including consumers of varying degrees of brand affiliation (Arvidsson and Caliandro 2015), the media (Humphreys and Thompson 2014), and brands, to name a few.

To examine situations of experiential consumption that span both the emplaced and online, we ground our conceptual framework in theories of performance (Deighton 1992; Giesler 2008; Grove and Fisk 1983; Thompson and Üstüner 2015). Complementing and extending existing perspectives in the marketing literature, we extend the performance paradigm in marketing via social performances (Alexander 2004a, 2004b, 2011, 2017). Social performances are processes during which actors attempt to create emotional connections between themselves, their script, and an audience in order to "display for others the meaning of their social situation" (Alexander 2004a). A performance is successful to the extent others find the performance sincere and authentic in its portrayal of relevant symbolic cultural content. For Alexander, successful performances achieve fusion between actor and audience consistent with the shared understanding typically ascribed to rituals, where action and cultural scripts are seamlessly woven together (Bradford and Sherry 2015; Rook 1985). Fusion occurs when an actor conveys cultural meaning to an audience and elicits an emotional connection between audience, actor, and script. Such performances are considered to be "real," "authentic," and "truthful" (Alexander 2004a). De-fusion is the failure of the performance to achieve connection and results in audience feelings of disbelief and inauthenticity of the performance and actor(s) involved.

Unsuccessful performances typically spawn attempts by audiences to enact counterperformances designed to articulate alternative cultural meanings (Alexander 2004b, 2004a). Alexander theorizes de-fusion to be the norm, rather than the exception, in complex societies consistent with conditions of social drama (Alexander 2017). Thus, for all performances fusion is not guaranteed. The central issue becomes how actors attempt to achieve fusion during the performance as well as audience dynamics associated with the performance's reception.

In this research, we observe brands behaving as actors enacting social performances to convey cultural scripts for the purpose of convincing consumers that brand actions and behaviors are sincere, authentic, and culturally valid. The extent that fusion occurs between brand and consumer audiences is partially an outcome of dynamics linked with audiences that are multimedium (i.e., emplaced and online). In this project, we address the question: How do consumers consume social performances in both emplaced and online settings, and what audience dynamics emerge as brands conduct social performances?

Context and Method

To explore the consumption of social performances, we employ a multi-methodological approach to analyze Taco Bell's *The Bell: A Taco Bell Hotel and Resort*. Founded in 1962 in Southern California, Taco Bell serves valued-priced Mexican-style food to a devoted fan following. When announced in May 2019, The Bell hotel promised to provide guests with an immersive, thematic experience in Palm Springs, California, which included everything from welcome tote bags, to in-room mini bars stocked with complimentary Taco Bell items, custom 'The Bell' hotel robes, Taco Bell-themed merchan-

dise, on-brand décor, custom menu items, poolside food service, and various poolside entertainment.

Our data consists of Netnographic (Kozinets 2020) data in the form of Twitter postings and real-time observation of online social media discourses, as well as phenomenological depth interviews conducted with consumers and media involved in the performance. We supplement these sources with examination of traditional media content, company reports, and sociohistorical accounts of the brand's history and cultural connections.

We began our immersive performance investigation when the performance was announced by observing The Bell hotel via Twitter (May 16, 2019) and continued observations until the performance ended in August 2019. We did not contribute to the performance but merely observed via out own personal Twitter accounts. Our immersive investigation includes our own attempts to RSVP on June 27, 2019 and field notes generated during the most intense period of the performance – the dates over which The Bell hotel was operational.

Web scraping techniques, consistent with prior work (Arvidsson and Caliandro 2015), captured "online traces" (Kozinets 2020) relevant to the performance of interest. Between May 16, 2019 and September 11, 2019, (approximately one month after The Bell hotel occurred), we gathered tweets via a Python-based script monitoring select terms (e.g., 'taco' and 'bell' and 'hotel'; '#tacobellhotel'); in sum, our Twitter data set contains 15,832 tweets.

Following the conclusion of the performance, iterative analysis of the Twitter data set led us to identify potential individuals for in-depth phenomenological interviews (Thompson, Locander, and Pollio 1989). Between November 2019 and February 2020 we completed ten interviews via a variety of ways (e.g., skype, in-person, email). Interviews were semi-structured, beginning with grand tour questions (McCracken 1988) and collect and preserve the participants' unique lived experience of the performance in rich detail.

Our qualitative analysis of The Bell hotel performance aggregates our immersive performance observations, Twitter data set, and depth interviews, triangulated with media articles and video artifacts. Social media data was examined iteratively as it was gathered. Twitter data was examined both qualitatively for theme derivation and quantitatively. Interview transcriptions were iteratively coded, analyzed, and compared against the interpretive findings from the Twitter data set, offering a rigorous and structured way to deepen our understanding of the online discourses via iterative sensemaking and triangulation (Spiggle 1994). Our goal is to develop an interpretation of how the performance is understood from the perspective of the emplaced and online audience members, as well as how these audience groups interact.

Research Findings

Brands Conducting Social Performances

Social performances express the meaning of one's social situation and are designed to appear sincere, authentic, and appropriate (Alexander 2004a). Our data illustrates Taco Bell conducting a social performance aimed at communicating aspects of the brand's identity and purpose to a target audience. We argue that The Bell hotel constitutes a particular kind of social performance. Taking inspiration from Singh and Sonnenburg (2012), we maintain that this type of experiential event is a brand performance; a social performance in which a brand attempts to communicate the "meaning of their social situation" (Alexander 2004a) to a target audience. Brand performances are theatrical in the sense that they are purposefully undertaking by a brand, involve a cultural script that aligns with a core identity the brand wishes to convey, and are executed in a time-delimited format (i.e., episodic). The brand's goal is to enact a performance that a

target audience interprets as sincere, authentic, and culturally legitimate (Alexander 2004a). In the case of The Bell hotel, this target audience consists of diehard fans who already know and love the brand and who desire an immersive, brand-curated experience that allows them to celebrate their brand affection in novel ways.

Mapping the Brand Performance Conceptual Trajectory

A conventional performance view would view The Bell hotel in terms of the four-day event where the emplaced audience engages with the hotel context face to face. However, a broadened performative view attunes our analysis to the ways the brand performance is consumed before and after this emplaced period by focusing on the broader time frame where the brand performs its core values and identity in relation to the hotel experience (Alexander 2004a). We argue that brand performances are consumed by emplaced and online environments simultaneously and our analysis reveals key events which serve to transition audience composition and interactions throughout the elongated trajectory of the brand performance, dividing the brand performance into distinct periods: awareness, expectation, event, and long tail (Table 1). Throughout the trajectory of the performance, we observe changes in the nature of the audience, both in how audience members communicate to one another, what roles are played by audience members (e.g., emplaced/online) and reflect audience sentiment regarding the sincerity, authenticity, and cultural validity of the performance.

Mechanisms of Brand Performances

Along the trajectory, we observe members of both the emplaced and online audiences interacting in pursuit of their own particular objectives connected with fusion and de-fusion of the performance. Following Gross (2009, 363), we characterize the purposeful interactions amongst audience members as social mechanisms due to their nature as 'intermediary processes' that unfold over specific portions of the brand performance trajectory (see Figure 1).

Speculating. Audience members invoke various cultural myths in discourses with online audience members to imagine what the event will be like. Conversations among online audience members foster speculation of the brand's identity and how it may map onto the hotel concept.

Campaigning for inclusion. Consumers campaign to be included in the event as emplaced audience members. Those that campaign for inclusion unify in their shared belief in the value of public demonstrations of sacrifice to attain access to the hotel experience. These efforts support audience perceptions that the experience will be valuable and unique—as one of the emplaced audience members told us, a "once in a lifetime event." However, campaigning also contributes to audience fragmentation—audience members who do not earn recognition from the brand of their willingness to participate may display dissatisfaction and ultimately exit the performance.

Recruiting interpreters. Following RSVP where a small number of audience members secure bookings at the hotel, those who do not secure a booking begin appealing to certain individuals, typically social media influencers, to act as interpreters and report back to the online audience about the hotel experience. Notably, members of the online audience wish for a vicarious encounter with the hotel through the 'eyes' of the interpreter's individual experience of it and not so much an objective overview of what the hotel experience offers.

Articulating the lived experience of the performance. Emplaced audience members take it upon themselves to report back to the online audience about the lived experience of the event. For each individual who experiences the hotel, there is special consideration as to who their own audiences include and how they think about showcasing their own lived experience of the hotel to their own audiences. Notably, the brand relies on emplaced consumers to understand, see, and interpret the performance for online audience members as they do not engage directly with consumers via the online environment throughout the performance.

Counterperforming. When performances do not fuse for audience members, some may choose to engage in deliberate attempts to question the validity of the performance by demonstrating alternative interpretations of the performance itself (Alexander 2004a, 2004b). In our data, online audience members enact counterperformances by drawing on cultural myths present within the brand performance as a way to resolve their inability to be part of the emplaced audience. Counterperformances target online audience members and present alternative expressions of the brand performance which showcase elements of fragmentation present in the perspectives of the online audience while allowing their own audiences to unify around the intent of their own counterperformances.

Rejecting. While some audience members engage in counterperforming when a brand performance does not fuse, others reject the performance entirely. While emplaced audience members can literally exit the performance (e.g., exit the experience), online consumers also engage in forms of exit, signaled through their rejection of the performance. We see evidence of rejection arising throughout the event period, continuing through the long tail period.

Discussion

While prior scholarship focuses on communications between brands and consumers in either emplaced or online settings, our study analyzes how consumers consume extraordinary experiences in a context that blends both emplaced and online consumption audiences with a view to understanding how interactions within and across audiences contribute to the unity and fragmentation of these groups. By adopting a performance theory framework drawn from cultural sociology (Alexander 2004a, 2004b, 2011, 2017), integrating existing theatrical (Deighton 1992; Grove and Fisk 1983; Humphreys and Carpenter 2018) and performativity views (Giesler 2008; Thompson and Üstüner 2015; Üstüner and Thompson 2012), we extend the nascent concept of brand performances (Singh and Sonnenburg 2012) to theorize complex social interactions occurring in extraordinary experiential contexts.

Our analysis reveals a more complex audience ecosystem than prior examinations of performances, highlighting that performances take place over a trajectory consisting of distinct periods characterized by changes in audience interactions. We identify six social mechanisms capturing audience interactions linked with fusion and de-fusion of the brand performance.

Through our social performance lens, we illustrate consumers asserting their agency through interactions aimed at both online and emplaced audiences. Critical reflection by those members of the audience for whom the performance de-fuses leads them to pursue counterperformances aimed at asserting alterative interpretations of the cultural contents of the original brand performance. Thus, counterperformances share some characteristics with consumer activism (Kozinets and Handelman 2004) and institutional entrepreneurship (Scaraboto and Fischer 2013) yet are not necessarily aimed at subverting the brand's goals—they do however, serve as cultural material that fragments the audience by providing alternative cultural interpretations of the brand performance.

Finally, brand performances live on in the archived memory of online platforms and thus, continue to serve as cultural material that fans draw on during future interactions across emplaced and online audiences (Anderson 2006). Consumers leverage this cultural

material to make sense of future brand performances. We identify opportunities for further research in the domain of consumer-brand dynamics, which must be more inclusive and expansive in exploring the social ecosystem of which consumer-brand interactions occur.

Disclosure of Positive and Negative Experiences as Social Utility

Emily Prinsloo, Harvard Business School, USA
Irene Scopelliti, City University of London, UK
Joachim Vosgerau, Bocconi University, Italy
George Loewenstein, Carnegie Mellon University, USA

EXTENDED ABSTRACT

We propose that disclosing one's positive and negative experiences carries social utility for both senders and recipients. We show that consumers consider this utility when deciding whether to disclose their experiences with others. In three preregistered studies, consumers respond in kind to the disclosures of positive and negative experiences by others.

Disclosure of Positive and Negative Experiences as Social Utility

Sharing one's experiences with others, especially on digital platforms, has become an integral and prominent part of many consumers' lives. In this paper, we argue that consumers' decision to disclose their positive or negative experiences to other consumers - for example, by engaging in positive or negative word of mouth - is driven by a form of social utility. Specifically, we argue that context matters, i.e., a consumer's disclosure depends on what type of experiences have been disclosed by others.

Maximizing social utility through the disclosure of personal information requires emotional perspective taking, a task that people are typically not very good at (Scopelliti, Loewenstein, and Vosgerau 2015; Sezer, Gino, and Norton 2018). The disclosure of personal information is governed by two competing needs, the need to instil favorable images in others through impression management (Baumeister 1982; Leary and Kowalski 1990) and the need to belong (Baumeister and Leary 1995; Leary 2010). People often get this tradeoff wrong; self-promoters tend to overestimate recipient's positive emotions and underestimate recipients' negative emotions, and they fail to appreciate the positive effects that sharing personal failures would have on their counterparts (John et al. 2016; Wood-Brooks et al. 2019). Calibrating other's emotions may be easier when one *responds* to the disclosure of personal positive and negative experiences of a conversation partner. In such cases, it is easier to imagine how the counterpart will feel in response to one's own disclosure after having been in a similar situation.

We hypothesize that consumers are likely to respond in kind to the disclosure of personal positive and negative experiences by others. When a conversation partner discloses a personal negative experience (positive experience), the recipient attempts to reduce the social status imbalance by also disclosing a personal negative experience (positive experience) and attempts to prevent the imbalance from deepening by not disclosing a personal positive experience (negative experience). In sum, we hypothesize that in response situations, people are likely to respond in kind to the disclosure of personal positive and negative experiences by others. We tested this prediction in a set of three preregistered experiments.

In a first experiment (N = 812), we randomly assigned participants to one of eight conditions in a 2 (participant's outcome: offer vs. rejection) x 2 (counterpart's outcome: offer vs. rejection) x 2 (relationship: good vs. bad) between-subjects design. In the Participants imagined that they had recently applied to positions at companies in Silicon Valley, and that they had just completed an interview for which they had either secured an offer or received a rejection. Then, participants imagined to have unexpectedly run into Alex, an old acquaintance from college, at the airport on the way home. Alex was

remembered as either likable ("You had good feelings toward him," good relationship condition) or not likable ("The contact you had did not make you like him," bad relationship condition). Next, participants imagined chatting with Alex, who in turn shared that he interviewed for a similar job, and that he was given either an offer or a rejection. To ascertain participant's propensity to disclose, we asked them to distribute 100 percentage points between two response options, (1) a message in which they only acknowledged their counterpart's outcome and (2) a message in which they acknowledged their counterpart's outcome and shared their own.

When the sender disclosed a personal success, recipients were likely to also disclose their own success. More importantly, however, when the sender disclosed a personal failure, recipients were more likely to also disclose an own failure and to not disclose their own success than to disclose their own success. Disclosure of own successes and failures did not depend on the quality of the relationship between the two parties. These results provide initial evidence for social utility maximization.

In a second preregistered experiment (N = 794), we provide more evidence that the disclosure of personal successes/failures is driven by social utility maximization, rather than being the manifestation of a preference for the outcomes themselves captured as recipients' emotional reactions to their own successes and failures. We used the same scenario as in the previous experiment, and examined participants' feelings in response to outcomes (-100 = *Extremely bad*; 0 = *Neither bad nor good;* +100 = *Extremely good*). Participants in the experiment felt better when succeeding and worse when failing, yet these feelings did not translate into corresponding likelihoods of disclosing their successes and failures; these results indicate that the disclosure of outcomes is not a direct consequence of the preference for the outcomes themselves.

In a final experiment (N = 1614), we tested whether recipients' disclosure behavior is a response to the success/failure information per se, or a response to the sender's act of disclosing that information. The results showed that participants were more likely to disclose information on their successes or failures when their counterparts also directly disclosed their successes or failures. The pattern of disclosure observed in the first experiments replicates when the sender disclosed the information herself or himself, but was diminished when the information about the sender was disclosed through a third party. These results corroborate the idea that it is the disclosure of successes and failures within a conversation that carries social utility.

The results of these studies provide a new perspective on information disclosure. Past research suggests that consumers may be motivated by self-enhancement when disclosing their experiences to others in the form of word of mouth or when posting on social media (Hennig-Thurau et al. 2004; De Angelis et al. 2012; Packard and Wooten 2013; Barasch and Berger 2014; Dubois et al. 2016). Our results indicate that consumers are not uniquely motivated by self-promotional motives when choosing to disclose their experiences. Instead, consumers strategically modify their disclosure behavior. Specifically, they share or withhold their negative or positive experiences depending on the context and the requirements of the social situation. These findings enrich our understanding of what type of

experiences consumers disclose, and their reasons for engaging in self-disclosure.

When Benefactors Backfire: Examining the Interactive Effects of Just World Beliefs and a Benefactor versus Beneficiary Focus

Rebecca Rabino, Texas Tech University, USA
Aparna Sundar, University of Washington Bothell, USA

EXTENDED ABSTRACT

In order to appeal to potential donors, marketers try to determine the most effective strategies for positioning their charitable appeals. One common strategy centers on the beneficiaries of a charitable cause. For instance, a charitable appeal may emphasize a beneficiary's need or highlight their deservingness (Lee, Winterich, and Ross Jr. 2014). Alternatively, charities may choose to highlight the effectiveness of their efforts by describing the contributions or participation of other benefactors – such as other donors or corporate sponsors (Bennet, Kim, and Loken 2013; Reingen 1982). We investigate the effectiveness of these two strategies – a focus on beneficiaries versus benefactors. We suggest that a beneficiary versus benefactor focus represent different stages of justice restoration. A beneficiary focus reminds consumers of the potential, and need, for justice restoration efforts. Alternatively, a benefactor focus indicates that justice restoration efforts have begin.

In order to shed light on the efficacy of these relative foci, we investigate the moderating role of consumer beliefs in a just world (BJW; Lerner 1998; Furnham 2003; White, MacDonnell, and Ellard 2012). Just-world theory proposes that individuals need to believe that the world is a fair, equitable place (Lerner 1980). Individuals 'get what they deserve'; that is, good people and good behavior receive positive outcomes, and bad people and bad behavior receive negative outcomes (Lerner 1980; Hafer and Bègue 2005). By their very nature, charitable appeals threaten justice beliefs by suggesting that all is not well – and, in the case of innocent beneficiaries, that there is injustice in the world.

Notably, however, charitable appeals also offer a route by which to reduce such threat by offering an opportunity to redress the injustice by donations to the charitable cause (Lerner 1998; White et al. 2012). Unfortunately, consumers may instead employ other methods of threat-reduction (Lerner 1980; White et al. 2012). Consumers may rationalize different elements of the situation, reducing perceptions of injustice and thus donations. Contextual considerations influence which threat-reduction strategy is adopted.

We suggest that a beneficiary versus benefactor focus will influence which threat-reduction strategy is enacted. Emphasizing the plight of innocent beneficiaries will result in heightened donations for consumers with high (versus low) belief in a just world. A benefactor focus will instead promote rationalization of the charitable context. While a threat to just world beliefs is still present, the injustice is in the process of being resolved. This rationalization mitigates the need for a consumer to donate to the charitable cause.

Study 1 features a 2(charity focus: beneficiary vs. benefactor) x measured belief in a just world design. Participants were instructed to either focus on "people struggling with hunger" or on "people working to end hunger" before reading a Feeding America appeal. Participants then indicated their support for the charity and completed the Just World Scale (Rubin and Peplau 1975). As predicted, there was a significant charity focus and belief in a just world interaction on charitable support ($p = .004$). When participants focused on beneficiaries, there was a positive effect of BJW ($p = .0008$). The positive effect of BJW was attenuated when participants focused on benefactors ($p = .41$).

Study 2 is a 2(benefactor focus: absent versus present) x measured belief in a just world study. All participants were instructed to focus on the beneficiary before viewing a charitable appeal. The benefactor-absent condition merely included a request, at the bottom of the appeal, to consider supporting the charity. The benefactor-present condition highlighted how easy and accessible such support was for donors. We predict that, when the beneficiary is the sole focus of the appeal, we will replicate the positive effect of BJW on charitable support found in Study 1. However, we predict that the addition of a benefactor focus will reduce donations, as the potential to rationalize other donors' efforts is present. A regression revealed a two-way interaction on charitable support ($p = .02$). There was a positive effect of BJW when a beneficiary was the sole focus ($p = .0006$). This effect was attenuated when a benefactor focus was also included ($p = .72$)

In Study 3, we shed additional light on the moderating role of just world beliefs by manipulating the salience of [un]fairness at a societal level (Lee et al. 2014). In the studies above, we suggest that the threat to just-world beliefs was present in both the beneficiary and benefactor focus conditions, but that the threat-reduction techniques varied. Emphasizing societal unfairness is consistent with this threat and should replicate previous findings. Societal fairness, however, is conceptually similar to a benefactor focus: it should reaffirm that injustices will be redressed by society at large, thus attenuating the positive effect of BJW.

Study 3 features a 2(society cue: fair vs. unfair) x 2 (charity focus: beneficiary vs. benefactor) x measured belief in a just world design. Participants first read a brief article about how American society is becoming more fair [unfair] over time (Laurin, Fitzsimons, and Kay 2011). Participants were then instructed to focus on a beneficiary [benefactor], viewed the charitable appeal, and completed the charitable support and BJW measures.

There was a marginal three-way interaction of societal cue, charity focus, and belief in a just world on charitable support ($p = .06$). The unfairness conditions mirror the results of Studies 1 and 2: there was a significant positive effect of BJW when the appeal focused on beneficiaries ($p = .0016$), but not benefactors ($p = .76$). Emphasizing societal fairness revealed a different pattern, such that BJW no longer increased donations for a beneficiary-focused appeal ($p = .22$), but interestingly had a marginal positive effect on the benefactor-focused appeal ($p = .06$). Overall, these effects offer support for our predictions regarding threat and threat reduction associated with these appeals.

In sum BJW consumers are threatened by injustice and may reduce this threat by redressing or rationalizing injustice. We demonstrate that high (vs. low) BJW consumers provide greater charity support when a beneficiary focus is engaged. However, this effect is attenuated for a benefactor focus, which reflects existing justice restoration efforts.

Psychosocial Determinants of Children's Healthy Eating Behaviour. The Role of Siblings and Peers

Tija Ragelienė, Aarhus University, Denmark
Alice Grønhøj, Aarhus University, Denmark

EXTENDED ABSTRACT

The prevalence of childhood obesity worldwide has risen several times in the past few decades and is anticipated to grow in the future (OECD, 2017). Obesity-related illnesses bring a large financial, social and psychological burden to individuals and society (Seidell & Halberstadt, 2015; Tremmel et al., 2017). Childhood obesity is often linked with unhealthy diets and consumption of foods high in fat and sugar (Kuzbicka & Rachon, 2013; Setayeshgar et al., 2017) and can be prevented by changing diets, including increasing children's consumption of fruits and vegetables (Tetens & Alinia, 2009).

Since eating is a social activity it is important to consider the socio-cultural context and underlying social relations to understand children's food choice and eating patterns (Delormier, Frohlich, & Potvin, 2009). Parents' influence on children's eating behaviour, has been confirmed in many studies (Scaglioni et al., 2008; Yee, Lwin, Ho, 2017), but peers have also been found to have a significant impact for children's consumer socialization in shaping food preferences and eating patterns (Davidson et al., 2014; Fitzgerald et al, 2009; McClain et al., 2009; Moschis & Churchill, 1978). However, the evidence regarding peers' influence is rather mixed (Coppinger et al., 2010; Stok et al., 2014; Watts et al., 2018), and it is still not clear which psychosocial factors are most important for explaining peers' influence on children's food choice.

Approximately 80 per cent of western children have at least one sibling, and relationships with siblings are considered to be one of the longest-lasting relationships in one's lifetime (Howe & Recchia, 2014). Therefore, siblings perform an important role in children's consumer socialization (John, 1999; Kerrane, Bettany & Kerrane, 2015). Siblings also are considered to have an impact on children's eating behaviour (Datar, 2017; Povey, Cowap & Gratton, 2016; Vanhelst et al., 2018). However, the studies done in this field are very sparse, and further research on siblings' influence is needed to understand the extent to which siblings' influence can be relevant for the development of children's eating habits.

The present study aims to explore the psychosocial factors related with peers and siblings influence on children's eating behaviour and answer the following research questions: 1) How are friends' and siblings' support for healthy eating and the frequency of eating with siblings and friends related to children's eating behaviour and food preferences? 2) How do children perceive healthy eating behaviour in the context of social interactions with siblings and peers?

Consents from parents and participants were obtained before conducting a survey and qualitative interviews. In total there were 278 (46.4% boys) 8-13 years old (M = 10.61, SD = 1.11) children who filled in the questionnaire. Semi-structured interviews were conducted with 20 children (50% boys), whose age varied from 9 to 12 years old (M=10.65, SD=1.09). A mixed-methods convergent parallel design was used in this study (QUAL+QUAN; Morse, 1991). To analyse the qualitative data, thematic analysis was performed using a general inductive approach (Thomas, 2006). The emerged categories were coded using the NVivo software package version 10 (QSR International, 2010). Quantitative data analysis was conducted using SPSS26 for MacOS software.

A food preference questionnaire (Smith et al., 2016) was used to measure preadolescents' preferences for vegetables (16 items, α=0.85) and snacks (9 items, α=0.88). A ten items social support for diet scale (Sallis et al., 1987) was used to measure social support for a healthy diet of siblings (α=0.88) and friends (α=0.86). Relationships with siblings were measured with two separate items representing how well children get along with their siblings and how satisfied they are with the relationships. Eating frequency with siblings and friends and the intake of fruit, vegetables and snacks per day were assessed with separate items using 5-point Likert type responses.

Multiple regression analyses revealed that the frequency of eating with friends (β=.188, p=.002, R^2=.054) was a significant predictor of children's vegetables preferences. Friends' support for healthy eating (β= -.134, p=.027, =.037) and frequency of eating with friends (β= -.121, p=.046, =.037) were significant negative predictors of actual snacks intake. The interaction of friends' support for healthy eating and frequency of eating with friends did not change the significantly (p>.05) and did not predict snacks intake (β= -.043, p=.478, Δ =.002). The regression models on snacks preferences, actual fruit, and vegetables intake were insignificant.

No significant differences in the eating behaviour variables were found between the groups of participants who had siblings and those who did not. There was also no significant difference in the eating behaviour variables between groups of children who had siblings of different age. Analyses of multiple regression models revealed that siblings' gender, number of siblings, as well as sibling support for healthy eating, satisfaction with the relationships with siblings, getting along with siblings, and frequency of eating together with siblings, were not significant predictors of children's vegetables and snacks preferences, and actual snacks intake. However, siblings' support for healthy eating was found to be a significant predictor of actual fruit intake (β=.232, p=.001, =.07). Siblings' support for healthy eating (β=.189, p=.007, =.093) and frequency of eating together with siblings (β=.212, p=.003, =.093) were significant predictors of vegetable intake.

Two main themes representing influence of peers and siblings emerged from the qualitative interviews and are presented in _Table 1_. Siblings' influence was found to be inconspicuous for children's food choice and preferences since eating with siblings was not perceived as important or because of having bad quality relationships with siblings. Peers' influence was found to be more salient for children's eating behaviour, since observing peers consuming snacks sometimes lead to temptation to try these unhealthy food items. Peers' unfavourable reaction to healthy eating was also perceived as a barrier to eat healthily.

The results of this study contribute to our understanding of peers' and siblings' influence on children's eating behaviour and help to identify important aspects of this influence that could be targeted when creating interventions aiming to encourage healthy eating habits among children and for marketing healthy food products to young consumers.

Persuasion Knowledge Model Reimagined

Vahid Rahmani, Rowan University, USA
Elika Kordrostami, Rowan University, USA
John B. Ford, Old Dominion University, USA

EXTENDED ABSTRACT

Persuasion knowledge (PK) refers to individuals' ability to identify and resist outside agents' purposeful manipulation attempts (Friestad & Wright, 1994). This article investigates the factors that influence consumers' propensity to acquire new knowledge and their ability to use their existing knowledge to protect themselves from marketers' persuasion attempts.

We argue that consumers can learn PK via automatic and effortful cognitive processes. The automatic route to learning PK entails learning PK from experiences of interactions with marketers. Consumers could also learn the PK via external sources of information (e.g., reading books, articles, blogs, or other consumers' reviews to gather information about PK). This process will by cognitively taxing. Consequently, building on the elaboration likelihood model (ELM, Petty & Cacioppo, 1986) and Heuristic-Systematic Model (HSM, Chaiken et al., 1989), we argue that in order to learn from external sources of information, consumers should have motivational and cognitive resources.

Factors Influencing The Learning Process of PK

Gender

According to selectivity model men and women differ in the way that they process the information (e.g., Meyers-Levy, 1988). Women tend to engage in a more detailed elaboration of information and are more likely to recognize subtle cues in a message, while men are inclined to engage in schematic information processing and tend to miss subtle cues (Darley & Smith, 1995). Therefore, we argue that compared with men, women should have a higher motivation to engage in the effortful thinking process and subsequently are more likely to acquire PK via external sources of information.

Involvement

High involvement products are those that are expensive and/or have significant consequences in terms of addressing consumers' belonging/esteem needs. We contend that In high-involvement product categories versus low-involvement ones, people are more inclined to engage in an effortful thinking process, and subsequently, are more prone to acquire PK from external sources of information.

Regulatory focus

The regulatory system refers to the motivation system that drives people's behavior and can be categorized into two main categories of promotion and prevention (Higgins & Crowe, 1997). Compared with promotion-focused people, prevention-focused people are more vigilant against ulterior motives, are more prone to process the information systematically, and are more likely to focus on the negative information when faced with mixed information (Kirmani & Zhu, 2007). Therefore, we argue that compared with promotion-focused people, prevention-focused people should be more motivated to process the information systematically, and subsequently, should be more likely to learn PK using external sources of information.

Factors Influencing Consumers' Ability To Use Their PK

O'Keefe (2013) argues that the common denominator of all persuasion techniques is their explicit or implicit assurance of positive consequences. Recent evidence from the neuroscience literature supports this perspective of "subjective-value-maximization" in persuasion scenarios (Falk & Scholz, 2018). Therefore, a persuasion attempt could be summarized as any direct or indirect insinuation that a certain action (e.g., buying the product) could enhance positive self-related or social consequences. Factors that increase the ability to identify marketers' ulterior motives should enhance consumers' ability to distinguish between the marketing offerings that are likely to result in desirable self-related or social outcomes and the ones that are not. Therefore, we propose that a greater level of acquired PK will positively influence consumers' ability to select desirable marketing offerings.

The depth and the direction of information processing

Existing research suggests both the depth and the direction of information processing should influence the activation process of PK (e.g., Oppenheimer & Kelso, 2015). As ELM and HSM models of persuasion suggest, to identify marketers' subtle manipulative intentions, consumers need to have the motivation and the ability to pay attention to details and process the information at a greater depth. The direction of information processing could also influence consumers' ability to identify marketers' persuasion tactics. When presented with mixed evidence, consumers could focus on positive or negative information. Focusing on negative information could enhance consumers' ability to identify any ulterior motives that may exist in a persuasion scenario.

Emotions

The relationship between PK and emotions is complex and twofold: On one hand, consumers' PK enables them to cope with emotional appeals (Hibbert et al., 2007). On the other hand, emotions and mood affect preference (Lee et al., 2009), memory, evaluation, and information processing (Bagozzi et al., 1999), and subsequently, they affect PK through influencing both direction and depth of processing the information.

The Consequences of Consumer Persuasion Knowledge

Persuasion knowledge enables consumers to resist outside agents' persuasion attempts and successfully demonstrate persuasion coping behavior. Extant literature demonstrates that consumer persuasion knowledge can negatively affect consumers' attitudes toward advertisement messages and appeals (Campbell, 1999; Kirmani & Zhu, 2007), sales techniques (Campbell & Kirmani, 2000; Holmes et al., 2017), brands (Laran et al., 2011; Wei et al., 2008), product placement (Tessitore & Geuens, 2019), CSR claims (Skarmeas & Leonidou, 2013) marketers' persuasion attempts (Kachersky, 2011; Kachersky & Kim, 2011; Nelson et al., 2009), and deceptive pricing strategies (Hardesty et al., 2007; Kachersky, 2011; Kachersky & Kim, 2011).

Chefs Secrets to Engage Their Followers on Instagram

Karine Raies, EM Lyon Business School, France
Mariem El Euch Maalej, PSB Paris School of Business, France
Marielle Salvador, Institut Paul Bocuse, France

EXTENDED ABSTRACT

Social media has now become essential communication tool and is present in all sectors. Haute gastronomy, considered a highly experiential luxury field is no exception. Some starred chefs have therefore converted to social media as a means of communication to gain visibility in this highly competitive sector marked by the growing importance of culinary influencers. Indeed, social media, and in particular Instagram, provides channel which enables chefs to get closer to their customers, extend their media coverage to a wider audience and direct traffic to the starred establishment's website. A general trend towards consumption of culinary photos on social media has proved highly popular with Internet users in recent years. Food lovers represent 27% of Instagram's social network users, and the #Food hashtag is one of the most widely used since the platform's launch in 2010 (Digimind 2018).

Starred chefs now face the challenge of building a strong highly recognizable brand. Thanks to social media, we know these starred chefs, each one's history and personality even before, or without, tasting their cuisine. In this context, chefs are exhibited and 'consumed': they take part in television programs, meet with journalists, publish cookbooks and have accounts on social networks in order to develop reality-based personal marketing. They are the archetype of personal brands. Chefs are using digital platforms to share their "art" with their followers and improve their own visibility as well as the visibility of their restaurants. They endorse their restaurant's brand and use their own notoriety as a personal brand. Taking these communication tools into account in the construction of a natural person as a brand is interesting from both a managerial and a theoretical point of view. However, the literature has so far shown little interest in explaining how and why consumers are interested in chefs' Instagram accounts.

Studying starred chefs as a personal brand via social media is all the more relevant as the literature is poorly developed, with most studies focusing on celebrity endorsement of brands alone. The development of personal branding by starred chefs often include the restaurant's own brand awareness which can benefit the chef brand and vice versa. Indeed, the human brand has the ability to convey a level of authenticity and powerful cultural meaning that non-human brands cannot match (Fournier and Eckhardt 2018). At the same time, it presents many risks because the brand must be symbolic, immaterial and immortal, while the person is physical, has a personal life and is mortal (Dion and Arnould 2016; Fournier and Eckhardt 2018). It's then possible to see Chef's Instagram accounts that are more oriented towards the expression of their humanity (i.e. with a lot of personal photos of them and their family) or in opposition towards their belonging to the restaurant (i.e. with a commercial link to the restaurant's website). In this context, what characteristics enhance consumer engagement?

Platforms like Instagram enables brands to create owned media and to engage with their followers by constructing posts using visual modalities (Rietveld et al. 2020). Despite the growing interest of managers to communication strategies based on visual content on social media, the majority of academic research focused on text content (Chevalier and Mayzlin 2006; Chintagunta, Gopinath and Venkataraman 2010). Some recent exceptions (Li and Xie 2020; Ri-etveld et al. 2020) highlighted the importance of understanding how communication strategies based on visual content can help brands to increase their users' engagement.

This research explores causal configurations of factors that lead to a high level of engagement on 18 French chefs' Instagram accounts. We then extracted the totality of the selected chef publications (8075 pictures) from the launch of their Instagram accounts thanks to a collaboration with Heuritech, a company specialized in Instagram data collection and machine learning models. Using a fuzzy-set qualitative comparative analysis (fsQCA) (Ragin 2000), several configurations of conditions have been identified as sufficient to lead to a high number of likes and followers.

Following previous studies, we consider in this research four variables to capture the strategy of communication adopted by chefs on Instagram: 1/the number of pictures for capturing the intensity of publication activity; 2/ the average number of hashtags used for capturing the level of informativeness related to a rational strategy of communication;3/ the number of pictures containing humans for capturing an emotional strategy of communication on one side but also a human-oriented branding; and 4/ the average number of commercial links related to the published pictures to capture the weight of the restaurant's brand related to the chefs' profile. Our study aimed at identifying which mechanisms can explain consumers' engagement on Instagram profiles of personal brands like starred chefs.

The results show that the number of followers is observed in two situations: the first one corresponds to an extensive and informative strategy of publications with a high number of published pictures and a high number of hashtags while the second one is associated to a less extensive and more inconspicuous strategy that is more emotionally oriented and a strongly assumed position of the chef as highly attached to the restaurant's brand with a low number of published pictures and a low number of hashtags but associated with a high number of pictures containing human figures and a high number of commercial links associated to those pictures.

We show different strategies that can lead starred chefs to maximize their social media marketing activities to influence follower's engagement behaviours and to manage successfully their accounts. We underline the interest of studying the sector of haute gastronomy, a field where elements of luxury and the existence of the personal brands of the chefs come to build not only their own notoriety, but also the notoriety of the restaurant and sometimes even the hotel that hosts the restaurant.

These findings can be extended to other types of personal brands. Several influencers need to develop strategies that can serve their collaboration with other brands while positively impact their follower's engagement. Understanding what are the successful strategies is then very valuable for different types of personal brands.

How Counter-Stereotypical Sources Attenuate Polarization Over Consumption-Related Policy Issues

Guilherme Ramos, FGV/EBAPE, Brazil
Eduardo B. Andrade, FGV/EBAPE, Brazil

EXTENDED ABSTRACT

Political polarization is rising across the globe and shows no sign of stopping (Abramowitz and Saunders 2008). As political orientation becomes increasingly central to one's identity, preferences become more clearly divided along ideological lines. Liberals and conservatives have been shown to display different consumer behaviors in multiple contexts, such as donations (Winterich, Zhang, and Mittal 2012), recycling (Kidwell, Farmer, Hardesty 2013), purchase-based signaling (Ordabayeva and Fernandes 2018), and multiple policies related to product or service purchase and consumption (e.g., gun control, cannabis legalization; Daniller 2019; Shaeffer 2019). Indeed, the predictive power of political orientation on preferences is particularly pronounced for public policies (Bail et al 2018). Although much has been documented on how political orientation helps explain divergent opinions and tastes, less is known on what can bring them together. Our research addresses this general gap.

Although this strong predictive power has been attributed to different needs to manage uncertainty and threat (Jost 2017), there is also evidence that preferences can shift with relative ease. Because political orientation is a form of social identity (Green, Palmsquit, and Schindler 2002), it becomes fertile ground for the operation of group biases. Indeed, researchers have documented that preferences are partly shaped by perceptions of in-group norms (i.e., preferences in-group members ought to hold). Oftentimes, people draw on stereotypes regarding each group's norms (Bergan 2012). In this sense, liberals might endorse abortion not only because this policy fits their motivational needs, but also because this is their normative preference. Frequently, however, such norms are not spontaneously inferred, but rather communicated (Cohen 2003). Multiple studies have shown that source cues tend to increase (decrease) support for policies among in-group (out-group) members (e.g., Cohen 2003; Van Boven et al 2018). Overall, these results indicate that people´s propensity to assimilate with in-group and diverge from out-group can moderate potential differences in needs held by those from opposite political leanings. Thus, instead of fomenting polarization, source cues may attenuate the preference gap if they are counter-stereotypical. Specifically, when a counter-stereotypical source endorses a policy (e.g., conservative politician endorses cannabis legalization), the policy stereotype contradicts the norms communicated by the source. Consequently, normative preferences become less clear, and the effect of political orientation should reduce.

This research offers several contributions to the literature. First, while previous studies have shown that political orientation predicts preferences in politics (Bail et al 2018) and in marketing (Jost 2017), we demonstrate that counter-stereotypical sources can significantly reduce this predictive power. Second, we document that such attenuation happens asymmetrically. When a counter-stereotypical source endorses a policy, it persuades in-groups more than it dissuades out-groups. Thus, we help reconcile mixed findings about the predominance of in- and out-group effects by highlighting its context-dependency (Nicholson 2012; Samuels and Zucco 2014). Finally, by conducting our studies in Brazil, which, unlike the US, has a highly fragmented multi-party system, we assess the extent to which general political orientation rather than strong party identification plays a social-based role into people's consumption-related policy preferences.

In our studies, we examined how the effect of political orientation on preferences toward consumption-related policies varied as a function of the source. Although we use the terms "liberals" and "conservatives" to communicate with the literature, the meaningful labels for ideological distinction in Brazil are "left" and "right", respectively. Thus, we treat them as equivalent (Hasson et al 2018). In study 1, we had participants (n=226) evaluating a real bill to legalize marijuana, which could be endorsed by a former left-wing Congressman (stereotypical source), or a former right-wing President (counter-stereotypical source). The participants, then, indicated their level of support for the policy and completed a measure of political orientation (see summary table). The analyses yielded the expected interaction between source condition and political orientation (β=0.41, t(220)=2.21, p=.03). In the stereotypical condition, political orientation was a strong predictor of preferences (β=-0.48, t(105)=-3.47, p=.001), but this effect faded away in the counter-stereotypical condition (β=-0.12, t(113)=-0.95, p=.34). To further examine the results, we constructed a binary indicator of political orientation. The analysis revealed an interesting and, to our knowledge, novel asymmetry. Left-wing participants were quite insensitive to whether the source was stereotypical (M=3.20, SD=1.39) or counter-stereotypical (M=3.02, SD=1.48, t(220)=-0.94, p=.35). However, right-wing participants increased their support for marijuana legalization in the counter-stereotypical condition ($M_{counter\text{-}st.}$=2.88, SD=1.37; $M_{st.}$=2.45, SD=1.44, t(220)=2.45, p=.01).

Study 2 sought to increase internal validity and replicate the results of study 1 with a policy stereotypically associated with the right. Participants recruited on an online Brazilian platform (n=450) were presented with a bill to increase access to guns. The bill could be endorsed by "right-wing" (stereotypical source), "left-wing" (counter-stereotypical source), or "some" (control) Congressmen. The same dependent and independent measures of study 1 were collected, with the difference that the latter included an option to identify respondents who were unfamiliar with the right-left distinction (n=108, dropped from analyses). Political orientation emerged as a strong predictor of preferences in the control condition (β=0.89, t(332)=6.96, p<.001), and this effect was not statistically different in the stereotypical condition (β = -0.14, t(332) = -0.78, p = .44). However, polarization attenuated when the source was counter-stereotypical (β = -0.54, t(332) = -3.02, p=.003). Further, this attenuation happened asymmetrically: while right-wing participants did not significantly shift their opinions when the source was counter-stereotypical ($M_{counter\text{-}st.}$=3.09, SD=1.41; $M_{control}$=3.26, SD=1.54, t(332)=-0.6, p=.55), left-wing participants significantly increased their support ($M_{counter\text{-}st.}$=2.30, SD=1.45; $M_{control}$=1.59, SD=1.06, t(332)=2.65, p=.008). Study 3 employed the same procedure of study 2, but applied to the context of abortion, an even more salient and familiar policy where preferences should therefore be less responsive to the source (Mondak 1993). Even so, we replicated the results (see summary table).

This research demonstrates that even in a polarized world, political orientation might not be such a strong predictor of preferences. In addition to showing how to diminish polarization over policy issues, our results help reconcile previous findings regarding in- and out-group effects by showing a condition under which in-group ef-

fects predominate. Finally, this research broadly proposes a way to diminish disagreement.

Unanticipated Practice Disruption: Experiencing Purgatory

Kamran Razmdoost, ESCP Business School, UK
Leila Alinaghian, Cranfield University, UK
Elmar Kutsch, Cranfield University, UK

EXTENDED ABSTRACT

Practices — as routinized behavior consists of bodily and mental activities orchestrated by things and their use, knowledge, knowhow and state of emotion (Reckwitz, 2002) — are integral part of our living and consumption efforts. Repetition and anticipation are ways through which we manage uncertainty, risk and potential anxiety. In fact, routinization is the fundamental mechanism through which a sense of ontological security (or deep trust in life activities) are achieved (Gidden, 1984; Phipps and Ozanne, 2017). Focusing on anticipated disruptions (i.e., decreased rainfall), Phipps and Ozanne (2017) illustrated the emergence of new ontological states of (in)security as a result of a routine disruption. Nonetheless, disruptions are not always anticipated, nor are managed through reflexive efforts. Unanticipated disruptions such as unanticipated war, flood, fire, cancelled flight, car accident, power cut or illness create an unwanted, unplanned and in many cases unimaginable situational context for consumers. In this study, we aim to unpack the enactment of physical, mental and social processes by which consumers experience the state between unanticipated disruption and the original state of security, the state that we titled purgatory.

We adopted an ethnographic approach in this study to account for observable actions as well as feelings, sense making processes and meanings associated to those actions. Unanticipated disruptions are challenging (if not impossible) to observe. Hence, we chose K2 2008 disaster as the context of our study, an event which has been accurately documented and has been visually recorded (i.e., through GoPro videos). Further reflexive interviews with key people involved in the incident provided the full understanding of the context. The early morning of 1st August 2008 saw a total of 32 climbers preparing themselves in their quest to conquer the summit. The slow pace eventually led to climbers (18 out of 32) reaching the summit as late as 8 pm, a dangerous situation on a peak where 2 pm is considered relatively safe. On their descending effort, climbers faced multiple disruptions including lack of energy, darkness, lack of oxygen, avalanches and loss of ropes. Eventually, 11 climbers lost their lives, three were severely injured and the rest were emotionally affected including those who had lost their families.

We identified three key processes through which climbers made sense and managed disruption:

Apprehension

There have been multiple interpretations of what the disruption was including the slow ascent, too many climbers, low skilled climbers, disrespecting responsibilities, communication failure, high attitude, avalanche etc. Not only climbers had dissimilar perceptions of disruption but also their realization of disruption occurred at different points in the journey. Interestingly, a few climbers did not even perceive any disruption and completed their experience in a routinized way (although they realized it retrospectively). Apprehension involved a set of activities (rather than a moment of realization) including the sense making of disruption, re-evaluation of disruption signals, anxiety management and coping decision. Climbers' identity work was salient in this process, where they constantly defined and redefined themselves, their status and differences with others opposing their views.

Improvisation

The coping actions were improvised by the climbers and they (individually or collectively) adopted different ways of dealing with the disruption. The improvisation heavily was based on the evaluation of resources and their imagination of the situation using the most similar experiences in the past. Furthermore, climbers engaged in boundary spanning practices to create new resources or bring new use to the existing resources. Climbers engaged in two set of practices: a) the ones routinized through previous resource interactions based on available resources (e.g., descending on ice using their physical skills) and b) those practices that they invented through their boundary work (e.g., descending with no use of axe).

Recovery

The survivors and the families and friends of those who died went through a physical and mental recovery from the course of events. At the initial stages after the crisis, recovery involved a deep reflection on the causal attribution of disruption and finding the truth. Given the fluid nature of the disruption, there was a gap on the way events were interpreted by different actors, however the views have converged over time through direct and indirect dialogue. Finally, affected climber moved on from the crisis by managing their emotional engagement with the event. Moving to the state of embedded security was evident in those initiating similar practices (e.g., another adventurous expedition). Throughout the interview however, we have realized that not all of the climbers achieved ontological security and some may never engage with such practices.

Our findings have theoretical implications for routine disruption and practice literature. Firstly, we showed that consumers facing unanticipated disruptions aim to move to the original state of embedded security, in contrast with anticipated disruptions where they adapt to the new state of security (Phipps and Ozanne, 2017). Secondly, we illustrated that practice disruption is a cultural process, socially constructed by people going through it. In fact, in many cases consumers may consider their state of ontological insecurity as a component of the practice rather than a disruption. In those cases, climbers perceive disruption signals as betrayals of the nature and engage with a set of practices to take back the control of the nature (refer to purifying practices, Canniford and Shankar, 2013). Consumers respond to disruption signals to defend, enhance and recreate their identity and use their apprehension of disruption as a form of demythologizing practices to disentangle their consumption investment from a devaluing myth associated with the disruption (Arsel and Thompson, 2011). Finally, we indicated that institutions, their boundaries and identities defined within those boundaries disappear at points between practices disruption and state of embedded security. In this setting, timeflow (i.e., "a practice's ability to induce a certain pattern of experienced temporality in those performing the practice", Woermann and Rokka, 2015, p. 1487) does not exist as no pattern of temporality is embedded in cultural resources. Indeed, consumers experience full power over institutions and social boundaries (Foucault, 1982), whereas they are bounded by time to create new resources and institutions.

"Branding the Past: Constructing Brand's Heritage"

Fatima Regany, University of Lille, France
Helene Gorge, University of Lille, France
Ludovic Cailluet, EDHEC Business School, France

EXTENDED ABSTRACT

Introduction

History has the potential for being managed and used by organizations as a strategic resource (Cailluet et al. 2018). Research in marketing shows that historical narratives of brands are transformed into marketing resources by corporations and are embedded into brand identity which gives rise to the concept of heritage brand (e.g. Balmer and Burhausen, 2019; Pecot and De Barnier, 2017; Urde et al., 2007). Brands mediate the commercialization of past memories, which play a vital role in creating markets (e.g. Brunk, Giesler and Hartmann, 2018; Holt, 2004). We assume that the past can offer benefits to corporations, which transform it into a branding heritage resource (Chronis, 2005; Penaloza, 2000). However, little is known about the process of constructing a brand heritage resource. More specifically how are managed dynamics and tensions in the construction of a brand's historical heritage? While conducting a qualitative study, we address this issue by showing in which way different types of memories (Ricoeur, 2004) are constructed by a set of actors engaged in the construction of brand heritage.

Literature

Urde et al. (2007, 4) define heritage brand "as a dimension of a brand's identity found in its track record, longevity, core values, use of symbols, and particularly in an organizational belief that its history is important". Cultural branding scholars explore an alternative temporality of the brand and have conceptualized it as an historical artifact evolving over time and subject to collective interpretations by numerous actors over historical moments (Hatch and Rubin, 2006; Holt, 2004). Research highlights different forms of ambiguities and controversies in brand's use of historical resources - glorification, embellishment, augmentation, invention, deformation (e.g. Balmer and Burhausen, 2019; Brown et al. 2103; Beverland, 2006; Beverland, Lindgreen and Vink, 2008; Hobswawn and Ranger, 1992). Ricoeur (2004) took up the question of memory and recollection. History is the learned heir of memory and is always responsible for giving meaning to a past, through a configuration and narrative choices (Pellauer and Dauenhauer, 2016). With the aim to study dynamics of brand heritage construction, we analyze how organizations attempt to transform the past into a brand resource and more specifically how different actors construct memory. To do so we use the theoretical framing on memory proposed by Ricoeur (2004): history presupposes a policy of « just memory » that is to say an ethics, by distinguishing three types of problems: blocked memory (for example following a trauma), manipulated memory (for example to ideological aims) and forced memory (as obligated by commemorations). These problems are reflected in organizations' forgetting or remembering strategies.

Methods

We have collected data on six French based brands with hold a historical heritage (Air France, Hermès, Lacoste, La Vache qui Rit, Michelin and the French national railway company SNCF) according to various criteria: i) they all have a long enough existence (respectively born in: 1933, 1938, 1921, 1933, 1837, 1889) ii); they have also been chosen to represent diversity in terms of sectors and products. To explore the tensions that may occur in the construction and management of the brand heritage, we have collected data from different sources. This variety allows for triangulation to build a robust set of data (Flick, 2018), and makes for greater reflexivity and critical analysis of sources. Table 1 summarizes our empirical materials and data collected. All these data have been analyzed through hermeneutics (Belk et al., 2012; Thompson, 1997).

Findings and discussion

The analysis of our data reveals that the construction of brand's heritage is shaped around the three types of « memories » advocated by Ricoeur (2004) as abuses in constructing history: blocked memory, manipulated memory and forced memory. Each type of memory shows how different actors interact in constructing the brand heritage and highlights the instrumentality of this process.

Literature on brand heritage considers that a consensus is established in organizations as regard the nature of this heritage (Burghausen and Balmer, 2014; Hudson, 2011; Pecot and DeBarnier, 2017; Urde et al., 2007). We question it in the following research by showing that actors involved with the construction of brand heritage have conflicting interests. We highlight an additional "use-of-the-past" ambiguity (Brown and al., 2013; McAlexander et al. 2002) with the embeddedness in the construction of brand's heritage of two competing approaches: a scientific historical approach versus a narrative heritage branding approach, both confronting each other to find a consensus.

An important element in this discussion related to Ricoeur (2004) is the relationship between ethics and truth. How to define truth and what is it? These truths can be really diverse when historians elaborate their research questions. This suggests a further discussion on the absence of falsification. Marketers do not even have to forge the past. Most historical efforts are expressed as a narrative. The crafting of this narrative is central to the perception of the audience and affects the understanding of the message. There is no neutrality in the narrative itself that contains a plot, heroes and a conclusion that orients the reader. Manipulating the past is however limited by the collective nature of memory that tends to be difficult to be controlled entirely by organizations.

Reclaiming Control: A Multi-method Investigation of Consumer Response to Privacy Violations

Brandon Reich, Portland State University, USA
Chi Tran, University of Oregon, USA
Hong Yuan, University of Oregon, USA

EXTENDED ABSTRACT

Consumers are outraged by privacy violations from some brands (e.g., Facebook; Nivea 2019) but not others (e.g., Amazon; Lynskey 2019), representing a "privacy paradox" (Norberg, Horne, and Horne 2007). Clarity is lacking around this paradox (Krasnova et al. 2010) and around privacy as a consumer construct more generally (Martin and Murphy 2017). The current research uses a multi-method approach to address this dearth of knowledge. A pilot study clarifies the privacy construct, which is then applied to examine the privacy paradox using scraped Twitter data (study 1) and an experiment (study 2). We hypothesize and find that consumers' sense of control plays a central role in differential consumer responses to otherwise equivalent privacy violations across companies.

Privacy violations threaten consumers' subjective control (Martin, Borah, and Palmatier 2017), leading to control-reclaiming behaviors (Deci and Ryan 2000) such as brand selection (Schiele and Venkatesh 2016) or verbal expressions (Thimm, Rademacher, and Kruse 1995). However, these reclamations emerge only when regaining control is objectively possible (Skinner and Zimmer-Gembeck 2010). Otherwise, a sense of helplessness inhibits control-reclaiming behaviors (Dweck 1999). We therefore expect a severe (vs. moderate) privacy violation to prompt greater control-reclaiming behaviors, only when the violating company operates in an industry with high variability of privacy practices. This is because, in this market context, regaining control is still objectively possible. However, in a more homogenous industry, consumers are unlikely to engage in control-reclaiming behaviors regardless of violation severity because, objectively, regaining control is impossible.

In the pilot study, participants (N=139 MTurk workers) were presented with twelve recent instances of consumer privacy violations and asked to rate their perceived level of privacy violation for each (1=*Not at all a privacy violation*; 7=*An extreme privacy violation*). A PCA found that the twelve ratings converged into three components (see figure 1), reflecting scenarios in which companies merely collected consumer information (*recording*; M=3.38, SD=1.30), used consumer information for personalized targeting purposes (*targeting*; M=5.16, SD=1.21), and shared consumer data with third parties (*sharing*; M=6.12, SD=1.06). A repeated-measures ANOVA with polynomial contrasts showed a significant linear trend ($F(1, 138)$=376.36, p<.001), suggesting progressively increasing levels of privacy violation associated with these three dimensions.

Study 1 used text analysis of Twitter data to compare linguistic response to *targeting* or *sharing* privacy violations from Facebook and Amazon, creating a 2 (violation type: targeting, sharing) × 2 (company: Facebook, Amazon) quasi-experiment. We expected increased control-reclaiming behavior in response to *sharing* (vs. *targeting*) from Facebook because it operates in an industry with high variability in privacy practice (Ahmad 2018). However, because Amazon operates in a more standardized industry (Paul 2020), felt helplessness should inhibit consumers' control-reclaiming behavior regardless of the company's privacy-violating action. Control-reclaiming behavior was operationalized as use of first-person plural ("we") and second-person singular ("you") pronouns, which serve as verbal expressions of power (Cassell et al. 2006) and control reclamation (Thimm et al. 1995).

We scraped 3,805 tweets from the Twitter API using matched keywords reflecting privacy-violating action (*targeting* or *sharing*) with either Amazon or Facebook. Keywords regarding *targeting* (*sharing*) were "targeting," "targeted," "targets" ("sharing data," "shares data," "shared data," "third party data," "3rd party data"). Using LIWC (Pennebaker et al. 2015), we recorded frequencies of "we" and "you." A 2 (violation type) × 2 (company) MANOVA (df=1, 3801 for F-tests; see table 1 for means and SDs) revealed the expected interaction for "we" (F=6.85, p=.009) and "you" frequencies ($F = 70.49$, $p < .001$). Planned contrasts showed that, for tweets referencing Facebook, *sharing* (vs. *targeting*) was associated with significantly greater usage of "we" ($F = 6.85$, $p = .009$) and "you" (F=189.60, p<.001), whereas no effects of violation type were observed among tweets referencing Amazon (ps > .14). This pattern may be explained by an industry-level characteristic—variability in privacy practice—that differs between Facebook and Amazon.

Study 2 (N=214 MTurk workers) used a 2 (violation type: targeting, sharing) × 2 (industry variability: low, high) full-factorial design to replicate these findings in a more controlled setting. Participants were told "Industry X" contained four companies (A, B, C, and D) and were asked to imagine themselves as current customers of "Company A". In the low (high) variability condition, all companies in Industry X used consumer data in the same way (different ways). Participants in the *targeting* (*sharing*) condition then saw a pop-up detailing Company A's policy of using consumer data to deliver targeted ads (share with third-parties), and indicated whether they would continue onto Company A's website (0) or switch to another brand (1). An ANOVA (df for F-tests=1, 210) on brand switching revealed main effects of violation type (F=9.12, p=.003) and industry variability (F=6.81, p=.01), qualified by the expected interaction (F=4.39, p=.04). Planned contrasts revealed that, in the high industry variability condition, participants were significantly more likely to switch brands following a *sharing* (vs. *targeting*) violation (F=11.26, p=.001). However, in the low industry variability condition, violation type had no effect on switching behavior (p=.50). This suggests that consumers only attempt to reclaim control after a severe privacy violation when market constraints permit such a possibility.

Privacy is more prescient than ever before, yet, the literature provides little clarity around privacy violation as a construct and the alleged privacy paradox. The current research unveiled three increasingly severe dimensions of privacy violation (*recording*, *targeting*, and *sharing*) and showed that consumers are more likely to engage in control-reclaiming behaviors following a *sharing* (vs. *targeting*) privacy violation when the company operates in an industry with high (but not low) variability in privacy practices. Our findings suggest that privacy violation is primarily a matter of what companies do with consumer data rather than the type or quantity of data collected. Furthermore, this research helps explain an otherwise opaque privacy paradox, showing an industry-level characteristic that moderates the relationship between different privacy violations and consumer response. Thus, not all privacy violations are equal, and so asking consumers for ubiquitous privacy consent might instigate backlash (e.g., through brand switching) as they later discover intrusive company actions.

A History of Failed Intentions:
When Focusing on Unintentional Outcomes Promotes Ideation

Taly Reich, Yale University, USA
Kelly B. Herd, University of Connecticut, USA
Alexander G. Fulmer, Yale University, USA

EXTENDED ABSTRACT

Companies increasingly rely on input from consumer ideation to steer new product development (Bayus 2013; Knipp 2014; Olenski 2015). Through a synthesis of literature on intentionality and personal control, the current research proposes a previously unknown and surprising procedural strategy to promote ideation: focusing on one's own history of failed intentions in a target domain. Concentration on one's own history of failed intentions seems counterproductive given purported benefits of self-affirmations (Downing 1986; Schmeichel and Vohs 2009). However, the current research explores whether focusing on histories of unintentional outcomes can actually benefit individuals by promoting subsequent ideation in that domain. We propose that because reflection on a history of failed intentions motivates individuals to regain threatened control, focusing on these past failed intentions promotes ideation relative to focusing on successful intentions.

We define ideation as "the formation of ideas or concepts" (Oxford University Press 2020), in line with Osborn's (1963) original proposition of the ideation protocol "brainstorming" with which one is to generate as many total ideas as possible. This operationalization is considered an appropriate metric to capture ideation in both consumer research and beyond (Brucks and Huang 2020; Dennis et al. 1996; Diehl and Stroebe 1987, 1991; Fitzsimons, Chartrand, and Fitzsimons 2008; Glover and Gary 1976; Mullen, Johnson, and Salas 1991; Stroebe and Diehl 1994). Because of a connection between intentionality and feelings of control, we propose that reflection on histories of unintentional outcomes influences subsequent ideation.

Our theorizing is based on the psychological association between intention and effort (Heider 1958), the latter increasing feelings of control (Lafargue and Franck 2009; Minohara et al. 2016). This suggests focusing on unintentional outcomes might reduce feelings of control. Personal control is characterized as "a belief that individuals can intentionally produce desired outcomes and prevent undesired ones" (Skinner, Chapman, and Baltes 1988). In non-depressed populations, baseline control is generally high and people only reach low levels of control when their sense of control is threatened (Alloy and Abramson 1979; Cutright, Bettman, and Fitzsimons 2013; Langer 1975; Taylor and Brown 1988). Our interest is in the potential ability of focusing on unintentional outcomes to lower this high state of baseline control.

Past research has found that threats to control elicit an automatic inclination to regain control (Fiske, Morling, and Stevens 1996). Such attempts can manifest through heightened preference for utilitarian products associated with problem solving (Chen, Lee, and Yap 2017), products requiring consumers to engage in hard work allowing them to feel like they achieved outcomes themselves (Cutright and Samper 2014), and product extensions that provide external structure by fitting well with a parent brand (Cutright et al. 2013). These findings indicate threatened control can steer consumers towards exertion of effort, not away from it. We build on these findings to predict reflection on a history of failed intentions promotes ideation in a target domain by inciting motivation to regain threatened control.

This theorizing predicts focusing on failed intentions should only promote ideation in domains in which failure elicits motivation to regain control. When circumstances are perceived as uncontrollable such that behavior and outcomes appear independent, the "helplessness hypothesis" would suggest motivation to regain threatened control is subverted (Mischel, Zeiss, and Zeiss 1974; Peterson, Maier, and Seligman 1993; Staub, Tursky, and Schwartz 1971). Because domains vary in perceived malleability (Dweck, Chiu, and Hong 1995), focusing on failed intentions should promote ideation only in domains in which ability is perceived as malleable, but should discourage ideation in nonmalleable domains in which one does not expect to regain control.

Our first study demonstrates that focusing on a history of failed intentions promotes ideation relative to focusing on a history of successful intentions and a control condition. A posttest establishes a causal link between focusing on unintentional outcomes and threatened personal control. Our second study reveals that consumers do not intuit this effect, illustrating that this cognitive strategy may be overlooked and underused. Our third study rules out an alternative explanation, demonstrating that it is truly focusing on intentional versus unintentional outcomes, not merely focusing on failures versus successes, that influences ideation. Our fourth study investigates our proposed mechanism of an attempt to regain threatened control as driving the promotion of ideation, showing that promotion of ideation is specific to domains in which ability is perceived as malleable suggesting a belief that personal control can be regained.

The current research illuminates a novel mechanism through which cognition can be employed to positively influence behavior by promoting ideation through focusing on a history of one's own failed intentions. Research concerning procedural strategies to influence ideation has shown that structural aspects such as individual versus group brainstorming (Diehl and Stroebe 1987, 1991; Mullen et al. 1991; Stroebe and Diehl 1994), priming with different corporate brand images (Fitzsimons et al. 2008), using different reinforcement criteria (Glover and Gary 1976), and simultaneous versus sequential presentation of information about the topic of ideation (Dennis et al. 1996), all differentially impact ideation. The present research is the first to examine the impact of focusing on histories of one's own failed intentions on subsequent ideation, and adds to the literature on ideation by finding that such a process promotes ideation through attempts to regain threatened control. Further, it contributes to research highlighting beneficial effects of reduced control (Averill 1973; Burger 1987, 1989; Chen et al. 2017; Cutright et al. 2013; Cutright and Samper 2014). By having consumers focus on their unintentional outcomes, we reveal a novel process by which threatened control can be harnessed to create more value than high control.

These results have interesting implications for organizations ranging from LEGO to the U.S. Army that are increasingly turning to customers to develop creative ideas for the marketplace. Gartner Inc. estimates soon more than half of consumer goods manufacturers will get 75% of their innovation and R&D capabilities from this type of "crowdsourcing" (Knipp 2014). Our research suggests consumers may offer more insights, ideas and solutions to fulfill the marketplace's needs and wants, if they reflect on their previous failed intentions.

How Chunking in Graphical Information Processing Affects Consumer Decision Making

Julia Reinhard, University of Cologne, Germany
Hernán A. Bruno, University of Cologne, Germany

EXTENDED ABSTRACT

Graphs depicting changes of a magnitude over time or space are used widely in marketing, educational material, news, and public announcements. Consumers use graphs to make decisions in various contexts such as health (e.g., infectious diseases, product effectiveness over time), personal finance (e.g., interest rates), politics (e.g., immigration, elections) or climate change (e.g., global temperatures). A vast and disparate body of research has established the substantial impact of line graphs on decision outcomes (e.g., Hutchinson, Alba, and Eisenstein 2010).

This research investigates to what extent individuals process graphical information by grouping data points into subsets called chunks and how this process ("chunking") affects consumer decisions. Time series are characterized by uncertainty, discontinuity, and changes in level or trend, and graphs are often presented with additional design elements such as event markers, specific labels, superimposed trend lines for selected periods or other analytical information. It is still largely unknown how these characteristics and design elements affect consumer decision making. In two studies, we investigate how visual chunks delimited by changes in the data and design elements affect forecasts and decisions.

We extend prior research showing that graph comprehension is based on the chunk processing of information (Carpenter and Shah 1998) and propose that discontinuities in the graphical information flow serve to determine chunk boundaries. We build this argument based on previous research finding that object and event perception include processes in which points of discontinuities serve to segment objects into separate parts (Biedermann 1987) and ongoing experience into discrete events (Zacks 2020). Similar to how discontinuities guide attention in object and even perception, salient graph features and unexpected changes affect the attention of graph readers (O'Connor, Remus, and Griggs 1993, 1997; Ratwani, Trafton, and Boehm-Davis 2008). In line with these findings, we predict that changes in the data (e.g., changes in trend) and graphical design elements (e.g., event markers) serve to build visual chunks.

The literature documents that, when asked to make a forecast, individuals use heuristics to make inferences about trends or future values of data portrayed in graphs and weigh the most recent data points more (Alvarado-Valencia and Barrero 2014). We generalize these findings to a larger chunk being determined by discontinuities in the information flow. We predict that individuals rely relatively more on the last visual chunk to forecast future developments or decide between alternatives and ignore other available information (e.g., overall trend, developments in earlier chunks). Based on evidence that individuals assume past developments and trends to continue into the future which affects judgments and decisions (Harvey and Reimers 2013; Maglio and Polman 2016), we predict that the development in the last visual chunk influences decision making such that upward (vs. downward or flat) trends have a more positive effect on forecasts and decisions.

Study 1 (N=240) was conducted as paper and pencil survey on the campus of a large European university. Participants were shown line graphs depicting monthly product sales of fictional industrial products for 60 time periods. We manipulated the trend in the last visual chunk by introducing a change in trend from period t=40 either downwards or upwards. We generated different graphical patterns and used a counterbalanced within-subjects design such that each participant was presented with four graphs varying in the last trend and pattern but having exactly the same linear overall trend and statistical prediction. For each graph, we asked participants to forecast the future product sales at t=80. A linear mixed-effects regression showed that forecasts were significantly higher for graphs where an up- versus downwards trend in the last chunk was introduced (β=3.01, SE=.20, $p <$ .000, 95% CI=[2.66, 3.53]). These results showed that line graphs with varying trends in the last chunk led to significantly different forecasts despite having the same overall trend and statistical prediction.

Study 2 (N=271) recruited participants from the same population and consisted of two parts. Part 1 was similar to study 1 and employed a 2 (marker: early vs. late) x 2 (overall trend: negative vs. positive) within-subjects design. All graphs had the same functional form including two trend changes delimiting three visual chunks with a 1) flat, 2) positive or negative (depending on overall trend), and 3) flat chunk. For the early (late) condition, we included a marker at the first (second) change in trend which highlighted a trended (flat) last chunk. These markers were unrelated to the underlying data. While part 1 measured forecasts, part 2 consisted of a choice task and varied the location of the marker between-subjects. Each graph within a choice pair had the same linear prediction and overall mean, but differed in the underlying functional form such that graph A (B) had three visual chunks with a 1) positive (flat), 2) flat (positive), and 3) positive (flat) trend. Adding an early (late) marker highlighted a similar positive trend for both graphs (a positive vs. flat trend for graph A vs. B).

Study 2 showed that forecasts and choice shares for identical line graphs differed depending on the location of a superimposed marker. In part 1, forecasts were significantly closer to the series mean for the group which viewed graphs with a late (vs. early) marker highlighting a flat (vs. trended) last chunk (β=-1.08, SE=.24, $p <$ .000, 95% CI=[-1.63, -.56]). In part 2, a logistic regression showed a significant effect of the marker on choices (β=.99, SE=.26, $p <$ .000) such that in the early (late) condition option A was chosen by 48.9% (72.0%) and option B by 51.1% (28.0%).

Taken together, this research provides evidence for the role of chunking in graphical information processing and shows that chunks determined by discontinuities in the graph such as changes in trend and design elements affect forecasts and decisions. It generalizes existing findings on heuristics in graph-based decision making to show that individuals pay more attention to the last visual chunk and ignore information available in the whole data being presented. These results add to the literature on graph perception and have implications for the communication of quantitative information and public policy.

Dynamics of Consumption Experience – The Case of Eastern Express in Turkey

Bernd F. Reitsamer, University of Innsbruck, Austria
Andreas Kallmuenzer, La Rochelle Business School, France
Ayça Katitas, MCI Management Center Innsbruck, Austria

EXTENDED ABSTRACT

Delivering seamless consumption experiences has been a key priority for marketing scholars and practitioners over the past years (e.g., Lemon and Verhoef 2016). In fact, companies are increasingly seeking to expand their on-site experience towards early pre- and later post-consumption stages in the context of digital transformation. However, the question remains how to create consistent, memorable and seamless experiences. And even more important: How do consumption experiences unfold over time? This study targets to answer these questions and provides empirical evidence on the dynamic nature of experiential consumption.

Consumption experiences (CX) are subjective and embodied occurrences based on the interaction of the consumer and the environment (Holbrook and Hirschman 1982). They involve a great degree of sensory stimulation and can vary considerably in their intensity, valence and time-frame. Although extant research has accumulated a large body of knowledge addressing the nature of the concept, its dimensions, measurement, and consumers' responses (e.g., Brakus et al., 2009), it is striking that scholars have yet begun to conceptualize experiences from a dynamic perspective (e.g., Voorhees et al. 2017). This development is important because a considerable amount of the experience occurs during pre-consumption (i.e., need-recognition, information search, initial contact and booking) and post-consumption stages (i.e., memory retrieval, formation of attitudes and future behavior). Building on this dynamic perspective, the present research follows the call from Lemon and Verhoef (2016) towards a more journey-oriented, consumer-centric approach in the study of CX. We therefore conceptualize CX as embodied phenomenon (Barsalou, 2008), with consumers starting to form sensory perceptions, feelings and thoughts from early pre-consumption stage on towards the core encounter, storing them in memory and retrieving them as mental simulations throughout later post-consumption stages (Reitsamer et al. 2020). Since much of these projections and retrievals tend to be more positive than consumers' actual moment-by-moment evaluation (Wirtz et al., 2003), our study further builds on the rosy prospection and retrospection principle from cognitive science (Mitchell et al. 1997).

Our longitudinal research design follows a qualitative case study approach to explore CX over a period of four weeks. The context revolves around the Eastern Express (Doğu Ekspresi), an overnight passenger train departing from the Turkish capital Ankara to the city of Kars. Given the popularity and significance of the train ride, its long history and the high degree of sensory stimulation, the journey represents a suitable research setting to study the dynamics of CX. An ethnographic field study consisting out of three waves was conducted in February 2019. A total of 30 semi-structured interviews (each participant was interviewed before, during and after the train journey) and corresponding observational field notes were collected.

Results show that sensory, emotional, cognitive and behavioral dimensions of CX strongly differ in both their importance and their potential for prospection and retrospection. Among sensory cues, visual and motor impressions constitute the most important drivers for retrospection. Absorbing scenic impressions and sensing the continuous movement of the train resulted in rich cognitive schemata, which became stronger and more positive throughout post-consumption. This is consistent with previous consumer research confirming the dominant role of visual and motor input (Hecht and Reiner 2009). Auditory and haptic properties, however, played a subordinate role for both pro- and retrospection, even though previous research found that audition and touch become equally important to vision throughout post-stages (Fenko et al. 2010). The smoothing potential of the rosy view was particularly salient for olfactory impressions, as negative perceptions faded completely during later stages. Conversely, negative gustatory impressions persisted throughout post-consumption, unsusceptible of any rosy momentum. Similar to sensory input, emotions act as strong driver for cognitive processing. Particularly joy, comfort and happiness expressed during early stages of the experience gave rise to even more positive retrospective moments. As with sensory input, certain emotions were found to fade quickly (disgust), whereas others (dissatisfaction) continued to persist at later stages. Likewise, cognitive moments of nostalgia and learning simplified prospection and retrospection, as they enabled participants to relate the experience directly with their personal lives. Among behaviors, talking about the journey and sharing the experience with others constituted the two most prevalent themes. The conversational element was crucial during the journey and further expanded to post-stages by means of digital, customer-induced touchpoints (WhatsApp, Skype, Facebook, Instagram).

Practical implications of this study are manifold. From a corporate perspective, it is surprising how many (digital) touchpoints for interaction, bonding and persuasion remain unexploited during all three stages. Although consumers are taking the initiative for interaction with each other, show a clear desire to stay in touch and want to repeat similar experiences, the service provider in this study almost exclusively focused on the core-encounter and only showed marginal efforts to interact with consumers during pre- or post-core stages. Drawing on the study's results, firms are well advised to focus their CX strategies on visual and motor content and transfer them to pre- and post-encounters via company-induced, digital touchpoints. Since participants showed a strong tendency to share their experiences, firms need to ease the sharing process on digital channels, for example, by using memorable hashtags, creating social media sites of interest for their target audience or a dedicated mobile app to connect with co-travelers. Further, firms could stimulate cognitive learning experiences by providing a digital tour guide.

The present study is not without limitations as it focused on a specific peak-experience with a high level of visual and motor input people tend to remember well. Further, the valence of each experiential dimension might vary considerably in other servicescapes, different cultural areas or for alternative configurations along the product-service continuum. Lastly, since the sample consisted of a predominantly young group of international travelers, it would be interesting to study how touchpoints and retrospection differ for other target segments, such as elderly travelers.

"Recyclable or Not?" Consumers Cognitive Mechanisms Involved in an Everyday Uncertain Decision

Fanny Reniou, Université Rennes, CNRS, CREM-UMR 6211, France
Elisa Monnot, CY Cergy Paris Université, CNRS, THEMA, F-95000 Cergy, France

EXTENDED ABSTRACT

Encouraging households to recycle their waste is a major objective of sustainable development. Previous studies show that recycling is a matter of motivation, context or logistics. Following research on the cognitive determinants of recycling (Vining and Ebreo 1990; Ellen 1994; Kennedy et al., 2009; Izagirre-Olaizola, Fernández-Sainz and Vicente-Molina 2015), we argue that the way individuals use their knowledge about recycling is also crucial to understand this behaviour. Indeed, individuals' misunderstanding and doubts still lead to many mistakes, which may have damaging consequences. Using categorization theory (Rosch et al. 1976; Cohen and Basu 1987), this research aims at studying the cognitive mechanisms that underlie recycling behaviour. The objective is to answer the following question: how specific is the consumers' decision-making process in everyday recycling situations?

Research on waste recycling often study the determinants of recycling behaviour: socio-demographic variables (age, income, education level, gender, Guiot, Malas and Urien 2019), internal (environmental attitude, beliefs, values) and external motivation (social norms, financial incentives, laws, Shrum, Lowrey and Mc-Carty 1994) but also contextual and logistics variables (place at home, distance from collection points, Monnot, Reniou and Rouquet 2014). More recently, the literature investigates how several product-related characteristics influence disposal decisions to recycle (Trudel and Argo 2013; Trudel, Argo and Meng 2016). Few studies focus on cognitive determinants, i.e. knowledge about recycling, whereas some show that it is a significant determinant of recycling behaviour (Vining and Ebreo 1990; Ellen 1994; Kennedy et al. 2009; Izagirre-Olaizola et al. 2015).

The categorization theory is a relevant theoretical framework to study recycling decision-making. Indeed, recycling is an everyday decision of intermediate level (Cooper and Shallice 2000) but it can be complex for individuals who may doubt about their judgment on waste recyclability. Categorization mechanisms may help them resolve these doubts as they simplify the decision-making process. Other structuring effects may appear such as intuitive judgmental biases or "heuristics" (Tversky and Kahneman 1974), which simplify the decision-making process. The aim of this research is to understand the cognitive process that underlies recycling behaviour using the categorization theory.

We used a qualitative research design, which consisted in a data collection with twenty-four French recyclers. In a first step, respondents had to accomplish a recycling task of eighty types of waste (either recyclable or not). All respondents were in the same context and place, faced the same set of waste to recycle, without any time constraint and with two recycling bins ("recyclable" *vs.* "non-recyclable"). To reveal the respondents' thoughts and their internal system of categorization, we used the verbal protocols method; respondents explained aloud how they made their decision and why. In a second step, we conducted interviews to have a better understanding of the potential sources of error and difficulties linked to the recycling decision as well as consumers' emotions during this task. We used NVivo software to conduct a thematic content analysis of the data and a double coding.

This work enriches research on the cognitive dimension of recycling. It shows that recycling classification relies on packaging's representations (packaging materials, packaging category and packaging attributes) as well as on product's representations (product category, brand positioning and image). Beyond, individuals may use heuristics (such as representative heuristic, availability heuristic, anchoring heuristic, law of contagion, affective recruitment heuristic or imagination heuristic) to construct a mental representation of the recycling decision problem. Indeed recycling is a routine task for which individuals look for the easiest solution. Heuristics, cognitive biases and situations of mental discomfort, especially incongruence, may disrupt the categorization process in the case of recycling. All these disruptions of the categorization process may explain the famous gap between attitude and behaviour (Carrigan and Attalla 2001; Chatzidakis, Hibbert and Smith 2007). This research enriches the studies that used categorization theory for brands (Kreuzbauer and Malter 2005) or food products (Gallen et al. 2019). We apply this theoretical framework to the specific context of recycling, which implies a different relationship to the object of categorization (waste) leading to a particular categorization process. Recycling, as an everyday action of intermediate level (Cooper and Shallice 2000), often generates routine actions, which, surprisingly, do not necessarily imply a reduction in uncertainty. Indeed, individuals strongly rely on their representations to ease their recycling decision but they still may have doubts. Even habitual behaviours such as recycling require thought and may be associated with emotions, contrary to what the literature supports (Wood, Quinn and Kashy 2002).

By focusing on the cognitive dimension of recycling, this research raises some cognitive barriers that may lead to recycling errors. Therefore, it has implications for both manufacturers/packagers and public authorities who may use our results to improve packaging choices and consumer education regarding recycling.

Battling Fear, Building Trust: How Service Providers Manage Emotions When Consumers Fail

Ramona Riehle, University of Innsbruck, Austria
Verena E. Wieser, University of Innsbruck, Austria
Niklas Woermann, University of Southern Denmark, Denmark

EXTENDED ABSTRACT

This video-ethnographic study in a ski-schooling context explores how service providers manage consumers' emotions in situations of consumer performance failure. Drawing on the concept of emotional scaffolding (Meyer and Turner 2007; Rosiek 2003; Rosiek and Beghetto 2009), we reveal how service providers apply three strategies: decelerating, trust building, and goal aligning. These reduce unconstructive, and foster constructive emotional responses to consumer performance failure.

Consumer performance failures refer to situations in which consumers do not fulfill their own or other's performance expectations (Tumbat 2011). They often appear unexpectedly, and bring forth emotions of fear (Celsi, Rose, and Leigh 1993) or frustration (Seregina and Weijo 2017). If not being managed, consumers' emotional responses can impede positive consumer experience (Lindberg and Eide 2016; Molander and Hartmann 2018; Seregina and Weijo 2017; Tumbat 2011).

How do consumers overcome destructive emotions in case of performance failure? So far, consumer research has mostly focused on consumers' self-management of emotions in cases of failure, particularly suspending (Tumbat 2011), adjusting (Molander and Hartmann 2018), or circumventing destructive emotions (Mick and Fournier 1998; Seregina and Weijo 2017). However, some consumers may also seek and receive emotional support from service providers or more experienced peers.

To generate an in-depth understanding of how service providers manage consumers' emotional responses to performance failures, we conducted a video-ethnographic study of ski schooling services. We combined verbal with video-observational methods (Arnould and Wallendorf 1994; Le Guen 2009), participated in and video-recorded adult skiing lessons and conducted semi-structured interviews with novice consumers and experienced ski instructors. Subsequently, we applied open coding and analyzed the data set in several rounds of iteration.

Drawing on the concept of emotional scaffolding (Meyer and Turner 2007; Rosiek 2003; Rosiek and Beghetto 2009), which evolved from Vygotsky's (1978) sociocultural learning theory, we demonstrate that service providers play a crucial role in turning failed consumer performances into positive consumer experiences via interactive emotion management. We reveal that consumers' performance failures can be preceded and followed by unconstructive but also by constructive emotions. Furthermore, we uncover that service providers apply the three emotional scaffolding strategies of *decelerating, trust building, and goal aligning* to manage consumers' emotional responses to potential and actual performance failure.

Decelerating physically and mentally slows consumers down and reinforces body awareness (Husemann and Eckhardt 2018). Ski instructors apply decelerating to scaffold an emotionally calm and constructive atmosphere that gives consumers the time needed to accept potential risks and emotionally recover from failures. If performance failures occur, service providers balance unconstructive emotions by staying calm and patient, giving time to refocus, and adjusting tasks and terrain to a slower pace.

Trust building creates an emotionally supportive atmosphere of trust (Mahn and John-Steiner 2002), so that consumers can ac-

cept the risk of performance failure and reveal their emotions. To strengthen trust, ski instructors foster constructive emotions. From the first second of the lesson onwards, instructors demonstrate a friendly and open nature and praise consumers. After performance failures, instructors aim to restore trust. They react in a supportive manner, show physical proximity, and rationalize failure and accompanying emotions.

Goal aligning adapts performance goals to consumers' individual abilities. Consumers have only vague ideas about the process of learning and are often unaware of how their individual fitness level, previous experiences, or cultural backgrounds influence their performance. Consumers may become frustrated by a lack of progress, or being unable to keep up with their group members. Ski instructors avoid such unconstructive emotions through carefully exploring consumers' boundaries and adapting their lesson goals accordingly.

Our contributions to consumer research are twofold: First, we complement research that reveals how consumers self-manage their emotions in case of performance failure (Mick and Fournier 1998; Molander and Hartmann 2018; Tumbat 2011) with a case of interactive emotion management. While we have focused on service providers' emotional support, further research may study how peers help consumers to resolve "emotional tension" from failures (Lindberg and Eide 2016). Second, our research suggests that consumer performance failure may enhance consumer experience, rather than compromise it—if emotions are managed well. In contrast to previous managerial literature, which has proclaimed that prevention is key to managing consumer failure (Tax, Colgate, and Bowen 2006), our research reveals that there is a constructive emotional potential in performance failure and that consumers can turn failure into a learning opportunity in interaction with service providers. Further research may study how consumers and service providers embrace failure as a "critical first step in a journey of discovery and learning" (Cannon and Edmondson 2005, 299) in other service contexts.

You Betrayed Me: The Dark Side of Reciprocal Reviewing

Laura Rifkin, Brooklyn College, USA
Canan Corus, Pace University, USA
Colleen P. Kirk, New York Institute of Technology, USA

EXTENDED ABSTRACT

The peer-to-peer (P2P) sector of the sharing economy is unsustainable without reciprocal reviewing reputation systems. Whereas researchers have examined the effect of reviews by consumers on sellers, in this research we examine, for the first time, a turn of the tables in which sellers review consumers. We propose that, given the reputational harm consumers can perceive from a negative review, P2P consumers retaliate using negative word of mouth (NWOM) not only against the peer provider, but also against the platform.

Psychological contracts are implicit agreements that arise when one party believes another is obligated to perform certain behaviors, and psychological contract violations can lead to feelings of betrayal that motivate retaliation (Robinson and Morrison 2000). P2P consumers expect platforms to protect members from harm inflicted by other peers (Perren and Kozinets 2018). Therefore, we propose that unless individuals knowingly commit a transgression, a negative review is considered a violation of the psychological contract between the consumer and the platform, resulting in perceived betrayal by the platform and NWOM (studies 1 and 2). Further, whether a violation leads to retaliation depends on attribution of the violation to the other contractual party, the fairness of procedures following the violation, and the magnitude of the perceived outcomes of the violation (Robinson and Morrison 2000). Accordingly, we demonstrate that the effect of review valence on NWOM through betrayal is intensified when the platform endorses (does not endorse) a host (study 3); does not allow (allows) a response to the review (study 4); and makes the review public (keeps it private; study 5).

Study 1. 87 students joined *Students4Students,* an ostensibly real P2P platform. After borrowing and using a textbook and reviewing the lender, participants received either a positive or negative review from the lender. They then reviewed the *Students4Students* platform with a star rating and comment on an independent review website. A negative (positive) review elicited *Students4Students* a lower star rating (M = 4.1 vs. 4.6; F(1, 85) = 7.88; p = .006); more negative comments (36.4% vs. 16.3%; χ^2(1) = 4.51; p = .034); and greater NWOM (M = 2.54 vs. 1.98; F(1, 85) = 3.88; p = .052).

Study 2. 222 Mturk participants imagined they had rented a house from Vacation Connections, a P2P platform, and followed (did not follow) the house rules. They received a negative (positive) review from the host. When participants received a positive review, perceived obligation fulfillment did not affect NWOM. However, when participants received a negative review, they reported greater NWOM when they fulfilled their obligations (M = 5.28) than when they did not (M = 3.14; F(1, 208) = 61.14; p < .001). Bootstrap analysis confirmed moderated mediation by perceived betrayal in this study and Studies 3, 4, 5.

Study 3. 360 Mturk participants read the study 2 scenarios and then read their host was (was not) a Premier Partner endorsed by Vacation Connections. When participants received a positive review, host endorsement had no impact on NWOM. However, after receiving a negative review, participants reported increased NWOM (M = 5.2 vs. 4.6; F(1, 337) = 5.73; p = .017) and made more negative comments (73.5% vs. 56.5%; χ^2(1) = 5.49; p = .019) when the platform endorsed (did not endorse) the host.

Study 4. 362 Mturk participants read the study 2 scenarios, then that the platform's response policy allows (does not allow) guests to respond to host reviews. Upon a positive review, response opportunity had no impact on NWOM. However, after receiving a negative review, participants reported increased NWOM (M = 5.5 vs. 4.5; F(1, 348) = 23.29; p < .001) and made more negative comments (85% vs. 54%; χ^2(1) = 19.94; p < .001) when the platform provided no opportunity (vs. an opportunity) to respond.

Study 5. 367 MTurk participants imagined renting a car from *Car Connections*, a P2P car sharing platform, and read that host reviews were public (private). When participants received a positive review, public/private had no impact on NWOM. However, when participants received a negative review, NWOM was greater (M = 5.2 vs. 4.5; F(1, 350) = 9.27; p = .003) and participants rated the platform fewer stars (M = 1.98 vs. 2.33; F(1, 350) = 5.29; p = .015) when the platform made the review public (vs. private).

In summary, although reviews of consumers originate from peer providers rather platforms, we show that consumers target platforms with NWOM when they are negatively reviewed. This effect is explained by perceived betrayal, and is augmented by commonly used platform intermediation choices.

Mistakes Were Made: The Unintended Consequences of
Lighting and Identity-Relevant Mistakes on Marketplace Evaluations

Christine Ringler, University of Alabama, USA
Tracy Rank-Christman, University of Wisconsin - Milwaukee, USA

EXTENDED ABSTRACT

Personalization, a successful retail practice, is not only becoming more common, but these days, is practically expected by consumers (Byron 2019). Personalization has an overall positive impact on sales, with one retailer showing that when employees were able to tailor product recommendations to consumers, via an app, the company "generated a 10% lift in incremental sales and a 5% increase in transaction-size growth" (Boudet et al. 2018). From using consumer names (e.g., Starbucks) to knowing specifics about consumers, such as shoe size or color preferences (e.g., Nike; Safdar 2019), personalization varies from brand to brand in terms of just how personal the marketer is willing to get with their consumers. With the rise of personalization in a marketplace of billions, marketers have and will continue to make some mistakes (Kapner 2017).

There are a variety of ways that retailer's attempts at personalization can backfire. For instance, recognizing consumers may not always occur. Henderson et al. (2018) show that identifying returning customers of various races by face, at times, can be difficult for frontline employees. In addition, in retail environments that use names (e.g., Panera) to identify consumers orders, people may experience being called by the wrong name or even addressed as the wrong gender (Rank-Christman, Morrin, and Ringler 2017). All of these are examples of failed attempts at personalization that are tied closely to the consumer's identity, which is where we focus our research. Specifically, we ask, how do these identity-relevant mistakes impact consumers?

We investigate identity-relevant mistakes or errors that occur in the marketplace that pertain to the consumers identity, both personal and social. Personal identity relates to a consumer's individual identity, "a decontextualized description of personal traits, characteristics, and goals" (Oyserman 2009, p. 251), including their age, gender, and name. While social identities are contextualized and describe a group of people (e.g., university name; Oyserman 2009). Using various types of identity-relevant mistakes, we explore their impact on our dependent measures, consumer evaluations and negative post-purchase intentions, across four studies. Specifically, we look at the consumer's overall evaluation of the experience (product or service) and we explore negative post-purchase intentions, which is a combination of repatronage intentions, negative word-of-mouth, and complaint behavior (DeWitt and Brady 2003). These two dependent measures are vital, as they are clear indicators of consumer satisfaction and loyalty (Blodgett, Grandbois, and Walters 1993; DeWitt and Brady 2003). However, we believe the relationship between identity-relevant mistakes and our dependent measures will be moderated by something out of the consumer's control, atmospherics – specifically, lighting levels.

One of the easiest and most important (Areni and Kim 1994) ambient factors to change in brick-and-mortar stores and restaurants is the lighting level. Restaurants lower the lights during dinner and retail stores, such as Abercrombie & Fitch and Hollister, keep their lighting levels lower during store hours. In addition, concert venues, stadiums, and other establishments change the environments lighting levels throughout the consumers consumption experience. As it relates to identity, dimmer lighting has been shown to increase feelings of deindividuation (e.g., Zhong, Bohns, and Gino 2010). Interestingly, deindividuation has also been linked to decreased feelings

of uniqueness, which is an important dimension in feeling like one matters (Flett 2018).

To date, the literature has shown that deindividuation diminishes self-regulation and self-awareness (Diener 1980) and decreases honesty (Spears and Lea 1994). Bright lights often have the opposite effect, that is people feel more individuated (Maslach, Stapp, and Santee 1985). One unintended consequence of lowering (raising) the lighting levels in retail and service establishments is increased (decreased) feelings of deindividuation (e.g., Zhong et al. 2010). Yet, to our knowledge, it remains unknown as to how lighting, which results in deindividuation or individuation, interacts with marketplace identity-relevant mistakes and the impact these variables have on consumer evaluations and negative post-purchase intentions. Given past research in this area, we would expect identity-relevant mistakes to result in lower evaluations and increase negative post-purchase intentions, however, the interaction effect of these marketplace mistakes combined with consumer deindividuation as a result of lighting, has yet to be explored.

Since bright lights have been shown amplify, as the "the hot emotional system" becomes activated (Xu and Labroo 2013, p. 207), there is a chance that identity-relevant mistakes that occur in a brightly-lit environment will become amplified and thus, will have a negative impact on marketplace evaluations and negative post-purchase intentions. Yet, in four studies, we demonstrate the opposite actually occurs. That is when identity-relevant mistakes occur in a dimly-lit environment (i.e., consumer is deindividuated; pre-tested), the mistake becomes magnified, which results in lower experience ratings and higher levels of negative post-purchase intentions. We believe that this magnification occurs because when the consumer enters an environment that has dim lighting, the consumer experiences deindividuation, which has been identified as an important dimension of mattering (Flett 2018). When an identity-relevant mistake is added to that initial feeling of deindividuation, the consumer not only experiences an identity-relevant mistake, but experiences a sense of not mattering, which in turn amplifies the negative effect of the mistake.

In several studies, we show that feelings of not mattering are the underlying driver of this effect. Mattering reflects a customer's need to feel significant, which is often determined by how others see us (Cooley 1998; Flett 2018; Rosenberg and McCullough 1981). This notion is important and is based on the "looking glass self," (Cooley 1998), which suggests that one's identity exists, only as a result of the social other, as people see themselves based on how others see them. Therefore, feeling like one does not matter by a social other, in this case the service provider or marketer, is likely to have profound negative effects on the consumer. Building on this work, we predict that when consumers are in a dimly-lit room (deindividuated) and experience an identity-relevant mistake, they will experience feelings of not mattering. Feeling like one does not matter will then negatively impact consumer evaluations and increase negative post-purchase intentions. We explore this prediction across four studies utilizing different marketplace contexts.

The purpose of **Study 1** is to demonstrate that consumers who experience an identity-relevant mistake (vs. no mistake) in a dimly-lit room will rate the experience more negatively. While those in the brightly-lit room should not rate their experience any different. Participants completed a 2 (Mistake Type: identity-relevant mistake, no

mistake) X 2 (Lighting: bright, dim) between-subjects design. For mistake type, participants were addressed by their correct last name (no mistake) or by their last name but with an 'ie' added to the end (identity-relevant mistake).

Results indicate that those in the identity-relevant mistake condition, rated their experience as lower when the room was dimly-lit (M = 4.83) versus brightly-lit (M = 5.18, $F(1, 515) = 6.49$, $p = .01$). For those in the no mistake condition, there was no difference in evaluations (M_{dim} = 5.34 vs. M_{bright} = 5.25, $F < 1$). See table 1 for the main effects in studies 1-4.

In **Study 2**, we replicate and extend the effects established in Study 1, by exploring the underlying process driving these effects (i.e., feelings of not mattering). Participants completed a 2 (Mistake Type: identity-relevant mistake, no mistake) X 2 (Lighting: bright, dim) between-subjects design. For mistake type, participants were addressed by their correct last name (no mistake) or by the last name of Smith (identity-relevant mistake).

Results suggest that those in the identity-relevant mistake condition, rated the product as lower when in the dimly-lit (M = 4.79) versus brightly-lit (M = 5.64, $F(1, 422) = 25.97$, $p < .0001$) condition. Further, those in the identity-relevant mistake condition, indicated more negative post-purchase intentions when in the dimly-lit (M = 3.01) versus brightly-lit condition (M = 2.68; $F(1, 422) = 8.31$, $p = .004$). Additionally, those in the identity-relevant mistake condition, indicated greater feelings of not mattering when in the dimly-lit (M = 3.38) versus brightly-lit (M = 2.92, $F(1, 422) = 7.84$, $p = .01$) condition.

Using PROCESS model 8 (Hayes 2017), we find that feelings of not mattering mediated the relationship between mistake type and lighting on both dependent variables (product evaluation and negative post-purchase intentions), but only when in the dimly-lit condition.

Study 3 demonstrates that while all mistakes are likely to result in lower evaluations and more negative post-purchase intentions, identity-relevant (vs. marketplace-relevant) mistakes magnify those negative effects due to feelings of not mattering for the consumer. Participants, all in a dimly-lit room, completed a 2 (Mistake: mistake, no mistake) X 2 (Relevance type: identity-relevant, marketplace-relevant) between-subjects design. For identity-relevant mistake, participants received the rival team cup or the home team cup (no mistake). For the marketplace-relevant mistake, participants received iced tea instead of the drink they ordered. They received the drink they ordered in the no mistake condition.

Results suggest that when a mistake was made, participants a lower experience rating in the identity-relevant (M = 2.31) versus marketplace-relevant condition (M = 3.83, $F(1, 629) = 98.47$, $p < .0001$). However, when no mistake was made, participants rated the experience higher when in the identity-relevant (M = 6.00) versus marketplace-relevant condition (M = 4.36, $F(1, 629) = 135.59$, $p < .0001$), highlighting that when personalization is done wrong, there can be negative consequences; yet, when personalization is done right, it can boost evaluations.

Further, when a mistake was made, participants indicated increased negative post-purchase intentions when in the identity-relevant (M = 5.36) compared to the marketplace-relevant condition (M = 4.09, $F(1, 629) = 141.10$, $p < .0001$). However, when no mistake was made, participants indicated decreased negative post-purchase intentions when in the identity-relevant (M = 2.18) versus marketplace-relevant condition (M = 2.52, $F(1, 629) = 11.22$, $p = .001$) again highlighting the benefits of personalization.

Additionally, when a mistake was made, participants indicated greater feelings of not mattering in the identity-relevant condition (M = 4.19) compared to the marketplace-relevant condition (M = 3.29, $F(1, 629) = 49.87$, $p < .0001$). When no mistake was made, participants indicated marginally lower feelings of not mattering in the identity-relevant (M = 2.56) versus the marketplace-relevant condition (M = 2.78, $F(1, 629) = 3.50$, $p = .06$).

Using PROCESS model 8, we find that feelings of not mattering mediated the relationship between mistake and relevance type on both dependent variables, but only when an identity-relevant mistake was made.

Study 4 demonstrates how the negative effects seen in studies 1-3 can be mitigated, specifically by using a marketing message that highlights customer recognition. Participants, all in a dimly-lit room, completed a 2 (Mistake Type: identity-relevant mistake, no mistake) X 2 (Recognition message: present, absent) between-subjects design. Mistake type was manipulated as in Study 3. When the recognition message was absent, participants heard: "Thank you for shopping at the concession stand." When the message was present, an additional line was added: "We recognize you for being a great customer!"

Those in the identity-relevant mistake condition rated their overall experience as more positive when the recognition message was present (M = 3.20) versus absent (M = 2.32, $F(1, 217) = 16.73$, $p < .0001$). However, those in the no mistake condition rated their overall evaluation as being no different regardless of whether the recognition message was present (M = 6.06) or absent (M = 6.07, $F < 1$). Further, those in the identity-relevant mistake condition indicated less negative post-purchase intentions when the recognition message was present (M = 4.16) versus absent (M = 4.65, $F(1, 217) = 7.73$, $p = .006$). For those in the no mistake condition, negative post-purchase intentions were no different regardless of the presence of the recognition message ($M_{present}$ = 2.11 vs. M_{absent} = 1.99, $F < 1$).

Results also suggest that those in the identity-relevant mistake condition indicated greater feelings of not mattering when the recognition message was absent (M = 4.53) versus present (M = 3.96, $F(1, 217) = 8.87$, $p = .003$). Those in the no mistake condition rated their feelings of not mattering no differently as a result of the recognition message being present (M = 2.12) or absent (M = 2.16, $F < 1$).

Using PROCESS model 8 (Hayes 2017), we show that feelings of not mattering mediated the relationship between mistake type and recognition message on both dependent variables for the identity-relevant mistake condition.

Results from these four studies add to conversations in sensory marketing, identity-relevance, mistakes, and consumer feelings of not mattering. From this work, we show that consumers feel like they don't matter (e.g., Flett 2018) when identity-relevant mistakes occur in the dark and in turn, they evaluate their marketplace experience more negatively and they report higher negative post-purchase intentions compared to those that feel they have been recognized. Important theoretical and managerial implications result from these findings.

When Wanting Closure Reduces Patients' Patience

Annabelle Roberts, University of Chicago, USA
Ayelet Fishbach, University of Chicago, USA

EXTENDED ABSTRACT

In the consumption of healthcare, waiting is ubiquitous. Patients need to wait for an available appointment, wait until the doctor is ready to see them at the appointment, and wait until a treatment is ready to be administered. Despite the frequency of its occurrence, waiting is an unpleasant experience. According to surveys, one in five patients have switched doctors because of long wait times and 30% of patients have left a doctor appointment before receiving any care due to a long wait (Mattio 2018). Thus, patients' experiences while waiting influence their consumption of medical care. It affects their medical decision-making and evaluations of the care they receive.

What makes the experience of waiting for medical care so unpleasant? We hypothesize patients are impatient because they are tempted to reach closure quickly and put the medical procedure out of mind. This is because completing a goal is a gain and leaving a goal unresolved is a cost. Specifically, finishing the goal is a gain because it is a source of satisfaction. People are eager to finish their goals and this eagerness to achieve a goal increases when people get closer to goal attainment (Hull 1934; Kivetz, Urminsky, and Zheng 2006; Koo and Fishbach 2012). Further, not finishing a task can be costly because people either cannot get the unresolved goal off of their mind (Zeigarnik 1927) or actively invest effort in trying to remember to complete the goal.

We thus predict that one reason why patients are impatient is because they desire closure on their medical goals. Specifically, people are willing to endure worse health care more when it enables them to achieve goal closure sooner than the better health care (H1). For example, people may be willing to compromise the quality of health care or ease of a procedure if it allows for earlier closure.

Moving beyond intertemporal choice, we further predict that the experience of impatience has consequences for health habits. Whereas patience was traditionally studied within the intertemporal choice paradigm (Ainslie and Haslam 1992; Frederick, Loewenstein, and O'Donoghue 2002), many medical situations that involve patience do not impose a choice between options that differ in their timing and value. For example, people are often simply required to wait for a medical appointment or test results. We define the experience of patience as one's ability to wait without suffering. It stands in contrast to feeling discomfort, agitated, frustrated, and ultimately, impatient, while waiting.

Previous research documented that impatience in intertemporal choice (i.e., high discount rates) is negatively associated with healthy habits (Urminsky and Zauberman 2017). Here we predict that the *experience of impatience* would also be negatively associated with healthy habits (H2). For example, we predict people who experience more impatience in everyday life are less likely to go to the doctor for regular checkups or eat healthy meals instead of opting for fast food.

Finally, based on the notion that eagerness to complete a goal increases when closer to goal attainment we predict people experience more impatience when they are closer to completing a medical appointment (H3). For example, we predict people will have a harder time tolerating wait periods when they expect the appointment to start soon (vs. in a while) or when they are waiting at the end of an appointment (vs. at the beginning). Relatedly, we predict people will experience more impatience when waiting in the exam room than in the reception area, as the exam room is closer to completing the medical appointment.

In what follows, we describe six preregistered studies (N=1,908) that tested these hypotheses.

Study 1

Using an incentive-compatible task, Study 1 tested whether people would prefer a worse healthcare product more when it enables earlier goal closure (H1). Participants chose between two health products, one superior to the other, which would arrive at the same time. The only difference was in the time participants would complete the work to receive them.

This study used a 2 (Timing: inferior product sooner vs. simultaneous) between-participants design. Prolific participants read about a pulse oximeter, which is a medical device that clips onto the finger to read blood oxygen levels and heart rate. The device became popular during the COVID-19 pandemic because having low oxygen levels can be a sign of the disease.

Participants were invited to choose between completing a bonus task for a chance to win a standard pulse oximeter (inferior option) or a premium pulse oximeter (superior option). In order to enter either lottery, participants read they would need to complete a bonus task at a later time. The bonus task for the premium pulse oximeter would occur in two weeks. We manipulated the timing of the bonus task for the standard pulse oximeter. In the inferior-product-sooner condition, participants read they could complete the bonus task for the standard pulse oximeter lottery tomorrow, while in the simultaneous-products condition, participants read they could complete the bonus task for the standard pulse oximeter in two weeks. Importantly, participants learned they would receive the pulse oximeter in three weeks regardless of which lottery they chose to enter. Completing the bonus task sooner would not result in getting the product sooner.

In support of H1, participants were more likely to choose to enter the lottery for the standard pulse oximeter in the inferior-product-sooner condition (26%) than in the simultaneous-products condition (14%), $X^2(1,N=367)=8.21$, $p=.004$.

In this incentive-compatible study, participants preferred to finish work sooner, even if it meant an inferior reward. People valued advancing goal closure more than the additional benefit from receiving a better healthcare device.

Study 2

Study 2 tested whether people prefer a painful treatment more when it allows them to achieve closure sooner (H1).

This study used a 2 (Timing: painful treatment sooner vs. simultaneous treatments) between-participants design. University students read they were leaving for an international trip in one month. Before they leave the doctor recommended boosting their immunity to several infectious diseases that they can only catch while abroad. There were two, equally effective options for boosting their immunity: a painful shot or a painless medication.

Participants read the medication would be available in two weeks. We manipulated the timing of the shot. In the painful-treatment-sooner condition participants read they could come back to the doctor to get a shot tomorrow, while in the simultaneous-treatments condition participants read they could come back to the doctor to get a shot in two weeks.

In support of H1, participants were more likely to choose the painful shot in the shot-sooner condition (68%) than in the shot-simultaneous condition (31%), $X^2(1,N=201)=27.99$, $p<.001$.

Taken together, Studies 1-2 find that the ability to achieve closure on a health goal increases impatience. Specifically, people opt for inferior medical devices (Study 1) and procedures (Study 2) when it enables them to achieve closure sooner.

Study 3

Study 3 tested whether the experience of impatience is negatively associated with healthy habits (H2). We also tested whether high discount rates (i.e., impatient decisions) are negatively associated with healthy habits.

University students completed an impatience scale (Schnitker 2012), healthy habits scale, and discount rate questions. The impatience scale assessed participants' interpersonal impatience, impatience with life hardships, and impatience with daily hassles. The healthy habits scale measured: exercise, healthy eating habits, weight control, sleep, temper, reckless driving, addiction, physical health care, oral health care, and a friend's description of their healthy habits. To measure participants' discount rate, participants imagined choosing between receiving $100 immediately and another amount later (Hardisty, Thompson, Krantz, and Weber 2013). Participants reported how much the future amount would need to be to make it as attractive as receiving $100 immediately. We then used these responses to calculate participants' hyperbolic discount rates.

In support of H2, the impatience index ($M=3.33$, $SD=0.93$) was negatively correlated with the healthy habits index ($M=5.37$, $SD=0.76$; $r=-.227$, $p=.022$). Participants who exhibited more impatience were less likely to engage in regular healthy habits. Additionally, participants' discount rates were negatively correlated with the healthy habits index at six months ($M=6.82$, $SD=11.99$; $r=-.287$, $p=.003$) and one year ($M=12.35$, $SD=29.09$; $r=-.391$, $p<.001$). Importantly, the experience of impatience predicted adherence to healthy habits when controlling for the discount rates ($b=-0.19$, $p=.015$).

These findings suggest that impatience is associated with health behaviors in everyday life. People who both feel more impatient and have a higher discount rate are less likely to engage in regular healthy habits, including going to the doctor for regular check-ups and vaccinations.

Study 4

In Study 4, we assessed whether people become impatient when they are close to completing a medical goal (H3). We predicted that after waiting for 9 minutes, those expecting the total wait to be 10 minutes would be more impatient than those expecting the wait to be 20 minutes.

This study used a 2 (Expected wait: 10 minutes vs. 20 minutes) × 2 (Time of measurement: 3 minutes vs. 9 minutes) mixed design, where the expected wait time was a between-participants factor and time was a within-participants factor. MTurkers read a scenario where they had an appointment at the doctor's office and were waiting until the doctor was ready for the appointment. Participants rated how impatient they would be after 3 minutes and after 9 minutes.

Participants reported they would feel more impatient after waiting for 9 minutes than after waiting for 3 minutes, $F(1,333)=194.05$, $p<.001$, $\eta_p^2=.37$. There was no significant main effect of the Expected wait time ($p=.295$).

In support of H3, we also found a significant Expected wait × Time of measurement interaction, $F(1,333)=19.75$, $p<.001$, $\eta_p^2=.06$. After 3 minutes, participants reported a similar level of impatience, regardless of whether they expected to wait for 10 minutes or 20 minutes, $t(333)=0.19$, $p=.850$. However, after 9 minutes, participants reported more impatient if they expected the wait to take 10 minutes compared to 20 minutes, $t(333)=2.26$, $p=.025$. We summarized these findings in Figure 1.

Study 4 found that the same experience of waiting was worse for patients when they were closer to completing the wait period.

Study 5

In Study 5, we tested H3 by comparing people's impatience when waiting for the doctor to sign a form before receiving a medical checkup versus after receiving a medical checkup. We predicted that participants would be more impatient when waiting after the checkup, when they were closer to completing the appointment.

This study used a 2 (Wait: before vs. after) between-participants design. Prolific participants read that they have been waiting for the doctor to sign a medical form for 30 minutes already. In the wait-before condition, participants read that the nurse practitioner is ready to start the checkup, but the doctor needs to sign the form before the checkup can start. In the wait-after condition, participants instead read that the nurse finished the checkup, but the doctor needs to sign the form before the participant can go home.

In support of H3, participants reported more impatience when waiting after the checkup ($M=5.15$, $SD=1.37$) compared to when waiting before the checkup ($M=5.43$, $SD=1.21$), $t(395)=2.14$, $p=.033$.

In Study 5, participants experienced more impatience when they were closer to finishing a medical goal.

Study 6

When checking into a medical appointment, patients typically expect to first wait in the reception area with other patients and then wait again in the individual exam room. Clinics can choose what portion of the time patients wait in the reception area versus the exam room. What are the implications for patients' patience? Because the exam room is closer to finishing the goal of receiving medical care, we predicted people experience more impatience when waiting in the exam room compared to the reception area (H3).

This study used a 2 (Waiting Area: exam room vs. reception area) between-participants design. Prolific participants read a scenario where they are at the doctor's office for a routine annual check-up, and the nurse has them either sit in the exam room or the reception area until the doctor is ready to see them.

In support of H3, participants felt more impatient when waiting in the exam room ($M=3.98$, $SD=1.39$) compared to the reception area ($M=3.63$, $SD=1.43$), $t(378)=2.49$, $p=.013$.

Participants experienced more impatience when waiting for an appointment to start in the exam room than the reception area. Considering the desire for goal closure can improve the consumption of healthcare, such as by reducing the amount of time spent waiting in the exam room as opposed to the reception area to minimize impatience.

General Discussion

Across six studies, we explored how people's desire for goal closure affects impatience in the domain of health decisions. We find that people choose to receive worse medical devices and procedures in order to achieve goal closure. We also find that the chronic experience of impatience has important consequences for health habits above and beyond discount rates. Finally, when the desire for goal closure increases—as a function of getting closer to goal completion—people experience greater impatience. We propose that considering the desire for goal closure can improve the design of medical waiting periods to minimize impatience.

Whereas impatience was traditionally studied within the intertemporal choice paradigm, many everyday situations involving impatience do not impose a choice between options that differ in timing and value. People are often required to wait, either because they have no alternative or because they already chose the larger-later option in an intertemporal choice. In the present research, we explore patience as both the decision to wait for the larger-later option and the experience of waiting without suffering. To that end, we believe this work exposes a fundamental new dimension to what it means to be patient.

Additionally, our findings reveal a novel cause of impatience. While impatient decisions are often thought to be the result of an individual's ability to resist immediate temptations (Loewenstein 1996; Mischel, Shoda, and Rodriguez 1989), we find many impatient medical decisions are not driven by the appeal of the immediate temptation. Impatience in these contexts is due to an individual's desire to achieve closure on a health goal.

Critically, our findings offer practical implications for the consumption of healthcare. We propose that medical facilities can minimize patients' impatience by reducing the amount of time patients spend waiting in the exam room versus the reception area or having patients complete administrative tasks at the beginning of the appointment when the desire for goal closure is low. Implementing changes to reduce patients' desire for goal closure can improve both their emotional well-being and evaluations of the medical care.

Building Brands for the Emerging Bicultural Market: The Appeal of Paradox Brands

Maria A. Rodas, University of Southern California, USA
Deborah Roedder John, University of Minnesota, USA
Carlos J. Torelli, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

One of the most important challenges marketers face is how to build and manage brands to respond to demographic changes taking place around the world. One of the most visible changes is the growth of bicultural consumers, who are individuals who have been exposed to and internalized two different cultures, such as Hispanic Americans and Asian Americans. In the U.S. alone, bicultural consumers are 120 million strong, representing more than a third of the population and with $4.1 trillion in buying power. Further, they are the fastest growing segment of the U.S. population, accounting for 92% of the total growth in the U.S. population from 2000 to 2014 (Nielsen 2015).

This opportunity is widely recognized by marketers, as indicated by the increasing media spending to target bicultural consumers, but there is relatively little research that investigates brand building practices that could be particularly successful with these consumers. Most of the research to date in this area has focused on advertising, specifically bilingual advertising (e.g., Kubat and Swaminathan 2015; Luna and Peracchio 2005; Noriega and Blair 2008) and advertising that promotes particular cultural values (Lau-Gesk 2003), or on the shifting responses of these consumers upon assimilation to an accessible cultural frame (Chen, Ng, and Rao 2005; Ng 2010). The vast majority of cultural research compares consumers from different cultural orientations, such as collectivist versus individualistic cultures or cultures with independent versus interdependent self-construals. However, this work focuses on consumers with a single cultural orientation (monocultural), not bicultural consumers.

In this article, we begin an examination of what types of brands are likely to be more successful with bicultural consumers. We focus on how to design brand identities for bicultural consumers, asking the question: Are there certain types of brands that are more appealing to bicultural (vs. monocultural) consumers? We focus on brand identities because they represent the firm's definition of what the brand is and how it is positioned vis à vis other brands, which provides the platform for communicating with consumers and competing in the marketplace (Aaker 1996; John and Torelli 2017; Keller 2013).

We identify a novel type of brand that proves to be particularly appealing to bicultural consumers, which we refer to as paradox brands. Paradox brands have identities that incorporate contradictory meanings, such as opposite brand personalities (e.g., rugged and sophisticated) or brand values (e.g., openness to change and conservation).

We test our predictions in five studies. In study 1, the objective was to demonstrate that bicultural consumers respond more positively to paradox brands than do monocultural consumers. This study was conducted in a field setting, with monocultural participants recruited from a farmers' market in a predominantly White neighborhood of a large U.S. city, whereas bicultural participants were recruited from a vendors' market targeting Latinos in the same city and on the same weekend. Participants took the survey in exchange for a tote bag. We find that bicultural consumers respond more positively to paradox brands than do monocultural consumers 60.6% vs. 45.3%, $\chi^2(1)=5.51$, $p=.02$), and in fact, bicultural consumers choose paradox brands over non-paradox brands ($t(116)=2.36$, $p=.02$).

In study 2, we examine cognitive flexibility as the mechanism responsible for why bicultural consumers respond more positively to paradox brands. To do so, we recruited monocultural (non-Hispanic White Americans) and bicultural (Hispanic Americans) participants and presented them with information about either a paradox or non-paradox brand. We show that cognitive flexibility mediates the effect of culture in response to paradox brands (mediated effect=.17, SE=.11, 95% CI=.02 to .47).

Study 3's objective was to provide further evidence for cognitive flexibility by showing that even monocultural consumers can respond positively to paradox brands if they are primed to be more cognitively flexible. Results revealed that participants in the cognitive flexibility prime condition had more positive evaluations of the paradox brand than participants in the control condition ($M=5.11$ vs. 4.69, $F(1,198)=4.96$, $p=.03$, $\eta_{partial}^2=.02$).

In the last two studies, we examine bicultural consumers in more detail. In study 4, we find that individual differences in cognitive flexibility among bicultural consumers produce different responses to paradox brands (mean indirect effect=.25, SE=.11, 95% C.I.=.05 to .47). Specifically, bicultural consumers with greater cognitive flexibility (+1SD) respond more positively to paradox brands (indirect effect=.42, SE=.12, 95% C.I.=.19 to .67) than bicultural consumers with lower cognitive flexibility (-1SD, ns). This result provides further evidence for cognitive flexibility as the process underlying cultural differences and rules out the possibility that the cultural differences we observe in our prior studies could be attributed to other differences between these groups. That is, differing levels of cognitive flexibility among bicultural consumers produce the same pattern of response to paradox brands as do differing levels of cognitive flexibility between bicultural versus monocultural consumers.

In study 5, we examine differences among bicultural consumers of particular importance to marketers. Specifically, we study subgroups of bicultural consumers based on acculturation strategy, either integrated (cultural backgrounds are integrated) or separated (cultural backgrounds remain separated). We find that bicultural consumers who are integrated, and possess greater cognitive flexibility (Tadmor and Tetlock 2006), respond more positively to paradox brands than bicultural consumers who are separated, and possess less cognitive flexibility ($M=6.17$ vs. 5.23, respectively, $p=.002$). This result contributes to our findings regarding the role of cognitive flexibility, and also underscores the important insight that bicultural consumers are not all alike with regard to their response to brands.

Our findings make contributions to theory and practice. First, we show the importance of understanding bicultural consumers to develop brands that have special appeal to this growing segment. Second, our findings provide guidance for several dilemmas that marketers face in building brands for the bicultural market. One dilemma is that the bicultural market is not homogeneous, including subgroups with different cultural mixes, such as Hispanic Americans and Asian Americans. A second dilemma is how to tweak an existing brand identity, which has been developed for the general consumer market, to resonate more with bicultural consumers. Finally, we also contribute to multicultural research by showing how contradiction impacts the attitudes of bicultural consumers.

Understanding Obese Patients' Engagement by Their Empowerment Level: The Case of Bariatric Surgery

Angélique Rodhain, Université de Montpellier, France
Andréa Gourmelen, Université de Montpellier, France

EXTENDED ABSTRACT

Called 'one of the greatest public health challenges of the 21st century' (World Health Organisation – Europe), obesity has nearly tripled since 1975[1]. This fact is particularly alarming since, in addition to the direct deaths it implies, obesity is also a major risk factor for many other diseases such as diabetes. Since obesity is difficult to overcome, bariatric surgery is then presented as a solution for patients. It aims at reducing drastically the patient's ingestion capacity by reducing the stomach size (*sleeve*) or by short-circuiting a part of the stomach and of the small intestine (*by-pass*). Nevertheless, even if bariatric surgery is almost systematically efficient in the short-run, its success in the long-run is far from being satisfactory, and it relies heavily on the patient's engagement which is mainly based on regular physical activities, a suited diet and regular medical monitoring.

Thanks to life narratives of 14 patients (more than 36 hours of recording, 420 single-spaced pages) who are about to get a bariatric surgery, this study aims at offering a patient-centered perspective on their own engagement and empowerment. A bulk of research on public health deals with patient empowerment. Schneider-Kamp and Askegaard (2019) have emphasized four dimensions of patient empowerment: participation, control, education and autonomy. Even if a consensus on the definition of this concept is still needed, since it is defined as a process, a state or some behaviors (Fumagalli et al., 2015) and according to the sense of the process (top-down or bottom-up) (Fayn et al., 2019), we understand patient empowerment here as "a process which help patients reject their passivity in their health behavior and assume their responsibility in their own care process" (Ben Ayed and El Aoud, 2016, p.9). The case of bariatric surgery is theoretically interesting in the consumer behavior field since it can be either imposed by the surgeon for medical reasons or chosen by the patient for personal reasons but, whatever the case, the patient has to prove his/her engagement in a suited physical activity and diet for the surgery to be accepted by the medical team. Therefore, the link between patient's empowerment and engagement remains to be deepened (Cases, 2017), and particularly in this case of bariatric surgery.

By crossing engagement and empowerment levels, 4 profiles arise:

(1) the group of "*watchers*" is composed by 7 people who are rather passive in the medical protocol and low in engagement. For example, Stéphane underwent the mandatory protocol to have surgery without seeking any information: he started and continues the process following a succession of advices from his general practitioner. He doesn't realize how his diet will have to change in the future. He claims that he has already changed, but still describing fairly limited modifications, or procrastinates. For the "*watchers*", the doctors bring the solution to their problem in a somewhat miraculous way. Most of them having never been sportspeople, they don't seem ready to start any physical activity afterwards. They know they are supposed to be involved, but their discourse show that they hope bariatric surgery should change their lives without their participation.

(2) The "*contributors*" (4 women – high engagement – high empowerment) are strongly engaged in the medical protocol, have implemented changes in their current behavior, and think about other changes in their daily life after surgery. For example, Tania, who chose to consult a psychologist, an endocrinologist and a nutritionist for many years, has internalized the reasons for her weight gain. She understood that it was time to take care of herself by adapting her diet and starting physical activity. The "*contributors*" engage in a win-win relationship: the medical staff give them a boost, but it's up to them to be active for a long-term weight loss;

(3) the (small) group of "*repentants*" (2 people – high engagement / low empowerment) doesn't seek to emancipate themselves from the medical profession. They follow the protocol and opt for the surgeon and the doctors they have been advised. They differ from "*the watchers*" in the sense that their respect for the medical staff lead them to internalize their discourse. They started the bariatric surgery process because they operated a reflexivity leading to an understanding of their weight gain responsibility. For example, even if Pierre initiated the first discussion with his general practitioner about the operation, he then followed all his recommendations. Particularly attentive to the specialists he met, he has integrated the mistakes he made, wishing to readjust himself. He really becomes aware of the need to change his whole way of life;

(4) finally, the (very small) group of "*cheaters*" (1 woman – high empowerment / low engagement) uses information learned on social networks to set up strategies to get around the rules. Only one patient out of the 14 we met confesses to be in this case. Thus, Karine explains that she followed up to 150 virtual accounts in social media in order to learn the "tricks" to get the "green light" for surgery: "*There is…What we should tell the psychologist?*". In terms of engagement, she says: "*I know that I eat too much, I know it, too much junk food*" without talking about any actual or planned changes. In addition, she understood the paradoxical injunctions given to patients: to pretend that one is in the process of losing weight, but to have a high BMI at the appointment. Thus, the strategy is to gain weight just before the first appointment, to show 2-3 months later that one has been able to lose few pounds (by pretending to change one's behavior, but without doing so): it is therefore a matter of integrating the rules to turn them to one's personal advantage.

To sum up, the majority of interviewees showing strong empowerment also shows high engagement. This taxonomy could serve as a first basis for the health care staff during appointments throughout the process, to personalize the doctor-patient relationship as much as possible, and for public policies to better inform about the consequences of such a surgery in terms of engagement.

The Moral Foundations of Pro-Guns' Digital Proselytism in Brazil

Benjamin Rosenthal, FGV-SP, Brazil
Massimo Airoldi, EM Lyon Business School, France

EXTENDED ABSTRACT

"Today I will recommend two models of guns for home protection… following the new guns decree of president Bolsonaro, which aims to guarantee everyone's right to have firearms for self-protection… since in Brazil there is this bullshit of restricted calibers I will attain to the allowed guns… a caliber 12 semiautomatic shotgun and a semiautomatic pistol, which would be my choice too, but I prefer a weapon of manual recharge, a pump-action shotgun, and I will chose a caliber 38 revolver, just to make this video different than the other one…"

This is part of a video of a Brazilian YouTuber, a social media influencer (SMI) who owns a YouTube channel that is dedicated to guns. The video is a review of two gun models for home protection, recorded at a shooting club. Besides technical elements (e.g., usability in the context of a home invasion), the video also contains critics towards the restricted laws imposed by the Brazilian State, impeding Brazilians to have access to guns or limiting the type of caliber that can be used. There are more than 200 comments, the most common being praises of the moral correctness of an armed man, and expressions of frustration with the Brazilian State and anger with the opponents of the liberation of guns in Brazil.

Outside of Brazil, the main reason for purchasing a gun is usually self-defense, as it is in the USA (Stroebe, Leander, and Kruglanski 2017), followed by sports practice, hunting and collecting (Shapira and Simon 2018). The desire to own and carry guns due to the perception of having one's life at risk (Shapira and Simon 2018) is not contextually independent (Carlson 2014). The sociocultural context that embeds this self-protection motivation and these gun-related social practices is identity-related (Carlson 2015), ideological (McLean 2018), anchored in cultural myths (Barnhart and Huff 2018), and embedded in cultures with a distinctive experience of violence and crime (Carlson 2014).

Nowadays, public discussions about guns happen both online and offline, as social media platforms became mass media tools in which discursive actions take place and ideas and meanings are constructed by online collectives (Airoldi 2018; Bonilla and Rosa 2015), albeit with a concentration of the audience in a small percentage of the content producers (Arthurs, Drakopoulou, and Gandini 2018). Content in social media is discussed organically through the interests and opinions of individuals who collectively construct narratives and group identities (Bonilla and Rosa 2015). Although the importance of social media for the formation of public opinion has been extensively investigated (Barisione, Michailidou, and Airoldi 2019; Papacharissi 2015), there are few studies addressing the ways people are socialized towards guns, specifically in social media platforms.

The objective of this research is to map how pro-gun SMIs and their publics on YouTube collectively justify the right to own guns, fostering values and attitudes, in a market which, still, has rigid controls for purchasing guns (Brazil). We rely on Boltanski and Thevenot's (2006) framework of logics of justification to demonstrate that these right-wing SMIs are calling for the necessity and the right to posses guns based mostly on the logics and discourses of the Civic and the Domestic World (Boltanski and Thevenot 2006).

According to Boltanski and Thevenot (2006), individuals justify their position-takings in social interactions by situationally relying on a plurality of "orders of worth" – i.e. the *civic*, *domestic*, *market*, *industrial*, *inspired* and *fame worlds*, which consist of discourses that social actors use to position themselves in disputes. For instance, social actors can refer to the *civic world* when they argue for the benefit of the public common good. Social actors may also refer to multiple worlds, as their arguments center on more instances, such as the *domestic* and the *civic world*, prioritizing some of these worlds over the others. Briefly, the *domestic world* is associated with the family, and is based on tradition and hierarchy, commanded by firm and upbringing individuals who champion customs and conventions, honor and respect, and combat disorder; the *civic world* is based on the collective interest, and the worthy are narrated as those who act on the behalf of the community, fighting for fair common causes.

Aiming to explore and compare the justificatory discourses of guns-related SMIs and their platform-based audiences, this research combines the ethnographic content analysis (Altheide 1987) of YouTube videos shared by a sample of 33 Brazilian SMIs and the automated text analysis (Humphreys and Wang 2018) of about 10k user-generated comments to these videos. Thanks to Brazilian social media listening company Vert, metadata about all the videos published by these 33 SMIs (n=1,687) were collected.

Our preliminary findings indicate that there is a strong moral base in guns' proselytism in Brazil among SMIs and their publics. In the domain of the Civic World (Boltanski and Thevenot 2006), this moral is based on the defense of the individual freedom and the strong criticism of state intervention on personal matters. These moral justifications are accompanied by the use of evidences such as statistics and anecdotal logics to argument that, indeed, guns do increase safeness, which is illustrated by phrases continuously repeated in many YouTube channels such as "bandits never invade a gun store or a favela, because they know that the citizens there are heavily armed." SMIs also engage in criticisms of the out-group - the anti-gun advocates, usually portrayed as unreasonable left-wing individuals or as "specialists", a word charged with jocosity.

The moral base of the guns' proselytism also involves what Boltanski and Thevenot (2006) denominated the Domestic World. SMIs and their publics defend the principles of the right to use guns for self-defense, to protect their families, to be prepared for situations of confrontation in a context of urban and country violence, which can be associated with conservative values such as having the moral strength to stand up against external evils and protect one's family, which is the base of what Lakoff (2016) named *strict father morality*. These moral justifications also support the expression of a collective identity. SMIs and their audiences are portraying themselves as "citizen protectors" (Carlson 2014) and as champions of freedom, individuals who have the moral responsibility to protect the value of liberty, which can not be taken away by the State. Collectively, they are using justifications present in the Civic World, establishing their principles and modes of judgment, separating the worthy from the unworthy, and promoting themselves as champions of the human dignity.

The Market and the Industrial World seem to be used as secondary justifications. The monopoly and the quality of guns in Brazil are minor problems given the main questions being discussed by SMIs and their audiences.

In short, this research shows that the Brazilian sociocultural context of urban violence (anchored on perceptions of how concrete daily life is), and the liberal moral values of personal freedom and

less state interventionism are used by these SMIs and their publics to promote a gun culture in a country in which the majority of the population support rigid laws restricting the liberation of guns for the population (Datafolha 2019).

The Silver Lining of Sadness: How Sadness Promotes Subjective Well-being

Jeff D. Rotman, Deakin University, Australia
Andrew W. Perkins, Washington State University, USA

EXTENDED ABSTRACT

Research in marketing has focused on how sadness motivates mood-regulation, especially through greater self-focused and hedonic consumption (Cryder et al. 2008; Garg and Lerner 2013; Garg et al. 2007; Lerner et al. 2004; Andrade 2005; Andrade and Cohen 2007). The extant research in marketing has all but unanimously argued that sadness motivates individuals to seek out more pleasurable, hedonic, indulgent, or comforting consumption in order to alleviate their feelings of sadness. However, drawing from a functional perspective, we suggest that sadness serves a social function as a signal meant to evoke compassion and helping behavior from others (Hasson 2009). Building from this, we expect consumers made to feel sadness should desire affiliation. Consumers seeking to affiliate make choices to facilitate this connection (e.g. buy gifts for others). Subsequently, as social acts, can also lead to a sense of well-being to the giver (e.g. people who perform kind and generous acts report elevated well-being (Dunn et al. 2008; Pressman et al. 2015), we anticipate this affiliative behavior to result in improved well-being. Importantly, the current research examines the conflicting hypotheses of an increased DTA (suggested in this research) and an increased desire for self-focused hedonic mood-regulation consumption. Across the experiments participants are given both the opportunity for self-focused consumption (consistent with prior literature) and other-focused consumption, which should be tied to greater affiliation.

Study 1

We explore the effect of consuming sadness in an ecologically valid setting (a movie theatre) with a behavioral outcome. We rented a movie theater and a total of 170 participants were randomly assigned to watch one of four (2 sad and 2 control), twenty-two minute television episodes.

Participants then completed the PANAS (Watson et al. 1988) and then a chocolate assortment task (adapted from Rucker et al. 2012) that required each participant to decide how many chocolates they would give to other individuals versus keep for themselves. Finally, participants completed a measure of subjective well-being (Diener et al. 2010; α=.88), and a series of covariates (None of the covariates impacted the results).

Participants in the sad condition took fewer chocolates for themselves ($M_{self=}$4.22) and gave more chocolates to others ($M_{others=}$15.41) than those in the control condition ($M_{self=}$6.78, $p<$ .01; $M_{others=}$13.09, $p<$ .01). We examined the indirect effect of number of chocolates selected on the relationship between condition and well-being using mediation. The results revealed that participants in the sad (vs. control) condition reported increased well-being as a function of selecting chocolates for others (β=.08, CI=[.01, .18]). Negative mood did not affect the results.

Study 2

197 participants were recruited from MTurk (following attention check). Participants were randomly assigned to watch a single video clip in either the *sad* or *control* conditions.

Participants completed a five-item *DTA* scale (Park and Maner 2009; α=.92) and a measure of self, versus other-focused activities (self-focused, e.g., "buy a gift for yourself", α= .83; other-focused, e.g., "buy a gift for a close friend", α= .88). Other-focused was divided by self-focused scores and we used the quotient as a proxy

for each participant's *other-oriented consumption* (OOC). Mood was measured utilizing BMIS (Brief Mood Introspection Scale or BMIS; Mayer and Gaschke 1988).

Respondents in the *sad* condition reported higher scores on both *DTA* (M=4.43) and *other-oriented-consumption* (M=1.46) than respondents in the *control* condition (M=4.00 and M=1.05, respectively, *p*'s<.01). This pattern of results persists even after controlling for negative *mood*, as well as *fear*, *anger*, *disgust* and *joy*. Next, we examined the indirect effects of the sadness manipulation on other-oriented consumption through DTA and found significant mediation. (β= .06, CI=[.01, .13]).

Study 3

MTurk participants (*n*=185, after attention check) completed the study, Replicating the method from study 2, we also measured trait (Davis, 1983) and state empathy (Escalas, 2003),

Participants in the sad condition reported significantly higher DTA ($M_{DTA=}$3.87,) and other-oriented consumption (M_{OOC}=1.28) compared to those in the control condition (M_{DTA}=3.20, p< .01; M_{OOC}= 1.05, p<.01). The indirect effect of DTA demonstrated significant mediation (β=.10, CI=[.03, .19]. All results remain consistent when controlling for the trait-level empathy constructs, felt empathy, as well as fear, anger, disgust and joy.

Study 4

Participants (n=229 after the attention check) were recruited via Amazon's Mechanical Turk. Participants were randomly assigned to recall one of a self-selected autobiographical event that was associated primarily with feelings of sadness, anger, fear or disgust, or a control (an event that happened this week). Next participants completed the BMIS and the same DTA and self-vs-other consumption scale.

The sadness condition resulted in the highest DTA (*M*=4.60) and other-oriented consumption (*M*=1.18), which were significantly higher than all other conditions. Next, we examined the mediational relationship between sadness, DTA, and other-oriented consumption. Four separate mediations with sadness, compared to each one of the other conditions, revealed significant mediations as well as when the four control conditions were collapsed. Controlling for negative mood did not affect the results.

Study 5

We test the mediational relationship between feelings of sadness and well-being, expecting that DTA leads to other-oriented consumption, which then leads to well-being. Study 5 used the same single factor (*Movie: sad versus control*) between-subjects design as studies 2 and 3. A total of 227 participants were recruited from Mechanical Turk, (185 after failing the attention check). The measures used to assess DTA and other-oriented consumption and well-being are the same. Mood was assessed using the BMIS scale.

Participants' DTA ($M_{control=}$3.86 vs. $M_{sadness=}$4.31, *p*<. 05) and other-oriented consumption ($M_{control=}$1.13 vs. $M_{sadness=}$1.47, *p*<. 05) were both higher in the sadness condition. Next, we examined the serial mediating effect of sadness on well-being through DTA and other-oriented consumption. Participants in the sad condition report a greater DTA with others, and subsequent other-oriented consumption and heightened well-being (β= .02, CI= .00, .05). Controlling for negative mood, fear, anger and disgust did not affect the results.

Theorizing Relational Work in the Collaborative Economy:
An Application to Peer-To-Peer Renting

Dominique Roux, Université de Reims Champagne-Ardenne, France
Russ Belk, York University, Canada

EXTENDED ABSTRACT

Why, to whom and how do people rent out their possessions? Previous research explains why people prefer renting rather than owning (Durgee and O'Connor 1995; Moeller and Wittkowski 2010) and how peer-to-peer rental systems organize balanced short-term exchanges between strangers (Ikkala and Lampinen 2015; Philip, Ozanne, and Ballantine 2015; von Richthofen and Fischer 2019). Considered as 'pseudo-sharing' (Belk 2014), renting illustrates a growing tendency toward commodification whereby individuals marketize personal assets, including private goods/spaces (Belk 2020; Eckhardt and Bardhi 2016; Harvey 2007). Previous literature highlights the crucial role of platforms in "hybridizing" conflicting institutional logics between commerce and hospitality (Scaraboto 2015; von Richthofen and Fischer 2019)) and fostering 'market empathization' (Giesler, Veresiu, and Siebert 2015). In addition, extant literature on liquid relationships to possessions (Bardhi and Eckhardt 2017; Bardhi, Eckhardt, and Arnould 2012) argues that access-based modes of consumption fuel a new culture of circulation (Aronczyk and Craig 2012; Bardhi and Eckhardt 2012), which helps both renters to avoid unnecessary purchases and owners to make extra money from the temporary disposition of their personal possessions (Horton and Zeckhauser 2016). However, previous studies on renting present three gaps that our research intends to fill. First, they mostly concentrate on users and thus fail to examine how owners become renters, when and why (Belk, Bardhi, and Eckhardt 2019; Philip et al. 2015). Second, they pay little attention to what is rented, and in particular to the relationships owners have with their possessions before, during and after rental. Third, because they concentrate on short-term rental with Airbnb as a favorite focus of study (Ikkala and Lampinen 2015; von Richthofen and Fischer 2019), they also limit our understanding of rental activity as a whole. In short, examining "networked hospitality businesses" only (Oskam and Boswijk 2016) prevents us from understanding other contexts such as managing long term rentals or providing neighbors with everyday items.

Our approach to renting draws on Zelizer's (2010, 2012) contribution on relationality, i.e., the way social relationships shape economic lives (Zelizer 1985, 1995, 2005). Rather than considering sociality as an extra touch of soul brought into economic activities, we contend that distinctive social ties with renters result in specific economic transactions, meanings and media of exchange, what Zelizer (2012) terms "relational packages." We theorize renting as a set of "relational packages." In addition, we extend Zelizer's (2012) approach to objects. In particular, we consider the attachment and social bonds owners have with their possessions as the cornerstone of "relational packages." Through 'relational work', including the emotional labor (Hochschild 1983) that owners undertake both with relinquishing their items and with renters, we examine how various forms of economic exchange are articulated with specific moral valuation, meanings, communication channels and currencies that typify particular object-person and person-person-relationships (Zelizer 2012). With renting as a relevant but overlooked practice in the field of collaborative consumption (Albinsson and Perera 2018), we raise three research questions: How do possession-owner relationships result in assessing the rent-ability of private objects/spaces? Once a possession is deemed rent-able, what conditions make objects/spaces enter into an economic relation with others? And what are the appro-
priate means of exchange, associated meanings and social ties that owners develop with people whom they distinctively term tenants, guests or simply neighbors?

To answer these questions, we conducted a 3-year qualitative study with 43 French informants who rent dwelling, cars and other objects. Informants were sequentially recruited through social networks using a "snowballing" technique. The interviews were mostly conducted in homes where pictures and videos were taken with their owner's consent. Although no claim of representativeness is made, informants were almost equally distributed by gender (22 F and 21 M), ranging in age from 22 to 79 (average 35), and represented a mix of different types of occupation, levels of income and rented goods, namely dwellings (19), various equipment, tools and kitchen appliances (16), cars (9), washing machines (3) and a bicycle (1).

Our findings first focus on how possessions enter the realm of 'sharing out' (Belk 2010). We show how informants assess the 'rent-ability' of what they make available to others. This relational work with one's private goods consists of both shaping the boundaries of what is 'rent-able' and of sometimes excluding others from using parts of these things. While Philip et al. (2015, 8) argue that rented goods are preferably "unbreakable, fairly durable and not precious," our findings show that "rent-ability" is a feature attached to the closeness and secrecy of exchanges individuals have with their possessions (Simmel 1906). Hence rented goods never belong to informants' territory of intimacy (Goffman 1971), although this varies according to people's biographical sensitivity.

Next, we examine the circumstances under which possessions actually come to be rented and what relational work is performed both with objects and tenants/guests/neighbors as informants variously term them. We highlight three different circumstances whereby private goods/spaces come to be rented. For some informants, expensive goods such as dwellings, cars and luxurious objects (e.g., wedding dresses) are acquired from the beginning for a regular, long-term rental activity. These semi-professionals owners develop a quite intensive secondary occupation that competes with marketplace offering by providing other consumers with better prices and services. In such cases, relational work with objects/spaces appears to be demanding. It consists of selecting "interesting" goods in terms of investment such as well-situated houses, comfortable cars or highly demanded goods. Once goods are dedicated and adapted to renting, relational work with tenants requires finding the "proper renter" (i.e., liable, solvable and respectful) through various exchange media such as social networks, C2C websites and word-of-mouth. The second category of owners comes to rent goods usually after prior experiences as users of online short-term rental platforms. We call this 'generalized reciprocal sharing out' because it occurs outside the family circle (Belk 2010), but within a system of generalized reciprocity (Sahlins 1972) or mutuality (Arnould and Rose 2016) whereby owners welcome guests as they expect to be welcomed when they are themselves travelling. While shared meanings entangle commercial/hospitality logics that are shaped by platforms (von Richthofen and Fischer 2019), our findings demonstrate high variability in how hospitality is understood and performed. Likewise, we show that relational work with objects/places results in various approaches, from leaving everything in place to restricting access to some areas and sometimes excluding oneself from one's own place of living. Finally,

the third category of informants comes to rent goods because others – mostly neighbors or friends – request some things that they possess. What we call "local trade" includes lending a vacant garage, garden or DIY tools, or kitchen equipment whose request may be free before it turns into regular and paid rental. As the object is offered "as is," relational work with possessions is limited. Preference for paid rental gradually appears within existing relationships and is intended to tell renters that objects must be returned. Fees also serve to maintain distanced relationships that distinguish such exchanges from sharing 'in' (Belk 2010) and to enable owners to avoid renters' indebtedness.

We first contribute by extending the approach of P2P activities beyond single-field approaches thus showing that rental is a multifaceted activity. Second, we emphasize that relational work with possessions is required prior to making them available to others. In so doing, we extend Zelizer's (2012) work on relationality to objects. Third, we detect three different types of relational packages whereby different social ties, economic transactions, exchange media and negotiated meanings are articulated. Though limited to rental and an idiosyncratic cultural context, our study extends current research on the collaborative economy (Belk et al. 2019; John 2016; Widlock 2017) by offering a broader and theorized approach to an overlooked access-based mode of consumption (Albinsson and Perera 2018). It shows that using a unique action verb—here renting out but elsewhere sharing or accessing—may be problematic to embrace heterogeneous realities. Rather, we assume that renting, sharing and other collaborative activities can better understood by examining the various relationships owners have with their possessions and how these define the process whereby private goods/spaces are rented, shared, mutualized or sold (Lastovicka and Fernandez 2005), with whom and how. Finally, our research sketches fruitful ways of understanding how marketplace dynamics affect and is affected by particular institutionalizing processes of entanglement of economic and relational exchanges (Findlay 2018; Giesler et al. 2015).

Threat Appeals to Whom for What? Effects of Threat Appeal to Persuade Quitting a Dangerous Behavior versus Adopting a Preemptive Behavior

Hyerin Ryu, Sungkyunkwan University, Korea
Sunkyu Jun, Sungkyunkwan University, Korea

EXTENDED ABSTRACT

Threat appeal has been widely used for preventative communication but is a double-edged sword: Motivation to protect the self from danger prompts attention to the message whereas motivation to protect the self from threats elicits maladaptive responses. Meta-analyses revealed a positive monotonic influence of threat or fear level on persuasion (Tannenbaum, et al. 2015; Witte and Allen 2000), mostly owing to attention to and belief in the message. However, the influence of threat level could be non-monotonic and be negative due to maladaptive responses (Keller and Block 1996; LaTour and Pitts 1989; Ruiter et al. 2014).

We suggest that this inconsistency can be resolved by distinguishing the two variants of preventative communication: preventive communication aimed to persuade the audience engaged in a dangerous behavior to quit it and preemptive communication aimed to persuade the audience disengaged from a preemptive behavior to adopt it. For a threat-appeal preventive communication, the target audience engaged (vs. disengaged) in a dangerous behavior is more relevant to the threat; when threats are appraised as more personally relevant, defensive avoidance coping is more likely to occur, resulting in maladaptive responses (Carver et al. 1989). In contrast, for a threat-appeal preemptive communication, the target audience disengaged (vs. engaged) from a preemptive behavior perceives less relevance to dangerous consequences of forgoing the behavior; the threat appeal used in the preemptive communication increases attention to the message and efficacy perception in turn. We propose that for a preventive communication, threat appeal has a negative effect on persuasion for individuals engaged in dangerous behavior because of their maladaptive responses; and for a preemptive communication, threat appeal has a positive effect on persuasion for those disengaged from the preemptive behavior owing to efficacy perception.

In Study 1 employing a preventive communication in the texting-while-driving context, we presented either the high-threat or the low-threat message to 128 Californians age younger than 35. Engagement in texting-while-driving was measured with a question ("Do you send a text while driving?") in terms of yes or no. Persuasion was operationalized as beliefs in banning texting-while-driving. We predicted that increasing threat level would have a negative effect on the belief measure indirectly through maladaptive response, particularly for the engaged participants. The interaction effect between threat and behavioral engagement on maladaptive response was significant ($F(1, 124) = 4.53$, $p < .04$). The high-threat message increased the maladaptive response ($M_{high-threat} = 4.3$, SD = 1.22 vs. $M_{low-threat} = 3.6$, SD = 1.36, $F(1, 124) = 4.86$, $p < .03$), only for the participants engaging in texting-while-driving. The indirect effect of threat (1: high vs. 0: low) on the belief through maladaptive response was negatively significant for the participants engaging in texting-while-driving (95% CI: - .35 ~ - .01), but not for those disengaged from such behavior (95% CI: - .13 ~ .25), indicating that the threat appeal increased maladaptive response which lowered beliefs in banning texting-while-driving, particularly for participants engaging in texting-while-driving.

In Study 2 employing a preemptive communication in the context of healthy eating, we presented 110 adults with either the high- or low-threat message recommending healthy eating behavior. Then, the participants imagined to dine alone at a restaurant serving a five-course prix fixe menu in addition to beverage. For each course, half of the foods or beverages were low-calorie ones and another half were high-calorie ones; we used the number of low-calorie appetizer, dessert, and beverage chosen by the participant as a measure of persuasion (M = 1.7, SD = 1.03, range 0-3). We used attitude toward eating healthy foods, which did not differ between the high-threat and the low-threat messages (F < 1.0), as a proxy measure of engagement in healthy eating behavior. The interaction effect between threat and the attitude was negatively significant (B = -.56, SD = .23, t = 2.43, $p < .02$): A spotlight analysis showed that the high-threat message had a positive effect on choice of low-calorie foods at one standard deviation below (B = .49, SD = .27, t = 1.82, $p < .05$, with one-tailed test) but a negative effect at one standard deviation above the mean value of attitude (B = -.45, SD = .27, t = 1.68, $p < .05$, with one-tailed test). The results indicate that threat appeal used for the preemptive communication enhanced persuasion, particularly for the participants with poor attitudes toward eating healthy foods.

We conducted Study 3 in the context of commercial advertising aimed to promote a dietary program as a preemptive means of reducing health risk and presented either the high-threat or low-threat message to 154 participants age 30 and older. We measured engagement in the dietary behavior with three questions (e.g., "Are you currently on a diet?"), in terms of yes or no; ninety-one participants (59.1%) responding "no" for all the three questions were classified as those disengaged from dietary behavior. The interaction effect between threat and behavioral engagement on the intention to subscribe the dietary program was significant ($F(1, 150) = 7.58$, $p < .01$): The high-threat message increased the intention ($M_{high-threat} = 4.5$, SD = 1.72 vs. $M_{low-threat} = 3.5$, SD = 1.76, $F(1, 150) = 6.85$, $p < .01$) for the participants disengaged from the dietary behavior. The effect of threat on the intention was mediated by efficacy perception only for the disengaged participants (95% CI: .01 ~ 1.07). The results indicate that using threat appeal increased efficacy perception for the dietary program and enhanced intention to subscribe the dietary program in turn, particularly for the participants disengaged from the dietary behavior.

This study implies that there is a need to use the threat appeal selectively while clarifying the communication goal and target audience. The threat appeal may be preferred as a tactic to persuade adopting a preemptive behavior by targeting individuals who forgo the behavior, but not as one to persuade individuals to quit a dangerous behavior by targeting those who are engaged in the behavior.

Framing Consumers: Increasing Consumer Approach Behaviors
Towards and Within Public and Private Spaces

Kevin L. Sample, University of Rhode Island, USA
Julio Sevilla, University of Georgia, USA
Kelly Haws, Vanderbilt University, USA

EXTENDED ABSTRACT

We demonstrate through eight studies, including a virtual reality study, that consumers engaged in first-(third-) person visual perspective focused on the environment (themselves) derive more (less) pleasure from greater publicness leading to greater (lesser) approach behaviors. These findings contribute to environmental research while resolving seemingly conflicting research regarding public preferences

Consumer behavior is heavily influenced by the built environment (Bitner 1992; Kotler 1973; Mehrabian and Russell 1974). For instance, consumers feeling restricted by aisle width will exert their freedom by choosing more variety (Levav and Zhu 2009), while more space for products on shelves will lead consumers to deduce higher quality (Sevilla and Townsend 2016). Varying ceiling heights alters consumers' information processing (Meyers-Levy and Zhu 2007), a dimly lit environment can lead to less healthy food choices (Biswas et al. 2017), and the coldness of an environment can increase liking of romance movies (Hong and Sun 2011). Collectively, this prior research has demonstrated that the built environment can substantially shape consumer behavior; yet these environmental factors come into play only after a consumer is within a place. In the present work, we examine the environment's influence on getting consumers inside retail environments and the resultant behavior once inside. Specifically, we examine the nuanced role that publicness plays on consumer approach behavior in retail settings

Prior research has demonstrated conflicting consumer response to publicness. Theorists have posited that locales with greater publicness are more welcoming (Jacobs 2016), and that it is easier to garner consumer attention with greater publicness (Alexander, Ishikawa, and Silverstein 1977; Corbusier 1931). As consumer attention is directed inward, there are naturally more opportunities to glean information about what lies inside (e.g., products, store design, consumers). Further, well-executed retail designs, which can be perceived through greater publicness, have a positive effect on consumer behavior (Baker, Levy, and Grewal 1992). Thus, greater publicness allows a firm to showcase offerings inside, resulting in benefits for consumers and firms.

Greater privacy (the opposite of publicness) in retail environments naturally restricts the amount of information regarding what lies inside, but this restriction of information could potentially be beneficial. Limiting information can induce more curiosity for consumers (Goldsmith and Amir 2010; Lee and Qiu 2009; Loewenstein 1994). These curiosity-inducing moments can lead to higher interest in a place and the offerings inside. Additionally, greater privacy can restrict potential judgments, as consumers have privacy concerns (John, Acquisti, and Loewenstein 2011), think about how they might be seen by others (Ratner and Hamilton 2015), and will even leave if being watched by others (Esmark, Noble, and Breazeale 2017). Thus, greater privacy could be as equally beneficial to consumers as greater publicness. To resolve these seemingly conflicting dynamics, visual perspective theory is utilized to explain when and why preferences arise for one over the other.

Visual perspective theory posits that we tend to see ourselves either in first- or third-person perspectives when accessing memories or imagining events (Hung and Mukhopadhyay 2012; Libby and Eibach 2011; Nigro and Neisser 1983). Relevant to our current investigation, consumers assessing retail environments are imagining events (e.g., the possibility of entering a place, where to go once inside, how much time to spend inside), and, due to the design of the environment, should assess environments in one of these two perspectives. To answer when consumers will engage in one versus the other, an understanding of framed views is needed.

Framed views occur when an environment is designed such that consumer attention is directed towards certain areas (Friedberg 2006). Framed views are abundant in retail environments, as marketers are keen on garnering consumer attention (e.g., storefront windows, expansive lobbies). On the outside of a framed view, consumers are only spectators, but once inside a framed view they become someone to be observed (Read 2007).

A consumer on the outside of a framed view looking in is focused on seeing, not on being seen. Consequently, these consumers are more focused on environmental factors, akin to being in first-person perspective (Frank and Gilovich 1989). Consumers in first-person perspective perceive situations through their own eyes and focus on the environment around them more so than themselves (Jones and Nisbett 1972; Libby and Eibach 2011). Therefore, we propose that consumers outside of framed views exhibit greater approach behaviors to greater publicness, as more public environments provide more evidence as to the benefits and appropriateness of entering a place.

Conversely, once inside a framed view, consumers become part of the display to be seen and, become aware of being seen by others – akin to a third-person perspective. Consumers in third-person perspective are more prone to see themselves as others would see them (Frank and Gilovich 1989; Jones and Nisbett 1972; Nigro and Neisser 1983), giving rise to more self-conscious emotions such as embarrassment and shame (Hung and Mukhopadhyay 2012). Hence, we argue that consumers inside of framed views will exhibit less approach behaviors to publicness, as these consumers become aware of how they are seen by others and prefer not to be watched (Esmark et al. 2017). So, quite ironically, consumers approach behaviors when outside a public framed view will attenuate once inside this framed view, unless some privacy is provided.

Further, since consumers outside of framed views are more focused on seeing the environment, inducing consumers into a third-person perspective should increase awareness of how they are being seen and consequently attenuate approach behaviors towards publicness. Conversely, consumers inside of framed views are aware of being seen and inducing consumers into a first-person perspective should increase focus on the environment and should consequently exacerbate approach behavior towards publicness.

Hypothesis 1:   *Consumers outside (inside) of a public framed view are more (less) likely to exhibit approach behavior*

Hypothesis 2:   *A third-(first) person perspective attenuates (exacerbates) consumer approach behavior when outside (inside) of a public framed view*

Environmental influences on consumer behavior tend to be mediated by pleasure or arousal, as these emotional states are imme-

diate, visceral reactions to the environment (Donovan and Rossiter 1982; Mehrabian and Russel 1974). In our context, we contend that pleasure mediates the hypothesized approach behavior, as prior research points to environmental factors leading to pleasure (Baker et al. 1992; Donovan, Rossiter, Marcoolyn, and Nesdale 1994; Gorn, Pham, and Sin 2001; Machleit, Eroglu, and Mantel 2000; Orth and Wirtz 2014). Additional research notes that pleasure is the typical reaction experienced when imagining events engaged in a visual perspective (D'Argembeau and Van der Linden 2004). Accordingly, we argue that the experienced pleasure from framed views mediates this phenomenon.

Hypothesis 3: *The amount of pleasure experienced by consumers from framed views mediates consumer approach behavior*

Due to the magnitude of testing an environmental phenomenon, we conservatively test our hypotheses in a series of eight experiments. Our first three studies examine our hypotheses as they relate to consumers outside framed views, the next three investigate inside framed views, and our final two studies utilize marketplace methods, including virtual reality, to investigate our hypotheses collectively.

In Study 1, we examine consumer approach to a retail environment based on more versus less publicness when outside of a framed view. We predicted that participants would be more likely to engage in approach behaviors when outside a public framed view. 118 undergraduates were randomly assigned one of two images of the exterior of a retail store. To assess consumer approach behavior, participants were asked their liking, the attractiveness, and the estimated time spent in this place on 7-point Likert scales with 1 being negative and 7 being positive. An ANOVA with our indexed dependent variable of consumer approach (see results table for α, SD, and effect sizes) reveals that participants were significantly more likely to exhibit approach behavior towards the public framed view (M_{Public}=4.95, vs. $M_{Private}$=3.87; $F(1,116)$=19.622, p<.001), providing initial support for H1.

In Study 2, we manipulate visual perspectives. We predict that participants receiving a first-(third-) person perspective prime will be more (less) likely to choose a restaurant with a public framed view. 150 MTurk workers were randomly assigned a first- or third-person perspective adapted from Libby and Eibach (2011). Next, participants were shown two restaurant images offering differing levels of publicness and asked to choose which they preferred. Logistic regression reveals a significant effect based on the visual perspective manipulation received (choice of public framed view: $M_{1stPerson}$=94.1% vs. $M_{3rdPerson}$=83.1%; β=-.589, Wald $χ^2$ (1)=3.944, p=.047). Participants assigned to the third-person perspective condition were significantly less likely to choose the more public framed view, supporting H1 and H2.

In Study 3, we manipulate visual perspective while investigating the mediating role of pleasure predicting that consumer approach behaviors will be mediated by pleasure. 131 MTurk workers were randomly assigned either the first- or third-person perspective manipulation utilized in Study 2. Following, all participants saw the outside of a public framed view of a restaurant. On the next page, participants were asked to respond to the Self-Assessment Manikin (SAM) pleasure scale ranging from -4 to 4, and typically utilized to assess the range of displeasure to pleasure that consumers experience (Bradley and Lang 1994; Mehrabian and Russell 1974). Following, participants approach behavior was assessed using the same questions from Study 1. An ANOVA reveals that those with a first-person perspective were significantly more likely to engage in approach be-

haviors ($M_{1stPerson}$=5.63 vs. $M_{3rdPerson}$=5.19; $F(1,129)$=7.291, p=.008). Another ANOVA reveals that those with a first-person perspective experienced marginally significant more pleasure ($M_{1stPerson}$=2.52 vs. $M_{3rdPerson}$=2.09; $F(1,129)$=3.749, p=.055). Mediation analysis indicates that pleasure mediates consumer approach behavior (indirect effect=-.1181, SE=.06; 95%CI=-.2322 to -.0013; direct effect p=.07), supporting H3.

In Study 4, we begin to focus inside framed views. For this study, we predict that consumers inside of a framed view will exhibit approach behavior towards less publicness. 110 undergraduates were randomly assigned either a public or private framed view of a restaurant. Next, participants evaluated the restaurant using our previous approach measures. An ANOVA reveals that those inside a private framed view exhibited significantly greater approach behavior than those inside a public framed view (M_{Public}=4.16 vs. $M_{Private}$=4.78; $F(1,108)$=6.506, p=.012). This reveals a reversal of the findings from our first three studies, further supporting H1.

In Study 5, we focus inside a framed view of a retail store, while assessing mediation. 180 undergraduates were randomly assigned inside a public or private framed view. Following, participants evaluated the store using the pleasure scale with approach behavior assessed as previously. An ANOVA, in support of H1, reveals that those encountering the private framed view had a significantly more positive approach behavior towards the retail store (M_{Public}=3.62 vs. $M_{Private}$=4.19; $F(1,178)$=8.680, p=.004). Another ANOVA reveals that those seeing the private framed view experienced significantly more pleasure ($M_{MorePublic}$=1.24 vs. $M_{MorePrivate}$=1.69; $F(1,178)$=4.046, p=.046). Pleasure, again, mediates approach (indirect effect=-.2989, SE=.15; 95%CI=-.5967 to -.0071; direct effect p=.03), supporting H3.

In Study 6, we manipulate perspective while inside a public framed view. Consequently, we anticipate that participants with the first-person perspective will exhibit greater approach behavior. 124 MTurk workers were randomly assigned one version of the public restaurant image from study 4, with either a first- or third-person visual perspective. An ANOVA reveals that those seeing the first-person perspective reported significantly greater approach behavior than those seeing the third-person perspective ($M_{1stPerson}$=4.69 vs. $M_{3rdPerson}$=4.05; $F(1,122)$=6.358, p=.013), supporting H1 and H2. Another ANOVA reveals that those with a first-person perspective experienced significantly more pleasure ($M_{1stPerson}$=1.37 vs. $M_{3rdPerson}$=.65; $F(1,122)$=4.805, p=.030), and pleasure mediates approach (indirect effect=-.2317, SE=.11; 95%CI=-.4403 to -.0227; direct effect p=.22), supporting H3.

For study 7A, we show participants one of four rendered videos from a perspective of someone navigating an environment in real life. In these videos, participants had a view of a restaurant from outside the framed view, making their way inside this framed view, and then taking a seat in the restaurant. Every participant saw the same sequence and the same other consumers, however the texture of the glass in the restaurant was manipulated so that four distinct conditions were created (outside/inside): 1) public/private 2) public/public 3) private/public and 4) private/private. In alignment with H1, the optimal arrangement to increase approach behaviors both outside and inside of a framed view is to be outside a public framed view and then inside a private framed view. Thus, we predict that participants will have significantly higher approach behaviors for video 1, as this video had the optimal arrangement of public/private.

259 MTurk workers were randomly assigned one of these four videos. Once finished viewing, participants responded to our pleasure and approach questions. An ANOVA reveals a significant main effect ($F(3,255)$=3.175, p=.025). Simple contrasts (see results

table) reveal video 1 elicited significantly higher approach behavior than the other videos, supporting H1. Similar results also emerge for pleasure ($F(3,255)=3.559$, $p=.015$) and pleasure, again, mediates (indirect effect=.2023, SE=.07; 95%CI=-.3361 to -.0707; direct effect p=.78), supporting H3.

Increasingly, firms utilize virtual reality to allow consumers/clients to evaluate places before design changes and construction. In Study 7B, we provide participants with this marketplace experience of virtual reality while investigating actual behavior – time spent in a place. 104 undergraduates were randomly assigned one of two conditions: a very public restaurant to evaluate in either a first- or third-person perspective. In the first-person perspective they had an eye-height view, where they could see their avatar's hands. In the third-person perspective they had an over the shoulder view of their avatar. Research assistants kept time for each participant, making a note of when participants entered the restaurant. In alignment with H2, we predict that participants in a first-person perspective will have greater approach behavior directed toward the outside public framed view because they are more focused on the environment. This should lead them to entering the building before those in third-person perspective. Additionally, these participants should spend more time inside this public framed view because they will be less self-conscious than those in third-person perspective.

An ANOVA with the time spent evaluating the exterior of the restaurant reveals that those in a first-person perspective spent significantly less time evaluating the exterior ($M_{1stPerson}$ = 52.53, SD = 50.5 vs. $M_{3rdPerson}$ = 82.8, SD = 50.5; $F(1,102)$ = 9.337, p = .003; η^2 = .084). That is, they entered the building more quickly. An ANOVA with the time spent evaluating the interior of the restaurant reveals that those in a first-person perspective spent significantly more time evaluating the interior ($M_{1stPerson}$ = 51.10, SD = 26.2 vs. $M_{3rdPerson}$ = 32.68, SD = 26.2; $F(1,102)$ = 12.859, p = .001; η^2 = .112). This is a reversal of the time spent on the exterior supporting H1 and H2 in a marketplace context with actual behavior.

Our work contributes theoretically and practically. Theoretically, we integrate architectural theory with visual perspective theory, demonstrating that consumer location regarding framed views tends to dictate consumer approach behavior to more and less public areas. By so doing, we resolve this apparent conflict between prior research indicating that consumers prefer both more publicness and more privacy. Practically, our work provides important insights for marketers. In the design and construction of retail environments, it is crucial that marketers work closely with designers to ensure that retail spaces provide substantial publicness from framed views, but once inside these framed views that consumers are given ample opportunity for privacy. The implications of perspectives must be carefully considered by marketers designing environments for consumers, as well, while marketing researchers need to consider the allotted publicness of retail spaces when studying consumer marketplace interactions.

Pay Less, Spend More: Consumers' Mental Accounting for Discounted Gift Cards

Gianluca Scheidegger, University of St.Gallen, Switzerland
Thomas Rudolph, University of St.Gallen, Switzerland
Marc Linzmajer, University of St.Gallen, Switzerland
Severin Friedrich Bischof, Copenhagen Business School, Denmark

EXTENDED ABSTRACT

The downward pressure on prices seems to intensify across various industries worldwide. Companies are increasingly discounting their products to remain competitive and drive sales. Price- and deal-sensitive consumers are targeted by discount mechanisms that are becoming more and more opaque. These alternative discount forms and their effect on consumer behavior have attracted the attention of marketing and consumer-behavior researchers in recent years.

One increasingly popular discount mechanism that has not yet been subject to research are discounted gift cards (DGCs). DGCs are company-specific funds that can only be redeemed for purchases at the card-issuing company and. Gift cards are traditionally seen a gift, a bonus, or as part of a promotion, but a DGC can be attractive for self-purchase because its selling price lies below its face value. Thus, the topic is no longer limited to gift-givers and gift-takers.

We hypothesize that the combination of both the discount, accounted for as current income, and the low payment transparency (see Soman, 2003) of a gift card reduces consumers' perceived costs at the time of the purchase. Although the DGC resembles other price promotions designed to incentivize immediate purchases, such as regular price discounts, a DGC is distinct from these promotions. Receiving a DGC is conditional on purchasing the gift card and redeeming it for a future purchase. Therefore, DGCs represent partially prepaid consumption as well as a pre-received promotion compared to other similar price promotions. Based on that reasoning, we hypothesize:

Hypothesis 1: *Consumers who receive DGCs (a) report lower subjective costs and (b) spend more than consumers who receive a financially equivalent price discount.*

Temporally separating payment and consumption leads to counterintuitive decisions (Gourville & Soman, 1998). Sunk costs (Arkes & Blumer, 1985) are a prominent example of this effect. When consumption and payment are temporally separated, the impact of sunk costs decreases (Gourville & Soman, 1998). Hence, the less the consumption decision is influenced by the upstream costs, the greater the time difference. Gourville and Soman (1998) referred to this phenomenon as payment depreciation. Thus, we hypothesize:

Hypothesis 2: The longer the time span between DGC purchase and redemption, the lower consumers' subjective costs.

Study 1 (N=463) was a 2x2 between-subjects experiment conducted on MTurk. Half of the participants were told that they would acquire a $500 gift card for $400. Participants in the control condition bought the same gift card for $1. They were either told that they would redeem the DGC for a $800 laptop one day or six months later. Lastly, participants' subjective costs (in US dollars) during the laptop purchase were measured in an open-ended format.

Study 2 (N=212) consisted of real-world booking data from an airline who issued two different DGCs. DGCs had a face value of 30 and 90 monetary units (MU)[1] with an absolute discount of 6 and 15 MU, respectively. About nine months later, we received booking data for DGC and regular gift card bookings after issuing the DGCs. The booking data was limited to long-haul flights in Economy class. To ensure comparability, we only considered regular gift cards of the same face value as the DGC (30 and 90 MU) in our analyses.

In Study 1, we provide evidence for reduced subjective (H1a) costs and payment depreciation (H2) in the context of DGC-usage. Among DGC-users in the one-day-later-condition, the subjective costs (M = $578.07) were already lower than the objective costs of $700 (t(114) = -6.28, p < 0.001). Subjective costs for the $800 laptop purchase were significantly lower (t(228) = 2.05, p < .05) six months after (M = $520.91, SD = $215.49) the DGC purchase compared to one day after (M = $578.07, SD = $208.30). No differences were found in the control condition.

In Study 2, we found a significant interaction effect (b = 0.368, p = 0.032) between gift card type and time difference. A conditional effect of time difference on booking price only existed when consumers were using a DGC (b = 0.350, t = 2.074, p = 0.039). For regular gift card users, there was no significant conditional effect of time difference on booking prices (b = -0.017, t = -0.082, p = 0.423). This field evidence further supports H1b and H2.

The results from this article have both theoretical and practical implications. First, this article contributes to the mental accounting literature by demonstrating that payment depreciation exists not only in the context of sunk costs but also in regular product purchases that are based on partial rather than complete prepayment. Second, we introduce a new payment mechanism and promotion type to the academic literature which extends and combines evidence from recent publications in this field. On the practical side, it is important for gift card providers to understand that DGCs are an attractive alternative to regular price discounts, which should be considered by companies in a price-sensitive environment. In our field study, we showed that even shallow discounts can lead to a significant increase in booking prices in a competitive industry.

Autonomous Products Make You Look Lazy!

Tobias Schlager, University of Lausanne HEC, Switzerland
Fabian Nindl, WU Vienna, Austria

EXTENDED ABSTRACT

Recently, autonomous products have entered our daily lives and have become rapidly more popular. These products take over mundane tasks such as cleaning, mowing, or driving and will likely change our lives (Jörling et al. 2019; Rijsdijk & Hultink 2003).

Evidence suggests that people choose products to communicate their desired identities, attitudes, and characteristics (Belk 1988; Holt 1995). Moreover, it has to be emphasized that products might provide an indicator for class and success (Flynn et al. 2016). Considering this evidence along with the ability of autonomous products to free up users' time, we propose that displaying the usage of such products systematically alters people's social perceptions. The question that we seek to answer by this research is: *How will autonomous products affect a peers' perceptions*?

Autonomous products free up people's time for other tasks by taking over daily chores (Leung et al. 2018; Festjens & Janiszewski 2015). Without any further information on why consumers delegate those tasks, one should assume that owners should thus complete less work. Accordingly, we propose that the peers of users of such products will perceive them to be less hardworking, or even lazy.

Drawing on prior studies, which analyzed the social perceptions of hard work and busyness (Burke & Ng 2007; Yang & Hsee 2019) it is hypothesized that owning autonomous products can have a significant effect on social perceptions. While people may understand owners of autonomous products as particularly busy, they might also construe them as those who are simply not motivated to do their daily chores. This suggests that other people's perceptions of owners of autonomous products depends on several moderators, such as how they use their time (i.e., for work, or leisure). While we assume that—without any further information—peers intuitively perceive owners of such products to be less hardworking, the opposite is true when the information is provided that they use the freed-up time for additional work.

Accordingly, we form the following hypotheses:

Hypothesis 1: *Peers will perceive users of autonomous products to be less hardworking.*

Hypothesis 2: *Time use (work vs. leisure) moderates the effect of autonomous products on perceptions of hardworking.*

Our key theoretical contribution is that autonomous products can send strong signals to their owners' peers (Belk 1988) and thus we uncover the social effects of this novel product class. A second contribution is that we extend prior work on busyness (Bellezza et al. 2016; Yang & Hsee 2019) by revealing a key antecedent, namely, product type. Moreover, we extend findings on the evolving research on autonomous products (Schmitt 2019; de Bellis & Johar 2020).

Five studies (using US respondents 2019 and 2020; see table below for further details) test and support the hypotheses that people perceive owners of autonomous products as less hard-working than those who operate traditional (i.e., non-autonomous) products.

In a pilot study we collected 52,859 tweets related to autonomous and traditional products of the same product category and found that responses to tweets on autonomous products included significantly less words related to work than those related to traditional products (M_{AP}=.27, M_{Trad}=.58; t(163,959)=8.99, Cohens *d*=.33).

In Study 1, 2, and 3 participants were randomly assigned to one of four conditions of 2×2 between-subjects experimental designs and we tested whether people perceive owners of autonomous products to be less hard-working than owners of traditional products. A series of ANOVAs showed that autonomous products can have a detrimental effect on people's perception of how hardworking a person is.

The objective of Study 4 was to provide further insights into how one can prevent the negative effects of autonomous products on perceptions of hard work. Moreover, this study used a highly realistic configuration of Facebook profiles. Another series of ANOVAs showed that autonomous products only reduce perceptions of hard-work when time is used for leisure, but not when time is dedicated for work, thus we reveal a critical moderator. We also shed light on the consequences of perceptions of hard working by revealing their effect on perceived success (moderated mediation index is significant).

We reveal a novel consequence of how those products affect social perceptions and provide three important insights: The key insight is that highlighting that freed-up time is not only used for work can attenuate the detrimental effect of autonomous products on perceptions of hard work. Second, even while owners of autonomous products are perceived to work longer, they are not perceived to be more hard-working than their counterparts with traditional products. Finally, we show that the effect of autonomous products translates to perceived success and thus a highly status relevant variable.

Consumers and companies will most likely benefit from autonomous products, however, potential negative consequences should be recognized: Autonomous products can have detrimental effects on peer perceptions in meritocratic societies. Therefore, marketers can adjust their communication strategy. For consumers, who are more intrigued by less hardworking people, one may proactively communicate the opportunity to relax. In cultures and environments where busyness is considered a status symbol, firms should highlight the opportunity to be productive while the autonomous product is completing work. In all societies, time saving and time pressure should be emphasized.

Time to be Happy: Autonomous Products Increase
Consumer Happiness by Reducing Time Stress

Tobias Schlager, HEC Lausanne, Switzerland
Emanuel de Bellis, University of St. Gallen, Switzerland
Ashley V. Whillans, Harvard Business School, USA

EXTENDED ABSTRACT

Products are increasingly becoming autonomous, able to initiate their own behavior to complete tasks on behalf of consumers (Beer et al. 2014; de Bellis and Johar 2020; Schmitt 2019). For example, robotic vacuum cleaners keep one's home tidy, robotic lawn mowers take care of one's garden, and smart kitchen devices implement various recipes. These autonomous products are quickly gaining in popularity, with over 14 million Americans owning solely a robotic vacuum cleaner (Statista 2020).

Although automated consumer products have a long history (e.g., kitchen appliances such as food processors and automatic transmission in cars), it is only now that products are being equipped with higher levels of autonomy and intelligence (Hoffman and Novak 2018; Schmitt 2019; Wertenbroch et al. 2020). Whereas autonomous products may be connected to other products and systems, they are typically meant to accomplish a specific task. Importantly, as autonomous products increasingly take over tasks from consumers, they provide consumers with the opportunity to take part in other tasks and activities (André et al. 2018; Leung, Paolacci, and Puntoni 2018; Rijsdijk and Hultink 2003).

In fact, a key sales argument for many of these technologies is that they free up time. Given that time may be the most limited resource in our lives (Chung et al. 2019), time savings are related to various beneficial effects. For example, consumers were happier when they spent money on a time-saving purchase, such as paying for housecleaning, than when they spent money on a material purchase, such as buying new clothes (Whillans et al. 2017). Other research argued that convenience and time savings are strong drivers of the adoption of new technologies (Willems et al. 2017; Wu 2018). We follow up on these findings and ask: Do the time savings generated by autonomous products also affect consumers' happiness?

Although prior work has provided initial insights into why people are reluctant to adopt autonomous products (de Bellis, Johar, and Schweitzer 2020; Leung et al. 2018; Longoni, Bonezzi, and Morewedge 2019), the larger consequences for people's lives have not been well understood. Our key proposition is that autonomous products affect happiness as they reduce the time stress of consumers. This builds on recent findings that time is indeed a key predictor of happiness (Whillans et al. 2017; Whillans, Weidman, and Dunn 2016).

Moreover, we also believe that compared to other ways of saving time in one's daily chores, autonomous products have one key advantage: Consumers tend to feel less guilty for delegating the tasks they should typically do. This is important, since prior work found that the psychological implications of outsourcing tasks is critically undermined by feelings of guilt (Whillans, Lee-Yoon, and Dunn 2020). Finally, we propose a key moderator of this effect by conceptualizing the extent to which consumers perceive autonomous products as more than just a product. In particular, we propose that ascribing human characteristics to a product may undermine the positive effect of autonomous products against other ways to delegate a task as consumers indeed develop a feeling of guilt in this case.

We tested these predictions in a series of four studies. Study 1 was designed with the objective of obtaining initial field evidence on whether people become happier when they own autonomous products. Study 2 was designed with the objective of getting correlational insights into whether people become happier when they own autonomous products. Study 3 was designed with the key objective of providing causal evidence on whether owning and operating autonomous products increases happiness. A second objective was to shed light on the psychological mechanism underlying the effect. Study 4 was designed with the objective of examining the effects of autonomous products compared to other ways of saving time. Specifically, this study tests the effects against delegating tasks to other persons, i.e., home helpers. A summary of methods and results is provided in Table 1.

The findings of these studies, conducted in the field and online, show that autonomous products may indeed make people happier as they free up time and as a consequence feel less pressed for time. Moreover, we also find support for the hypothesis that consumers feel less guilty when they outsource their tasks to autonomous products (vs. home helpers). Finally, we find that if consumers ascribe human characteristics to an autonomous product, this positive effect is undermined and they feel guiltier and less happy than if they would construe the product simply as an object.

Our findings make several important theoretical contributions: First, we examine a key characteristic of autonomous products (i.e., to save time) and its implications for consumer happiness. Identifying time saving as process also contributes to literature on the importance of time, which is an increasingly proliferating field in psychology research (Lee-Yoon and Whillans 2019; Rudd, Catapano, and Aaker 2019; Whillans et al. 2016). Finally, we contribute to research on consumers' relationships with products (Belk 2013; Seeber et al. 2020) and reveal a potentially negative consequence of too humanlike products.

Living in Glass Houses: The Effect of Transparent Products on Self-Presentation

Ann Schlosser, University of Washington, USA
Evelyn Smith, University of Washington, USA

EXTENDED ABSTRACT

What does she keep in that thing?

A recent article about stadium bags (i.e., clear bags) being required at football games posed the above question and continued: "That particular question has been a source of mystery surrounding women's purses for decades. But now fashion trends—and the National Football League—are making it completely, well, clear" (Fitzgerald 2019). What is unclear is what effect transparent (i.e., visually clear) products have on consumer behavior. In particular, will it cause consumers to be more honest with others and/or to manage their impressions more?

Visual stimuli and imagery can significantly influence consumer behavior (e.g., Andrade et al. 2014; Elder and Krishna 2010; Elder et al. 2017; Ittersum and Wansink 2012). For example, a red (vs. blue) background can cause aggression, leading people to bid with larger jumps (Bagchi and Cheema 2012), and people favor unusual colors in marketing messages (Miller and Kahn 2005). Furthermore, people use products' visual appearances to manage their impressions on others, such as favoring larger logo sizes to show devotion to a brand (Wang and Griskevicius 2014).

Transparency as a visual design feature has been examined primarily in the food packaging literature (e.g., Cavallo and Piqueras-Fiszman 2017; Deng and Srinivasan 2013; Simmonds, Woods, and Spence 2019). For example, transparent packaging can increase food salience as well as consumption monitoring (Deng and Srivivasan 2013). Our research question is whether transparent products (such as transparent backpacks or shopping bags) automatically trigger self-presentation concerns, and if so, what type? This is an important question from a practical standpoint given that transparent products are fashionable (e.g., Givenchy's Transparent Windbreaker, Christian Louboutin's Just Nothing Slide Sandal) and even required at large stadium events (e.g., sports, concerts). This is also important theoretically because it contributes to our understanding of how visual transparency might automatically prompt different self-presentation tactics, including the nuances underlying creating a desirable impression by being honest or self-flattering.

Self-presentation is defined as "the goal-directed activity of controlling information to influence the impressions formed by an audience about oneself" (Schlenker and Wowra 2003, 871), and can take one of two forms: being socially transparent or socially impenetrable (Gilovich, Savitsky, and Medvec 1998; Gilovich, Medvec, and Savitsky 2000; Schlenker and Wowra 2003). On the one hand, transparent products may trigger social transparency. Social transparency occurs when people feel that their "internal states are more readily discernible by audiences than they actually are" (Schlenker and Wowra 2003, 874). This causes people to present themselves more honestly to avoid any negative social repercussions resulting from being discovered as dishonest (Schlenker and Leary 1982). On the other hand, transparent products may trigger social impenetrability, where people feel that "their thoughts and feelings are hidden from others" (Schlenker and Wowra 2003, 874). Under such circumstances, people manage the impression they have on others by presenting themselves in more self-flattering ways, even if these presentations are not entirely true. In fact, transparent (vs. opaque) products may cause consumers to feel more exposed to others' scrutiny, which may cause them to present themselves in ways that are more favorable. Notably, such self-presentation effects can occur automatically (Schlenker and Wowra 2003). We propose that product transparency will be such an automatic cue priming self-presentation. Importantly, how such self-presentation tactics manifest (i.e., to be honest or self-flattering) will depend on whether the self-presentation measure is indirect (self-presentation is inferred from someone's behavior without explicit instructions to report it) or a direct measure (self-presentation is assessed with explicit instructions to report it; Greenwald and Lai 2002, 420-421).

People tend to portray themselves in a flattering manner (e.g., never swearing or littering) both intentionally and unintentionally (Paulhus 2002; Holden and Passey 2010; Ziegler, MacCann, and Roberts 2011). Yet, detecting self-presentation can be challenging because sometimes people divulge true information about themselves (e.g., "I read a book a week" or "I work out every day") because it conveys a desirable impression (e.g., a bibliophile or athlete; Schlosser 2020). One common method used in psychology to detect a positive distortion is the overclaiming technique (Bruce and Trapnell 1995; Müller and Moshagen 2019; Paulhus et al. 2003). A benefit of this technique is that compared to other impression-management and self-deception measures, it is the most distinct indicator of positive distortion that is not confounded with personality and/or cognitive ability (Bensch et al. 2019).

With this technique, participants rate their familiarity with a series of topics, some of which are nonexistent. The nonexistent topics eliminate the possibility that answers reflect an honest response. This technique is an indirect measure because a flattering self-portrayal is inferred by observing whether participants overclaim their knowledge without explicitly telling participants that this is being assessed. We predict that if transparent products cause consumers to present themselves in more self-flattering ways when doing so is ostensibly not detectable (i.e., with an indirect measure), then they should present themselves in more self-flattering (rather than entirely honest) ways by overclaiming their knowledge. We test this prediction in the first two studies.

In Study 1, 223 MTurk participants were randomly assigned to see a transparent, semi-transparent, or opaque backpack image (the transparency manipulation). Specifically, all participants began by imagining that they were going to a sporting event and listing in an open-ended textbox all of the items they would bring. Participants then saw one of three backpacks. To reinforce the transparency manipulation, participants reported where they would put each personal item in the backpack's different compartments. Afterwards, as part of an ostensibly separate study, participants completed the physics category of the Over-Claiming Questionnaire (OCQ; Paulhus and Bruce 1990; Paulhus et al. 2003). To reduce participants' fatigue due to a lengthy questionnaire, we chose a single category. We selected physics because we believed it would be outside the areas of expertise of most of the MTurk (and later, business student) samples.

Overclaiming occurs when participants claim familiarity with nonexistent topics. As predicted, a significant transparency effect emerged ($F(2, 220) = 3.05$, $p = .050$; see Table for all means across studies). Overclaiming was greater for those in the transparent condition than the semi-transparent ($F(1,220) = 4.18$, $p = .042$) and opaque conditions ($F(1,220) = 4.99$, $p = .027$).

In Study 2, 212 undergraduates at a large university were randomly assigned to have direct experience with a transparent or opaque bag. Specifically, participants were told that the university

bookstore was considering selling the bag with the university's logo on it, but before doing so, it wanted students' opinions of the bag. Participants were informed that in order to get a better sense of the bag, they should place their personal items in the bag. In actuality, this was done to reinforce the transparency manipulation. While their belongings were in the bag, participants completed the OCQ. As in Study 1, overclaiming was greater for those using a transparent (vs. opaque) bag ($F(1,210) = 6.42$, $p = .012$). Thus, the results of Studies 1-2 suggest that when self-presentation is measured indirectly, consumers will exhibit greater impression management when using a transparent (vs. opaque) product.

In Study 3, we further test the effect of transparent products on self-presentation in two ways. First, we use both an indirect measure (OCQ) and a direct measure of self-presentation. Specifically, the direct measure involves explicitly asking participants to disclose personal information. If consumers are portraying themselves in a positive light with transparent (vs. opaque) products, then they should disclose more flattering information about themselves (e.g., what they are proud of) and less unflattering information (e.g., what they feel guilty about). However, if they are responding more honestly, we should observe more flattering and unflattering disclosures. Second, we varied the extent to which the context supports disclosing more personal details about themselves to others. We expect that when the context does not support disclosing personal details, a transparent (vs. opaque) product will cause consumers to portray themselves favorably on the indirect measure: to overclaim their knowledge (as observed in Studies 1-2). Furthermore, if the results generalize to direct measures, then they should also disclose more flattering (but not unflattering) information. However, when the communication partner speaks more honestly (i.e., disclosing personal information), then the differences between the transparent and opaque product should be attenuated for both flattering and unflattering disclosures. Indeed, it appears that even when interacting with computers, consumers disclose more when the computer discloses (vs. does not disclose) information about itself (Moon 2000).

To test the predicted interactive effect, 194 MTurk participants were randomly assigned to a condition in a 2 (transparency: transparent vs. opaque) × 2 (disclosure: disclose vs. control) design. Participants were shown a picture of a transparent versus opaque artificial intelligence (AI) speaker (the transparency manipulation) and were told to engage in a conversation with this speaker. We chose an AI speaker because we wanted to assess whether the effects were driven by (a) product transparency itself or (b) participants' personal belongings being observable to others. With the transparent speaker, only its inside mechanics were observable. Furthermore, we varied whether the AI speaker disclosed personal information about itself or not. The questions and information provided by the AI speaker were like that used in prior research (Moon 2000). More specifically, the AI speaker asked eight questions (e.g., "what are your favorite things to do in your free time?") after stating either a similar answer of itself (e.g., "When this speaker doesn't have any work to do, it usually just runs its energy saver program"), or a control paragraph with similar word counts (e.g., "The next question in this part asks about the different things you like to do in your spare time"). Number of disclosures in participants' answers were coded by two independent judges blind to the conditions (αs > .83 between judges' codings across the questions). Afterwards, participants completed the OCQ.

For responses to the OCQ, there was a significant transparency × disclosure interaction for overclaiming ($F(1,190) = 4.22$, $p = .041$). Specifically, in the control condition (i.e., when the AI speaker did not disclose any information), overclaiming was greater for those who spoke to a transparent (vs. opaque) AI speaker ($F(1,190) = 3.43$,

$p = .066$), consistent with the results of Studies 1-2. However, the effect was attenuated when the speaker behaved honestly by disclosing flattering and unflattering information about itself ($F(1,190) = 1.13$, $p = .289$).

For number of disclosures to the AI's questions, we observed more disclosures in the transparent (vs. opaque) condition ($F(1,190) = 4.45$, $p = .036$), although closer examination revealed that the effects were stronger in the control condition as predicted (see Table). Looking more specifically at each question, we find that the transparent speaker led to more proud disclosures ($F(1,190) = 5.32$, $p = .022$). However, participants also disclosed more in areas that are unflattering, such as what made them furious ($F(1,190) = 3.37$, $p = .068$), and what they felt guilty about ($F(1,190) = 5.80$, $p = .017$). Overall, the results suggest that when self-presentation is ostensibly undetectable (i.e., with an indirect measure), participants present themselves in a self-flattering way by overclaiming their knowledge, replicating the results of Studies 1-2. This effect was attenuated when they had recent experience favoring honesty (i.e., interacting with an honest AI speaker). Moreover, when self-presentation is more clearly detectable (i.e., with a direct measure), participants in the transparency (vs. opaque) condition are more honest (i.e., disclose flattering and unflattering information about the self).

In the final study, we examine further the nature of self-presentation by applying a social comparison framework. According to social comparison theory, an upward (vs. downward) social comparison occurs when consumers compare themselves to someone who is better (vs. worse) off than themselves (Buunk and Gibbons, 2007; Festinger 1954; Taylor, Wayment, and Carrillo 1996). Being a smart shopper is one important positive self-evaluation and the failure to do so is self-threatening (Argo et al. 2006; Schindler 1998). For example, after learning that they paid more than another consumer for the same product (an upward comparison), consumers might be honest by admitting to paying a higher price (an unflattering portrayal), or they might manage impressions by stating that they paid a lower price (a flattering portrayal). In other words, impression management is most likely to emerge when one's shopping ability is more threatened (i.e., when they paid more for the same product as someone else).

To test this, 303 MTurk participants were randomly assigned to a condition in a 2 (transparency: transparent vs. opaque) × 2 (comparison: upward vs. downward) design. For the transparency manipulation, participants saw a picture of a transparent or opaque shopping bag. All participants were told to imagine carrying their newly purchased bath towels in the pictured shopping bag while walking through the mall and the parking lot to their car where they run into a co-worker. Based on prior research (Argo et al. 2006), we told participants that their co-worker informs them that they just purchased the same new car as they did for a specific price, which was either lower (upward comparison) or higher (downward comparison) than the amount they paid. Participants recorded the price they would tell the co-worker that they paid. They also learned that the co-worker had purchased the same set of bath towels for a lower (vs. higher) price. Participants reported the towel prices they would disclose to the co-worker.

We standardized the car and towel prices and analyzed them as repeated measures in a mixed-design ANOVA. The transparency × comparison interaction was significant ($F(1,299) = 3.75$, $p = .054$). As predicted, those in the upward condition (i.e., those who paid a higher price than their co-worker) stated higher prices to their co-worker when their shopping bag was transparent than opaque (Ms = 1.06 vs. .88; $F(1,299) = 6.33$, $p = .012$). There was no transparency effect in the downward condition ($F(1,299) = .49$, $p = .483$).

To assess the degree of shift in the price disclosed to the co-worker, we subtracted the actual prices paid from the disclosed prices paid based on the social comparison direction. By doing this, we control for the higher actual price paid by the participant in the upward than downward condition. We then standardized the differences. Again we observed a transparency × comparison interaction $(F(1,299) = 3.68, p = .056)$. In the upward comparison condition, although all participants said they paid a lower price than they actually did, the degree of shift was smaller in the transparent than opaque condition, thereby reflecting greater honesty (Ms = -.22 vs. -.54; $F(1,299) = 11.69, p = .001$). Furthermore, as predicted, this effect was observed only when revealing the actual price paid would be unflattering: there was no transparency effect when participants paid less than their co-worker $(F(1,299) = .05, p = .819)$. Thus, when disclosures were unflattering, participants in the transparent (vs. opaque) condition were more honest, suggesting greater feelings of social transparency.

In summary, we find that transparent (vs. opaque) products trigger greater self-presentation behaviors but that the type of self-presentation depends on whether honesty (vs. impression management) is detectable. Consequently, transparent products can make consumers more socially transparent (honest) and more impenetrable (self-flattering).

Do Survey Invitations Affect Non-Respondents?

Vicki G. Morwitz, Columbia University, USA

EXTENDED ABSTRACT

Research on the "mere-measurement effect" (MME) shows that the mere act of participating in surveys can modify consumers' preferences and behaviors (Morwitz, Johnson, and Schmittlein 1993; Spangenberg et al. 2016). The present investigation suggests that the mere act of *not* participating in surveys can also affect consumers' preferences and behaviors. Specifically, we find that companies' survey invitations impair non-responding customers' attitudinal and behavioral loyalty. We label this effect the "survey effect for non-respondents" (SEN).

Several well-known schools of thought (e.g., Bem 1972; Lord and Lepper 1999) emphasize that "individuals assess their current attitudes in part by reference to the actions they have taken toward the attitude object in the past" (McIntyre et al. 2004, 1162). We thus anticipate that non-respondents might interpret their reaction to a company's survey invitation (e.g., for telephone surveys, the act of declining and hanging up) as a signal of their own (negative) attitude toward the company. Consequently, behavior-induced attitude construction predicts that survey invitations may impair non-respondents' attitudes and relational behaviors toward the company—i.e., a negative SEN.

Importantly, attitude construction theory also emphasizes that links from behavior to attitudes only develop when individuals *interpret* a particular behavior as a diagnostic manifestation of their attitudes (Schwarz and Bohner 2001). Hence, we conjecture that the negative link from nonresponse behavior to attitudes weakens if non-respondents do not interpret their nonresponse decision as resulting from their attitude toward the company, but from contextual factors (e.g., lack of time). We designed four experiments to test our predictions and to explore how companies can avoid the SEN.

Study 1 was a field experiment in which 1173 customers of a car manufacturer were randomly assigned to a survey condition (invitation to a satisfaction survey via telephone) or a control condition (no invitation). The dependent variable was repurchase probability. The results of a causal mediation model (cf. Jo 2008) revealed that the survey invitation reduced non-responding customers' repurchase probability by 7% ($p<.05$)—a negative SEN.

Furthermore, we asked interviewers to categorize non-respondents' reasons for not responding into context-related reasons (e.g., lack of time) versus other reasons. Non-respondents mentioning other reasons had a lower repurchase probability (32.8%) than control group members (44.9%; $\chi^2(1)=4.68$, $p<.05$). Non-respondents providing context-related reasons had a similar repurchase probability (41.1%) to control group members (44.9%; $\chi^2(1)=.19$, $p>.10$). These results are consistent with an attitude construction account.

Study 2 was designed to revalidate study 1 in a more controlled setting. It was a 2 (context salience high vs. low) x 2 (rejection of focus vs. control company survey) between-subjects experiment ($N=158$). In the first study part, subjects read a newspaper article designed to prime high versus low context salience. The article either focused on time pressure (high context salience) or a neutral topic (low context salience). In the second part, subjects read a scenario about the car manufacturer "Proton" and imagined owning a Proton. In the scenario, subjects had just returned home and were surfing the web. They then saw a cell phone screen displaying an incoming call and heard a ring tone playing in loop. When they took the call by clicking the answer button, subjects received a survey invitation from a market research institute calling on behalf of Proton (focus company) or their telecommunications provider (control company). We then asked subjects to write down how they would decline participating. The interviewer then said goodbye and subjects ended the call by clicking the hang up button. Finally, subjects reported their attitude toward the *focus* company (alpha=.97).

Results revealed a significant interaction effect ($F(1,154)=3.91$, $p<.05$): For low context salience, not responding to the survey of the focus (vs. control) company reduced subjects' attitude toward the focus company ($M_{control\_company}=6.11$, $M_{focus\_company}=5.62$; $F(1,154)=5.85$, $p<.05$)—a negative SEN. For high context salience, however, the SEN was absent ($M_{control\_company}=6.00$, $M_{focus\_company}=6.09$; $F(1,154)=.16$, $p>.10$). These results are consistent with study 1.

In *study 3a*, we tried to eliminate the SEN by manipulating interviewers' survey invitation. We conducted a 2 (context-related vs. neutral invitation) x 2 (rejection of focus vs. control company survey) between-subjects experiment ($N=101$). We used the same basic materials from study 2. However, in study 3a, we manipulated interviewers' survey invitation to highlight context factors ("Do you have a couple of minutes to participate in this survey?") or not ("Would you like to participate in this survey?"). Then subjects wrote down how they would decline the invitation of the focus versus control company and reported their attitude toward the *focus* company (alpha=.94).

Results revealed a significant interaction effect ($F(1,97)=5.87$, $p<.05$): For the neutral survey invitation, not responding to the survey of the focus (vs. control) company reduced subjects' attitude toward the focus company ($M_{control\_company}=6.12$, $M_{focus\_company}=5.35$; $F(1,97)=11.46$, $p<.01$)—a negative SEN. However, the context-related survey invitation eliminated the SEN ($M_{control\_company}=6.10$, $M_{focus\_company}=6.06$; $F(1,97)=.03$, $p>.10$).

Study 3a indicates that interviewers can proactively prevent the SEN. However, context-related invitations may provide a welcome excuse for consumers to decline survey invitations, thereby potentially decreasing response rates. Hence, we next investigated a reactive strategy which, by definition, cannot affect response rates.

In *study 3b*, we manipulated interviewers' reply after consumers had decided not to respond. We conducted a 2 (context-related reply vs. neutral reply) x 2 (rejection of focus vs. control company survey) between-subjects experiment ($N=163$). We used the same basic materials from studies 2 and 3a, but manipulated interviewers' reply to subjects' nonresponse statements to either highlight context factors ("…I apologize for the interruption, I totally understand that you don't have time right now. Have a nice day.") or not ("…Have a nice day."). Subjects' then reported their attitudinal loyalty toward the *focus* company (alpha=.93) as a closer proxy of behavioral loyalty (cf. study 1).

Results revealed a significant interaction effect ($F(1,159)=4.38$, $p<.05$): For the neutral reply, not responding to the focus (vs. control) company survey reduced subjects' attitudinal loyalty toward the focus company ($M_{control\_company}=5.39$, $M_{focus\_company}=4.53$; $F(1,159)=6.55$, $p<.05$)—a negative SEN. However, the context-related reply eliminated the SEN ($M_{control\_company}=5.01$, $M_{focus\_company}=5.12$; $F(1,159)=.12$,

p>.10). Overall, study 3b suggests that interviewers can eliminate the SEN even *after* consumers have declined to participate.

A Sense of Who we Are: How TV Viewing Contributes to Negotiating Couple Identity

Julien Schmitt, ESCP, France
Mathilde Lapostolle, ESCP, France

EXTENDED ABSTRACT

"Before, to test if we could live together as a couple under the same roof, we used to adopt a cat or a dog; nowadays, we take out a Netflix subscription." In this observation, comedian Charline Voenenacker humorously encapsulates the importance that new digital TV platforms take in the everyday lives of romantic couples. A 2016 Netflix study shows that 72% of individuals feel that staying home and watching Netflix with their partners represents the ideal casual date night. This echoes the growing importance of TV viewing in consumer lives, and particularly the role played by new digital TV platforms in structuring everyday life and shaping social relationships (Feiereisen et al. 2019). Despite this increasing importance taken by digital TV in couples' consumption time, no research to date has explored how couples construct, negotiate, and enact their identity through shared (or unshared) TV viewing. Since, with digitalization, TV viewing has become more flexible and controlled by viewers, the practice configurations adopted by couples must inform much about the construction of their collective identity. The objective of this research is to investigate this process.

Existing research on couples' consumption is mostly based on a positivist and individualistic approach that focuses on topics such as how each individual partner participates in the decision or how they influence each other (Barlés-Arizón et al. 2013). The way a couple builds a collective identity through consumption is, however, largely overlooked. Yet, literature shows that people consume not only to benefit from products' utilities but also to enjoy their symbolic meanings, to create and sustain the self, and to locate the self in society (Wattanasuwan 2005). This is true both on an individual and collective level, as groups, including couples (Hickman-Evans et al. 2017), use market resources partly to construct, negotiate, and enact a collective identity (Lamont and Molnár 2001), particularly in the mundanity of everyday life such as TV viewing behavior (Edirisingha, Ferguson, and Aitken 2015). Therefore, in this research, we approach couples through the lens of family identity (Epp and Price 2008), seen as the collective enterprise, central to many consumption experiences, that defines "who we are as a family." We apply this concept to the context of couples in order to study "couple identity," by which we refer to "the partners' sense of who they are as a unit" (Miller and Caughlin 2013, 64). To this end, we do not consider a couple as the sum of its members' individual identities but as an integral consumption unit.

To investigate the construction, negotiation, and enactment processes of couples' identities through TV viewing, we focus on a specific type of content, TV series. This content is particularly well suited to study identity processes. First, TV series occupy an important place in couples' daily lives. Second, due to the serial dimension of this media, viewers tend to develop an important level of connectedness with TV series' characters and universes (Russell and Schau 2014). Third, this media is particularly affected by digitalization, which offers partners great flexibility in their viewing configurations (Watkins 2015). Drawing from a thematic analysis of 11 (seven individual and four collective) phenomenological interviews conducted with nine couples, we identify three processes through which informants negotiate their couple identity through TV series consumption:

- *Who is "we"* – This first process refers to the answers that partners give to the question "who do we want to be as a couple?" First, most couples spend a significant proportion of their shared time watching TV series. Therefore, the practice configuration adopted (for instance, the rituals surrounding the viewing activity) represents an important part of the shared experience constructed and meanings generated. Second, TV series viewing is charged with strong social stigma (i.e., passivity, isolation, or lowbrow culture). Therefore, the time allocated to this activity compared to other social or cultural occupations reflects a shared representation of what a "good" relationship should be made of.

- *How "we" works* – This second process represents the specific behavioral patterns that couples adopt to cope with certain contextual situations. First, with digitalization, TV series viewing is now one of the most adaptable activities in space and time. Therefore, couples can easily integrate this activity into the structure of their daily functioning and use it, for instance, to cope with irregular professional rhythms. This sometimes helps to overcome potential barriers to identity enactment. Second, TV series viewing practices also contribute to shaping couples' relational functioning and can even resolve conflicting situations, for instance by adopting solitary viewing when space and tranquility are required. With such coping strategies, tensions can arise from a misalignment between the negotiation of how "we" works and the pursued couple identity (who is "we").

- *Who am I within "we"* – This third process refers to the management of the interplay between the partners' individual identities and the collective performance of the couple's identity. Choosing among the plethora of available TV series is often a source of identity tension within couples as TV shows can be charged with strong stigma and contribute to shaping identities. Being a regular viewer of a specific TV show in order to please one's partner and fulfill the couple identity can threaten one's own individual identity. Specific coping strategies (distancing, implementing different rituals for these TV series, etc.) can allow the fulfillment of couple identity without endangering individual identities.

Our contribution is threefold. First, we help improve the understanding of the under-researched topic of couples' shared identity. Second, we show that Epp and Price's framework for family identity is well suited to the study of the construction, negotiation, and enactment processes of couple identity. Third, we extend this framework by identifying two additional moderating variables influencing the process of identity negotiation and enactment: individual conscience of couple identity (i.e., the degree of awareness a partner has of the fact that his/her couple has its own identity and of what he/she desires for the relationship) and social influence (i.e., the extent to which partners are influenced by social norms).

Twelve of One or a Dozen of the Other: How Numerical Expressions Influence Preferences

Gustavo Schneider, University of South Carolina, USA
Elise Chandon Ince, University of South Carolina, USA
Rajesh Bagchi, Virginia Tech, USA

EXTENDED ABSTRACT

Although extant research has considered the role of numbers on consumer decision making, past literature has mainly focused on framing effects using different numbers or quantities (Thomas and Morwitz 2005). Specifically, the focus has been on round (vs. precise) numbers of similar magnitude (Thomas et al. 2010; Yan and Pena-Marin 2017) or odd (vs. even) numbers (Wilkie and Bodenhausen 2012). In all these cases, although of similar magnitude, the numbers are objectively different.

In the current research, we focus on how to frame the *same* quantity using different formats, such as: 12-pack vs. a dozen pack of probiotics, memberships for 4 months vs. a semester. In these instances, a number (12) is compared to a numerical expression (dozen). We define numerical expressions as non-numerical quantifiers, such as pairs, trios, dozens, hours. Although numerical expressions represent a quantity, they do so without using an actual number such as 2, 3, 12, or 60 minutes, nor a written number such as twelve. We argue that written numbers, such as twelve, do not qualify as numerical expressions as they spontaneously elicit the number 12 itself and not a distinct non-numerical quantifier as the examples above. Numerical expressions, on the other hand, prompt consumers to focus on the collective unit (dozen, pair, trio, etc.), which can serve as a goal in and of itself. This is because, these numerical expressions appear complete and finite relative to their normatively equivalent values. While dozen appears bounded since there is no equivalent expression for 11 or 13, 12 does not suffer from the same constraint as it is part of a continuum (11, 12, 13, etc.). Consequently, we propose that consumers are more likely to aspire towards numerical expressions.

Prior research has shown that perceptions of completeness are malleable and influence consumer judgment for visual stimuli and numbers (Sevilla and Kahn 2014; Yan and Pena-Marin 2017). We similarly propose that consumers will perceive a quantity framed using a numerical expression (e.g., dozen bottles) to be more complete relative to the same quantity framed using numbers (e.g., twelve bottles). We argue that the increased perception of completeness will translate into an easier justification to purchase more or extend the duration of a planned service. We expect that the enhanced completeness when the offer is framed using numerical expressions will make it more easily justifiable, and therefore more likely to be preferred by consumers. We investigate these predictions in eight studies.

We contribute to this literature in two ways. First, focusing on numerical expressions allows us to examine new types of numerical frames (12 vs. dozen) never studied before. Second, in the current research we also investigate the role of numerical expressions when there is a change in the originally planned purchase or task duration (e.g., change from 11 to 12 vs. from 11 to a dozen).

In Study 1A, we demonstrate that participants are more likely to add a product to reach a dozen (vs. 12) products. In Study 1B we conceptually replicate our finding using a different numerical expression (detailed results available on Table 1).

In Study 2, we show that the proposed effect is unique to numerical expressions (e.g., dozen) and not general for written numbers (e.g., twelve) versus Arabic numerals (e.g., 12). Results revealed that when the offer was framed as dozen, participants were more likely to add the extra product compared to 12 and to twelve.

In Study 3, we provide evidence for the proposed underlying mechanism of completeness and justification. In this study, we asked students to imagine they were planning to buy a 3-month gym plan, then the gym associate offers them to add one more month to have a 4-month plan or a semester plan. As predicted, participants were more likely to extend the duration of their gym plan in the numerical expression condition, and a bootstrap analysis showed that the indirect effect of numerical expression on likelihood to add via completeness and justification was significant $CI_{95\%}$ [.090, .385].

In Study 4, we test a boundary condition of the effect, namely when a numerical expression itself is incomplete (i.e., part of a semester). We replicate the findings from previous studies in the complete expression condition (more likely to extend membership to semester rather than 4-month plan). However, when the numerical expression was incomplete there was no difference in likelihood to add the extra month between part of semester or 2-month membership. Confirming our expectations, a bootstrap analysis revealed a significant index of moderated mediation

In our final set of studies, we provide evidence that consumers are also willing to pay more for offers framed using numerical expressions and that restaurants and online retailers put a premium on products framed using numerical expressions. In Study 5, we show that consumers are willing to pay more for kitchen utensils framed using a numerical expression relative to an equivalent number. In Study 6, we compared actual restaurant menu prices (6A) and Amazon products (6B) and find that items described using numerical expressions sell for an average higher price compared to items described using equivalent numbers.

In this research, we unveil a novel type of numerical framing, namely: numerical expressions. We find evidence that consumers are more likely to include additional products or extend the duration of a service when the offer is framed using numerical expressions (vs. the equivalent number). On the theoretical side, we expand prior research on the role of units, we show that numerical expressions increase perceptions of offer completeness, we empirically test the link between completeness and justification, and show that numerical expressions also serve as consumption goals. From a managerial standpoint, our results offer insights on how managers can frame their offerings when they have the possibility of using numerical expressions. We show that these effects are consistent across different types of numerical expressions (i.e., numbers, time, units) and purchase contexts.

Seeing and Believing: A Performative Perspective on Augmented Reality

Joachim Scholz, Brock University, Canada

EXTENDED ABSTRACT

Existing AR research predominantly adopts cognitive perspectives when analyzing augmented reality product visualization apps. The current paper offers researchers a new set of eyes by developing a performative perspective on AR. This novel perspective provides a more nuanced and substantially broadened assessment of augmented reality's potential for marketing and retailing.

Over the last few years, many brands have launched augmented reality product visualization (ARPV) apps to help consumers imagine how furniture, appliances, clothing, makeup, and other products will look like in their own spaces or on their own bodies. Prior research has examined how ARPV apps impact consumers' responses to products (e.g., Beck and Crié 2018; Hilken et al. 2017; Yim, Chu, and Sauer 2017) and relationships with brands (e.g., Huang 2019; Scholz and Duffy 2018). While this research has demonstrated AR's potential for marketing, the current paper argues that many more benefits can be identified through a shift in analytical perspectives.

Existing AR research typically adopts cognitive perspectives to examine how ARPV apps help consumers process abstract information when evaluating and selecting products for purchase. In contrast, the current study adopts a performative perspective to examine how ARPV apps facilitate consumers in their ongoing and multi-faceted consumption projects (e.g., Maciel and Wallendorf 2017). Guided by a practice theory lens (Schatzki 1996) and through a market ethnography of makeup consumers, it explores how ARPV apps help consumers become capable practitioners of everyday practices. In particular, the following two research questions are examined: (1) How do augmented reality product visualizations relate to the various components of practice performances (i.e., objects, doings, and meanings)? And (2) how can ARPV apps help consumers become and feel like capable practitioners through reducing the complexity of a practice, validating consumers' performances, or any other means?

The findings of this study contribute to AR research by providing a more nuanced and also broadened assessment of AR's potential for marketing and online retailing.

Theory background: Cognitive perspective on AR

Augmented reality, and ARPV apps more specifically, overlay three-dimensional digital simulations of products onto consumers' physical bodies or their physical environments in real time (Scholz and Smith 2016). ARPV apps have been found to make product selection easier, more interesting, and perceived to be less risky (e.g., Beck and Crié 2018; Huang and Liu 2014; Javornik 2016b). ARPV apps have also been linked to higher purchase and word-of-mouth intentions (e.g., Hilken et al. 2017; Poushneh and Vasquez-Parraga 2017; Yim, Chu and Sauer 2017).

These benefits of ARPV apps are often explained by showing how embedding information in consumers' immediate environments — the defining property of augmented reality (Javornik 2016a; Scholz and Smith 2016) — reduces the mental burden consumers face when evaluating products. Consumers who examine AR product visualizations are more immersed in the task (Javornik 2016b; Yim, Chu, and Sauer 2017) and feel more at ease with their decisions (Hilken et al. 2017), compared to web-based product representations. Drawing on situated cognition theory, which states that information processing occurs within physical environments and can be aided by bodily factors (Robbins and Aydede 2009), Hilken and colleagues

(2017) show that ARPV apps offer a more intuitive way to process information.

It is important to note that 'embodiment', in this conceptual lens, refers to how consumers utilize their bodies whilst processing product information (Barsalou 2008; Brown, Collins and Duguid 1989). Using ARPV apps, consumers can apply the same physical movements to evaluate product simulations as they would when assessing actual material products (i.e., simulatedphysical control; Hilken et al. 2017). Such naturalistic movements can lead to perceptual re- enactments of previous, actual product experiences that have been stored in memory (Petit, Velasco, and Spence 2019). In other words, the situated cognition perspective conceptualizes AR as a decision-making tool (Porter and Heppelmann 2017) that facilitates consumers' understandings of abstract product characteristics through a superior visual format.

While informative for immediate decision situations, the cognitive perspective does not capture the full potential of ARPV apps for at least two reasons: First, attention is focused on AR's benefit for evaluating product attributes (i.e., a product-centric approach). As has been pointed out by prior research, it is also important to understand the wider impact of AR across all stages of the customer-decision journey (Hilken et al. 2018; Javornik 2016a). This includes a deeper understanding of how consumers actually use AR applications (Scholz and Duffy 2018) as part of their consumption behaviors (i.e., a customer-centric approach). Second, research in psychology (e.g., Pouw and Looren de Jong 2015) and marketing (e.g., Yakhlef 2015) has pointed out that the cognitive perspective — even in its 'situated' incarnation — is still premised on a Cartesian thinking subject.

In contrast to the situated cognition perspective, which construes the body as a physical apparatus for thinking (Schürkmann 2013; Pouw and Looren de Jong 2015), a performative perspective focuses on consumers' 'embodied experiences' that unfold as they actively and continuously engage with the world and objects around them (Heidegger 1968; Merleau-Ponty 1962). Focusing on 'embodied experiences', rather than 'embodied cognition', directs attention to the material and bodily practices through which consumers experience their world in a holistic manner (Yakhlef 2015). Such a performative perspective enables researchers to adopt an alternative, customer-centric approach to AR by examining how ARPV apps facilitate consumers in their embodied routines and ongoing, complex consumption projects.

Lens: Performative perspective on AR

Practice theory (Schatzki 1996; Warde 2005), which highlights the complex relationships between consumers' minds, bodies, things, and cultural meaning systems, provides a theoretical lens for this research. Practices are defined as "routinized types of behavior" (Reckwitz 2002, p. 249) that combine bodily and mental activities. Attaining abstract knowledge about product characteristics thus remains important, but so is cultivating practical knowledge (Schatzki 1996), cultural competence (Maciel and Wallendorf (2017), and an embodied and unarticulated sensibility (Phipps and Ozanne 2017) of how and when to use things. Consumers, in this theoretical lens, are thus not simple buyers of products; rather, they are seen as practitioners who assemble various components of a practice — commonly consolidated into objects, doings, and meanings (Maggauda 2011)

— into a configuration that aligns with a discursively constructed normative system, called a taste regime (Arsel and Bean 2013).

The habitual embodiment of a taste regime is something that must be continuously achieved (Watson and Shove 2008; Wenger 1998). Consumers often worry that their own practice performances may be insufficient or incongruent with the normative system laid out by the taste regime (Arsel and Bean 2013; Entwistle 2000). Thus, consumers benchmark their performances against shared standards, engage in deliberate sampling and experimentation, and interact directly with other practitioners in order to confirm their status of being capable practitioners (Maciel and Wallendorf 2017).

Consumers also frequently draw on market-mediated resources, such as online communities and websites (e.g., Arsel and Bean 2013), to improve their practice performances. ARPV apps present an additional yet hitherto unexamined marketing touchpoint for consumers to orient and improve their practice performances. The current research thus leverages practice theory to gain insights into consumers' holistic and embodied consumption experiences, which in turn provide the foundation for analyzing how ARPV apps can facilitate consumers in their quest of becoming capable practitioners.

Empirical Context and Methodology

This study employs a market ethnography of beauty consumers. Data collection proceeded in two phases: In phase one, 31 millennial, female consumers were recruited to use the AR components within Sephora's ARPV app. Up to three rounds of mini-interviews were conducted over a period of 4 weeks. The mini-interviews ensured informants continued to use the ARPV app. Furthermore, the mini-interviews produced data regarding informants' inspirations, techniques, purchasing habits, and in-situ experience of using the ARPV app. Phase one resulted in 68 mini-interviews that lasted, on average, about 4 minutes.

This data shaped phase two, in which 16 informants from the initial group of 31 were selected (i.e., those who completed all tasks during phase one) to conduct depth interviews. Interviews lasted, on average, 1.25 hours and were transcribed verbatim, resulting in 418 pages of transcripts (1.5-spaced, 12-font). All data were analyzed using a hermeneutical approach that compared commonalities and differences in informant's responses and perceptions until saturation was reached (Arnold and Fischer 1994; Thompson 1997).

Findings

The study's findings show how ARPV apps can help consumers cultivate confidence, competence, and creative control as they pursue complex consumption projects (see Table and Figure). At the center of such customer-centric analysis lies an understanding of the core tensions consumers face (Richardson 2010). In the current context, consumers want to expand their own individual 'look' by incorporating new trends, but they worry whether their makeup performances are executed in technically proficient and socially acceptable ways (see inner triangle in Figure). There is a certain "line" they believe they must not cross, because if they do they would be perceived as "looking funny" (Lisa). This struggling for actualizing their desire for experimentation serve as the anchoring point to examine how the ARPV app helps consumers become capable practitioners.

The next three themes (see circles around the outer triangle's corners in Figure) discuss how the ARPV app helps consumers gain abstract and practical knowledge about products (i.e., objects), techniques (i.e., doings), and styles (i.e., meanings). With regards to selecting products (theme 2), the ARPV app provides consumers with *visualization* of how a certain shade or color will look like within the consumption constellation of their own faces. In contrast

to other marketing touchpoints (e.g., social media influencers), the ARPV app provides consumers with more accurate and personally tailored information about "whether or not a makeup 'look' will look good" on them (Allison). However, the *immateriality* of AR makes informants wonder about "how realistic" (Fiona) product simulations really are.

To successfully perform their makeup 'looks', consumers also must skillfully execute routines and correctly use a variety of tools. With regards to executing such techniques (theme 3), the ARPV app provides consumers with *deconstruction* and *confirmation*. Visual clues show "exactly where to put things so it's really easy to follow" (Lisa). Through deconstructing the complexity of a technique via step-by-step instructions that can be completed at "your own pace" (Lydia), the ARPV app helps even less experienced consumers learn new 'looks'. More importantly, the ARPV app provides external and even objective confirmation that consumers have executed a technique competently "because it tells you exactly where to fill in" (Abby).

Appropriating various makeup styles from a constantly evolving repertoire is the creative core of one's 'look.' The ARPV app provides *articulation* (theme 4) by allowing consumers to create a 'look' from the ground-up, based on their own vision and through playful experimentation.

Kacey notes that "you get more room to play around with [the ARPV app], because you aren't trying to replicate a 'look' that was already on someone else." The ARPV app thus supports informants' desire for a self-revealing and rapid-prototyping process that allows them to explore and play with different versions of themselves. Even informants who are intimidated by makeup are able to bring out their "punky side" (Chloe). The ARPV app thus provides informants with feelings of autonomy and creative control.

Discussion

Adopting a performative perspective clarifies and broadens the potential of augmented reality. Prior research has mostly examined how ARPV apps affect consumers' attitudes and behavioral intentions through visualizing a single product (e.g., Hilken et al. 2017; Javornik 2016b; Yim, Chu, and Sauer 2017). Expanding on these findings, the current study demonstrates that consumers derive value from ARPV apps because they can group together multiple virtual and actual products in a consumption constellations (Solomon 1983). AR's ability to bridge this *constellation-imagination gap* may provide customer value that remains relevant even after the initial novelty of AR has worn off (Yim et al. 2017) and that appeals to consumers who prefer visual information processing styles (Hilken et al. 2017); however, these issues need to be further tested through empirical research.

More importantly, this study broadens AR's potential for marketing by introducing the *competence gap* (i.e., receiving confirmation about the correct execution of techniques; theme 3) and the *autonomy gap* (i.e., feeling creatively in control when articulating styles; theme 4). From a performative perspective, augmented reality is more than just a tool that lets consumers *see* products *on themselves*: AR provides opportunities for consumers to *believe in themselves* and construct their own selves more playfully and autonomously. Additional research is needed to more fully explore this broader potential. For example, future research can examine how ARPV apps that augment spaces rather than faces can also help consumers to feel more confident in their domestic consumption projects. Aside from visualizing products, augmented reality can also be used to simulate certain doings (e.g., blood donation simulation by Britain's National Health Service). Future research can explore

how simulating doings (versus objects) impact associated meanings and actual behavior. Altogether, research that adopts performative perspectives would broaden our understandings of what value this emerging marketing touchpoint provides to consumers and marketers.

The performative perspective employed here also highlights an important shortcoming of ARPV apps that has been downplayed by prior research: AR's inherent lack of materiality. Prior research often implies a near-equivalency between simulated and actual experience by suggesting, for example, that consumers may "feel that they are actually trying on […] a pair of sunglasses" (Hilken et al. 2017, p. 92). This may be due to situated cognition's focus on forming world-mirroring mental representations through bodily movements (Pouw and Looren de Jong 2015). However, oversimplifying differences between simulated and physical experiences is problematic, at least in the online retailing sector. 'Embodiment' is a multi-faceted term, as the above discussion has shown. In order to arrive at a more nuanced understanding of AR's value in marketing, it is necessary to explore how AR facilitates (or does not) consumers' actual and embodied experiences with material artifacts. In the retailing sector, the lack of materiality is an issue for selecting products, but it becomes an asset for executing techniques and (especially) articulating styles.

For practitioners, this study's findings have important implications of how to leverage AR in their marketing strategies. Helping consumers believe in themselves, through increasing their competence in certain activities (i.e., bridging the competence gap) and enabling them to take creative control over their own self-explorations (i.e., bridging the autonomy gap), presents enormous and mostly untapped opportunities. For example, in the automotive sector, AR is typically used to bridge the constellation-imagination gap (e.g., enabling consumers to customize cars via displaying life-sized three-dimensional virtual models in specially designed showrooms, or smaller models via AR print ads). Future applications could close the autonomy gap by displaying life-sized virtual models in consumers' own driveways and by letting consumers peek through a virtual windshield onto the actual, physical world around them. ARPV apps like these would convey the experience of owning the car, rather than mere product information, which can help consumers feel in creative control and more confident in their consumption choices. Other AR apps that are integrated into the actual car's windshield, for example to assist whilst parking, would furthermore bridge the competence gap.

Conclusion

By adopting a performative perspective, this research encourages academics and practitioners to view augmented reality with a new set of eyes: Looking through the lens of practice theory, the biggest potential of this emerging touchpoint might lie less in enabling consumers to *see products on* themselves, but to *believe in* themselves.

How Choosing for Others Impacts Self-Indulgence Within Caregiving Relationships

Anika Schumacher, Grenoble École de Management, France
Caroline Goukens, Maastricht University, The Netherlands
Kelly Geyskens, Maastricht University, The Netherlands

EXTENDED ABSTRACT

Taking care of close others or being taken care of as a child is a central aspect of human life.

As soon as we are born, we depend on the care provided by our primary caregivers. Later in life, it is our turn to take care of children, aging parents, or pets. There are over 63 million families with children under the age of 18 in the United States (US Census 2019) and 34.2 million Americans reported providing unpaid care to an adult aged 50 or older in 2015 (National Alliance for Caregiving and AARP 2015). Furthermore, 68% of American households own at least one pet (APPA 2018).

Despite this omnipresence of caregiving and care-receiving in our lives, relatively little is known about how taking care of others or receiving care provided by others influences our consumption behavior.

In this research, we draw on literature on caregiving, moral licensing and consistency behavior and suggest that within caregiving relationships, the relationship between virtuous other-oriented deeds and subsequent self-indulgence depends on the chooser's care-role within the relationship.

Caregiving implies providing nurturance and protection to a dependent, vulnerable care-receiver. Good caregiving has been considered a moral experience (Kleinman 2012, 2013). Furthermore taking responsibility and acting in the best long-term interest of a care-receiver is often defining the caregiver's identity (Bhattacharjee, Berger, and Menon 2014). Care-receivers are often integrated into the caregiver's self-concept (Brummelman et al. 2013; Thai et al. 2019). Providing care for care-receiving others may thus serve to boost one's moral self-concept. In line with literature on moral licensing, we thus expect that caregivers who make a virtuous (compared to vice) consumption choice for a care-receiving close other are more likely to self-indulge thereafter.

Conversely, we predict that for care-receivers, making virtuous choices for their caregiver will not lend itself to license self-indulgence. Care-receivers are dependent on the caregiver for protection, nurturance, and support (Bornstein 1992). To secure care and maintain a nurturing relationship with the caregiver, the care-receiver usually complies with the caregiver (Bornstein 1992; Overall and Sibley 2008; Vaish, Hepach, and Tomasello 2018). Thus, it is likely that care-receiving others act consistently with their caregiver's inferred health goal and use consumption in service of affiliation (Lee and Shrum 2012; Mead et al. 2011). We thus expect—in line with behavioral consistency—that care-receiving others are less likely to self-indulge after making a virtuous (compared to vice) choice for a caregiver.

In the following, we present four studies in which we asked participants to make a food choice for a care-receiving other (i.e., a child, a pet), or a caregiving other (i.e., a parent) respectively, and study how this initial other-oriented choice impacts the chooser's subsequent personal consumption behavior.

In **study 1**, we consider a common consumption dilemma between indulgent foods (vice choice) and healthy foods (virtuous option; Vohs and Heatherton 2000). We recruited seventy parents in a kindergarten and asked them to choose between gummy worms (unhealthy snack) or grapes (healthy snack, Fedorikhin & Patrick, 2010). After making their choice, parents completed a chocolate tast-

ing. The amount of chocolate consumed served as dependent measure of self-indulgence. Parents who first chose the virtuous product (grapes) for their child subsequently consumed significantly more chocolates ($M = 56.55$, SD = 30.19) than parents who chose the vice product (gummy worms) for their child ($M = 36.80$, SD = 30.12; $t(68) = 2.74$, $p = .01$, $d = 0.66$), in support of our predictions. In an additional **study 1b** we replicated these effects with 56 dog owners. Dog owners who chose the healthy treat for their dog were subsequently more likely to choose the chocolate bar (vice option) for themselves than dog owners who chose the unhealthy treat for their dog ($\chi^2(1) = 5.19$, $p = .02$, table 1).

In **study 2**, we investigated the downstream consequences of making a virtuous other-oriented choice among care-receivers. Specifically, we asked 118 undergraduate students (care-receivers) to make a choice between two restaurant vouchers for their parents: A "chain of restaurants which serves healthy foods"(virtuous option) and a "chain of pure indulgence"(vice option). Undergraduate students are often dependent on their parents – especially financially (Goudreau 2011; Hughes et al. 2018; Kahn, Goldscheider, and García-Manglano 2013; Schneider 2000). Similar to study 1, the amount of chocolate consumed in a subsequent chocolate tasting served as dependent measure. Students who made a virtuous choice for their parent consumed significantly less chocolates than students who chose the vice option ($t(1,113) = 2.23$, $p = .03$, $d = 0.45$).

In **study 3**, a framed field study, we recruited 204 caregiver-care-receiver (parent-child) dyads (n = 408) and randomly assigned the dyads to one of three choice conditions in a 3(no choice, healthy choice, unhealthy choice) x 2(caregiver vs. care-receiver role) between-subjects design with choice manipulated and care role measured (caregiving parent/care-receiving child).

A linear mixed model (LMM) analysis yielded a significant Other-Oriented Choice x Care Role interaction effect ($F(2, 402) = 6.68$, $p = .001$, $\eta_p^2 = .032$). Caregiving parents displayed a higher relative preference for vice products after making a virtuous choice for their child than after making no initial choice ($t(1, 402) = -1.79$, $p = .037$), or after choosing the vice option ($t(1, 402) = -2.178$, $p = .015$). Conversely, care-receivers (prospective students) who had made an initial virtuous healthy choice for their parents displayed a significantly lower relative preference for the vice consumption options than care-receivers who had not made an initial other-oriented choice ($t(1, 402) = -2.10$, $p = .018$) or initially had chosen a vice option for their parents ($t(1, 402) = -1.28$, $p < 0.10$). Controlling for age did not change the results ($F(2, 397) = 7.38$, $p = .001$).

Our findings shed light on how interpersonal dynamics and choices in social relationships—and familial caregiving relationships in particular—impact self-regulation (Fitzsimons and Bargh 2003; Fitzsimons and Finkel 2011; Hofmann, Finkel, and Fitzsimons 2015) by identifying role of the chooser (caregiver vs. care-receiver) as an important moderator of licensing/consistency effects.

Building "Pyramid of Oneness" - Delineating Differences among Human Brands, Celebrities and Person-Brands

Karthik Selvanayagam, Indian Institute of Technology Madras, India
Varisha Rehman, Indian Institute of Technology Madras, India

EXTENDED ABSTRACT

"In the future, everyone will be world-famous for fifteen minutes"

- Andy Warhol 1968 (Benabou and Ok 2001)

It was perhaps the foresightedness of present reality that had led Andy Warhol, over fifty years ago, to believe in the existence of a dynamic environment of branded humans. Marketing research has embraced the idea of a human brand since its conceptualization by Matthew Thomson (2006) as *"any well-known persona who is the subject of marketing communications efforts"*. However, throughout this field of research, we find that the concepts of celebrity and human brands have been adopted to be applied interchangeably within their context. With emergence of recent theories of person-brands (Fournier and Eckhardt 2019), it becomes essential to understand the uniqueness in the natures of human brands, celebrity, and person-brands. We present our work within this emerging discourse to posit underlying distinctness between these entities.

Understanding specific differences in meaning provision and types of trust that develops within a relationship between a consumer and the popular person would enable drawing clarity upon the distinctness in the three entities of human brands, celebrity, and person-brands. Through Lewicki and Bunker's (1995) cross-discipline meanings and evolution of trust in a relationship, we posit the possible differences in consumer trust in *human brands, celebrity, and person-brands*. Further, by describing the nature of resulting equity in each of these relationships, we develop a conceptual framework that would help towards understanding human brands, celebrity, and person-brands as distinct stages of popularity of a person.

Three Stages of Trust

Lewicki and Bunker (1995) posit a sophisticated, and sequential approach to trust in interpersonal as well as professional relationships. The model presents three stages of trust: calculus, knowledge, and identification-based trust. Calculus-based trust is transactional in nature and derived on the value of the benefits of the relationship, and knowledge-based trust is grounded on the increased predictability the actions of the relationship partners, identification-based trust which emerges out of complete internalization of the other's desires and intentions. We posit the placing of the human brand-consumer relationship at the stage of calculus-based trust.

Human Brand

Calculus-Based Trust and Professional Equity

Examining the antecedents of strong attachments formed by consumers with human brands, Thomson (2006) presents that enabling feelings of autonomy and relatedness in the consumers as more significant than the human brand competence. As Wohlfeil and colleauges (2019) suggest, dominant literature in this area considers the 'dehumanized' celebrity as the human brand, making them archetypes of cultural meanings. Meaning provision for a consumer is culturally constructed through the human brand's performance as a professional, with little insight into the real person. This position makes human brands tenable for endorsements. At this stage the consumers develop an exchange based trust in the relationship with the human brand We posit that at this stage a *professional equity* develops for the human brand (Parmentier and Fischer 2010).

At the human brand stage of a popular person, this equity is developed through consistent expression of ability to achieve high standards in her/his field of practice. As the consumer's meaning provision of the well-known person develops into polysemic appeals through knowledge of the real person through her/his values, personality, in real situations, a knowledge-based trust develops in the relationship. At this stage, we posit that the human brand becomes a celebrity.

Celebrity

Knowledge-Based Trust and Celebrity Equity

Information about a popular person reaches the consumer through public appearances, interviews, social interactions with fans and other well-known individuals, and biographical content like books or documentaries, among other similar sources. When the information contained in these sources are beyond the functionality of the popular person, giving insights about her/his private life, it provides knowledge to the consumer that contributes to predictability in her/his actions. Lewicki and Bunker (1995) describe the trust that emerges in this stage as knowledge-based trust. At this stage the popular person becomes a celebrity, allowing for individual consumers to co-create meanings, allowing for polysemic appeals and heteroglossia of perspectives about the celebrity (Wohlfeil et al. 2019). At this stage, the celebrity would be able to reach consumers who are unfamiliar with the celebrity's field of practice.

We posit here the emergence of *celebrity equity*, built upon the authentic persona of the popular person (Moulard, Garrity, and Rice 2015; Speed, Butler, and Collins 2015; Thomson 2006). It is at this stage celebrities become brands in and as themselves. As celebrities build a convergence of the performer and the real person, celebrities move to the subsequent stage of being person-brands.

Person-Brand

Identification-Based Trust and Personal Equity

Fournier and Eckhardt (2019) adopt Ernst H. Kantorowicz's theory of the King's two bodies to present that the person is "*inextricably united with the person-brand*". With internalization occurring over a long period of time, consumers begin to perceive the convergence of the personal life and professional skills of the popular person as a single self. Consumers would substitute the brand for themselves in the social landscape. Lewicki and Bunker (1995) describe the nature of trust at this stage as the strongest in relationships.

At this stage, the popular person earns a *personal equity* that unifies the private and professional lives of the individual. A holistic and interdependent nature of the person and the brand establish a singular equity for the person-brand, where the private-self and the professional-self converge toward one purpose.

Conclusion

In this work we have intended towards building an understanding of developmental stages of human brands, celebrities, and person-brands. Drawing upon an interdisciplinary approach to trust, meaning provision, and brand equity, we present a conceptual frame-

work delineating the differences between human brands, celebrities and person-brands that would enable research and practice in better understanding and management. Future research on this work, conceptual and empirical, could contribute to the marketing scholarship in bringing forth underlying drivers as well as movement between these stages of a popular person's brand. Comparisons between brands from related and unrelated fields of practice could also provide insights into consumer perceptions in the digital age.

Risk is Preferred at a Lesser Causal Depth

Rumela Sengupta, University of Illinois at Chicago, USA
Jeffrey Parker, University of Illinois at Chicago, USA

EXTENDED ABSTRACT

Consumers face risk and uncertainty every day, for example, selecting between medical treatments, choosing whether to join an online dating website or not, or allocating funds across available investment options. The current work examines preferences between equally risky sequences of events (or processes) that differ with respect to when the risk arises within the sequence.

A substantial body of research has tried to understand how decision makers incorporate risk in their choices. Majority of extant literature examine the relative preferences for options with greater or lesser relative risk or uncertainty; preference for certain over risky gains (e.g., Duke, Goldsmith, and Amir 2018; Gneezy, List, and Wu 2006; Kahneman and Tversky 1982), preference for uncertainty over certain gain options (e.g., Dhar, Gonzalez-Vallejo, and Soman 1995; Goldsmith and Amir 2010; Mazar, Shampanier, and Ariely 2016), factors moderating the preference for risky over certain options (e.g., Laran and Tsiros, 2013; Larrick, Heath, and Wu 2009; Levav and Argo 2010). In contrast to the previous work, the current research examines preferences between equally risky processes that differ only with respect to when or where the risk arises within the sequence: either in the early stages (hereafter, "deep-risk") or in the later stages (hereafter, "shallow-risk"). We posit that, people tend to *feel* that the deep-risk sequence is riskier overall than is the shallow-risk sequence and, thus, tend to prefer shallow-risk sequences. This is because, given the temporal nature of the sequences, earlier nodes have more direct and indirect effects on the overall sequence than later nodes. Consequently, deeper risk may be viewed as propagating throughout the process more than would be the case with shallower risk.

Four studies tested the basic proposition and the potential accounts for the effect. In Study 1, participants (N=100) were asked to imagine that they could order the same product from two different websites, each of which had experienced delivery issues in the past. One of the websites was described as having a shallow-risk delivery sequence (i.e., the risk arose later, at the delivery stage) and the other was described as having a deep-risk delivery sequence (i.e., the risk arose earlier, at the package-addressing stage). The overall risk associated with the processes were equivalent: either the delivery service lost the package 5% of the time (shallow-risk) or the website mistakenly sent the package to the wrong address 5% of the time (deep-risk). The participants were then asked to indicate which website would they choose to order from. A significant majority (61%) of participants indicated they would choose the shallow-risk website ($\chi2(1)=4.84$, $p<.03$).

Study 2 tested a potential account of the effect – greater perceived importance of events arising earlier. Since earlier events might be perceived as more important for the process, individuals might prefer more certainty in those events. Participants (N=196) were told to imagine that they were playing a 4-player "Telephone Game." The participants had to decide who would fill the 2nd and the 3rd position in the game – Friend-1, who was always accurate or Friend-2, who was accurate only 50% of the time. Additionally, they were asked to indicate which of the two positions was more important for winning the game. A significant majority (77.8%) of participants indicated they would assign Friend-2 (risky friend) to Position 3 (i.e., preferred shallower risk; $\chi2(1)=58.33$, $p<.001$). However, the perceived importance account was not supported. A significant ma-

jority (62.4%) of participants indicated that both the positions were equally important for winning the game ($\chi2(2)=73.37$, $p<.001$) and, of those, a significant majority assigned the risky player to Position 3 (85%, $\chi^2(1)=56.98$, $p<.001$).

Study 3 examined the proposed felt risk account. Participants (N=277) were asked to imagine that they were playing a game wherein they had to pull a lever to release a ball. For them to win the game, the ball had to pass through two doors and enter a hole. They were asked to choose between two versions of the game. In shallow-risk (deep-risk) version, the 1st (2nd) door opened every time but the 2nd (1st) door randomly opened sometimes and remained closed other times. Additionally, the participants were asked to indicate the overall riskiness of the two versions of the game. A significant majority (67.9%) of participants indicated they would choose the shallow-risk version ($\chi2(1)=35.051$, $p<.001$). The perceived risk account was supported as participants considered deep-risk version of the game significantly riskier ($M_{deep-risk}=6.48$, $M_{shallow-risk}=6.27$, $p<.01$).

Study 4 further tested the felt-risk account via formal mediation analyses. Participants (N=200) were asked to imagine that they had caught a rare infection. They were asked to choose between two possible treatments for the infection, both of which involved two medications. In shallow-risk (deep-risk) treatment, the 1st (2nd) medication worked every time but the 2nd (1st) medication randomly worked sometimes and failed other times. The order in which the treatments were presented was counter-balanced among the participants. Results from a binary logistic regression indicated that participants' preferences for Treatment A were significantly driven by whether it offered the shallow-risk (dummy=1) or deep-risk sequence (dummy=0; b=.935, Wald=9.325, $p=.002$). A mediation analysis (Hayes 2013, model 4) revealed a significant indirect effect of risk-depth on choice through the difference in the perceived risk between the two sequence (b=.0824; CI: LL=.0126, UL=.16; $p=.018$). In sum, four studies find that individuals prefer options with risk arising later in the sequence. This is because deep-risk sequences feel riskier.

The present research makes theoretical contributions to the literature on decision making under uncertainty and risk preferences. It reveals that preferences can be influenced by risk even when it is objectively equivalent across options. In addition to making theoretical contributions, this research also has managerial implications. The results from the studies reveal that, when consumers must choose between different risky options, their preference depends on not only on the amount of risk arising in each option, but also when that risk arises. Managers can use this insight as an input during new product development as well as new service offerings that are typically processes where some amount of risk is unavoidable.

Insights on New Information Consumption

Amir Sepehri, Western University, Canada

Rod Duclos, Western University, Canada

EXTENDED ABSTRACT

As scientific progress matures in many fields, interdisciplinary research is gaining popularity to push further the boundaries of knowledge. Testifying to this trend, funding worldwide is directed to universities and research centers that champion a transversal approach. A natural consequence of interdisciplinary research is interdisciplinary ideas.

Likening new ideas to new intellectual products, we explore their diffusion through the lens of innovation. That is, how are ideas that span different fields (or encompass distant concepts) received, adopted, and promulgated?

Past research has shown that categorization plays a central role in understanding new products (Sujan 1985). Drawing on categorization research, we argue that interdisciplinary ideas may receive less favorable ratings because of their conceptual heterogeneity. Specifically, we posit that interdisciplinary ideas are harder to understand, and categorize, which causes confusion and in turn reduces their rate of adoption. Our reasoning is as follows.

When concepts within an interdisciplinary idea lack internal logic/connection, confusion ensues (Benson and Miller 1982). As a result, consumers of these ideas will try to comprehend them by categorizing them under pre-defined topics. Indeed, information structure plays an important role in information acquisition (Lurie 2004). The more categories employed to form an idea, the more difficult it will be for recipients to categorize said idea, form an information structure, and, in turn, to comprehend it. Ultimately, this complexity decreases the recipients' evaluations of conceptually-heterogeneous ideas. However, we expect Need for Cognition (NFC; Cacioppo & Petty 1982) to play a moderating role on this effect. It has been shown that High NFC individuals process information with more depth and breadth (Levin, Huneke, & Jasper 2000). Therefore, we expect this negative effect to weaken and even reverse at high levels of NFC.

Given the rise of interdisciplinary research and/or the tendency of communicators to borrow from various fields and topics, this project endeavors to understand the effect of information heterogeneity on new information consumption in an online video-sharing context.

Study 1: Evidence from a large dataset of online videos featuring novel ideas

Methods: We tested our predictions on a real-world dataset of ~2500 online talks. Said talks come from a popular platform dedicated to disseminating "novel" ideas (Mean number of views for each talk = 1,754,062). We report below two proxies aimed at testing the relationship between conceptual heterogeneity (i.e., the extent to which talks are conceptually tight vs. broad), liking, and online views.

Regardless of the method and consistent with our theorizing, we find repeatedly that talks encompassing a higher number of different topics receive fewer views or are liked less.

First proxy: Number of Tags

Each talk on our platform of choice is accompanied by a series of "tags" (also known as "categories") aimed at describing its topic and scope[1]. Using the number of tags as a coarse proxy for concep-

tual heterogeneity, we find that talks characterized by more tags are viewed less (B=-34015.13, SE=11854.02, p = .004). The effect holds even after controlling for the duration of each talk.

These findings are noteworthy for their counter-intuitiveness. Indeed, the more descriptive tags a talk has, the more likely it appears in search attempts. Hence, the overall negative effect identified here is large enough to negate the otherwise positive effect one would expect from keyword searches.

Boundary condition: Of note, we also find preliminary evidence for a boundary condition to the aforementioned main effect. The talks were transcribed into text and mined for their use of "analytical language". Analytical language score is the extent to which the author has used words that indicate formal, logical, and hierarchical thinking patterns (Pennebaker et al. 2014). The mining task was carried out by LIWC 2015 (Pennebaker, Boyd, Jordan, & Blackburn, 2015), a dictionary-based approach validated in past research (Humphreys & Wang, 2017; Tausczik & Pennebaker, 2010).

While using analytical words has a negative main-effect on the number of views (B=-36,834.12, SE=5823.69, p<.001), its interaction effect with *number of tags* is positive (B=1739.62, SE=701.39, p=.01). In other words, as more analytical words are used in a talk, the negative effect of *number of tags* on the number of views becomes weaker and eventually non-significant. The floodlight illustration for this interaction can be found in figure 1. And similar to our initial finding, the main effect of the number of tags is itself negative (B=-127327.20, SE=40,999.29, p<.01). The pattern and level of significance of these findings hold even after controlling for the duration of talks.

In short, using analytical words can be a remedy to the otherwise detrimental main-effect that the number of tags has on talk virality. This insight is valuable, particularly for talks that are inevitably heterogeneous in nature (i.e., for talks that cannot be concentrated around one or two topics). In such cases, using analytical language will assuage the adverse effect exerted by the number of tags, hence promote the viewers' evaluations. This is some initial indication of the role Need For Cognition may play as potential individual difference moderator. We will put this idea to test later in the article.

Proxy 2: Topic Modeling

We used latent Dirichlet allocation (LDA; Blei, 2012) to discover the main topics discussed within talks. This method mines the transcript of each talk and measures the co-occurrences of the words both within and across texts. Doing so, the algorithm uncovers (1) the latent topics composing each talk and (2) the words that constitute each topic (see table 1 for examples). LDA has been used in psychology and marketing as a method to identify latent themes or topics (e.g., Berger & Packard 2018; for a full review see Berger et al. 2019).

In order to find the optimal number of topics, we modeled topics within the text starting with 10 topics (all the way to 100 topics) with a step of 2. Using log-likelihood values from each topic number, we identified the optimal number of topics to be 34. Next, we modeled the topics across all transcripts extracting 34 topics. This gave us the proportion or share of each of the 34 topics in each of the talks. Of note, if a talk is uniformly distributed across all 34 topics, each topic

---

[1] These descriptive tags are generated by an algorithm (i.e., by artificial intelligence).

would have a share of 2.9412%. We thus used 3% as a natural cut-off point to determine the number of topics covered in each talk[2].

Results. Replicating the pattern of results unearthed in our previous approach, an ordinary least squares (OLS) regression revealed a significant negative effect by the number of topics on the number of views received by each talk (B=-135944.54, SE=33268.22, p<.001). The effect holds even after controlling for the duration of each talk.

We considered an addition measure: the standard deviation across topic proportions. Our rationale is as follows. Less standard deviation in topic proportions should reflect that a talk covers more topics (i.e., that a talk has more conceptual heterogeneity). Conversely, more standard deviation across topic proportions should reflect that certain topics are more emphasized than other topics (i.e., that a talk has less conceptual heterogeneity).

Putting this idea to the test, we find that lesser standard deviation in topic proportions within a talk (i.e., more conceptual heterogeneity) is again associated with fewer views (B=-15731158.74, SE=4010486.97, p<.001).

Is number of topics the same thing as number of tags?

Further analyses revealed that the negative effect that the number of topics (proxy 2) has on views is *separate* from the negative effect exerted by the number of tags (proxy 1)[3]. Indeed, while both main effects remain negative and significant in presence of each other (B$_{Num-Topic}$=-250785.54, SE= 68455.72, p<.001; B$_{Num-Tag}$=-132223.11, SE= 52086.93, p=.01), the effect of the number of tags moderates the negative effect by the number of latent topics (interaction term: B=16222.52, SE=8264.32, p<.05). Specifically, when talks are described by a large-enough number of tags, the adverse effect exerted by the number of topics discussed in a talk becomes non-significant (see floodlight illustration of this interaction in figure 2). Stated differently, the deleterious effect caused by the number of tags overwhelms/overtakes the negative effect caused by the number topics; giving the latter no room to operate.

Study 2a: Evidence from a within-subjects experiment

The aim of this study is to test the hypothesis in a more controlled setting and to provide some evidence on the underlying mechanism.

Methods: We recruited 99 undergraduate students (M$_{age}$ = 18.74, 57.6% female) at a large university in North-America to take part in our study in exchange for course credit. Eight videos were selected from our dataset. Half of these videos comprised of 9 topics (High group) whereas the other half did only 3 (Low group). We had a within-subjects design whereby each participant watched 2 online talks randomly chosen from each High and Low group. The order of display was counter-balanced.

The participants were then asked to indicate how much they liked each talk (2 items, both alphas > .9). They were also asked to rate the cognitive complexity of each talk (2 items, both alphas > .7).

Results: We used repeated measures ANOVA to test our main effect and the MEMORE macro (Montoya, 2019) to test our indirect effect. The results confirm that talks featuring a high number of topics (M$_{liking}$ = 4.22, SD= 1.69) were liked less than the talks comprising of a low number of topics (M$_{liking}$ = 5.44, SD= 1.46; F(1,98)= 44.06, p< .001). Moreover, the talks covering a high number of topics were seen as being more complicated and more difficult to understand (M$_{complictaed}$ = 3.43, SD= 1.53) than their counterparts featuring

a low number of topics (M$_{complictaed}$ = 2.31, SD= 1.23; F(1,98)= 37.18, p< .001). This preliminary evidence for the underlying mechanism is illustrated in figure 3.

MEMORE macro results indicate that cognitive complexity mediates the effect of number of topics on liking (B$_{indirect}$ = -.41, SE= .14, 95% CI= [- .71, -.17]. The direct effect stays significant after cognitive complexity is accounted for (B$_{direct}$ = -.82, SE= -.2, 95% CI= [-1.22, -.42]. This means that although cognitive complexity partially explains the negative effect of number of topics on liking, there are other underlying mechanisms that can account for it, too. This is conducive to future research in this area.

Study 2b: Evidence from a between-subjects experiment

Study 2b builds on study 1a in three ways: (a) it tests the effect in a between-subjects design, (b) it offers additional evidence on the underlying mechanism, and (c) provides evidence on a crucial individual difference moderator that leads to a full effect-reversal.

Methods: We recruited 70 undergraduate students (M$_{age}$ = 19.14, 52.9% female) at a large university in North-America to take part in our study in exchange for course credit. The design of the study was similar to the previous study with the only difference being randomization on the number of topics factor. Participants randomly watched a video featuring either a high or a low number of topics and indicated how much they liked it (two-items, 1-7, alpha > .8). After that, they indicated how difficult was it for them to categorize the video under a topic. The study concluded with the 18-item Need For Cognition scale (Cacioppo, Petty, & Feng Kao 1984) and demographic questions.

Results: We replicate the main effect of high vs. low number of topics such that participants liked the videos featuring a low number of topics (M$_{low}$ = 5.63, SD= 1.41) more than those covering a high number of topics (M$_{high}$ = 4.41, SD= 1.46; F(1,68)= 12.51, p = .001). We also find that high-number-of-topic videos were deemed as more difficult to categorize (M$_{high}$ = 4, SD= 1.91) than the ones covering a low number of topics (M$_{low}$ = 3.08, SD= 1.65; F(1,68)= 4.65, p = .035). Based on this preliminary evidence, we conducted a mediation analysis using PROCESS model 4. We find that categorization difficulty mediates the effect of topics on viewers' liking of the videos on a 90% CI (B$_{indirect}$ = .19, SE= .13, 90% CI= [.005, .427]). This means that compared to videos covering a low number of topics, videos covering a high number of topics were deemed as more difficult to categorize which in turn led to lower audience liking for them.

In order to test the moderating role of Need for Cognition (NFC), we conducted a moderation analysis using PROCESS model 1. While replicating the main effect of number of topics, we find a main effect of NFC on liking such that higher NFC values lead to lower liking of the videos (B= -2.59, SE= .96, p= .009). More importantly, we find a significant interaction between number of topics and NFC (B= 1.89, SE= .56, p= .001). At low levels of NFC, we find that more topics in a talk lead to lower liking for the video. However, as NFC increases, this effect becomes non-significant, and at high levels of NFC, it becomes significant in the opposite direction such that videos covering numerous topics are liked more. A floodlight illustration for this interaction can be found in figure 4. The pattern of results is consistent with the theorizing we had in front end.

General Discussion

Likening new ideas to new intellectual products, this article sets out to examine the effect of information heterogeneity on how new information in the form of interdisciplinary novel ideas are received. Using a repository of ~2500 talks from a popular e-platform dedicated to the dissemination of novel ideas, we find that videos richer

---

2 Results are robust if 2.9% or 2.9412% (i.e., 100/34) is used as cut-off point instead of 3%.
3 Despite the large number of observations, the correlation between the number of tags describing each talk and the number of topics developed within each talk is insignificant (r=.3, p=.15).

in conceptual heterogeneity (i.e., talks spanning numerous different fields) are viewed less. We do so by using machine-generated tags provided by the platform, machine-learning methods modeling the topics in the text, and controlled lab experiments.

Public speakers and, more generally, communicators (e.g., politicians, professors, scientists, journalists) are another audience who may benefit from our findings. Indeed, while many seek to integrate various topics/ideas into their communications in order to improve the convincingness of their overall argument, doing so comes at a cost (i.e., ideas with conceptual heterogeneity spread less).

We also find that this effect depends on the audience to which the idea is presented. As we found, high-NFC individuals would prefer ideas covering a high number of topics while the opposite is true for low-NFC persons. This speaks to the potential role of expertise: While an expert audience may prefer a boundary-spanning idea, lay people would find it difficult to categorize and like it less.

As alluded above, the number of views received by a talk online is a strong test of virality. Content that goes unseen/unshared is unlikely to get adopted by the market. We hope this work will help spur interest in the psychology of contagion (i.e., when, how, and why new products/ideas propagate).

The Pros and Cons of Multitagging in Online Retailing

Amir Sepehri, Western University, Canada
Rod Duclos, Western University, Canada
SeyedNasir HaghighiBardineh, Washington State University, USA

EXTENDED ABSTRACT

To help search for the products they offer, online retailers attach descriptive tags (a.k.a. *categories* or *genres*) to their inventory. A recipes website, for instance, may do so by way of cuisine (e.g., French, Mexican) or dishes (e.g., tacos, fish). Similarly, Apple's AppStore organizes its lineup of games by interest (e.g., strategy, sports) while Amazon tags its books by genre (e.g., thriller, science fiction, romance). In turn, when consumers type a keyword describing what they are looking for (e.g., romance novel), a search algorithm retrieves matching options from the retailer's database. To summarize, tags chosen by marketers to characterize products constitute strategic decisions that will in turn shape the set of options viewed by consumers during their search.

The practice of tagging being pervasive across industries, this manuscript asks whether tagging is in fact good or bad. Stated differently, to what extent do retailers benefit from a practice they have so uniformly adopted?[1]

At first brush, both intuition and scholarly work support the practice. Indeed, tagging facilitates search (particularly online, where options are sometimes limitless) and increases product visibility/exposure (Hedden 2008; Lamere 2008).

To cumulate the benefits of tagging, retailers have now turned en masse to "multi-tagging" (i.e., describing any given item by not one but multiple tags). The reasoning is simple. The more tags/categories ascribed to product X, the more often will X emerge from consumers' keyword searches.

While the above thinking is appealing, we submit multi-tagging comes with unforeseen costs. In what follows, we argue that more tags ascribed to a given product may hurt (rather than merely help) how said product is ultimately judged/perceived by consumers. We ground our argument in the learning and categorization literatures.

When considering a new product, consumers first attempt to attach said product to a specific class/category of products so the knowledge they have in said category can serve to assess the new product (Waldmann, Holyoak, and Fratianne 1995). By shaping consumers' search-results, then, tagging (in)directly influences the primary knowledge-structures recruited by consumers to make evaluations (both prospectively and retrospectively). The rationale for the latter is best explained by Moreau, Markman, and Lehmann (2001). By giving consumers a category label (e.g., a "romance" novel), marketers encourage categorization-based knowledge-transfer whereby the label emboldens consumers to make more extensive mappings from the category to the target item than when no label is present. From this derive three implications.

First, Moreau, Markman, and Lehmann (2001) find that the product category cued by marketers shapes consumers' categorization of the new product in the direction of the cue and away from other plausible categorizations. Second, expectations of a product's performance are shaped by the performance of fellow products within which the new product was categorized. Third, expectations of a new product's performance will affect consumers' liking for the new product (i.e., higher expectations will lead to higher preferences).

We contribute to this line of work by showing that multi-tagging hurts marketers in unanticipated ways. For illustration, consider the case of a book: an action-packed thriller set 100 years from now in space, with hints of attraction between the two lead characters. The retailer may classify the novel simply as a "thriller." Alternatively, s/he may tag it as "thriller," "action," "science fiction," "love," and "romance." The latter approach (i.e., multi-tagging) would increase product visibility/exposure online since the item would now emerge in not one but five different keyword-searches. By doing so, however, we argue that marketers may inadvertently bias the knowledge structures through which consumers will in turn judge the book. A consumer searching for a romance novel, for instance, would recruit her knowledge of the category and use said knowledge to (i) form expectations about the book and, in turn, (ii) assess the book. If the book is only tangentially related to romance, her evaluation of it will be negatively affected.

Extrapolating from this particular example to the broader context, our prediction is as follows. All else equal, multi-tagging is likely to activate the wrong knowledge structures in consumers. Stated differently, the more tags/categories describe a product, the less liked will be said product ultimately. The underlying cause for this misfortune is that the knowledge structures activated to judge the product are less likely to be pertinent (e.g., using romance schemas to gauge a book that is primarily a thriller).

Five studies using real-world datasets test our theorizing and uncover the hidden costs of multi-tagging. Rather than declaring multi-tagging as good or bad, our investigation reveals the practice to be good *and* bad (i.e., with both benefits and drawbacks). So doing, we corroborate prior findings related to the "positivity bias" (i.e., the more reviews/ratings a product receives, the more favorable becomes the overall average of said reviews/ratings). Importantly, however, we uncover that the benefits of greater visibility/exposure for the overall favorability of reviews/ratings are in fact *outweighed* by the deleterious effects of inadequate knowledge-structures (e.g., when consumers assess an item by the wrong set of schemas/criteria, they end up liking the product less on average).

Study 1: Recipes

Our investigation begins in the food industry. We obtained data scraped from a popular recipe-sharing platform (>209K recipes overall). For each recipe, the author attaches any number of tags to describe her entry (e.g., seafood, beef, vegan, tacos). In turn, when consumers search for a particular dish (e.g., tacos), entries matching their keyword-search are retrieved[2]. Our data also include ~992K ratings ranging from 1 to 5 which served as proxies for the liking/favorability of each recipe.

Analysis and Results. The above data set the stage for testing our theorizing on the costs and benefits of multi-tagging. First, we find that assigning more tags to a given recipe does indeed increase its visibility/exposure (i.e., the product is evaluated more often; B=.14, SE=.005, p<.001). And per the positivity, as visibility/exposure increases, so does the average liking for the item (B=.0014, SE=.0001, p<.0001). The indirect effect of the number of tags on liking through

---

[1]   While tagging can sometimes be done by consumers themselves, our primary interest lies in supply-side tagging-strategies (i.e., the strategic decisions made by marketers).

[2]   Tags were specified at the time recipes themselves were posted. This guarantees that tags (i.e., our IV) chronologically preceded ratings (i.e., our dependent variable).

the number of ratings was significant on a 95% CI ($B_{Indirect}$=.0002, 95% CI=[.0002, .0002]).

The novel finding we contribute, however, is that the *direct* effect by the number of tags on liking (i.e., on 1-5 ratings) is itself *negative* (B_{Direct}=-.0015, SE=.0002, p<.0001) and more powerful overall (B_{Total}=- .0013, SE=.0002, p<.0001; figure 1).

Study 2: Mobile Games

Study 2 examines our effect in a new context: mobile games. We obtained data scraped online from a popular AppStore. The dataset includes the tags describing >7,000 e-games as well as favorability measures for each (i.e., likeability ratings ranging from 1 to 5).

Once again, we find benefits of multi-tagging for visibility/exposure (i.e., more tags lead to more views/ratings) and, in turn, for overall product-likeability. These benefits come at a cost, however. Indeed, the *direct* effect of multi-tagging on product-liking is itself harmful and more powerful overall.

Study 3: Books

We obtained data scraped online from the world's largest book club. The website describes itself as "the" place for readers and book recommendations. The data available to us include the tags (a.k.a. "genres") describing >50,000 books (min: 0; max: 18; median: 5) as well as favorability measures for each book (i.e., likeability ratings ranging from 1 to 5).

Analysis and Results. An OLS regression revealed that a greater number of tags drives visibility/exposure (i.e., novels described by more tags are viewed/rated more often; B=3241.1, SE=309.73, p<.0001). In turn and per the positivity bias, as the number of ratings increases, so does the average liking for each book (B=.00001, SE=.00001, p<.0001). The indirect effect of the number of tags on liking through the rating-count was significant on a 95% CI ($B_{Indirect}$=.0002, 95% CI=[.0002, .0003]).

Per our theorizing, however, the *direct* effect by the number of tags on book-liking itself is negative and stronger overall, (B_{Direct}=-.0111, SE=.0005, p<.0001). This leads to an overall negative total-effect (B_{Total}=-.0108, SE=.0005, p<.0001; figure 3). These results echo those of studies 1 and 2.

Study 4: YouTube Videos

Study 1-3 approximated product visibility/exposure via the *number of ratings* received by each item. In study 4, we expand our realm of proxies for product visibility/exposure by including the *number of views* received by videos on YouTube[3]. Similarly, whereas studies 1-3 operationalized "product liking" as 1-5 ratings, study 4 does so via the *number of likes*[4] received by each video.

Analysis and Results. An OLS regression revealed that a greater number of tags boosts visibility/exposure (i.e., videos described by more tags are viewed more often: B=2598.08, SE=659.11, p<.001). In turn and per the positivity bias, as the number of views surges, so does product liking (B=.04, SE=.0002, p<.0001). The indirect effect of the number of tags on liking through the number of views was significant on a 95% CI ($B_{Indirect}$=108.89, SE=22.58, 95% CI=[63.48, 152.14]).

Per our theorizing, however, the *direct* effect by the number of tags on liking is itself negative and stronger overall (B_{Direct}=-.181.02, SE=22.72, p<.001), which leads to an overall negative total-effect (B_{Total}=-72.13, SE=35.76, p=.04; figure 4).

Study 5: Scientific-Journal Publications

Study 5 buttresses our case on the hidden costs of multi-tagging for overall product-liking by expanding our realm of measures in yet a new product-category: journal publications. Our approximation of product liking (i.e., our DV) is *citation count*. Indeed, the number of published articles being nearly infinite across journals and sub-disciplines, we contend the citation count of any given article is a reasonable proxy for how well said article is liked, respected, and/or valued by consumers[5].

Study 5 also innovates on the IV side. Whereas studies 1-4 used the number of tags describing a product as predictor of overall product-liking, S5 focuses on *full product-descriptions* (i.e., manuscript abstracts). If accurate, our predictions on the deleterious effects of multi-tagging for product liking should extend from tags to product-descriptions themselves.

Data. The data available to us consists of >51,000 abstracts of papers[6]. We also know how many times each abstract was viewed/accessed online. Our DV is the number of citations earned by each manuscript[7].

Analysis and Results. Since we did not have access to the keywords that often describe the topics of a paper, we approximated them ourselves through latent Dirichlet allocation (LDA; Blei 2012). In a nutshell, this text-mining technique measures the co-occurrence of certain words both within and across abstracts. In the end, the algorithm uncovers the latent topics constituting each abstract and the words naturally attached to each topic.

The rest of our analyses is straightforward. The "number of tags" characterizing each product is merely replaced by the "number of topics" characterizing each manuscript.

An OLS regression revealed that a greater number of topics boosts visibility/exposure (i.e., abstracts containing more topics are viewed more often: B=30.68, SE=3.84, p<.0001). In turn, as the number of views surges, so does product liking (i.e., citations increase with abstracts being accessed more often; B=.03, SE=.0002, p<.0001). The indirect effect of the number of topics on citations through the number of views was significant on a 95% CI ($B_{Indirect}$=.80, SE=.10, 95% CI=[.61, 1.00]).

Per our theorizing, however, the *direct* effect by the number of topics on citations is itself negative and stronger overall (B_{Direct}=-2.25, SE=.14, p<.0001), which leads to an overall negative total-effect (B_{Total}=-1.45, SE=.17, p<.0001; see figure 5 and table 1).

General Discussion

Across platforms and product categories, our data reveal that multi-tagging is slightly beneficial but mostly detrimental for product liking overall. The benefits are intuitive and come in the form of a chain reaction. By increasing the likelihood of a given item to match the keyword search of a consumer, multi-tagging increases product visibility/exposure. In turn, greater visibility/exposure boosts product liking thanks to the "positivity bias" (i.e., online reviews tend to be favorable because satisfied customers are more likely to share their opinions than dissatisfied counterparts; Pan & Zhang 2011, Hu, Zhang, & Pavlou 2009, Chevalier & Mayzlin 2006). Our contribution comes in the form of a counterintuitive finding: the *direct* effect of multi-tagging on product liking is itself negative and more powerful than the indirect effect described earlier. We show this to

---

[3]   >30K videos published between 2014 and 2018 in the US and Canada. For context, the median number of views for each video was 230,993 and the median number of tags describing each video was 19.

[4]   To be precise, our measure of liking is a "net" score (# likes - # dislikes) such that positive values signal greater product-liking.

[5]   In the present context, the pool of consumers consists mainly of academic researchers. Through their choices of which article(s) to cite in their own manuscripts, researchers reveal which papers they deem to be of greatest quality and/or of the highest authority.

[6]   Published between 1996 and 2016 (21 years) in a premier academic journal.

[7]   For context, the median number of views was 1363 and the median citation-count was 38.

be true for recipes, mobile games, books, videos, and even journal manuscripts (on average, the direct effect is 15.59 times the size of the indirect effect; table 2).

In addition to the breadth of product categories examined, a strength of this paper lays in the realm of measures used to test our theorizing. Tags were either counted directly (studies 1-4) or inferred by LDA (study 5). Visibility/exposure was approximated by the number of ratings (S1-3), views per video (S4), and views per abstract (S5). Lastly, product liking itself was assessed either directly (i.e., 1-5 ratings in S1-3) or indirectly (i.e., net number of likes minus dislikes in S4; citation count in S5). Regardless of the approach, consistent findings emerged. This speaks to the robustness and ecological value of our results.

Implications. Our findings have prescriptive implications for a variety of audiences. For instance, whereas an online retailer may be tempted to describe its products with multiple tags to maximize their likelihood of emerging from consumers' keyword searches, our results show this practice proves detrimental in the end for product liking. Similarly, individuals who use online platforms to either sell or share intellectual property (e.g., recipes, manuscripts, songs, music, photos, poetry) would do well to resist the maxim "more is better." If the goal is for their material to be liked, respected, and/or valued, less *is* better when it comes to product descriptions. The reason for the latter relates to categorization and learning (Moreau et al. 2001). Indeed, circling back to the illustration at the onset, a consumer looking for romance novels will use "romance" schemas/criteria to judge a book whereas said book was primarily an action-packed thriller set in space (i.e., it merely happened to feature romantic interests between two characters). Multi-tagging (i.e., thriller, action, science fiction, love, and romance) would increase visibility/exposure but it would ultimately hurt product reviews because the schemas/criteria recruited to evaluate the novel are mismatched/misaligned. And given the importance of reviews/ratings for sales[8], maximizing visibility/exposure (rather than favorable reviews/ratings) may be ill-advised.

---

8   For illustration, the Spiegel Research Center (2017) reports that (i) displaying reviews increases conversion rates by up to 270%; and (ii) having five reviews multiplies the purchase likelihood by four. Similarly, Luca (2016) finds that a one-star increase on Yelp increases revenues by 5-9%.

The Height Premium: When Shorter Men Pay More

Nuket Serin, Florida International University, USA
Jayati Sinha, Florida International University, USA

EXTENDED ABSTRACT

Across cultures, people who are above average height are more prosperous, successful, and considered more attractive (Jackson and Ervin 1992; Judge and Cable 2004). However, men who are below average height function more poorly in social spheres (Stulp and Barrett 2016), such as dating and marriage (Lynn and Shurgot 1984; Pawlowski and Koziel 2002), workplace interactions (Judge and Cable 2004), and political elections (McCann 2001). Additionally, male height is positively associated with higher social status (Blaker et al. 2013). Given that status is essential for humans as it is related to personal and social advantages (Anderson et al. 2012; Anderson, Hildreth, and Howland 2015), having a lower status can create an aversive state for shorter men. Indeed, research has shown that shorter men tend to reduce feelings of inadequacy through indirect aggression (Knapen, Blaker, and Vugt 2018). Moreover, when consumers perceive being low in appearance or power, they tend to engage in compensatory behavior by purchasing products that convey status (Braun and Wicklund 1989; Hoegg et al. 2014; Rucker and Galinsky 2008, 2009). However, we know little about how being shorter than average height influences the status consumption of men.

Thus, this research is positioned at the intersection of two important research streams—one dealing with status consumption and the other with the effects of height for men. We posit that shorter men are more willing to purchase and more willing to pay (WTP) higher prices for status-signaling products to improve their low social standing induced by being short. This happens because shorter men have a higher desire for status, leading them to flaunt the status-signaling products they own. However, we argue that sense of purpose moderates the effect: shorter men who are more driven by a sense of purpose will be less likely to resort to status consumption.

To assess our hypotheses, we conducted three studies. Study 1 examines the impacts of height on product size preference. In Study 1, we show that men who are below average height are more willing to pay higher prices for a status product (larger TV). Study 1 also confirms that women differ from men in that shortness does not evoke status consumption among women. Therefore, the subsequent two studies (Studies 2 and 3) featured men only.

In Study 2, we test the underlying mechanism of our proposed effect in a different status consumption context. Study 2 replicates the results of Study 1 and shows that shorter men (vs. taller men) reported relatively higher preferences for the more expensive/less luxurious green (vs. less expensive/more luxurious non-green) backpack. Moreover, Study 2 provides process support via mediation by demonstrating that shorter men have a higher desire for products that can effectively signal status.

Our final Study 3 shows that sense of purpose moderates the effect of height and status consumption. Specifically, we demonstrate that sense of purpose moderates the effect of male height on status consumption. Indeed, only participants who had a lower sense of purpose showed alignment with the previous results. We find consistent effects across various height, namely measured in Studies 1 and 3, and manipulated in Study 2, across status consumption contexts, suggesting robust findings.

Our research has theoretical implications and makes several managerial contributions. To the best of our knowledge, we are the first to explore the relationship between height, status consumption, and a sense of purpose. Thus, our research contributes to the compensatory status consumption literature. Additionally, our findings provide useful and practical implications. For example, marketers can appeal to consumers who face the adverse effects of shortness by highlighting the status-signaling potential of their products and services.

'Operation Vin': Uncorking the Swedish Wine Market

Luigi Servadio, Jönköping International Business School, Sweden
Jacob Ostberg, Stockholm University, Sweden

EXTENDED ABSTRACT

Swedish consumers have access to one of the world's broadest assortments of wine through the state monopoly Systembolaget. What market dynamics led up to this focus on wine on a market where consumers' preferences had traditionally been for hard liquor and beer? Answering this question will give us important insight about the potential role of governance units as agents of market change, which is a perspective that has hitherto been overlooked.

During market change, governance units play an important role in setting the degrees of freedom that various market actors – from producers to retailers, distributors, service providers and consumers – have. In the market formation literature drawing boundaries between legitimate and illegitimate marketplace behaviors is typically the role that the state plays (e.g., Humphreys 2010). This fairly passive and reactive role of the state is a reflection of a particular ideological political system. There are, however, ideological political systems wherein the state plays a more active role in shaping market dynamics (Askegaard & Östberg 2019).

By drawing on strategic action field (SAF) theory (Fligstein and McAdams 2011; 2012) our case foreshadows the state as an active agent in creating market change. Wine consumption in Sweden took off in 1957 when the Swedish state, via its retailer Systembolaget, set in motion an initiative that worked as an endogenous shock to the market. In order to reconstruct the history of the strategic operation we relied on historical data sources. We collected online and physical archival data such as magazine and newspaper articles and books as well as historical cultural artefacts, such as original pamphlets, ration books, and objects. We also collected market-oriented ethnographical data.

The Swedish state first disrupted the Swedish market for alcohol. Traditionally, consumption of alcohol in Sweden has been focused on hard liquor. To change this the state decided to strategically promote a new alcoholic drinking culture through the massive campaign "*Operation Vin*". This can be seen as the origin of the mainstream consumption of wine in Sweden. The basic idea of *Operation Vin* was to promote a shock in the market to replace the current established market logic with a new one.

Second, the Swedish state attempted to frame wine as a viable alternative. In order to successfully facilitate such radical change, especially in a culturally laden area such as alcohol, "discursive framing that resonate with underlying cultural currents must take place" (Kjeldgaard et al., 2016, 53). Our empirical findings show how utilizing the culturally embedded connection between money and alcohol served as a tool to gain acceptance for this new practice.

Third, this gradually led the settlement of a new alcohol culture. Today, lots of different wines from around the world crowd the shelves of Systembolaget. For consumers lacking cultural immersion in the world of wine, choosing amongst the many different wines can be a daunting task. Many labels look similar, names are tricky and hard to pronounce and the taste can be difficult to understand and remember. In order to translate the seemingly complicated world of wine for the Swedish consumers Systembolaget took a number of initiatives.

The present study takes a SAF theory perspective (Fligstein & McAdams 2011) to discuss how markets may change as the result of strategic actions by governance. We thus contribute to a literature which conceptualize market change as the outcome of consumer collective action (e.g. Kjeldgaard et al. 2016; Laamanen & Skålén 2014). Extending these studies, we illustrate the paradoxical nature of governance units. Fligstein and McAdams contend that "ordinarily, then, governance units can be expected to serve as *defenders of the status quo* and are a generally *conservative force* during periods of conflict within the SAF" (emphasis added) (2011, 6). Previous studies echo this conservative nature of governance units in acting as opposing force to the challenger actors (Kjeldgaard et al. 2016) or even as a non-existent force in the field dynamics between incumbents and challengers (Pedeliento et al. 2020). Our case instead shows how Systembolaget before *Operation Vin* played the role of defender of the status quo. During and after *Operation Vin* the state played the role of promoter of change. Finally, studies building on strategic action field theory (Fligstein & McAdam 2012) typically show that exogenous shocks is the most frequent source of field-level changes (Pedeliento et al. 2020; Laamanen & Skålén 2014). In contrast, our case illustrates a situation where the field is changed by an endogenous shock operated by the governance unit, that typically defends the status quo.

Delaying Reward Choice: Anticipating Choice Is More Motivating Than Choice Itself

Marissa A. Sharif, The Wharton School of the University of Pennsylvania, USA
Raghuram Iyengar, The Wharton School of the University of Pennsylvania, USA

EXTENDED ABSTRACT

Imagine that you want consumers to complete some marketing research surveys about your company. As a result, you decide to offer them their choice from a set of rewards, depending on the number of surveys they complete. However, you are debating *when* it is best to have them make the choice between the rewards. In five real-behavior studies (N = 3,511), we demonstrate that consumers are more motivated with a delayed (vs. immediate) reward choice.

In Study 1, 600 participants from Amazon Mechanical Turk were informed that the study had two parts. In the first part of the task, they would be asked to answer 40 matrix task questions. In the second part of the task, they would be asked to type a series of CAPTCHAs, which they were informed was considered to be dull and frustrating. Depending on the number of matrix tasks they solved, they could substitute the CAPTCHA task with another more enjoyable task. There were 5 enjoyable tasks they could replace the CAPTCHA task with: watch a funny video about cats (requires 40 matrix tasks), watch funny ads (requires 30 matrix tasks), do a word search (requires 20 matrix tasks), read funny cartoons (requires 15 matrix tasks), and watch a clip of a national geographic video (requires 10 matrix tasks).

After learning about the task, in the Immediate condition, participants were asked to temporarily indicate which activity they would like to complete instead of the CAPTCHA task. Participants were **not** constrained to this choice and were aware they were not constrained. In the Delayed condition, participants were not asked to make this temporary choice.

Participants in both conditions then began the matrix task. After every matrix question, participants had the option to skip completing them to move on to the CAPTCHA task. Participants completed more matrix questions in the Delayed condition than in the Immediate condition ($p = .004$).

Study 2 followed the same design as Study 1; however, we measured motivation in a different manner: we asked participants how many matrix tasks they wanted to complete. We replicated our main effect: participants chose and thus completed more matrix tasks in the Delayed condition than in the Immediate condition ($p = .001$).

In Study 3, we aimed to examine the underlying process behind the effect. We propose that consumers with a delayed reward choice anticipate greater enjoyment from choosing than those who make an immediate non-binding choice, and this greater anticipatory enjoyment of choosing drives motivation. This study followed a similar design as Study 2. Participants in the Immediate condition made a non-binding reward choice. Afterwards, participants in both conditions were asked about their anticipated enjoyment of choosing, "After completing the first part of the study, depending on the number of matrix tasks you complete, you will choose among a set of activities to replace the CAPTCHA task with. How much do you think you will enjoy choosing among the more enjoyable activities to replace the CAPTCHA task with?" on a 100-point scale.

Afterwards, participants were asked to indicate the number of matrix tasks they wanted to complete prior to goal pursuit. As predicted, participants chose to complete more matrix tasks in the Delayed condition than in the Immediate Condition ($p = .031$). Participants anticipated that it would be more enjoyable to make a choice between the rewards in the Delayed (vs. Immediate) condition ($p <$ .001). Further, the greater anticipatory enjoyment of choosing significantly mediated the effect, (95% CI = [-.93, -.24])

In Study 4, we examined whether (1) our effect replicates with monetary rewards and with a different task (2) and if immediately *ranking* rewards will similarly lead consumers to be less motivated. Thus, in this study, we assessed whether merely deliberating on a future choice, via non-consequential ranking rather than a non-binding choice, can similarly lead consumers to be demotivated, relative to delaying when consumers deliberate on their choice. Lastly, we examined how immediately ranking rewards compares to being constrained to one reward.

604 participants had the opportunity to type 100 word sets. They received 20 points for each word set they typed, with each 10 points worth $0.01 towards a gift card. They could only redeem their points for one gift card at the end of the survey. Participants were randomly assigned to one of three conditions (Immediate-Not Constrained, Delayed, and Immediate-Constrained). At the start of the task, participants in both the Immediate-Not Constrained and Immediate-Constrained condition were asked to rank the gift cards in terms of how much they would like to have a $2 gift card to each of the stores listed above. After ranking the gift cards, participants in the Immediate-Constrained condition were informed that the gift card that they had ranked as most preferred would be the gift card they could redeem their points on at the end of the survey. They were restricted to this choice, and thus had no future choice among reward options. However, in the Immediate-Not Constrained condition, after the ranking task, participants were informed they could redeem their points for any one of the gift cards at the end of the survey. Thus, they were not restricted to any choice and were aware of this. In the Delayed condition, participants did not rank the gift cards until after typing the words and were informed they could redeem their points for any one of the gift cards at the end of the survey. We measured the number of word sets participants typed as our measure of persistence.

Participants typed more word sets in the Delayed condition than in the Immediate-Not Constrained condition ($p = .010$) and the Immediate-Constrained condition ($p = .016$). There was no difference between the Immediate-Constrained conditions and the Immediate-Not Constrained conditions ($p = .866$).

Across five studies, we document the motivating effect of delayed reward choice. In order for rewards programs to be the most motivating, our findings suggest they should be designed such that consumers make a delayed reward choice.

Clothing Consumption: Developing a Theory of Mindful Consumption

Deirdre Shaw, University of Glasgow, UK
Katherine Duffy, University of Glasgow, UK

EXTENDED ABSTRACT

Increasing levels of consumption represent a formidable challenge to society. This raises important questions concerning how best to establish a more sustainable consumption culture. Research has suggested that mindfulness may provide an antidote to consumerism via encouraging conscious reflection of the impact of behavior (Bahl *et al*., 2016; Sheth *et al*., 2011). While mindfulness and sustainability would appear to complement one another, current insights are limited by weak results and lack definitional and measurement clarity (e.g., Fischer *et al.,* 2017). Mindfulness may offer the potential to be transformative and challenge consumerist understandings of prosperity, however, current research falls short of offering an empirically grounded theory of mindful consumption.

Sustainability and mindfulness

Mindfulness has received attention in research in sustainable consumption as a means to disrupt automatic thinking, enhance awareness and foster prosocial values and behaviors (e.g., Stanszus *et al*., 2017). While important in exploring the potential of mindfulness to encourage sustainable consumption, key concerns remain:

Definition - The precise meaning of mindfulness remains elusive, much of the research in sustainability, following scholarship more generally, focuses on attention enhancement and present moment awareness (Kabat-Zinn, 2003). Sheth *et al.* (2011) take a wider definition of mindfulness but do not provide guidance as to how to achieve a mindful mindset. Current definitions of mindfulness in research limits its scope in encouraging sustainable behaviors.

Ethics – We argue that approaches to mindfulness in sustainability are limited as they do not move beyond the self to compassion for others and the planet, and a questioning of current values and ideologies. Current conceptions of mindfulness, fail to recognize a role for ethics (e.g., Stanley *et al.,* 2015).

Research Design –Research to-date examining sustainability and mindfulness has been quantitative, using measurement scales (Fischer *et al.,* 2017). There are many different scales that claim to define and measure mindfulness, however, a rationale for scale selection is rarely provided and an evaluation of these is lacking.

Decontextualization - Within Mindfulness Based Stress Reduction and Mindfulness Based Cognitive Therapy (e.g., Stanley and Longden, 2016), there is an absence of critical enquiry to the conditions, ideologies and values that lead to, for example, unsustainable consumption behaviors (Walsh, 2016), abstracting mindfulness from our everyday lives.

Methodology

In approaching our empirically grounded theorization of mindful consumption, we focus on the context of clothing as presenting a pertinent challenge to sustainability. Employing a multi-method qualitative study: interviews (McCracken, 1988), wardrobe audits (Pilcher, 2011), diaries (Day and Thatcher, 2009) and videography (Hietanen *et al.,* 2014), we engaged with 18 'mainstream' consumers over a period of 1 year. The focus was on the subjectivity of the participants in seeking to better understand and identify the logics of action. The analysis integrated into an interactive, iterative process to build the critical insights pertinent to shifting consumers towards more sustainable clothing behaviors, offering mindfulness as a tool to facilitate the process.

Findings

We orientate our findings around five stages of mindfulness whilst considering the role of ethics and links with sustainability (Table 1).

The first mindfulness phase of *recognition* led to consumer awareness and increased ability to notice and attend to potentially problematic issues associated with clothing (such as, lack of space, hoarding, repetitive buying, anxiety) and their own existing behaviors (e.g. impulse buying, wearing and discarding, excessive consumption). We found an *ethical sensitivity* whereby empathy regarding the negative impacts of clothing behaviors developed. Challenges emerged including, feelings of powerlessness, and a reluctance to problematize further.

In the second phase we identify *compassion*, whereby consumers transcended entrenched behaviors and questioned their clothing consumption (such as, the origins of the clothing, impact of production, volume owned and disposal channels). Consumers sought out and developed new knowledge, which enhanced the development of their *ethical knowledge.* Challenges remained, including, a lack of self-belief in their new found intentionality, also questioning led to consumers feeling paralysis around knowing how best to action knowledge into marketplace behaviors.

In the third phase of *responsibility*, consumers found a language to problematize and adapt their own clothing behaviors (e.g., detoxing, culling, not buying). We see *ethical competence* develop here as a key quality. Challenges prevailed, such as, how best to adopt more radical and transformative behaviors to align with this accepted responsibility.

The fourth mindfulness phase identified is *reflexivity*. Within this phase we found consumers centralizing their intentionality and finding liberation which conflated with their intentionality (e.g., replacing clothing buying with other activities, removing clothing apps from phones, checking garment labels). We see *ethical purpose* being invoked which guided reasoning and judgement. Challenges remained as to how to manage a potential misalignment between consumer values and behaviors, within the dominant market ideology.

In the final phase, we refer to the *courage* that the approach to mindfulness facilitated for consumers. Participants challenged and fully committed to a congruence between their value regime and behaviors. Challenges still prevailed for those who reached this phase in framing their value regime within an opposing dominant market ideology.

Conclusion

In offering an empirically grounded theory of mindful consumption we challenge linear and dyadic understandings (Sheth *et al.,* 2011; Bahl *et al.,* 2016); as to how mindfulness can be linked to sustainability at a given point in time. The experience and meaning of mindful consumption is different for different consumers at different points in time and, perhaps unsurprisingly, multiple challenges inhibit progress as mindful consumption evolves. We offer a richer picture of the potential of mindfulness to disrupt patterns of overconsumption and facilitate more sustainable approaches, the points of opportunity and barriers to change.

Bargaining with Algorithm: How Consumers Respond to the Offer Proposed by Algorithms Versus Human

Zhengyu Shen, Fudan University, China
Liyin Jin, Fudan University, China

EXTENDED ABSTRACT

Algorithms are involved in an increasing number of managerial decisions; given this trend, scholars have explored whether, when, and why people trust and are willing to use algorithms (Castelo, Bos, and Lehmann 2019; Logg 2018; Longoni, Bonezzi, and Morewedge 2019). Although these studies have advanced our knowledge on how to increase human decision-makers' reliance on algorithms when the algorithms outperform humans, the default role of algorithms assumed in the literature is that of an "assistant" for human decision-makers to improve their outcomes, overlooking other roles (e.g., opponents, counterparties) that algorithms might play in human-algorithm interactions.

The present research aims to examine this overlooked question in the context of human-algorithm negotiations. As a social interaction between two or more parties who aim to influence each other to accept their proposal regarding the value of a specific object (Maaravi, Ganzach, and Pazy 2011), negotiation occurs throughout consumers' everyday lives and has historically been viewed as an activity that takes place between humans (Purdy, Nye, and Balakrishnan 2000). Due to the increasing usage of algorithms with the ability to negotiate, it is possible that consumers can choose to bargain the price/ bid with robots in platforms such as eBay.

Past research suggests that laypeople believe that algorithms will be more effective at objective tasks that require logical, rule-based and quantitative analysis (Castelo et al. 2019; Haslam et al. 2008; Logg, Minson, and Moore 2019). As a result, algorithm appreciation seems lower among less numerate people (Logg et al. 2019). Similarly, consumers also believe that, on average, algorithms are more accurate than humans in calculating and forecasting tasks, and therefore, they show less tolerance for algorithms after seeing them err (Dietvorst et al. 2015; Logg et al. 2019). The reason algorithms provide more accurate forecasts and are more effective in quantitative analysis than humans is that they are assumed to be able to integrate huge amounts of information as inputs when making decisions and to process information without constraints related to computational capability (Hedén et al. 1997). On the other side, in the context of negotiation, Mason et al. (2013) found that negotiators who use precise first offers (i.e., $5115) made more conciliatory counteroffers because they seem more informed of the good's true value than negotiators who used round first offers (i.e., $5000).

Based on these findings, the current research hypothesized that consumers would assume that the initial offer is more reasoned when it is perceived as being accurate, which can be influenced by whether it comes from algorithms or humans. This perception of accuracy will lead consumers to believe that the room for negotiation is limited; thus, they will adjust the counteroffer less. If this mechanism exists, we can expect that once this belief is challenged, the proposed effect will disappear or even reverse. For example, people judged slow algorithmic predictions as being less accurate while they regarded slow human-generated predictions as being more accurate (Efendić, Van de Calseyde, and Evans 2020). Also, if the initial offer proposed by an algorithm is not reasonable (e.g., a very round price), consumers may no longer assume that the decisions made by this algorithm are accurate because they will suspect that the algorithm made the err. We thus consider two important boundary conditions

(respond speed and precision of initial offer) that might lead to break individual's lay belief between algorithm and accuracy.

Study 1 ($N = 204$) adopted a two-cell between-subject design. Participants were asked to negotiate the purchasing price of coffee beans as a hotel manager. They received the initial offer ($246) either from an algorithm or a person (sales manager), then they chose to accept or reject this price. If they accepted the initial offer, the negotiation ended as is; if they rejected this initial offer, they were prompted to make a counteroffer, i.e., a price that was lower than the initial offer. Regardless of what counteroffer (i.e., what price the participants proposed to counter the initial offer) the participants made, their counterparty (human or algorithm) always rejected the counteroffers and asked the participants to make another counteroffer (e.g., a higher affordable price). The negotiating process continued up to three rounds. We found a significant effect of the counterparty type manipulation on counteroffer adjustment[1], such that the participants in the algorithm condition adjusted their counteroffer less compared to those in the human condition ($t(202) = 2.24$, $p = .027$). Also, we found that the effect of counterparty type (algorithm vs. human) on counteroffer adjustment was sequentially mediated by the perception of accuracy and room for negotiation (indirect effect = .41, 95% *CI* [0.01 to 1.09]).

Study 2 ($N = 209$) adopted a 2 (counterparty type: algorithm vs. human) x 2 (response speed: fast vs. low) between-subjects design. Participants were asked to sell a used decorative carpet on an online recycling platform and bargain the selling price with either an algorithm or a staff. We manipulated the response speed by differentiating the response time either the algorithm or the staff had to make the quote in each round. We found that in the fast respond condition, when the initial offer came from an algorithm, the participants who believed that they were bargaining with an algorithm (vs. human) adjusted their counteroffer less ($F(1, 205) = 4.46$, $p = .036$). However, this pattern reversed when the counterparty's response speed was slow ($F(1, 205) = 28.26$, $p < .001$).

Study 3 ($N = 289$) tested another potential moderator—the precision of the initial offer (precise vs. round). In the precise initial offer condition, the initial offer proposed either by algorithm or human staff was $317, whereas in the round initial offer condition, the initial offer proposed either by algorithm or human staff was $300. The results suggested that when the initial offer itself was precise, the participants who received the offer from an algorithm adjusted the counteroffer less, compared to the participants who received the offer from a staff ($F(1, 285) = 18.38$, $p < .001$). However, this pattern disappeared when the initial offer itself was round ($F(1, 285) = 1.67$, $p = .197$).

Publicity as Justification

Kao Si, University of Macau, China
Xianchi Dai, Chinese University of Hong Kong, China

EXTENDED ABSTRACT

In many cases, social perceivers can infer opposite motives that can both plausibly underlie a given behavior. For example, a student may read fiction in the night before an important exam because he is addicted to the book and lacks self-discipline, or because he is trying to relieve himself of stress and getting better prepared for the exam. In this research, we focus on such behaviors which are only *apparently negative*. By apparently negative behaviors we mean behaviors that seem to be inconsistent with relevant norms or goals in appearance but are not necessarily so in nature. While negative construal might be the predominant response for such behaviors, in the current research, we investigate an important question: when would social perceivers be more likely to construe them positively? Put differently, what affects social perceivers' choice of construal of such apparently negative behaviors?

Theory and Hypothesis

Publicity, or the state of being observed by others, can influence people's behaviors via several mechanisms (e.g., Ratner and Khan 2002; Zajonc 1965). One major way through which publicity can exert its effects is that being observed by others activates people's image or reputational concerns which shape their behaviors more in line with social norms and others' positive expectations (Leary and Kowalski 1990; Schlenker 2003). For example, cues of being observed increase people's prosocial and ethical behaviors (Fehr and Fischbacher 2003; Kurzban et al. 2007) whereas anonymity prompts people to engage in socially deviant behaviors (Diener, Fraser, Beaman, and Kelem 1976).

Research in attribution theory revealed that people are much more likely to engage in more extensive forms of causal analyses about the possible causes of an outcome when the outcome disconfirms rather than confirms their expectations (Pyszczynki and Greenberg 1981; Weiner 2012; Wong and Weiner 1981). This is because for outcomes which conform to their expectations, people are disposed to construe or explain them using pre-existing and predominant causal theories or heuristics which are low in cognitive costs (Pyszczynki and Greenberg 1981; Wong and Weiner 1981). To the extent that publicity of an apparently negative behavior disconfirms social observers' expectations regarding the actor's image concerns, it should instigate the observers to search for alternative causes or motives that could explain or rationalize the behavior with regard to their expectations (Jones and Davis 1965; Kelley 1973).

Therefore, social observers, in an effort to make their construal of an apparently negative behavior more in line with their expectations about the actor, might strive to explain or rationalize the behavior in a positive light. In other words, we propose that social observers should evaluate the behavior to be *relatively* more positive when they are done in public than when they are done in private. Further, we propose that social perceivers could reach relatively more positive construal of the behavior via both weaker inferences about the negative motives or impacts of the behavior and stronger inferences about the positive motives or impacts of the behavior.

Moreover, we propose two boundary conditions of the current hypothesis. First, there must be certain degrees of ambiguity in interpreting the nature of the behavior. If the behavior unambiguously violates pertinent norms or goals, it becomes a negative behavior in nature, leaving no alternative choice for people's construal. Second,

the effect may only occur when social observers perceive the actor to have adequate agency in the situation. Here we refer to *agency* as the extent to which the actor has control or discretion in how the behavior is carried out. If publicity of the behavior is the result of some external factors that are uncontrollable to the actor, then it does not necessarily disconfirm social observers' expectations regarding the actor's image concerns.

In the following parts of this paper, we describe three experiments that provide support to our propositions. Experiment 1 demonstrated the effect in moral judgment and showed that it only occurred when there was room in interpreting the nature of the behavior. Experiment 2 demonstrated the effect in the context of goal pursuit and showed that it emerged when the actor had high agency but not when the actor had low agency. Finally, Experiment 3 provided evidence that it disconfirmed social observers' expectations when an apparently negative behavior was done in public than when it was done in private, and that disconfirmation of expectations prompted social observers to construe the behavior more positively.

Experiment 1

Method. Three hundred one participants (M_{age} = 36.55, SD_{age} = 11.32; 54% male) took part in an online experiment. They were randomly assigned to conditions of a 2 (public versus private) × 2 (rule: absent versus present) between-participants design. Participants were told that this was a short study about workplace behavior. Participants in the rule-absent condition read the following scenario:

> *Alex works in a grocery store. The store throws away all unsold perishable items of the day. Alex often takes some of these leftover foods home. Alex does it publicly (privately), where everybody (nobody) could see.*

Participants in the rule-present condition read the same scenario but also read that there is explicit rule prohibiting employees from taking the leftover foods. After reading the scenario, participants were asked to evaluate Alex's behavior by indicating the extent to which they thought that it was appropriate/acceptable (1: not at all appropriate/acceptable, 7: very appropriate/acceptable). Their answers to the two items were averaged to form a single measure (r = .83). Finally, as in other experiments, participants reported their demographic information.

Results. Analysis of participants' behavior evaluation as a function of publicity and rule-presence showed that rule-presence had a main effect, $F(1, 297) = 55.51$, $p < .001$. Not surprisingly, participants' evaluation of the behavior was much more positive when there was no explicit rule that inhibited the behavior ($M = 5.26$, $SD = 1.51$) than when there was ($M = 3.85$, $SD = 1.79$), $d = .85$. The main effect of publicity was not significant, $F < 1$.

Importantly, the analysis revealed a significant interaction effect, $F(1, 297) = 8.81$, $p = .003$, partial $\eta^2 = .029$. Consistent with our hypothesis, planned contrasts showed that when there was no explicit rule that inhibited the behavior, participants evaluated the behavior to be significantly more positive when it was done in public ($M = 5.53$, $SD = 1.33$) than when it was done in private ($M = 4.99$, $SD = 1.64$), $F(1, 297) = 4.08$, $p = .044$, $d = .36$. In contrast, when the behavior violated an existing rule, participants evaluated it significantly less favorably when it was done in public ($M = 3.57$, $SD = 1.79$) than

when it was done in private ($M = 4.14$, $SD = 1.75$), $F(1, 297) = 4.58$, $p = .033$, $d = .32$.

Experiment 2

Method. Two hundred five participants ($M_{age} = 35.10$, $SD_{age} = 11.67$; 52% male) took part in an online experiment. They were randomly assigned to conditions of a 2 (public versus private) × 2 (agency: high versus low) between-participants design. In the high-agency conditions, participants read the following scenario:

> *Aaron is going to take the SAT soon and has been preparing for the exam. The exam is important and Aaron knows that he should concentrate on his study. However, Aaron also wants to finish a fiction book he has started. As a result, Aaron reads the book for about one hour every night before he studies for the exam. He reads the book at home publicly (privately), where his family could (could not) see.*

Participants in the low-agency conditions read the same scenario, except that the last sentence of the above scenario was replaced by the following paragraph:

> *Aaron used to read books either in his own bedroom or in the living room. However, the lighting in Aaron's bedroom (the living room) has been malfunctioning recently and Aaron has to read the book in the living room (his own bedroom), where his family could (could not) see.*

All participants then evaluated Aaron's behavior by indicating the extent to which they thought that it was appropriate/suitable for his study goal (1: not at all appropriate/suitable, 7: very appropriate/suitable). Their answers to these two items were again combined to form a single measure ($r = .73$). On the next pages, participants reported the strength of their inferences about both the negative impacts (e.g., "reading the book hurts exam preparation") and the positive impacts (e.g., "reading the book helps reduce stress") of the behavior by answering some relevant questions.

Results. Analysis of participants' behavior evaluation as a function of publicity and agency revealed only a significant interaction effect, $F(1, 201) = 9.48$, $p = .002$, partial $\eta^2 = .045$. Consistent with our hypothesis, planned contrasts showed that in the high-agency conditions, participants evaluated the behavior to be significantly more positive when it was done in public ($M = 4.91$, $SD = 1.57$) than when it was done in private ($M = 4.03$, $SD = 1.33$), $F(1, 201) = 8.99$, $p = .003$, $d = .60$. In the low-agency conditions, however, the difference in behavior evaluation between the public ($M = 4.57$, $SD = 1.62$) and the private condition ($M = 4.98$, $SD = 1.44$) was non-significant, $F(1, 201) = 1.89$, $p = .170$.

Furthermore, results about participants' inferences about the negative and positive impacts of the behavior were largely parallel to their behavior evaluation. That is, in the high-agency conditions, participants agreed to a significantly less (greater) extent that reading fiction would negatively (positively) impact the student's exam preparation when the student read in public than when he read in private, ps < .05. The differences became nonsignificant in the low-agency conditions, Fs < 1.

In the high-agency conditions, we further tested the indirect effects of publicity on behavior evaluation via both weaker inferences about the negative impacts of the behavior and stronger inferences about the positive impacts of the behavior. The two constructs were examined as simultaneous mediators. With 5000 bootstrap samples, the indirect effect of inferences about the negative impacts of the behavior was estimated to be .21 (boot $SE = .13$), with a 95% bias-

corrected confidence interval (.03, .56) excluding zero. The indirect effect of inferences about the positive impacts of the behavior was estimated to be .38 (boot $SE = .17$), with a 95% bias-corrected confidence interval (.09, .77) excluding zero. The results therefore suggested that the effect of publicity on behavior evaluation was driven by these two routes.

Experiment 3

Method. One hundred one participants ($M_{age} = 34.85$, $SD_{age} = 11.23$; 49% male) took part in an online experiment. They were randomly assigned to two between-participants conditions (public versus private). Experiment 3 used a similar goal pursuit context as that in Experiment 2. Participants first read that Aaron read fiction every night before the exam and were asked whether they would expect Aaron to read it at home publicly or privately (1: Aaron is likely to read the fiction privately, 7: Aaron is likely to read the fiction publicly). On the next page, participants continued to read that Aaron read the book publicly or privately and indicated the extent to which Aaron's behavior confirmed their expectation (1: very much disconfirm my expectation, 7: very much confirm my expectation). Finally, participants were asked to write down their thoughts about why Aaron would read fiction at home publicly (privately) during exam preparation. They were told that their task was to explain Aaron's behavior and to see its implications for Aaron's goal attainment.

Results. Participants expected that Aaron was more likely to read the fiction at home privately rather than publicly, $M = 2.92$ ($SD = 1.60$), which was significantly lower than the midpoint (4) of the scale, $t = 6.76$, $p < .001$. Accordingly, Aaron's behavior (i.e., reading fiction at home publicly [privately]) was more likely to disconfirm participants' expectation in the public condition ($M = 3.60$, $SD = 1.99$) than in the private condition ($M = 5.41$, $SD = 1.70$), $F(1, 99) = 24.25$, $p < .001$, $d = .98$.

Next, we analyzed participants' explanations about the possible causes or motives that underlay Aaron's behavior. Two research assistants who were blind to the current hypothesis independently grouped the explanations into three categories. The first category included all explanations that implied a conflict between reading fiction and the attainment of the study goal while the second category included all explanations that endorsed positive impacts of reading fiction on the attainment of the study goal. Explanations that did not clearly suggest a negative or a positive impact of Aaron's behavior on his goal attainment were categorized as "others". Initial agreement between the two research assistants was 90%, and disagreements were solved through discussion.

Categorization of participants' explanations differed significantly across the two conditions, $\chi^2(2) = 39.63$, $p < .001$. The majority of participants in the private condition (71%; 36/51) construed Aaron's behavior negatively whereas only a small proportion of participants in the public condition (10%; 5/50) did so, $\chi^2(1) = 38.43$, $p < .001$. Further supporting the current theorizing, significantly more participants in the public condition (34%; 17/50) construed the behavior positively than in the private condition (6%; 3/51), $\chi^2(1) = 12.57$, $p < .001$. In addition, significantly more explanations in the public condition (56%; 28/50) fell in the "others" category than in the private condition (24%; 12/51), $\chi^2(1) = 11.13$, $p = .001$.

General Discussion

Past research has revealed circumstances in which negative publicity turns positive. For example, overt self-derogation and negative acknowledgement can elicit social support and help enhance others' evaluation towards a person (Powers and Zuroff 1988; Ward and Brenner 2006). Publicity of negative information about a prod-

uct can sometimes increase rather than decrease consumer evaluations (Berger, Sorensen, and Rasmussen 2010; Ein-Gar, Shiv, and Tormala 2012; Shoham, Moldovan, and Steinhart 2017). We contribute to this stream of research by proposing and testing a new mechanism through which negative publicity is able to positively influence people's judgment about others.

Future research should further test the validity of the current mechanism by examining some additional moderators. First, the positive effect of publicity should be contingent on ease of justification. If justifications for the behavior are difficult to find, then people are less likely to arrive at positive conclusions in their causal analyses and thus the effect is less likely to emerge. Second, the effect should be less likely to occur for actors towards whom social perceivers hold certain negative impressions. This is because for these actors, the fact that they perform negative behaviors in public is unlikely to disconfirm the expectations of the social perceivers.

Another interesting question is that whether people would strategically use publicity as a justification for their own behaviors. Our observation is that people are often sophisticated enough to use such strategies to garner social approval (Powers and Zuroff 1988; Smith, Snyder, and Handelsman 1982; Ward and Brenner 2006). We believe that empirical work that investigates people's strategical use of publicity as justification would be meaningful and would greatly enrich our insight into many of the phenomena in an age of social media.

Rethinking Perceptions of Disability: The Unintended Harm of Simplified Positive Inferences

Helen van der Sluis, Arizona State University, USA
Adriana Samper, Arizona State University, USA
Kirk Kristofferson, Ivey Business School, Canada

EXTENDED ABSTRACT

Understanding how disabilities shape marketplace interactions is crucial, particularly as businesses prioritize inclusion and accessibility (Laluc 2018). While policies like the Americans with Disabilities Act and Affirmative Action seek to protect and empower people with disabilities, recent work continues to document that individuals with disabilities face common misperceptions in day-to-day interactions (e.g., Lindsay and Cancelliere 2018), and suggests that the marketplace can improve its accessibility especially in terms of person-to-person interactions. Most marketing-relevant work on perceptions of disabilities generalizes to create one group, despite a wide range in the nature and manifestation of disability. For example, disabilities vary greatly in how visible they are and encompass a range of issues of varying severity. We seek to document how inferences of disability shape person-perception, how these inferences vary depending on the visibility of a disability, and how they can result in unidimensional impressions of individuals with disabilities.

We show that consumers view individuals with disabilities as more moral than those without disabilities due to the perception that they have overcome adversity (study 1). Importantly, we show that when the disability is less visible, these moral character perceptions weaken significantly (studies 1, 3), and when people with less (versus more) visible disabilities utilize accessibility resources afforded them, other consumers may be more apt to punish them (study 3). We also show that our stereotyped inferences of individuals with disabilities are limiting in that we expect their preferences to be less indulgent and highly utilitarian (study 3).

This work contributes to the limited research shedding light onto how disabled consumers are perceived and, ultimately, stereotyped. We extend work on person perception to reveal the powerful impact of physical cues of disability while highlighting how harsh fellow consumers can be in response to individuals with less visible disabilities.

Most prior research reflecting societal stereotypes of disability (Fiske et al. 2002; Cuddy et al. 2007; Lucas 2007) generalizes across various disabilities, yet physical disabilities vary broadly. For example, Furnham and Pendred (1983) found that attitudes toward individuals with physical disabilities are significantly more positive than attitudes toward individuals with mental disabilities, and Gouvier et al. (1994) showed that people talk more during interactions with individuals who display an observable physical disability than with those who do not display one. These findings suggest that perceptions of these groups differ despite both falling under the same umbrella of "disability." In the present research, we suggest that different instantiations of more and less visible physical disabilities can also differentially affect person perception.

Visual characteristics powerfully influence person perception (e.g., Dion et al. 1972; Otterbring et al. 2018) and associated evaluations of one's core character (Van Overwalle et al. 1999). Visible cues of disability are no exception. We propose that certain cues of physical disability positively affect perceptions of having overcome adversity, which influence perceptions of moral character. Moral inferences are readily assessed because moral character is diagnostic of whether a person may be harmful or helpful to others (Wojciszke, Bazinska and Jaworski 1998), thus making it a vital dimension of person perception (Goodwin, Piazza, and Rozin 2014; Goodwin 2015). Because many settings favor those who do not have a disability (Hehir 2007), distinct needs may emerge for those with a disability. Individuals with physical disabilities may have difficulty moving through their environments or performing daily activities (Goldenson, Dunham, and Dunham 1978), suggesting that they regularly overcome adversity simply by making their way through life. Relatedly, people often perceive those with disabilities as inspirational for having overcome adversity (Ellis 2008), an emphasis upon which may result in perceiving people with disabilities as having superhuman character (Clogston 1994).

We propose that these perceptions of having overcome adversity drive moral character inferences. Recent work from Schaumberg and Mullen (2017) suggests that seeing someone experiencing unavoidable misfortunes may positively affect our inferences of that person's moral character. People also tend to believe that adversity is beneficial for character (Affleck and Tennen 1996), and like to root for individuals who are struggling (Kim et al. 2008). Extant research shows that moral character inferences emerge even in situations where morality does not seem clearly relevant (Tannenbaum, Uhlmann, and Diermeier 2011; Samper et al. 2018). Because observable characteristics are salient and readily accessible, consumers make these inferences quickly and without much, if any, additional information. Importantly, based on our theorizing, among people whose disabilities are less visible, implicit assessments of adversity and hence, inferred moral character, are not as likely to be as strong, weakening the disability-morality link. Further, these perceptions are likely to be very dependent on disclosure of disability, which may or may not occur.

Notably, we also suggest that inferences made about adversity and morality among individuals with disabilities may have downstream consequences. First, perceived adversity itself should make the need to assuage hardship more salient, eliciting a greater focus on utilitarian solutions and choices for disabled individuals. Second, some work suggests that highly moral people should be more virtuous, and even may be nudged away from hedonic pursuits. Aristotle claimed that any pleasure-seeking in life was antithetical to being a moral human (*The Nichomachean Ethics*). As a result, we predict that because individuals with disabilities are already prone to being perceived as not fully human (Clogston 1994; Luborsky 1994; Murphy et al. 1988), increased perceptions of hardship and high moral character inferences may contribute to expectations that someone with a disability prefers more utilitarian items instead of more hedonic ones.

In study 1, we establish our basic effect in a context where spontaneous inferences are often made of others: while waiting in line. In a three-cell (no disability vs. low visibility disability vs. high visibility disability) between-subjects design, 385 TurkPrime participants imagined chatting with a person named Alex next to them in line. In both disability conditions, participants learn that Alex lives with cerebral palsy. However, in the low visibility condition, participants notice he doesn't have any visible indication of the disability, whereas in the high visibility condition, they note a wheelchair. In the no disability condition, participants simply notice Alex is wearing a blue shirt. Participants then rated Alex's morality (e.g., moral;

Samper et al. 2018; α=.91) and adversity overcome (e.g., "He has overcome adversity;" α=.85).

We found main effects of disability on both moral character ($F(2, 382) = 4.14$, $p = .016$; $\eta_p^2 = .02$) and adversity ($F(2, 382) = 26.83$, $p < .0001$; $\eta_p^2 = .12$). Participants thought Alex was significantly more moral when his disability was highly visible ($M = 5.72$) than when he had no disability ($M = 5.35$; $F(1, 382) = 8.07$, $p = .005$; $\eta_p^2 = .02$), and marginally more moral compared to when the disability was less visible ($M = 5.49$; $F(1, 382) = 3.21$, $p = .074$; $\eta_p^2 = .0083$). There was no significant difference between the no disability and low visibility disability conditions ($p = .29$). Shifting to adversity, participants felt Alex had overcome more adversity in the high visibility disability ($M = 5.88$) relative to either the low visibility ($M = 5.36$; $F(1, 382) = 18.67$, $p < .0001$; $\eta_p^2 = .047$) and no disability conditions ($M = 4.17$; $F(1, 382) = 194.49$, $p < .0001$; $\eta_p^2 = .34$). Further, perceived adversity overcome was higher in the low visibility versus no disability condition ($F(1, 382) = 92.27$, $p < .0001$; $\eta_p^2 = .19$).

To test our prediction that perceptions of having overcome adversity underlied Alex's morality inferences, we conducted a mediation analysis using disability as the independent variable, perceptions of adversity as the mediator, and morality as the dependent variable (Model 4, Hayes 2013; MacKinnon et al. 2007). A multicategorical mediation analysis (Hayes 2013) with the high visibility disability condition as our reference group revealed a significant indirect effect of perceived adversity when comparing the high versus low visibility disability condition (D1: B = -.18, CI_{95}: -.29, -.09), and also when comparing the high visibility disability to the no disability condition (D2: B = -.57, CI_{95}: -.84, -.34).

While study 1 examines inferences consumers make of those with disabilities, study 2 seeks to examine behaviors associated with these inferences in a gift-giving context. People typically expect more hedonic items as gifts (Lu et al. 2016). However, given the study 1 result that individuals with any disability face higher adversity than individuals without a disability, we expected that having explicit information about a disability will lead consumers to choose a more utilitarian (vs. hedonic) gift for that person, whether or not it is visible. In a three-cell (no disability vs. low visibility disability vs. high visibility disability) between-subjects design, 453 Prolific users imagined leading an office birthday present pool for a colleague they don't know well. In the two disability conditions, participants recall that when they first met, the colleague (Michelle) told them that she has lived with a physical disability since she was born. They either notice she gets around in a wheelchair (high visibility disability condition) or do not notice any visible indication of the disability (low visibility disability condition). Participants in the no disability condition recall that Michelle told them that she has actually lived in this city since she was born. After hearing that she sometimes gets massages, they choose between two massage options as the group gift: one, more utilitarian; the other, more hedonic. The description of the former was tested to be more utilitarian and less hedonic than that of the latter. Participants rated which massage the office should give Michelle (1 = Definitely Therapeutic Massage (Utilitarian), 7 = Definitely Luxury Massage (Hedonic)).

Results revealed a main effect of disability on choice rating ($F(2, 449) = 13.09$, $p < .0001$; $\eta_p^2 = .055$). Planned contrasts showed that participants tended to opt toward the utilitarian massage in the high ($M = 3.54$; $F(1, 449) = 15.49$, $p < .0001$; $\eta_p^2 = .033$) and low visibility disability ($M = 3.32$; $F(1, 449) = 22.94$, $p < .0001$; $\eta_p^2 = .048$) conditions relative to the no disability condition ($M = 4.54$), providing evidence for consumers expecting people with disabilities to prefer utilitarian (vs. hedonic) items, even as a gift, and whether the disability is more or less visible.

While study 1 showed that consumers assign individuals with disabilities elevated moral character and study 2 showed that consumers may be more likely to give these individuals utilitarian (vs. hedonic) gifts, both of these studies used inherently friendly contexts that are relatively information-rich. In study 3, we sought to examine the limits of the morality perceptions when information about the target is limited: when observing someone in a parking lot. Given less context, we expected that consumers would be harsher here than in study 1. We used a subtle signal of disability: parking in an accessible parking spot. In a three-cell (no disability vs. low visibility disability vs. high visibility disability) between-subjects design, 281 undergraduates imagined needing to go to the mall and having trouble finding parking. When they finally parked and walked toward the mall, participants in the two disability conditions see someone pull into the handicapped space in the first row, and participants in the no disability condition see someone pull into one last space in the first row. They then imagined seeing the person get out of the car: in the high visibility disability condition, participants saw the person take a wheelchair out of the car and wheel toward a physical rehabilitation building, and in the low visibility and no disability conditions participants saw the person get out of the car and walk to the building. Participants then evaluated the person's moral character ($\alpha = .95$) and adversity overcome ($\alpha = .83$).

Results again revealed main effects of disability on moral character perceptions ($F(2, 278) = 17.25$, $p < .0001$; $\eta_p^2 = .11$) and perceptions of adversity overcome ($F(2, 278) = 30.50$, $p < .0001$; $\eta_p^2 = .18$). Participants thought the person was marginally more moral in the high visibility disability ($M = 4.64$) versus no disability condition ($M = 4.32$; $F(1, 278) = 2.71$, $p = .1007$; $\eta_p^2 = .01$), and significantly more moral compared to when the disability was less visible ($M = 3.54$; $F(1, 278) = 32.43$, $p < .0001$; $\eta_p^2 = .10$). There was also a significant difference between no disability and low visibility disability conditions ($F(1, 278) = 16.53$, $p < .0001$; $\eta_p^2 = .056$). Planned contrasts of adversity revealed that adversity overcome in the high visibility disability condition was rated higher ($M = 5.34$) than either that in the low visibility ($M = 4.24$; $F(1, 278) = 59.76$, $p < .0001$; $\eta_p^2 = .18$) and no disability conditions ($M = 4.64$; $F(1, 278) = 23.81$, $p < .0001$; $\eta_p^2 = .079$). The perceived adversity overcome was lower in the low visibility disability condition than in the no disability condition ($F(1, 278) = 8.14$, $p = .005$; $\eta_p^2 = .029$).

We predicted that perceptions of having overcome adversity would mediate the elevated morality inferences of the person participants imagined seeing in the parking lot. We again utilized multicategorical mediation (Model 4, Hayes 2013; MacKinnon et al. 2007) using the same variables as in study 1. As predicted, the indirect path of disability on morality through perceptions of adversity overcome was significant in both pathways (D1: B = -.58, CI_{95}: -.80, -.38; D2: B = -.37, CI_{95}: -.55, -.21). Thus, we replicate the high visibility vs. no disability pattern from study 1, and newly demonstrate that with little information, consumers may actually be exceptionally harsh in their perceptions of adversity overcome and moral character toward individuals with less visible disabilities.

We find that consumers assign higher moral character to those with disabilities due to the perception that they have overcome adversity. However, these higher moral perceptions seem only to be linked to disability when people can easily observe the disability, and thus infer greater adversity. Further, these moral character elevations may not be all good, and in fact may lead people to only give gifts of utility instead of hedonic gifts (despite people typically preferring to give hedonic gifts (Lu et al. 2016)), thus depriving people with disabilities of normal life enjoyments. We contribute to existing theory by showing how the magnitude of a physical cue affects moral char-

acter. We also square psychology work on disability with the range in actual disabilities in the marketplace. Our work reveals that consumers with disabilities may still face stereotyping generalizations and those with less visible disabilities may face particularly harsh scrutiny in using necessary resources. We also highlight a potential difficulty in encouraging more hedonic gift-giving for individuals with disabilities. In recognizing this pattern, we highlight inherent contradictions in how we perceive and judge individuals with disabilities that can limit the intended goals of policies that attempt to protect and empower these individuals, ultimately suggesting that we still have a long way to go to alleviate person misperceptions.

Predicting and Choosing for Others: How and Why We Fail

Stephanie M. Smith, UCLA, USA
Ian Krajbich, The Ohio State University, USA

EXTENDED ABSTRACT

Being able to learn another person's preferences and choose on their behalf are important skills for functioning successfully in society. Sometimes, we have to predict what others will choose. Other times, we need to make decisions on their behalf. Surrogate decision making happens throughout society, but past research in the area has established a robust and consistent finding: people are not very good at choosing what another person would choose for themselves (Fagerlin et al. 2001; Faro and Rottenstreich 2006; Fernandez-Duque and Wifall 2007; Garcia-Retamero and Galesic 2012).

Important, unresolved questions are exactly *how and why* people are bad at choosing for others. The research into *how* people fail is somewhat contradictory: while some research (e.g., Beisswanger et. al 2003; Hsee and Weber 1997) finds that people choose too riskily for other people, other research (e.g., Faro and Rottenstreich 2013; Stone et al. 2013) provides evidence that people choose too safely for others. Another discrepancy in the literature is whether people choose too similarly to their own preferences (as in Fagerlin et al. 2001) or not similarly enough (as in Givi and Galak 2017). Thus, in our study of *how* participants' predictions/choices for others differ from what the recipient would choose for themselves, we use methods designed to address/eliminate the potential reasons for these discrepancies.

Why people are bad at choosing for others is also an understudied issue. Does the failure arise from an innate inability to predict what others would choose for themselves? Or does it come from a misuse of available information? As humans, we use various sources of information to make our decisions, but sometimes we don't use it appropriately. There are a number of different types of information that surrogate choosers might rely on: (1) the preferences of the recipient, (2) their own preferences, and (3) societal norms/expectations. Across two studies, we investigate how these sources of information contribute to the decision process, using process-related analyses (i.e., mouse-tracking) to better understand why people choose what they do.

In Study 1, Participants (N = 44) first observed choices made by each of six deterministic algorithms (with a variety of risk preferences) and then predicted what the algorithms "chose" in a new set of decisions. Each trial comprised two options: a sure thing and a gamble. Participants earned money for each correct prediction. Participants also made incentivized choices for themselves. Participants were able to learn the "preferences" of the deterministic algorithms (average accuracy = 82%; table 1). There is a significant, positive relationship between the actual risk parameters of the algorithms and the risk parameters fitted on participants' predictions (regression of fitted risk parameter on actual risk parameter with random slope and intercept at the participant level, $\beta = 0.82$, $p < .0001$).

The design of Study 2 was very similar to Study 1, with the following differences. All participants (N = 165) observed choices made by 6 participants (with a variety of risk preferences) from Study 1. Then, participants either predicted what the recipients chose *or* chose for them in a new set of choices. In Condition P_S, participants earned money per correct prediction, similar to Study 1. In Condition P_O, a randomly selected *recipient* earned money for each correct prediction. In Condition C, a randomly selected *recipient* received the outcome from a participant's choice in a randomly selected trial. Throughout all observations and decisions, participants' mouse movements were tracked.

On average, the predictions from Condition P_S and P_O participants were more accurate than the choices from Condition C participants (Condition P_S: $t(108.5) = 3.40$, $p = .0009$; Condition P_O: $t(95.73) = 3.91$, $p = .0002$; table 1). There is a significant, positive relationship between the actual risk parameters of the recipients and the fitted risk parameters, based on participants' predictions/choices (Condition P_S: $\beta = 0.81$, $p < .0001$; Condition P_O: $\beta = 0.78$, $p < .0001$; Condition C: $\beta = 0.27$, $p < .0001$; Fig. 1). The slope in Condition C is significantly shallower than that of conditions P_S and P_O (ps < .001), implying that participants were significantly less sensitive to changes in recipient risk preference when choosing for them (vs. predicting what they would do).

The behavioral analyses above provide some answers about the process involved in predicting and choosing for others, but we are also interested in the time course of participants' mouse movements. As in Sullivan et al. (2014), we estimated the timing of three competing influences: (1) the participant's own preferences, (2) the recipient's preferences, and (3) expected value maximization. This analysis provides us with a temporal understanding of how three competing influences predict participants' mouse movements.

Recipient preferences (expected value and participant preferences) became predictive later (earlier) in condition C than in the prediction conditions. We also find a positive correlation between time advantage for the recipient variable and accuracy in predicting/choosing for the recipient (participant-preferences: $r(158) = 0.27$, $p = .0005$; expected value: $r(158) = 0.24$, $p = .002$). This implies that people for whom recipient preferences became predictive of mouse position earlier (relative to participant-preferences and expected value) were better at predicting/choosing in line with the recipient's preferences.

Overall, these two studies provide new insight into the choice process invoked when deciding for others. In general, when participants (or their recipients) were incentivized for predicting accurately, they were highly accurate. Mouse movements provide evidence for different temporal processes, not only across conditions, but also across individual people. We provide evidence for a connection in processing speed (of the recipient's preferences) and accuracy in choosing for them.

This project provides us with robust evidence that people (1) can learn the preferences of others, (2) can implement this learned information when incentivized to do so, (3) but do not implement this info (as accurately as they could) when they are simply asked to choose for others. Instead, they rely too heavily on other sources of info (i.e. expected value and their own preferences). These findings advance our understanding of prediction and choice in the surrogate decision domain.

Robotic Relationships: Impact of Automation on Psychological Ownership

Leah Smith, University of Arkansas, USA
Randy Rose, University of Tennessee, USA
Heath McCullough, Auburn University, USA

EXTENDED ABSTRACT

"Alexa, begin vacuuming the living room." This simple verbal command accomplishes a previously routine task by delegating it to an automated product. Increasingly, such tasks are being accomplished by a verbal command to a smart home device or by a tap on a smartphone application without ever coming in contact with the end product.

Consumers achieve greater efficiency by not having to invest their own time and effort into routine tasks such as cleaning the floors or mowing the lawn. However, as this separation from products becomes more commonly integrated into consumers' lives, it also disturbs the normal consumer-product relationship development process. Just as digitally mediated communication changes how human relationships develop (Walther 1992), it will also impact how consumers perceive and relate to products. I propose that automation of products will lower consumers' psychological ownership of the target product and disrupt both the natural attitudinal and behavioral consequences that develop as a result.

Psychological ownership a cognitive and affective state of 'felt' ownership that develops towards a target, separate from any claims of legal ownership (Pierce et al. 2003). These feelings of ownership lead to positive attitudinal, motivational, and behavioral consequences related to the target (Pierce et al. 2003).

In marketing, psychological ownership has been used to explain how the ability to touch an object (or expected touch of an object) increases perceptions of ownership, and subsequent valuation (e.g. Atasoy and Morewedge; Peck and Shu 2009). However, other routes to psychological ownership, along with other potential consequences have largely been unexplored. Additionally, research has shown both contextual and individual differences play a role in how psychological ownership develops (Folse, Moulard, and Raggio 2012). Such differences are highlighted in previous research on psychological ownership of places (Asatryan and Oh 2008) and are proposed in the context of robotic service encounters (Van Doorn et al. 2017). I seek to demonstrate how mediated product interactions disrupt the process of psychological ownership development and produce predictable downstream consequences of relevance to marketers.

Smart technology has been extended to a variety of product categories including lighting, appliances, and many others. In many cases, such as thermostats and security systems, connected products offer greater capabilities and interactions than were possible before which actually increases the frequency of interaction. Under these conditions, psychological ownership may actually increase vs. traditional products because smart products are offering more information and enabling consumers to come to know the product more intimately. However, automated products are those that reduce or replace human interaction. Automated versions of traditional consumer products are already available for vacuum cleaners and lawn mowers, with self-driving cars on the immediate horizon. My research investigates how the automation of products impacts human interactions and relationship development with the product.

Developing predictions regarding how automation can disrupt psychological ownership requires an understanding of how ownership perceptions develop. As Pierce et al. (2003) explain, psychological ownership can develop in three ways: (1) through perceptions of control, (2) through acquisition of intimate knowledge of the target, or (3) as a consequence of investment of the self into the target. Some combination of the three mechanisms is also possible. Automated products operate independently, meaning without direct interaction. Although this may imply greater flexibility and convenience for the consumer, automated operation may undermine these routes to psychological ownership.

For example, a robotic vacuum cleaner can be conveniently operated while the legal owner is away from home. A traditional vacuum can be guided to directly address a problem area or go back over areas to pick up debris missed on the first pass. Robotic vacuums, by contrast, spend a predetermined amount of time covering all areas of the room equally rather than addressing a specific mess or high traffic area that may need extra attention. Debris left behind on the first pass will likely not be addressed in a second attempt. This may lead to feelings of a loss of control over how the product operates, especially if it means extra effort to repeat the cycle or picking up left behind pieces manually. Further, the same task done with a traditional vacuum provides direct feedback during operation. The operator can feel the weight of the vacuum in their hand, the noise provides confirmation of particles being picked up, the pull of resistance indicates the level of suction power. All of these help the operator to know the product more intimately and are absent when the product is automated. As the consumer interacts directly and repeatedly with the product, investment of the self into the product becomes more likely. All three routes to psychological ownership can be disrupted when products are automated, thereby leading to overall weaker psychological ownership perceptions. Formally stated:

Hypothesis 1: *Automated (traditional) products will undermine (enhance) feelings of psychological ownership toward a target.*

As a product becomes psychologically owned it develops a closer association with the self. This self-extension leads to more positive evaluations of the product (Belk 1988) because evaluating it closer to evaluating oneself, resulting in higher satisfaction. Over time, these higher evaluations of the product may also develop into attachment or an emotional bond between the consumer and the product (Kleine and Baker 2004).

Hypothesis 2: *Automated (traditional) products will have a negative (positive) impact on a) product satisfaction and b) emotional attachment, mediated by psychological ownership.*

Concurrently, behavioral outcomes of psychological ownership may also be disrupted by automation. Perceiving a product as part of the extended self also motivates consumers to preserve the object as a way of preserving the self (Belk 1988). This desire to preserve the product relationship may lead consumers to extend the life of that product through proactive maintenance behaviors. Additionally, preservation motives lead consumers to extend the relationship at time of replacement, leading to higher brand loyalty upon repurchase. These behavioral outcomes allow consumers to prolong and sustain the product relationship.

Hypothesis 3:   *Automated (traditional) products will have a negative (positive) impact on a) proactive maintenance behaviors and b) brand loyalty, mediated by psychological ownership.*

Evidence presented thus far has shown how automation may interfere with the way consumers interact with products and how that ultimately impacts the consumer-product relationship. However, understanding the process and routes to ownership allows marketers and designers to open new routes to psychological ownership. We believe anthropomorphizing automated products will mitigate the negative effect of automation.

Anthropomorphism occurs when people perceive humanlike characteristics in nonhuman creatures or objects (Epley, Waytz, Akalis, and Cacioppo 2008). When products are anthropomorphized, norms and expectations of the social world are more readily applied to the relationship with the product (Aggarwal and McGill 2012) leading to greater feelings of intimacy and subsequent psychological ownership. Additionally, anthropomorphized products allow owners to feel that the product is being operated by someone else, and not just moving randomly which may also restore feelings of control. Automated products have the capability to respond and adapt which will make them more readily anthropomorphized than traditional products. Therefore, we believe the effects of anthropomorphism on psychological ownership will be to ameliorate the negative impact of automation on psychological ownership.

Hypothesis 4:   *Anthropomorphism of products will attenuate the negative effect of automation on psychological ownership.*

Unlike previous studies of psychological ownership in marketing which focus on willingness to pay for an object prior to acquisition, I focus on the relationship dynamics that develop after usage. The differences in the way consumers experience traditional and automated products during ownership will change how psychological ownership develops and its downstream consequences.

Study 1

As an initial test of the hypotheses, I collected Amazon reviews of traditional and automated products to test for differences in the affective dimension of psychological ownership. Vacuum cleaners were chosen because they are currently the most widely adopted robotic product. Traditional and robotic vacuum cleaners vary in terms performance (suction power, dust bin capacity etc.). Therefore, the sample was restricted to 5-star reviews to control for those functional differences. The text of the combined reviews was analyzed using Linguistic Inquiry and Word Count software (LIWC; Pennebaker, Booth, and Francis 2015).

As expected, the emotional tone of the reviews for traditional vacuums was significantly more positive (98.95%) than those for robotic vacuums (85.59%, p<.01). This result suggests a weaker emotional connection to the automated product, even when initial satisfaction is high, and provides initial support for H_1. The more positive attitudinal response to the traditional product is indicative of the emotional characteristics of psychological ownership.

Study 2

Study 2 simulated the experience of product usage to understand the process of psychological ownership (H_1) development and its implications on attitudinal consequences of satisfaction (H_{2a}). In this study, a virtual driving experience was used to simulate product usage of either a traditional or self-driving car resulting in a 2 factor (product type: traditional vs. automated) experiment.

Participants were instructed to take a virtual test-drive of the car by driving two laps around the virtual track. Those in the self-driving condition were also told that it was a self-driving car and operated the car through voice commands. In the traditional car condition, participants controlled the car with the steering wheel and pedal controllers. Participants rated their psychological ownership of the car by indicating their agreement on a nine-point scale with five-items from Fuchs, Prandelli, and Schreier (2010) including: "Although I do not legally own this car yet, I feel like this is *my* car," "This car incorporates part of myself," "I feel that this car belongs to me," "I feel connected to this car," and "I feel a strong sense of closeness with this car," ($a = 91$).

As expected, psychological ownership was significantly higher for those in the traditional car condition ($M = 4.37$) than in the self-driving car condition ($M = 3.69$, $p = .03$), providing support for H_1. Similarly, satisfaction was higher for those who drove the traditional car ($M_{traditional} = 6.57$ vs. $M_{self-driving} = 5.76$, $p = .03$). Further, the effect on satisfaction was fully mediated by psychological ownership (= -.4808, 95% CI: -.9616 to - .0484). Providing support for H_{2a}.

Study 3

Study 3 collected field data from actual owners of traditional (n=301) and robotic (n=299) vacuum cleaners. As a full test of the model, I measured the psychological ownership, degree of anthropomorphism, and all of the downstream consequences of interest.

Results showed that traditional vacuum owners ($M_{traditional} = 4.57$) had significantly higher psychological ownership than robotic vacuum owners ($M_{automated} = 4.37$; $F(1,595) = 4.68$, $p = .03$) supporting H_1. This lowered psychological ownership fully mediated the effect on satisfaction (= -.0970, 95% CI: -.1888 to -.0095), emotional attachment (= -.1452, 95% CI: -.2771 to -.0178), providing support for H_2. Brand loyalty was also fully mediated by psychological ownership (= -.0562, 95% CI: -.1099 to -.0074) supporting H_{3b}. Psychological ownership partially mediated the effect on proactive maintenance behaviors (= -.0239, 95% CI: -.0498 to -.0025). However, indirect effect was still positive and significant indicating that other product attributes may contribute to greater need of ongoing maintenance.

Finally, adding anthropomorphism to the model as a moderator of the effect showed a positive interaction (p<.001) such that robotic owners who highly anthropomorphized the product, felt less loss of control which repaired some of the negative effect of automation on psychological ownership (index of moderated mediation: .0467, 95% CI: .0220 to 0769).

Currently about 32% of US households have begun to adopt some form of smart technology and that is forecasted to reach 53.1% of households by 2022 (Statista 2018). For consumers, automation allows for managing routine tasks more efficiently. However, this may lead consumers to feel more connected more to the interface device (smartphone or smart home device) rather than the end product itself. Previous research has explored types of consumer-product relationships and the downstream consequences of those relationships (e.g. Lastovicka and Sirianni 2011). Recent research in marketing has examined the effects of psychological ownership on product valuation pre-purchase (e.g. Atasoy and Morewedge 2017). I extend this line of research to show how differences in psychological ownership develop as a result of the product interface and demonstrate subsequent negative effects on post-purchase consumer-product relationships. Importantly, my work will also examine ways for marketers to overcome these limitations of automation.

Marketers need to understand how consumers interact and relate to products in order to avoid the consumer disconnect that may develop as a result of lowered psychological ownership. Unmanaged, this disconnect may lead to lower proactive maintenance behaviors, meaning lower aftermarket sales, and lower repurchase intent, meaning lower future sales. My research offers clear implications for managing customer lifetime value in the face of a highly automated future. If marketers incorporate affordance principles such as customization, they can not only potentially mitigate the negative effects of automation but also provide greater perceived differentiation and value to consumers.

The Effect of Resource Scarcity on Advice-taking

Jane So, City University of Hong Kong, Hong Kong, China
Nidhi Agrawal, University of Washington, USA

EXTENDED ABSTRACT

Consumers often feel resource scarcity when they feel they do not have enough necessary resources to meet their needs (Mani et al. 2013). Feelings of resource scarcity systematically affect how consumers think, perceive, feel, and behave (Hamilton et al. 2018; Haushofer and Fehr 2014; Mani et al. 2013; Shah et al. 2012; Sharma and Alter 2012; Tully et al. 2015; Roux et al. 2015). Adding to this line of research, we suggest a new scarcity effect on consumers' advice-taking tendency. We argue that when people are feeling resource scarcity such as time scarcity or money scarcity, people are less likely to take advice from others because they view that others are different from themselves.

Resource scarcity signals that the environment is harsh (Laran and Salerno 2013; S. E. Hill et al., 2012; Griskevicius et al. 2013), such that people need to compete with others for the scarce resource (Kristofferson et al. 2017; Roux et al. 2015). Insufficient resources make people protect what they have and become aggressive to others for the sake of their own benefit (Kristofferson et al. 2017; Roux et al. 2015). Thus, when feeling scarcity, people are more focused on the self than thinking from other's perspective. Furthermore, other empirical research on resource scarcity suggests that resource scarcity leads to more polarized view. For example, when people are primed with a scarce environment, they are more likely to narrow the definition of their in-groups and thus categorize others who have ambiguous group identity as outgroups (Rodeheffer, Hill, and Lord 2012). Moreover, a general sense of scarcity makes people show a greater preference towards an option that was already their favorite, and express greater dislike for an option that was already disliked (Zhu and Ratner 2015). Thus, we argue that consumers who are feeling resource scarcity may have a polarized view of the self and others, such that others are different from the self.

We suggest that such polarized view that the others are different from the self, will manifest in people's advice-taking tendency, especially when they have preexisting opinions. Ample research on advice-taking has documented that whether people view advisors to be similar to the self or not affects consumers' advice-taking tendency (Brock 1965; Churchill 1975; Faraji-rad, Samuelson, and Warlop 2015; Gino, Shang, and Croson 2009; Jiang et al. 2010). Consumers are more likely to take the advice from the advisor who are similar to the self. Thus, we expect that when people are feeling resource scarcity, they will see others as dissimilar and therefore will be less willing to accept their advice.

We test our hypothesis with money scarcity in three studies. We show that money scarcity lead to lower advice-taking tendencies, using measured scarcity (study 1) and manipulated scarcity (study 2). In study 3, we test the underlying process of perceived similarity by manipulating the similarity of advisor.

Study 1

A total of 150 Amazon Mechanical Turk participants completed the study for a small compensation. Participants were told to choose the more important option for a healthy life, from exercising and diet. Next, we presented a short paragraph about an opinion that supported the different option from the opinion of the participant. In other words, participants who indicated that exercising is more important than diet read an article about why diet is more important than exercising, and those who indicated that diet is more important than exercising read an article about why exercising is more important than diet. Then we measured participants' advice-taking tendency by asking 1) how much they agreed with the opinion of the article, 2) how likely they were to accept the advice from the article writer, and 3) how likely they were to change their opinion about diet and exercising (9-point scale; α = .89). By averaging these three items, we created an index of advice-taking tendency (α = .89). Next, we measured participants' perceived similarity of the advisor using the three items; 1) the reviewer is like me, 2) the reviewer behaves like me, and 3) the reviewer is similar to me (Faraji-rad et al. 2015; 7-point scale, α = .96). Finally, we measured money scarcity using the four items from Tully et al. 2015 (α = .82).

We conducted a mediation analysis (Model 4; Hayes 2013) to test the effect of money scarcity on advice-taking tendency and whether this effect is mediated by the perceived similarity. The analysis revealed a significant mediation (β = -.27, SE = .09, 95% CI from -.46 to -.09). The money scarcity had a significant negative effect on the perceived similarity (β = -.28, SE = .09, t = -3.02, p = .003) and the perceived similarity had a significant effect on advice-taking tendency (β = .96, SE = .08, t = 11.79, p < .001).

Study 2

A total of 202 people participated in the study via Amazon MTurk. We randomly assigned participants to either the control condition or the money scarcity condition. All participants were first asked to recall specific life experiences. Participants in the control condition were asked to recall "five things you did today" (adapted from Tully et al. 2015) and participants in the money scarcity condition were asked to recall a recent experience of feeling money scarcity (adapted from Roux et al. 2015).

After the recall task, participants were asked to evaluate a monitor as a part of consumer research. Participants saw a picture of a computer monitor with a description of features. Next, we showed participants a review of the monitor to help them evaluate the monitor. The review was very favorable and the reviewer highly recommended the monitor. After reading the review, participants rated the monitor using three items ("Very [bad/good] choice"; "I [dislike/like] the monitor very much"; and "I have a very [unfavorable/favorable] attitude"; from Faraji-rad et al. 2015) on a 9-point scale (α = .89). These items were averaged to create the persuasion score. Also, participants indicated their advice-taking tendency by answering 1) how likely they are going to accept the recommendation from the reviewer and 2) how likely they are going to change their opinion about the monitor based on the reviewer (9-point scale; r = .47). Participants also indicated perceived similarity of the reviewer using the same three items from the previous study (Faraji-rad et al. 2015; 7-point scale, α = .97).

As a manipulation check, we measured participants' feelings of money scarcity by asking them to indicate to what extent they were feeling money-constrained while answering the survey on a 7-point scale. Finally, participants answered demographic questions and were thanked for their participation.

Perceived Similarity. An ANOVA on the index of perceived similarity of the reviewer revealed a significant effect of condition (F(2, 201) = 12.25, p = .001). Compared to those in the control condition ($M_{control}$ = 6.33), participants in the money scarcity condition (M_{money} = 5.58) reported lower perceived similarity.

Persuasion, Advice-Taking, and Mediation. Next, we examined the effect of scarcity on our dependent variables, which were persuasion and advice-taking tendency. Both dependent variables yielded similar patterns. An ANOVA on persuasion revealed a significant scarcity effect ($F(2, 201) = 22.04$, $p < .001$). Compared to the control condition ($M_{control} = 7.59$), participants in the money scarcity condition ($M_{money} = 6.62$) were less likely to be persuaded by the review. An ANOVA on advice-taking tendency revealed a similar effect ($F(2, 201) = 14.63$, $p < .001$). Compared to the control condition ($M_{control} = 6.51$), participants in the money scarcity condition ($M_{money} = 5.58$) were less likely to accept the advice.

Furthermore, perceived similarity of the reviewer significantly mediated the effect of scarcity on both persuasion and advice-taking tendency. We ran mediation analyses using Process (Hayes 2013). Our independent variable was treated as dummy variable (control: 0, money scarcity: 1). We found that on the persuasion index, the indirect effect of scarcity through perceived similarity was negative and significant ($\beta = -.38$, $SE = .14$, 95% CI from -.68 to -.14). Similarly, the indirect effect of scarcity through perceived similarity on advice-taking tendency was negative and significant ($\beta = -.47$, $SE = .16$, 95% CI from -.82 to -.19). These results suggest that when people are feeling scarcity, they perceive others as dissimilar to themselves, which further leads to lower levels of persuasion and advice-taking tendencies.

Study 3

Our goal was to test the underlying process of perceived similarity. We expect that when the advice is from a similar advisor, the low advice-taking tendency of money scarce people will be increased. In this study, we used 2(scarcity: money scarcity vs. control) x 2(advisor: similar vs. control) between subjects design.

A total of 406 people participated via Amazon mechanical turk. Participants first conducted a recall task. Before starting the survey, we asked the demographic questions to participants including their age range, gender, highest level of education, region that they are living in, and their political orientation. This information was used later to manipulate the similarity of advisor. Next, participants in the money scarcity condition were asked to recall a time they felt money constraints. Participants in the control condition were asked to recall what they did on that day. 21 people were excluded from the analyses after reviewing the content they wrote. After manipulating scarcity, we asked participants to move on to the second part of the study. The procedure of the second part was similar to that of study 1. We told participants that the purpose of the second study is to understand people's thoughts on various issues. We first asked participants to choose the more important option for a healthy life, from exercising and diet. Then, we presented a short article about an opinion that supported the different option from the opinion of the participant. Before showing the article, we provided additional information about the article writer to the similar advisor group. We manipulated the similarity of advisor by matching the profile of the participant and the advisor (adapted from Gino, Shang, and Croson 2009). Participants in the similar advisor group were told that the article writer is similar to them in terms of gender, age, education, region and political orientation. Participants in the control advisor group did not received any information about the article writer. After reading the short article about health, we measured participants' perceived similarity of the advisor (article writer) using the three items from previous studies (Faraji-rad et al. 2015; 7-point scale, $\alpha = .94$). To measure more behavior related advice-taking tendency, we asked 1) how likely are you to hire this article writer as your health advi-

sor and 2) how likely are you to attend a health seminar held by this article writer ($r = .77$).

Perceived Similarity. An ANOVA on the index of perceived similarity of the reviewer revealed a significant effect of scarcity ($F(1, 381) = 9.19$, $p = .003$) and advisor type ($F(1, 381) = 48.67$, $p < .001$). We did not find a significant interaction, which is expected. Replicating our previous results, when there was no additional information about the advisor, the money scarcity condition showed lower perceived similarity than the control condition ($M_{control} = 4.00$ vs. $M_{money} = 3.56$; $F(1, 381) = 5.14$, $p = .024$). The control condition also showed increased perceived similarity when the advisor was similar ($M_{similaradvisor} = 4.87$ vs. $M_{controladvisor} = 4.00$; $F(1, 381) = 22.97$, $p < .001$), suggesting that our similarity manipulation was successful. More importantly, the money scarce participants who were in the similar advisor condition showed increased perceived similarity than those who were in the control advisor condition ($M_{similaradvisor} = 4.52$ vs. $M_{controladvisor} = 3.56$; $F(1, 381) = 25.73$, $p < .001$).

Advice-taking and Mediation. An ANOVA on advice-taking revealed a significant interaction ($F(1, 381) = 4.32$, $p = .038$). Replicating our previous findings, when there was no additional information about the advisor, the money scarcity condition showed lower advice-taking tendency than the control condition ($M_{control} = 5.00$ vs. $M_{money} = 4.21$; $F(1, 381) = 5.49$, $p = .02$). More importantly, the money scarce participants who were in the similar advisor condition showed increased perceived similarity than those who were in the control advisor condition ($M_{similaradvisor} = 4.90$ vs. $M_{controladvisor} = 4.21$; $F(1, 381) = 4.52$, $p < .034$). However, within the control condition, we did not find any significant difference between the similar advisor condition and the control advisor condition ($M_{similaradvisor} = 4.76$ vs. $M_{controladvisor} = 5.00$; $F(1, 381) < 1$). This suggest that there is a possibility of ceiling effect on advice-taking tendency of the control condition. We also conducted a mediation analysis using scarcity condition as independent variable (Control: 0, Money scarcity: 1), perceived similarity as a mediator and advice-taking tendency as a dependent variable. We found that the indirect effect of scarcity through perceived similarity was negative and significant ($\beta = -.34$, 95% CI from -.60 to -.10).

Taken together, we found that money scarcity leads to lower levels of advice-taking tendency because feelings of scarcity make people perceive that others are different from themselves. Our study 1 results showed that the more people feel money scarcity, the less likely they were to be persuaded by others' opinions. Study 2 showed that feeling time scarcity or money scarcity led to lower levels of perceived similarity between the self and the other, which further led to lower advice-taking tendencies. Finally, study 3 showed that when the advice is from a similar advisor, money scarce people shows increased perceived similarity and increased advice-taking tendency.

The Trouble With Trust: When Certification is Not Enough to Turn Trust Into Willingness to Share Data

Cynthia Sokoll, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

Smart products generate massive amounts of data—data which are often transferred to numerous parties (Schudy and Utikal 2017). This means that consumers do not have full control over their data privacy anymore (Pinchot, Chawdhry, and Paullet 2018).

The approach proposed in this work to solve this problem is to install a data certification authority between the consumer's smart product and the manufacturer, which gives consumers control over their data. This entity certifies, stores and anonymizes the smart product data before they are forwarded to the manufacturer based on customized settings. As the empirical evidence in this regard is scarce, this work examines the influence of such a certification authority on consumer behavior.

The literature on the effect of certification on consumer behavior is vast, for example, with regard to its influence on trust (Lee and See 2004) or on the willingness to provide data (Aiken and Boush 2006). However, with increasing technological changes, current certification approaches need to be adapted (Windhorst and Sunyaev 2013). Researchers, for example, propose an "approach for certifying security properties (…) that combines monitoring and testing data" (Katopodis, Spanoudakis, and Mahbub 2014, 394). However, which party should take over the role of the certification authority is unclear. Yet, in general, certification is superior to no certification (Rifon, LaRose, and Choi 2005).

Trust—which can be influenced by certification—is often subdivided in research, for example, into soft and hard trust (Head, Yuan, and Archer 2001). While hard trust focusses on technologically safe interactions, soft trust is concerned with trust in data privacy (Head and Hassanein 2002). Based on this, trust in the smart product (hard trust) and trust in data privacy (soft trust) are differentiated in this work. While trust in data privacy and certification are supposed to positively influence the willingness to share information, this is only true for trust in the smart product in certain cases.

The following hypotheses are proposed:

Hypothesis 1a: *The certification of smart product data by any certification authority (irrespectively of whether an independent third-party, a government, or a commercial entity assumes this role) is superior to no certification in terms of higher trust in data privacy and greater willingness to share data.*

Hypothesis 1b: *An independent third-party is a superior data certification authority compared to a government and a commercial entity in terms of higher trust in data privacy and greater willingness to share data.*

Hypothesis 2: *The effect of certification of smart product data by an independent third-party on the willingness to share data is mediated by trust in data privacy.*

Hypothesis 3: *While third-party certification increases the willingness to share data for low levels of smart product trust, it decreases the willingness to share data for high levels of smart product trust.*

Study 1 (N = 651) employed a four-condition between-subjects design: no certification authority (control condition) or an independent third-party, a government, or a commercial entity as certification authority. Participants read different scenario descriptions. In the control condition, the information was transferred directly from the smart speaker to the manufacturer. In the experimental conditions, there was a data certification authority in-between the data transfer from the smart speaker to the manufacturer. Participants differed marginally in their trust in data privacy in the four study conditions (F(3, 647) = 2.23, p = .08). Certification led to a significantly higher trust in data privacy compared to no certification (t(647) = 2.29, p = .02). There were no further significant differences across the study conditions. Regarding the willingness to share data, there was no significant difference across the experimental groups (F(3, 647) = .70, p = .55). A regression analysis (PROCESS Model 4, Hayes 2018) showed that trust in data privacy mediated the effect of certification on the willingness to share data in the independent third-party certification condition ($b_{indirectthirdparty}$ = .33; 95% CI = [.09, .59]), but not in the other experimental conditions. Both H1a and H1b have to be rejected. H2 is accepted. Consequently, the independent third-party was used as the certification authority in the following two experiments.

Study 2 (N = 558) employed a two-condition between-subjects design: no certification versus independent third-party certification. Participants in the third-party certification condition had higher trust in data privacy compared to those in the control condition (t(556) = 2.74, p = .01). However, there was no significant difference in the willingness to share data (t(556) = .22, p = .83). The results of the regression analysis confirm the mediating effect of trust in data privacy found in Study 1 ($b_{indirect}$ = .21, 95% CI = [.06, .36]). H2 is accepted.

Study 3 used a computer-based laboratory experiment (N = 75). As in Study 2, there was a significant difference in trust in data privacy between the two experimental conditions (t(73) = 4.10, p < .001), but not with regard to the willingness to share data (t(73) = 1.35, p = .18). PROCESS Model 5 was used for the regression analysis. Trust in data privacy did not mediate the effect of certification on the willingness to share data ($b_{indirect}$ = .15, 95% CI [-.11, .46]). However, trust in the smart product moderated the effect of certification on the willingness to share data ($b_{interaction}$ = -.44, 95% CI = [-.88, .00]). The Johnson-Neyman technique (Hayes and Matthes 2009) revealed that the presence of a certification authority significantly decreases participants' willingness to share data if the value for trust in the smart product is higher than or equal to 4.84 (p < .05). H2 was rejected. H3 was accepted. Overall, the results of Study 3 indicate that consumers strongly trusting their smart product do not need an additional control entity.

This work contributes to the literature on certification, trust in the digital age and data privacy. The research shows how and under which conditions data certification can influence consumer behavior and the willingness to share information. Managers should make the topic of data privacy one of their priorities and evaluate installing a third-party certification authority for smart product data certification thoroughly to avoid possible detrimental effects.

Not All Technoference Is Equal: Why Smartphone Snubbing Hurts the Most

Camilla Eunyoung Song, University of Florida, USA
Yang Yang, University of Florida, USA

EXTENDED ABSTRACT

Technology devices, such as smartphones and PCs, have unequivocally become an indispensable part of consumers' life. Consumers are now surrounded by multiple devices most of the time on a typical day. In a recent survey, we found that US respondents, on average, own 2.6 of the 4 major technology devices (i.e., smartphone, desktop computer, laptop, and tablet) and that 65% of them keep two or more devices at their fingertips over 8 hours during the day.

The proliferation of technology devices has revolutionized how people interact with each other. While technology devices allow people across the world to stay connected, they ironically take a toll on real, in-person relationships. The use of technology devices often interferes with in-person interactions and negatively influences the social relationships between users and people around them, a phenomenon termed "technoference." (McDaniel and Coyne 2016; Kushlev et al. 2019).

In the past few years, a burgeoning stream of literature on technoference has greatly advanced our understanding on this phenomenon (Chotpitayasunondh and Douglas 2018; David and Roberts 2017; Dwyer, Kushlev, and Dunn 2018; Kushlev et al. 2017; Kushlev and Dunn 2019; Misra et al. 2016; Przybylski and Weinstein 2012; Sprecher et al., 2016; Vanden Abeele et al. 2016; Vanden Abeele and Postma-Nilsenova 2018; Vanden Abeele et al. 2019). All of this work, however, has focused on the influence of device use versus no device use, and has yet to explore whether the use of different devices (e.g., smartphones vs. PCs) may have differential impacts on social relationships.

The current research suggests, instead, that not all technoference is equal. We hypothesize that during an in-person interaction, smartphone use has a more detrimental effect on social relationships than PC use (H1). Specifically, we predict that when an interruption is attributable to smartphone use (vs. PC use), the user is perceived to be ruder and less attentive, and their interaction partner experiences more negative emotions and more social exclusion. We further theorize that this effect is driven by differential inferences about the device use. Interaction partners perceive activities done on the PC to be work-related, important, and urgent, hence a priority deserving of users' attention. By contrast, the same activities done on a smartphone are perceived to be fun-related, less important, and less urgent, and anything but a priority (H2). As a result, interaction partners are less tolerant of smartphone use (vs. PC use).

The current research also aims to gain insights into the users' perspectives and decision processes. To the extent that consumers are surrounded by multiple technology devices most of the time every day (as shown in our survey), and most online activities can be done on different devices (Campaign Monitor 2019; The Manifest 2018), consumers are often faced with choices between different devices. During in-person interactions, which device will consumers use? We propose that users are more likely to use their smartphones during an in-person interaction, in part, because they erroneously believe that smartphone use has a *less* detrimental effect on social relationships than PC use (H3).

We have conducted seven studies that tested our hypotheses across a wide range of social interaction contexts, from getting acquainted with a fellow student in a lab, hanging out with a friend in a coffee shop, to catching up with a co-work in office. These studies examined the effect of different devices (i.e., smartphone, desktop,

laptop, work phone, and tablet) on the observer's reactions, as well as the user's device choice and predictions of the observer's reactions (see Table 1). Below, we will report four studies (Studies 1, 2A, 2B, and 3) due to the limited space.

STUDY 1

Study 1 aimed to test whether interruptions due to smartphone use (vs. PC use) have a more detrimental effect on social relationships (H1). In doing so, we recruited unacquainted dyads to interact in-person in a lab, introduced a brief interruption during which a member of the dyad was instructed to use their smartphone (vs. laptop), and then measured how their partner reacted to this interference.

Method

448 undergraduate students (M_{age}=19.7, 282 females) from a large university in the US participated in this study in exchange for course credit. They were randomly paired with each other to form 224 dyads. Each dyad engaged in a face-to-face get-acquainted interaction in a lab. Specifically, each member of a dyad was given 12 interview questions, and their job was to interview their partner and type their answers to each question. Critically, we asked half of the dyads to use their laptops for the interview and the other half to use their smartphones. Partner A interviewed Partner B first, and then they switched roles. Unbeknownst to Partner A, right before interviewing Partner A, Partner B learned that she was assigned to play the role of a confederate. Specifically, before Partner A was about to answer the 4th question, Partner B received a notification asking them to say "Oh, hang on a second, I just got something on my phone (laptop) and need to check it" and pretend to check something on their device for about 30 seconds.

Upon the completing of the interviews, participants rated the inappropriateness of partner's behavior ("I felt my partner behaved inappropriate," "I felt my partner behaved impolite," "My partner seemed involved with the conversation (reversed)," "My partner seemed to listen carefully (reversed)," "My partner seemed interested in my emotions and needs (reversed)", a=.83), and reported to what extent they felt socially excluded ("I felt ignored," "I felt rejected," and "I felt left out", a=.93) on 7-point scales. We also measured self-disclosure behavior ("How much did you tell your partner about yourself?) as a proxy of social bonds between participants (c.f., Sbarra, Briskin, and Slatcher 2019).

Results and Discussion

Consistent with H1, smartphone interference is more detrimental than laptop interference. Smartphone interference was perceived to be more inappropriate (M_{phone}=2.80vs.M_{laptop}=2.19,p<.01), and participants who were snubbed by smartphones (vs. laptops) felt more socially excluded (M_{phone}=1.97vs.M_{laptop}=1.40,p<.01), and disclosed less information about themselves to the device user (M_{phone}=4.06vs. M_{laptop}=4.61,p=.01).

STUDY 2A

Study 2A seeks to achieve the following goals. First, it aims to replicate H1 in a different context and gather evidence for the priority inference account (H2). Second, it examines important downstream consequences of deteriorated social relationships, such as people's willingness to interact with or help the person who snubbed them.

Third, it tests the robustness of H1 by disclosing what the user is doing on her device (e.g., checking or sending an email, checking others' posts on social media). We expect to replicate H1 regardless of the activity. That is, we predict that H1 will persist even when the activity is unambiguous and held the same across conditions. Finally, it tests an alternative explanation of H1. Namely, laptop use during an in-person conversation may strike participants as odd and unusual, and this unusualness may help justify the use.

Method

338 Mturkers (M_{age}=37.6, 160 females, 2 non-binary) completed this study in exchange for a nominal payment.

This study employed a 2x2 between-subjects design, manipulating the type of device used (smartphone vs. laptop) and the activity performed on the device (checking emails vs. social media). Specifically, participants imagined that they ran into a friend, Alex, at a local coffee shop and sat at a table to catch up. Participants read a dialogue between them and Alex and imagined that in the middle of their conversation, Alex received a notification on either her smartphone or laptop, said "Oh, hang on a second, I need to check something," and then checked her emails or social media for a minute.

Next, participants rated the inappropriateness of Alex's behavior (a=.91), to what extent they felt socially excluded (a=.94), as in Study 1, and their mood (1 = very bad, 7 = very good). To explore the underlying process, we also measured the priority inference ("To what extent did you think it was work-related?" "To what extent did you think it was urgent?", a = .93) and perceived unusualness ("To what extent did you think it was unusual that Alex was using her smartphone (laptop) while having the conversation?"). Finally, participants reported their willingness to interact with Alex ("If you were to host a party at your place, to what extent would you like to invite Alex?" "If you were to play an online game, would you want to play with Alex or alone?") and their willingness to help Alex ("If Alex is hunting for a job and asks you to write a recommendation letter for her, would you write her a strong letter?").

Results and Discussion

Unusualness. A 2(device: smartphone vs. laptop) x 2(activity: email vs. social media) ANOVA on unusualness did not reveal any significant effects, therefore we did not control for unusualness in the subsequent analyses. Including unusualness as a covariate does not change any of the conclusions.

Inappropriateness. A 2(device: smartphone vs. laptop) x 2(activity: email vs. social media) ANOVA on inappropriateness revealed a significant main effect of device, confirming that smartphone interference was perceived to be more inappropriate than laptop interference (M_{phone}=4.86vs.M_{laptop}=4.43,p<.01). The ANOVA also revealed a significant main effect of activity, such that checking posts on social media was more inappropriate than checking emails (M_{email}=4.29vs.$M_{socialmedia}$=5.02,p<.01). The interaction effect was not significant (p=.51).

Negative feelings. Participants who were snubbed by smartphones (vs. laptops) felt more socially excluded (M_{phone}=4.77vs.M_{laptop}=4.26,p<.01) and experienced more negative mood (M_{phone}=2.86vs.M_{laptop}=3.14,p=.02).

Priority Inference. Consistent with H2, participants perceived that activities done on smartphones to be less of a priority than those performed on laptops (M_{phone}=3.31vs.M_{laptop}=3.97,p<.01).

Behavioral Intentions. Participants snubbed by smartphones (vs. laptops) were directionally less willing to invite the user to their party (M_{phone}=4.49vs.M_{laptop}=4.73,p=.12), less willing to play games with the user (29.8%vs.39.5%, p=.07), and less willing to

write a strong recommendation letter for the user (M_{phone}=4.45vs.M_{laptop}=4.72,p=.06).

Mediation Analyses. We predict that the priority inference influences perceived inappropriateness and negative feelings, which in turn reduces intention to interact and intention to help. A series of two-stage mediations (Model 6; Hayes 2013) confirmed our prediction (see Figure 1).

Later, we successfully replicated these findings in two studies similar to Study 2A. In one study, we additionally manipulated whether Alex received notifications before using her device, and found support for H1 and H2 regardless of the presence of notifications. In another study, we used a different scenario (i.e., chatting with a co-worker during lunch break), replaced the laptop condition with a desktop condition, and found that people in the desktop condition responded just like those in the laptop condition in Study 2A.

STUDY 2B

Having demonstrated the detrimental effect of smartphone use (vs. PC use) from the observers' perspective, we turn to the users to gain insights into the users' perspectives and decision processes. Suppose consumers need to use their device in the middle of in-person interactions, and both the smartphone and laptop are equally accessible, which device will they use? And why? Study 2B aims to shed light on these questions.

Method

100 Mturkers (M_{age}=34.9, 33 females) were presented with the same scenario used in Study 2A except that, in this study, they were users instead of observers. Specifically, they imagined that they received notifications on their smartphone and laptop (both were equally accessible) and indicated which device they would use to check emails or check posts on social media. Next, they predicted which device use would be perceived as more inappropriate by their conversation partner, which device use would hurt their conversation partner's feelings more (1 = definitely the smartphone, 4 = indifferent, 7 = definitely the laptop).

Results and Discussion

Consistent with H3, the choice share of smartphone was marginally higher than if participants had picked randomly (63.2%,p=.06). This effect is robust across different activities—the choice share did not differ between checking emails and checking social media posts (p=.16).

Moreover, users erroneously believed that, compared with smartphone usage, laptop use was more inappropriate (M=4.74;one-sample t-test against the midpoint 4,p<.01)*,* making their conversation partner feel more socially excluded (M=4.71,p<.01) and experience more negative mood (M=4.62,p<.01).

These results were replicated in another study (47 Mturkers, M_{age}=37.0, 19 females) in which participants reported these measures before choosing which device to use.

STUDY 3

This study provides further process evidence (H2) by including two more conditions—a work phone condition and a tablet condition. If the detrimental impact of smartphone use (vs. PC use) is driven by their difference in priority inference, rather than differences in other aspects (e.g., appearance, functionality, unusualness), then we would expect the work phone condition to yield similar patterns to the laptop condition due to its high priority inference, and the tablet condition to look more like the smartphone condition due to its low priority inference.

Method

295 Mturkers (M_{age}=36.4, 139 females,1 non-binary) completed this study in exchange for a nominal payment.

The procedure was identical to that in Study 2A except that this study manipulated the type of device used by using four devices (smartphone vs. laptop vs. work phone vs. tablet) and did not manipulate activity. Participants answered the same questions as in Study 2A except one behavioral intention question.

Results and Discussion

Unusualness. A one-way ANOVA on unusualness did not reveal any significant effects ($p = .68$), therefore we did not control for unusualness in the subsequent analyses. Including unusualness as a covariate does not change any of the conclusions.

Inappropriateness. Consistent with our predictions, planned contrasts showed that smartphone and tablet interference were perceived to be more inappropriate than laptop and work phone interference ($M_{phone-and-tablet}$=4.05vs.$M_{laptop-and-workphone}$=3.56,p<.01).

Negative feelings. Participants who were snubbed by smartphones and tablets (vs. laptops and work phones) felt more socially excluded ($M_{phone-and-tablet}$=3.73vs.$M_{laptop-and-workphone}$=3.30,p=.04) and experienced more negative mood ($M_{phone-and-tablet}$=2.86vs.$M_{laptop-and-workphone}$=3.14,p=.02).

Behavioral Intentions. Participants snubbed by smartphones were less willing to write a strong recommendation letter for the user ($M_{phone-and-tablet}$=4.94vs.$M_{laptop-and-workphone}$=5.26,p=.06).

Priority Inference. Participants perceived that activities done on smartphones and tablets as less of a priority than those performed on laptops and work phones ($M_{phone-and-tablet}$=4.36vs.$M_{laptop-and-workphone}$=5.21,p<.01).

Mediation Analyses. A series of two-stage mediations (Model 6; Hayes 2013) suggested that priority inference influenced perceived inappropriateness and negative feelings, which in turn changed behavioral intention.

General Discussion

To conclude, we demonstrate that smartphone interference is more detrimental to social relationships than other interference. This effect is attributable to the low priority inference about smartphone use. Notably, while consumers can correctly predict this effect when imagining being snubbed, they make the opposite prediction when imagining snubbing others and consequently choose "the wrong device." Theoretically, this research extends the existing literature on technoference by exploring whether and why different devices may have differential impacts on social relationships. Practically, our findings suggest an easy-to-implement strategy to reduce tensions in social relationships—when you have a choice between different devices, stay away from your tablet and smartphone unless they have your employer's logo on them.

On Phone and Self: How Smartphones Influence Self-Expression in Choice

Camilla Eunyoung Song, University of Florida, USA
Aner Sela, University of Florida, USA

EXTENDED ABSTRACT

More and more consumers are using smartphones for online shopping. In 2019, smartphones accounted for the majority of global website traffic (Statcounter 2019) and a corresponding share of online transactions (Criteo 2019). Along with this trend, emerging evidence in the marketplace suggests that consumers behave differently on their smartphones. For example, compared with PC users, smartphone users tend to complete their shopping journeys faster and visit fewer websites before making a final decision (McKinsey & Company 2015), and use more conversational search terms (Google 2018). Further, due to their small physical dimensions and real-time usage, smartphones may lead consumers to generate more emotional and concise content on social media and in product reviews (Melumad, Inman, and Pham 2019; Ransbotham, Lurie, and Liu 2019). But might smartphones also change how consumers think of their choices and what they choose? If so, how?

We propose that choices made on a smartphone are more self-expressive, compared with identical choices made on a PC. Specifically, when people make a choice on their smartphone, they are more likely to see their choice as reflective of their unique individuality. Further, people prefer more self-expressive and unique options when using a smartphone, compared with a PC.

We reason that this shift occurs because smartphone use activates self-focus (or self-focused attention; Gibbons 1990; Ingram 1990). Comparing to other devices such as PC and tablet, smartphones are the most private and personal devices (Melumad and Pham 2020), and even at the extreme, they are often perceived as an extension of the self (Clayton, Leshner, and Almond 2015; Park and Kaye 2019). Therefore, when people use smartphones, their attention is shifted to the self, rather than to external environments and surroundings, almost feeling like they are in a "private bubble" (Hatuka and Toch 2016). Heightened self-focus emphasizes a sense of agency and a feeling of being distinct from the environment (Kircher and David 2003), and it often leads people to reflect on their individuality and uniqueness (Buss 1980; Chang and Hung 2018). Therefore, people perceive their choice reflects their unique individuality, expressing who they are, and they prefer unique options that can distinguish themselves from others.

We examine the effect of smartphone use on self-expressive choice in five studies, across different product categories, and test the underlying role of self-focus. We also test whether the effects can be accounted for by the physical characteristics of smartphones, such as modality (i.e., a touch interface) or its small display size. We also considered other factors known to vary across devices, such as emotionality and brevity of the content (Melumad, Inman, and Pham 2019), task difficulty, and annoyance with the task (Kim et al. 2015).

To test the causal effect of device use, we developed a procedure for randomly and reliably assigning participants to use either a smartphone or a PC (or a tablet computer, when applicable). The device was then verified for each response using an embedded UserAgent HTTP string, thereby ensuring compliance. We used this methodology in all our online studies (additional technical details are available from the authors).

Study 1 examines the effect of smartphone use on self-focus. We randomly assigned participants (Mturkers, N = 185, 44.9% females, M_{age} = 35) to use their smartphone vs. PC to write a short essay about a previous day activity. As a measure of self-focus, we calculated the proportion of first-person singular pronouns (i.e., I, me, my, mine) in participants' essays using the Linguistic Inquiry and Word Count tool (Duval and Wicklund 1972; Silvia and Phillips 2013; Wu, Moore, and Fitzsimons 2018). Confirming our predictions, smartphone use increased self-focus (M = 12.06), compared with PC use, (M = 9.89; $F(1, 183)$ = 8.02, p = .005, η_p^2 = .042). Of note, we did not find a difference for the proportion of first-person plural pronouns (i.e., we, us, our, ours) between devices (p = .40).

Study 2A tests the effect of smartphone use on the perceived self-expressiveness of one's choice. We also included a tablet PC condition to rule out alternative accounts such as modality (touch vs. non-touch interface). We randomly assigned participants (Mturkers, N = 218, 41.7% females, M_{age} = 36) to use their smartphone, tablet, or PC to make a hypothetical car choice and measured the extent to which they perceived their choice as self-expression (e.g., "The choice of the car brand expresses that I am unique," "The choice of the car brand shows who I am"; (Kaiser et al. 2017; Whitley et al. 2018). We pretested to create the generic option sets that none of the options is particularly different or unique, and preferred. As we intended, choice did not vary across devices ($\chi^2(8)$ = 6.46, p = .60), but importantly, participants using smartphones perceived their chosen option can express who they are (M = 4.69) than participants using PCs (M = 3.71; $F(1, 215)$ = 16.54, p < .001) and tablets (M = 4.01; $F(1, 215)$ = 6.52, p = .011). There was no difference between the PC and tablet conditions (p = .28).

Study 2B tests whether our effect might reflect differences in the size of the display between smartphones and PCs. A smaller display may lead respondents to feel spatially confined (Levav and Zhu 2009), disfluency (Kim et al. 2015) or narrow the scope of attention (Ghose, Goldfarb, and Han 2013), which may impact our dependent measures. We randomly assigned participants (students, N = 311, 65.9% females, M_{age} = 20) into a three-condition smartphone vs. PC vs. PC-small-screen between-subjects design. Specifically, participants in the PC-small-screen condition used their laptops but saw the entire study on a smaller display in the middle of their screen, similar in size to a smartphone's screen. They made a hypothetical sunglasses choice and measured the extent to which they perceived their choice as self-expression using the same measures as in Study 2A. The results revealed that participants in the smartphone condition perceived their chosen option can express who they are (M = 4.32, SD = 1.16) compared with participants in both the PC (M = 3.88, SD = 1.24; $F(1, 308)$ = 6.20, p = .013) and PC-small-screen conditions (M = 3.91, SD = 1.44; $F(1, 308)$ = 5.36, p = .021).

Study 3 uses a moderation approach to test the underlying role of self-focus. We randomly assigned participants (Mturkers N = 198, 55.6% females, M_{age} = 37) to one of four conditions in a 2 (device: smartphone vs. PC) × 2 (self-focus: low vs. control) between-subjects design. Participants imagined visiting an online sunglasses store. To manipulate self-focus, we followed prior research which showed that feeling awe decreases self-focus (Bai et al. 2017; Piff et al. 2015). In the low self-focus condition, we presented a picture of awe-inducing landscape as a background image for the online sunglasses store. In the control condition, we presented a monochromatic and less awe-inducing version of the same picture. Manipulation checks validated the effect of this manipulation on self-focus. After participants chose their sunglasses, we measured the extent to which they perceived that their choice could show who they are as in Study 2. A significant in-

teraction ($F(1, 195) = 5.30$, $p = .02$) confirmed our theorizing regarding the role of self-focus: In the control condition, replicating our previous findings, smartphones led participants to see their choice as more self-expressive ($M = 5.07$), compared with PC ($M = 4.19$; $F(1, 195) = 7.44$, $p = .01$). However, the effect attenuated in the reduced self-focus condition ($F < 1$, $p = .59$, Figure 1).

So far, we intentionally provided generic option sets in previous studies, testing that people using smartphones perceive choice as the vehicle to express who they are than people suing other devices. Then, the natural question arises; when including a unique option in the option set, people using smartphones are more likely to choose the unique option than other options? Studies 4A and 4B investigate this question, using incentive-compatible paradigms. We predict that smartphones would increase participants' preference for options capable of expressing their uniqueness and idiosyncratic preferences.

Study 4A uses an incentive-compatible choice task adapted from prior work on uniqueness-seeking (Wan, Xu, and Ding 2014, Study 2). We randomly assigned participants (Mturkers, $N = 154$, 41.6% females, $M_{age} = 35$) to use their smartphones vs. PCs. Participants saw two Adidas t-shirts, both priced at "around $30". One t-shirt (i.e., the mainstream option) was labeled "Adidas Basic T-shirt" and was described as the popular choice among previous participants (i.e., "In a previous study, 82% participants preferred this option"). The other t-shirt (i.e., the unique option) was labeled "Adidas Eccentric T-shirt" and was described as the less popular option (i.e., "In a previous study, 18% of participants preferred this option"). We told participants that three randomly selected participants would receive their chosen t-shirt. Confirming our predictions, smartphone users were more likely to choose the unique (i.e., less popular) t-shirt (40.8%) than PC users (23.6%; $\chi^2(1) = 4.77$, $p = .03$).

Study 4B examines the effect of smartphone use on self-expressive choices in a different context, namely, preference for individually customized offers that are tailored to the consumers' idiosyncratic taste (Kramer 2007; Simonson 2005; West et al. 1999). We randomly assigned participants (students, $N = 164$, 64.0% females; $M_{age} = 20$) to use their smartphones vs. PCs. Participants first completed a "Charity Navigator Quiz," where they answered questions about prior donations and provided demographic information. We told participants that the university was collaborating with 10 (fictitious) local charity organizations and wanted students to support one charity by joining its Facebook group. Participants received two recommendations for a charity they could endorse on Facebook. One charity was said to be individually customized ("a charity based on your unique preferences") and one said to be a majority-endorsed option ("based on others' choices"). Confirming our prediction, smartphone users preferred the individually customized option (62.8%) than PC users (42.9%; $\chi^2(1) = 6.41$, $p = .01$).

Our research makes several theoretical and practical contributions. First, relatively little is known about how smartphone use influences consumer choice and choice perception. With few exceptions (Melumad, Inman, and Pham 2019; Melumad and Pham 2020) most previous research on smartphone use has been exploratory, either because it used correlational data or because it did not directly compare the effect of smartphone use with that of other devices (e.g., PC) in a controlled setting. Our work examines the causal effect of smartphone use on consumer behavior. Second, we contribute to the literature on self-focus by examining a novel, albeit pervasive, cue that activates self-focus in everyday life. Self-focus has far-reaching implications for consumer behavior, impacting product evaluation (Dagogo-Jack and Forehand 2018; Hung and Wyer 2011; Weiss and Johar 2013), service satisfaction (Pham et al. 2010), affective decision-making (Chang and Hung 2018), and choice (Goukens, Dewitte,

and Warlop 2009). Considering the pervasiveness of smartphones, demonstrating that smartphones increase self-focus could have similar, potentially far-reaching implications. Third, we contribute to the literature on choice's self-expressive function (Schwartz and Cheek 2017) by investigating the effect of smartphone use and self-focus on self-expression. Consumers often see their choices as a form of self-expression, but the extent to which this occurs varies depending on the decision task (e.g., Maimaran and Simonson 2011), the product category (Berger and Heath 2007), decision-makers' culture and self-construal (Kim and Drolet 2003), their self-concept clarity and confidence (Morrison and Johnson 2011; Rozenkrants, Wheeler, and Shiv 2017), and their motivations (Sela, Berger, and Kim 2017; Whitley, Trudel, and Kurt 2018). We extend this literature by demonstrating that self-focus, activated by smartphone use, can influence the self-expressive role of choice.

In addition, we expect to provide important insights for marketers. This work provides important insights for marketers. Online vendors routinely track the device used by their customers and often tailor site format and content to the device used. Our results suggest that consumers may find individually customized, unique, and self-expressive offers particularly appealing when using a smartphone. Amazon.com, for example, could prioritize presenting "especially for you" rather than "best-seller" recommendations for smartphone customers and Chipotle may offer their mobile users more customizable menu options. Considering the emphasized self-expressive function of choices made on smartphones, compared with PCs, marketers may wish to craft persuasive messages that target the self-expressive role of attitudes when advertising on smartphones (Shavitt 1990). Smartphone users may be more responsive to an identity-related appeal, whereas PC users may be better persuaded by a benefit-based appeal. Similarly, because hedonic choices are often more self-expressive than utilitarian ones (Maimaran and Simonson 2011), a hedonic frame may be more persuasive on a smartphone, whereas a utilitarian frame may be more effective on a PC.

Smartphones are revolutionizing consumer behavior, but little is known about whether and how they change consumer decision making. This research indicates that smartphones may influence what people choose and how they perceive their choices, once made. Thus, smartphones appear to influence choice itself as well as the perceived meaning of choice.

Its Not All Kosher: Experience of Deviant Consumption In Context of Religion

Arti Srivastava, Indian Institute of Management Udaipur, India
Rajesh Nanarpuzha, Indian Institute of Management Udaipur, India
Prakash Satyavageeswaran, Indian Institute of Management Udaipur, India

EXTENDED ABSTRACT

Religion has been considered as a coping mechanism for individuals in difficult life situations (Cutright, 2012). For example, religious meta-narratives tend to help adherents cope with negative consequences associated with their non-compliant behavior (Muniz & O'Guinn, 2001). This could also explain why, even with increasing modernity and expected secularization, around 80% of the world population is affiliated to a religion (Pew Research Center, 2015).

Religious affiliations tend to manifest in peoples' life choices, including their consumption choices. But what happens when people deviate from their religious prescriptions in their consumption choices? Extant research shows that consumers experience severe identity conflicts when they leave the boundaries of their religious institution (McAlexander et al., 2014). However, it is unclear how consumers cope while making consumption choices that digress from their religious doctrines, even as they *continue to be affiliated* with their religion. For example, a large number of Hindus eat beef, many Muslims consume pork or liquor, and Catholics use contraception. We investigate deviant consumption in religious context through the enabling theoretical lens of 'edgework' to understand how consumers manage to operate within the boundaries of their religious institutions, while deviating from the doctrines that they believe are sacred to their institution.

Literature Review

A deviant consumption typically results in consumers' identities being threatened. In such situations, consumers sacralize their deviant consumption (Üstüner & Holt, 2007). They attach a religious metanarrative (Muniz Jr & Schau, 2005) to their deviant consumption to legitimize these choices.

In routine lives of consumers, religion specifies the norms to define standards of rights and wrongs (McAlexander et al., 2014). Consumers use religious norms to build their ideologies as well as identities. When they break away from this "central pillar of identity" (McAlexander et al., 2014, 859), they have to reconstruct their shattered identities even if they leave the field (religion). Thus, many find it difficult to exit the field of religion (McAlexander et al., 2014). But these individuals often violate certain prescriptions of the institution. How do such consumers manage to operate within the boundaries of their religious institutions, while deviating from the doctrines that they believe are sacred to their institution?

We investigate partial deviance from religious prescriptions when individuals continue to remain affiliated to their religion. These individuals who maintain their ties with the religious institution while negotiating with the limits of the acceptable behavior differ from those who are either outside the field (McAlexander et al., 2014) or remain inside its boundaries (Sandikci & Ger, 2010). Broadly, we situate our study within the broad contours of understanding individuals' negotiation between boundaries of acceptable verses non-acceptable consumption.

Theoretical Background

Individuals engaging in deviant consumption within religious boundaries simultaneously have to manage socially non-conforming consumption while continuing to be situated within the confines of religious norms. We adopt the enabling theoretical lens of 'edgework' to explain this interaction. Edgework has been studied in the context of high risk physical activities (Celsi et al., 1993; Lyng, 2004) as well as consumers challenging their identity boundaries (Thompson & Üstüner, 2015). Similar to Thompson & Üstüner's (2015) roller derby girls, our informants negotiate the boundaries of the field and try to make their deviant consumptionbacceptable. We use the concept of boundary work to explain this reconstruction of boundaries (Gieryn, 1983; Weinberger, 2015).

Methodology

We conducted sixteen depth interviews ranging with self-reported believers following McCracken (1988). Further, the informants were encouraged to recall critical incidents of non-adherence. All interviews were coded and conducted by the first author. Emergent themes were arrived at through a series of mutual discussions between all authors. Constant comparison was used to move between data collection, informant selection and data analysis (Glaser & Strauss, 2017; Miles & Huberman, 1984)

Findings and Discussion

Our participants described experiences of social exclusion and shaming within their social circles because of their deviant consumption. They also described religion as an important field of capital that provides them support, stability, and identity meanings.

Informants used phrases such as 'still there in upbringing', 'programmed that way', and 'I don't believe in it but can't break away' to describe their conformance. However, they described their deviant consumption experiences as transcendental and emancipatory. The contrasting experience of feeling entangled and liberated simultaneously means the consumer is neither bound to the field (religion) nor able to cross its boundaries.

In line with Thompson and Ustuner's (2015) findings, we found evidence of our informants challenging boundaries of religious institutions by *operating on the edge* of the field boundaries. For example, consumers engage in acts of deviant consumption that risks their social status, because they do not want to miss out on this experience. This behavior is close to the sociological concept of edgework. However, the perception of norms in the field of religion are not as fluid (McAlexander et al., 2014) as those in gendered spaces (Thompson & Üstüner, 2015). Thus, it is difficult to maintain the identity as follower of a religion and attempt to *reconstruct the boundaries* of the field norms.

In such cases, consumers try to legitimize their choices by detaching the spiritual aspect of religion from the religious dogma, which we term as *de-norming the institution*. In cases where the deviants were unable to separate these beliefs, we found that they *rationalize* their actions based on facts by finding reference points outside their religion. Further, to reduce the risk of status loss, they try to normalize their consumption choices by propagating their beliefs to others.

Conclusion

In the present research, we posit that in contexts where consumers value the field capital, they consciously choose to engage in deviant consumption because it provides them with the transcendental experience of operating on the edge. However, we also find deviant consumers using external reference points to

legitimize their consumption and expand the boundaries of acceptable behavior in their social domains. Combining boundary work with edgework allows us to explain this contradiction in behavior of deviant consumers, who maintain their field identities and yet deviate from its prescribed norms.

Guidelines on Acquiescence in Marketing Research

Janina Steinmetz, City University of London, UK
Ann-Christin Posten, University of Cologne, Germany

EXTENDED ABSTRACT

Worldwide, companies spend an estimated 46 billion U.S. dollars annually on marketing research (Statista 2019). Given these investments, international big players and small start-ups alike base consequential decisions on the results of marketing research, which often uses survey methods that are easy to administer and interpret. Thereby, marketers implicitly assume that survey responses adequately capture respondents' true attitudes and preferences. These implicit assumptions are presumably shared by academic marketing researchers, who frequently use self-report to assess consumer attitudes (Malhotra, Agarwal, and Peterson 1996). However, research has documented various response biases that systematically distort survey responses and therefore the results of academic as well as industry marketing research. Misguided investments of time and money based on biased findings can follow.

In this review, we discuss the acquiescence bias, which is the most prevalent response bias in survey-based research (Baumgartner and Steenkamp 2006). Acquiescence means to respond affirmatively to self-report items irrespective of their content. For example, if consumers indicate their interest in a product on a 5-point Likert scale ("1 = not interested", "5 = very interested"), acquiescence leads to higher observed values (i.e., greater measured interest) than justified by consumers' true interest. Also other types of self-report items (e.g., nominal true/false choices or ordinal scales) are affected by acquiescence (Welkenhuysen-Gybels, Billiet, and Cambré 2003). Furthermore, acquiescence can produce spurious correlations between otherwise unrelated constructs (MacKenzie and Podsakoff 2012; Steinmetz and Posten 2017). Thus, acquiescence can lead to false conclusions when comparing means and correlations from groups (e.g., different segments) that differ in acquiescence or when interpreting absolute values on survey scales or yes/no items.

Given that acquiescence can significantly distort survey responses, past research has been dedicated to measurement and correction strategies for acquiescence (e.g., Krautz and Hoffmann 2018). Several such strategies have been developed as a result (e.g., trait acquiescence measure, balanced scales, or heterogeneous items). Whereas the usage of these strategies can decrease acquiescence, they can introduce various validity problems and are costly in terms of respondents' time (Greenleaf 1992). In light of this trade-off, identifying factors that foster or attenuate acquiescence can help researchers and practitioners to create settings that reduce acquiescence; and to make informed decisions when using strategies to mitigate acquiescence. Ultimately, marketing research can thus be conducted more efficiently and reliably.

Synthesizing and extending previous research, we identify individual differences as well as cultural and situational factors that foster acquiescence. We analyze existing strategies to counter the effects of acquiescence. Furthermore, we highlight when such strategies are beneficial—and when alternative market research methods that are unaffected by acquiescence are especially useful. Based on our analyses, we provide eight guidelines for marketers to assess, control for, and prevent acquiescence.

Individual Differences in Acquiescence

Some of the earliest research on acquiescence defined it as a personality variable that differs between individuals (Couch and Keniston 1960). Based on this understanding, three main strategies have been developed to identify (and potentially exclude from analyses) individual high-acquiescence respondents. As the first strategy, researchers can use an explicit measure of trait acquiescence. This measure extends surveys by a 19-item acquiescence scale (Couch and Keniston 1960). However, this scale is rarely used and consists of items whose wording seems somewhat outdated. Second, researchers construct surveys consisting of heterogeneous items, such that respondents' agreement with unrelated items signals acquiescence. However, content-heterogeneous items are difficult to design as item heterogeneity is not clearly defined and operationalized (Baumgartner and Steenkamp 2006). Third, surveys contain both positively worded ("Vaccines can save lives") and negatively worded ("Vaccines cannot prevent deadly diseases") items to identify (and exclude if necessary) those who agree with both positive and negative items as respondents high in acquiescence (Welkenhuysen-Gybels et al. 2003). Such balanced scales are indeed less affected by acquiescence (Baumgartner and Steenkamp 2006). However, researchers have recommended that balanced scales are used with caution, as respondents might be confused and the item error-variance might increase as a result (Weijters and Baumgartner 2012).

Over and above the potential measurement concerns, marketers might find the use of these three strategies inconvenient despite their benefits. As market research is increasingly using web-based short surveys with large sample sizes (Wilson 2018), the addition of a substantial number of items is hardly feasible. Newer research potentially offers another measurement option. It shows that respondents who score high in habitual interpersonal trust acquiesce to questions across a wide variety of content (Posten and Steinmetz 2020). In this view, acquiescence emerges when respondents accept the questions-asker's propositions because they generally trust others, which can be measured by adding a single item. Consequently, measuring habitual trust could be an efficient way to identify respondents who might acquiesce.

Cultural Differences in Acquiescence

Acquiescence does not only differ between individuals, but also between cultures. Acquiescence is especially pronounced in East-Asian cultures that are high in power distance and cultural collectivism (Krautz and Hoffmann 2018). That is, respondents from cultures (e.g., India) with large hierarchical differences (i.e., high power distance) or cultures that value group cohesion over individual uniqueness (i.e., high collectivism) are more likely to acquiesce than respondents from cultures with low power distance or individualism (e.g., Sweden). Cultural differences in acquiescence can pose a considerable problem for cross-cultural marketing, which has experienced a surge in recent years due to globalization (Leonidou et al. 2018). For example, if 50% of Swedish respondents indicate that they are interested in the product (whether on a yes/no or Likert scale item) and 60% of Indian respondents give the same response, these differences might well be solely due to greater acquiescence in India.

To account for cultural differences in acquiescence, the three types of strategies discussed above (i.e., explicit acquiescence measures, heterogeneous items, balanced scales) have been suggested, with the same practicality issues. Recent research has taken a different approach, by combining different question types (i.e., scales and true/false responses) to measure a single construct (pARS; Krautz and Hoffmann 2018). Via the deviation between the scale responses

and true/false choices, acquiescence can be estimated. However, pARS can only be applied to contexts in which consumers' objective knowledge is assessed with true/false choices. In contrast, in the majority of consumer contexts, marketers ask about constructs that are much more subjective (e.g., brand loyalty, evaluation of an ad or product). Despite its benefits, pARS can thus be applied to a limited range of surveys, but its potential is evident to identify specific cultures, subcultures, or segments that are high in acquiescence. Once such groups have been identified, surveys to target these groups can add more specific strategies against acquiescence.

Situational Determinants of Acquiescence

Over and above individual and cultural differences that foster acquiescence, research has highlighted situational factors that amplify this bias. Among these situational factors are consumers' lack of ability or motivation to respond accurately. In line with this notion, acquiescence increases when the question wording is vague or when respondents are uncertain of their true attitude or under time pressure (Baumgartner and Steenkamp 2006). Marketers would certainly be wise to avoid vague or ambiguous question wording in surveys. Yet, acquiescence would likely persist, as respondents with ample time and motivation to respond accurately might be difficult to recruit, especially when using online surveys (Savage and Waldman 2008).

Recent research has identified additional psychological factors that foster acquiescence, namely respondents' motivation to affiliate with the question-asker (Posten and Steinmetz 2018; Steinmetz and Posten 2017). When respondents thought about a friend reading their answers, acquiescence was greater than when they thought about a stranger. Because friends are more common targets of affiliation, these results suggest that affiliation motives increase acquiescence. This effect might pose a paradox for marketers: Whereas affiliation with brands is a desirable outcome of marketing (Veloutsou 2009), affiliation might undermine the accuracy of research about these brands. Two situations in particular could be problematic: first, (perceived) rejection by a brand, and second, marketing a brand as a friend. Regarding the first situation, research has shown that feeling rejected by an aspirational brand leads consumers to desire affiliation with the brand (Ward and Dahl 2014), for example when a consumer cannot afford signature products by a desired brand. Regarding the second situation, research has shown that consumers believe to have (friend-like) relationships with brands, stores, and salespeople (Kim and Kwon 2011). Such friend-like relationships might emerge especially for identity-relevant products such as clothing or entertainment.

Guidelines for Marketing Researchers

So far, we have identified individual and cultural respondent characteristics and contextual factors that render acquiescence likely. Among these are, paradoxically, contexts that are typically desired by marketers, namely affiliation between the consumer and a given brand. Based on these findings, our guidelines identify circumstances that might have previously not thought of as problematic for market research (e.g., covering an aspirational brand). Broadly speaking, our guidelines build on the notion that circumstances that foster trust, affiliation, and friend-like feelings to the researcher and/or the brand targeted by market research might undermine the veracity of the results because such circumstances can also foster acquiescence. Thus, with our guidelines we attempt to put recent research into practice (see Table 1).

Guideline 1: *Assess the extent to which the respondents, the environment, or the research subject are prone to acquiescence.*

At the onset of a marketing research project, marketers could assess to what extent their survey is prone to acquiescence. As discussed above, acquiescence is likely a problem if informants come from cultures that are high in power distance or collectivism (Krautz and Hoffmann 2018), or are habitually trusting (Posten and Steinmetz 2020). Acquiescence is also likely if the survey covers an aspirational brand or a brand with which consumers have friend-like ties (Kim and Kwon 2011; Ward and Dahl 2014), or if respondents are motivated to affiliate with the brand (Steinmetz and Posten 2017). Under such circumstances, we recommend the use of strategies to counter acquiescence.

Guideline 2: *Assess to what extent the survey consists of item types that are prone to acquiescence, and to what extent responses inform decisions.*

We suggest that marketers consider whether their survey consists of item types affected by acquiescence. In particular when interpreting Likert scales, yes/no choices, or correlations, the error variance might be inflated and responses might not reflect true attitudes. In such cases, it would be wise to exert special caution if survey responses directly inform decisions. For example, in case a restaurant plans to roll out a new pizza topping if a certain percentage of customers reply "yes" to the question whether they would like this topping, acquiescence could inflate this percentage, such that the roll-out decision relies on incorrect information.

Guideline 3: *If the risk of acquiescence is high, use alternative methods if possible.*

If the risk of acquiescence seems high due to the above considerations (cf. Guidelines 1-2), marketers could use methods that are typically less affected by acquiescence. Such techniques include the application of ranking rather than rating scales (Harzing et al. 2009) or the item count technique developed for researching sensitive consumer issues (e.g., criminal behaviour, de Jong and Pieters 2019). Given their resilience to acquiescence, we suggest using such alternative methods whenever the research question allows.

Guideline 4: *Add single-item control measures of factors that foster acquiescence.*

When designing surveys and experiments, marketers could make use of the relation between trust and acquiescence (Posten and Steinmetz 2020). These relations suggest a novel means to assess and control for acquiescence. In some of their studies, Posten and Steinmetz (2020) used a single-item measure of respondents' interpersonal trust to predict acquiescence, in online as well as laboratory settings. Such a single-item measure (e.g., "How trustworthy did you find the person asking you questions?") could be integrated even into very short online surveys, and responses could be used as a control variable in the analyses.

Guideline 5: *Combine surveys with methods that are less prone to acquiescence.*

Over and above the previous suggestions to counter acquiescence, marketers could use multi-method approaches whenever acquiescence is likely. Surveys on existing products or services can be complemented by observational data (e.g., online search data), whereas surveys on novel products and services can be complemented by experiments that can provide physiological and behavioral data. Such multi-method approaches curb the effects of acquiescence on a single method because they combine different data sources.

Guideline 6: *Reduce environmental factors that could foster acquiescence.*

Regardless of the specific risk of acquiescence, we suggest that marketers ensure that the survey environment does not foster acquiescence. If respondents complete surveys face to face, this could take place in a physically neutral space that does not signal affiliation

through a friendly atmosphere. As one remedy, we suggest that marketers use, if possible, computer-administered surveys without much interpersonal interaction to reduce possible effects of personal affiliation on acquiescence.

Guideline 7: *Separate respondent recruitment and survey administration.*

Advising marketers to use interpersonally neutral environments might be contrary to the experience of market researchers who at times use affiliation, trust, and personal warmth to recruit survey respondents. On the one hand, affiliation is undoubtedly helpful to recruit respondents. On the other hand, affiliation can distort responses. A solution to this paradox could be to separate recruitment and survey administration as much as possible. One way to do so would be to create temporal, spatial, or personal distance, for example such that the recruiter is a different person than the survey administrator. Whereas the recruiter can capitalize on affiliation and trust to find respondents, the administrator can create a neutral space that is free of such cues to prevent acquiescence. The same applies to web surveys. Whereas the recruitment could take place in trusted apps, the survey itself could be taken on separate neutral websites.

Guideline 8: *Mask the recipient of the survey responses.*

An additional way to potentially reduce acquiescence would be to dilute the identification of the recipient of respondents' answers. As research has shown, acquiescence increases if respondents believe their answers will be read by a friend (Steinmetz and Posten 2017). By implication, if respondents believe their answers will be read by representatives of an aspirational or affiliative brand, they might acquiesce more. Thus, marketers could try to ask about several brands or products within one survey, and some questions could serve as filler items to obscure who will read the survey responses. Thereby, respondents might feel less motivation to affiliate through acquiescence.

Conclusion

Acquiescence can pose a significant problem for the validity of marketing research. As a result, a variety of strategies to assess it have been developed. We reviewed these strategies, and integrated them into a broader discussion of the individual, cultural, and situational factors that foster acquiescence. Therefrom, we developed guidelines for marketers to address the concern of acquiescence when designing, administering, and interpreting surveys.

Propelling Pride to Promote Healthy Food Choices
Among Entity and Incremental Theorists

Julia Storch, University of Groningen, The Netherlands
Jing Wan, University of Guelph, Canada
Koert van Ittersum, University of Groningen, The Netherlands

EXTENDED ABSTRACT

Past research suggests that people's beliefs about the malleability of their body weight influence their motivation to engage in healthful behaviors: people who perceive their body weight as fixed (entity theorists) engage less in healthful behaviors than people who perceive their body weight as changeable (incremental theorists; e.g., Burnette 2010; Lyons, Kaufman, and Rima 2015; Parent and Alquist 2016). The reason for more maladaptive behaviors among entity theorists appears to be disbelief in their personal ability to successfully engage in healthful behaviors and change their body weight (Ehrlinger et al. 2017).

We test whether the elicitation of pride from past achievements can serve as an intervention to promote healthful behaviors among entity theorists. In two studies, we examined the effect of pride recall based on different events – related and unrelated to the health domain – on entity theorists' food choice healthiness. We also examine how such pride recall affects food choice healthiness among incremental theorists.

We propose that pride recall has different motivational consequences for incremental versus entity theorists due to their tendencies to orient towards *effort* versus *ability*, respectively as dominant explanation for successful weight management. Incremental theorists tend to attribute success or failure to sufficient or insufficient expenditure of effort, whereas entity theorists tend to attribute success and failure to their ability to control their body weight thereby discounting the role of effort (see Hong et al., 1999). Owing to their tendency to attribute prior success to sufficient levels of ability, pride may serve as a validation of entity theorists' ability to successfully pursue a long-term goal. We hypothesize that pride will promote healthy food choices among entity theorists irrespective of wheher pride is *related* (a healthy food choice) or *unrelated* (a smart spending decision) to the health domain – the source of pride should not matter.

However, among incremental theorists the source of pride should matter. Although pride can signal the importance of achievement within a given domain (Hofmann and Fisher 2012) – people deduce from their feeling of pride that they value achievement – pride can also serve as a justification for self-reward after achievement (Salerno, Laran, and Janiszewski 2015; Wilcox, Kramer, and Sen 2011). A pride experience that is unrelated to the health domain may only signal a prior successful expenditure of effort without reinforcing the perceived desirability of achievement within the health domain. As such, we hypothesize that only health-related, but not health-unrelated pride will promote food choice healthiness among incremental theorists

Hypothesis 1: *The recall of a pride experience related to past healthful behaviors will increase subsequent engagement in healthful behavior compared to a situation when no pride is experienced, irrespective of implicit theories.*

Hypothesis 2: *Among those with stronger incremental theories, the recall of a pride experience unrelated to past healthful behaviors will decrease subsequent engagement in healthful behavior compared to a situation when no pride is experienced.*

Study 1 was conducted online using Mturk ($N = 282$). To elicit pride, participants either wrote about recent healthy consumption decision (health-related pride), or recent spending decision that allowed them to save money (health-unrelated pride), or described what their regular day looks like (control condition; see Salerno et al. 2015). As measure of food choice healthiness, each participant received seven virtual lottery tickets to allocate between either of the two prize packages – an indulgent "candy box" versus a relatively healthier "fruit and nut box". Implicit theories of body weight were measured as a continuous moderator (Levy, Stroessner, and Dweck 1998).

We find support for a non-significant interaction between implicit theories and health-related pride ($b = 1.49$, $SE = .14$, $p = .296$). Participants in the health-related pride condition were significantly more likely to prefer the fruit and nut box over the candy box, irrespective of their implicit theories, providing support for H1. Supporting H2, we find a significant interaction effect between spending-related pride and implicit theories ($b = -.29$, $SE = .14$, $p = .029$) – in the spending-related pride condition, preference for the fruit and nut box decreased with stronger incremental theories.

Study 2 was conducted in the lab ($N = 183$) using the same emotion induction task. As measure of food choice healthiness, participants made a real snack choice between an indulgent caramel chocolate bar versus a relatively healthier oat biscuit with raisins. Implicit theories of body weight (Burnette 2010) were measured as a continuous moderator as part of an unrelated study prior to the emotion induction task.

Replicating findings from Study 1 and supporting H2, we again find a significant interaction between spending-related pride and implicit theories of body weight ($b = -1.05$, $SE = .44$, $p = .016$) in Study 2. However, contrary to our expectations, we find directional support for an interaction between health-related pride and implicit theories ($b = -.74$, $SE = .47$, $p = .116$), thus providing no additional support for H1. Follow-up spotlight analysis suggests that the recall of health-related pride only increases food choice healthiness for entity ($b = 1.64$, $SE = .62$, $p = .008$), but not for incremental theorists ($b = .26$, $SE = .55$, $p = .643$).

Overall, our findings suggest that health-related pride may be the more suitable motivational tool compared with health-unrelated pride. Across two studies, we find that health-unrelated pride experiences instill reward-seeking behavior among incremental theorists, whereas health-related pride boosts entity theorists' motivation to engage in weight management practices without diminishing incremental theorists' motivation. This research contributes to the growing stream of literature studying how implicit theories affect health-related outcomes (e.g., Burnette and Finkel 2012; Lyons et al. 2015; Thai et al. 2018). Contrary to the prevailing notion that incremental theories are more adaptive with regards to many aspects of the self-regulation process than entity theories, our research reveals that incremental theorists may suffer from a higher potential to engage in self-indulgence after past achievements. Our research also points to a more nuanced picture of the emotion pride by suggesting that

whether pride is beneficial for goal-directed behavior in a focal domain depends on both its source and the lay beliefs of the individual.

A Global Consumer Culture Perspective on the Fresh Start Mindset

Yuliya Strizhakova, Rutgers University, USA
Robin Coulter, University of Connecticut, USA
Linda L Price, University of Oregon, USA

EXTENDED ABSTRACT

Recent work by Price and her colleagues (2018) introduced the "fresh start mindset," defined as a belief that people can make a new start, get a new beginning, and chart a new course in life, regardless of past or present circumstances. Their research, theoretically grounded in neoliberalism and conducted in the U.S., established a valid and reliable scale to measure the fresh start mindset and documented that the fresh start mindset is associated with greater consumer engagement in transformative (e.g., budget-related and health-related) activities, as well as greater support of charities aimed at transforming lives of disadvantaged populations (e.g., at-risk teens and veterans). Price et al. (2018) argued that the fresh start mindset is linked to liquid modernity, where consumer identity is multi-faceted and fluid within a global environment (Bauman 2001), suggesting that the fresh start mindset may not be restricted to the U.S., but rather manifest more broadly within the global consumer culture paradigm and beyond neoliberal Western societies.

The overarching purpose of this research is to situate the fresh start mindset within a broader global context. To that end, our research agenda is four-fold, and we conduct our empirical investigation in three countries (U.S., Mexico, and Russia; see method for rationale of choice for these countries). First, we seek to establish the fresh start mindset scale (FSM) as a valid and reliable measure cross-nationally; we expect to replicate the findings of Price et al. (2018) related to the fresh start mindset nomological network. Second, within the globalization and consumer culture paradigm and across countries, we examine the relationship between the fresh start mindset and measures related to global consumer culture. Specifically based on links to liquid modernity, we posit that the fresh start mindset has a positive relationship with expressions of global consumer culture, including global identity, global citizenship through global brands, and consumer environmental consciousness (Steenkamp and de Jong 2010; Strizhakova and Coulter 2013; Strizhakova, Price, and Coulter 2008; Zhang and Khare 2009), and a negative relationship with consumer ethnocentrism as an expression of local consumer culture (Steenkamp and de Jong 2010). Third, we examine select psychographic variables linked to global consumer culture (i.e., travel abroad, social media use, religion) as predictors of the fresh start mindset. Finally, we evaluate the fresh start mindset as a predictor of several brand-related outcomes, such as attitudes toward global brands, choices of global (over local) brands in a traditional local category of food, and involvement with global/glocal consumer culture.

Method

In exploring the fresh start mindset within the broader global arena, we included the U.S. as a "baseline" country. We chose Mexico and Russia as countries for investigation because they are linked to the U.S. as trade partners and provide variance on cultural traditions. As related to U.S. trade partners, Mexico ranked second ($235.7 million), China ranked third ($116 million), and Russia ranked twenty-fourth ($16.4 million) ("Top U.S. Trade Partners" 2016). Countries from the emerging markets have emerging global consumer cultures (Zhao and Belk 2004), and are marked by stronger cultural traditions grounded in family, collectivistic values (in contrast to the U.S.), as well as varying strnegth of their religious traditions. Christianity, however, is the dominant religious across all three countries. The U.S., often seen as the "land of opportunity," reports immigrants (1990 to 2014) from Mexico (11.7 million), China (2.5 million) and Russia (.5 million) (Zeigler and Camarota 2016).

We collected data using an online survey with Qualtrics panels in the U.S. (n = 300, M_{age} = 33), Mexico (n = 305, M_{age} = 31) and Russia (n = 310, M_{age} = 32); gender was evenly split in each country. Included in the survey were established scales (all seven-point Likert items) measuring: the fresh start mindset (six items; Price et al. 2018), growth mindset (four items; Dweck 2006), optimism (four items; Scheier, Carver, and Bridges 1994), future focus (four items; Shipp, Edwards, and Lambert 2009), desire for a fresh start (three items, Price et al. 2018), self-perceptions of being capable to get a fresh start (three items, Price et al. 2018), global identity (seven items; Strizhakova and Coulter 2013), global citizenship through global brands (three items; Strizhakova, Coulter, and Price 2008), environmental consciousness (seven items; Haws, Winterich, and Naylor 2014), and consumer ethnocentrism (four items, Shimp and Sharma 1987). Participants responded to questions assessing travel aboard ("Within the past two years, how many times have you traveled outside of [country]?", social media usage ("Please indicate your level of activity with social media, e.g., Facebook, Twitter, Instagram and other sites" 1= not at all active/ 7 = very active), and religion ("which of the following describes your religious affiliation? Christian, Islam, Buddhism, Judaism, Hinduism, Nonreligious/secular).

In relation to our dependent variables, we selected four global shampoo brands with high market shares across the four markets (Euromonitor GMID database: Pantene, L'Oreal, Schwarzkopff, Head & Shoulders) and measured consumer attitudes toward these brands on a seven-point scale (1 = dislike very much, 7 = like very much). We also asked consumers to imagine shopping for yogurt, chocolates, and soda and asked them to make a choice among three brands; two global brands – one U.S.-based and one non-U.S.-based – with the largest market shares across the four countries (Yogurt: Yoplait, Dannon; chocolates: Hershey's, Ferrero; soda: Coca Cola, Mirinda) and the national brand with the largest market share in the country (Euromonitor GMID database). As a measure of consumer involvement with glocal consumer culture, participants responded to Steenkamp and de Jong's (2010) brand involvement; for analyses, we merged responses that chose brand involvement with global, glocal, and national culture and contrasted them with those who expressed no brand involvement (averaged 15%-16% across countries).

Results

First, we examined FSM across countries. The model fit (CFA, AMOS 24) is acceptable (χ^2/df = 3.35, CFI = .98, TLI = .96, RMSEA < .05), and the scale achieved partial metric and scalar invariance (Steenkamp and Baumgartner 1998). Cronbach's α for FSM for each county ranges from .89 in Mexico to .93 in the U.S. Our cross-national comparison indicates that the mean for FSM is stronger in Mexico (M = 5.29, z-tests < .001), than in Russia (M = 4.75), and the U.S. (M = 4.60). There is no significant difference in FSM between Russia and the U.S. Our results indicate that a good fitting model of FSM and variables in the nomological network (χ^2/df = 1.76, CFI = .94, TLI = .94, RMSEA < .03), and consistent with Price et al. (2018), FSM has strong positive relationships with the growth mind-

set, optimism, future focus, desire for a fresh start and perceptions of being capable of a fresh start in all four countries (see table). Desire for a fresh start was lowest in the U.S. and highest in Mexico.

Second, consistent with our expectations, FSM is positively (significantly) related to global identity, global citizenship through global brands, and environmental consciousness in all countries. In contrast to our expectation, FSM has no significant relationship with consumer ethnocentrism (see table).

Third, using regression analyses, we explored the extent to which select psychographic variables predict FSM. As expected, consistent across countries, social media use is a significant positive predictor of FSM (β =.14 (U.S), p < .05; β =.21 (Russia), p < .00; β =.25 (Mexico), p < .001). Consistent with Price et al. (2018), Christian beliefs (Mexico: β = .17, p < .01; Russia: β =.16, p < .01; U.S.: β =.17, p < .01) is a significant positive predictor of FSM. Travel abroad was a significant predictor in Mexico (.13, p < .05) and marginally significant in Russia (.10, p < .09) but not a significant predictor in the U.S. (p > .10).

In relation to predictive validity of FSM in related to brand-related outcomes (see table), across countries FSM is a significant positive predictor of consumers' more positive attitudes toward global brands across all countries. FSM is also a significant positive predictor of consumer involvement with global/glocal consumer culture through brands and global brand choices of food products in the U.S. and Russia; its effects on involvement and global brand choices are positive but marginally (p < .08) significant in Mexico.

Discussion

Our research makes significant contributions to emerging research on transformative consumer research in the global arena. We support Price et al.'s (2018) proposition that the fresh start mindset is linked to global consumer culture, globalization and liquid modernity. Consumers appear to embrace this believe in markets that do not have traditional neoliberal Western roots. We further validate the fresh start mindset scale across two emerging markets – Mexico and Russia – with varying level of economic development, religious beliefs, socio-historical-cultural traditions. The fresh start mindset scale is reliable across markets and exhibits partial metric and scale invariance, which allows to compare it across consumers in these markets. Specifically, we observed consumers in Mexico exhibiting the highest and significantly different levels of the fresh start mindset versus consumers in other countries. Our findings support relationships of the fresh start mindset with other variables in its immediate nomological network – growth mindset, optimism, future temporal focus, desire for a fresh start and being capable of a fresh start. Interestingly, relationships between the fresh start mindset and desire for a fresh start was stronger in our emerging markets than the U.S. Importantly, we have positioned understanding of the fresh start mindset within the global consumer culture and its relevant constructs. Indeed, the fresh start mindset has significant positive relationships with other variables linked to global consumer culture, such as global identity, global citizenship through global brands and environmental consciousness (Steenkamp and de Jong 2010; Strizhakova and Coulter 2013). Effects between the fresh start mindset and consumer ethnocentrism were non-significant in our countries. Hence, the fresh start mindset is an additional belief that is shared among consumers who identify with global consumer culture, globalization processes and environmentalism.

Consistent with other global consumer culture predictions, consumers with a stronger fresh start mindset exhibit greater involvement with global/glocal branding culture, more positive global brand attitudes and higher rate of global brand choices. Further, consumers

with a stronger fresh start mindset are also more likely to use social media. Interestingly, similar to Price et al., religion (vs. none) was a significant positive predictor of the fresh start mindset. Hence, both global consumer culture and a more traditional Christian doctrine are likely to contribute to development of consumers' fresh start mindset worldwide.

Our research furthers our understanding the fresh start mindset from the global consumer culture perspective, and points to additional opportunities for investigation. Future research should examine effectiveness of the fresh start mindset and fresh start messaging in encouraging transformative choices in various markets. Examination of the fresh start mindset in relation to other global culture constructs, such as materialism, social responsibility and ethics, entrepreneurship and other global values offers promising opportunities for enriching both transformative consumer research and globalization theories. Our predictive network primarily focused on global culture constructs, but future research might further investigate relationships between the fresh start mindset and other localization-based beliefs, including, for example, fate, class structures, and nostalgia.

Looking Better by Making Others Look Worse: The Competitive Spillovers of Sustainability

Kristina Šubrtová, Wageningen University, The Netherlands
Ilona E. de Hooge, Wageningen University, The Netherlands
Ellen J. van Loo, Wageningen University, The Netherlands
Hans van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

Despite the ubiquitous presence of spillover effects in consumers´ lives and their indisputable influence on consumers´ perceptions, attitudes, and choices (e.g., Votola & Unnava 2006; Ahluwalia & Gurhan-Canli 2000; Cleeren, Van Heerde & Dekimpe 2013), research on the impact of spillover effects on competing brands is scarce. The product-harm crisis literature reveals that spillover effects may also occur between directly competing brands. Yet, the product-harm crisis spillovers concern the effects of extremely negative information about one brand. This makes is difficult, if not impossible, to generalize these findings to daily situations where consumers perceive products in a product assortment (e.g., in a supermarket). Although, a few studies examine the external sources of spillover effects, such as advertising of a brand (Sahni 2016; Janakiraman, Meyer & Morales 2006; Heilman, Nakamoto & Rao 2009) to competitors, these findings also do not translate to daily in-store situations.

The present research proposes that direct exposure to product attributes at an in-store comparison of products in a product assortment may already generate competitive spillover effects (see figure 1). Anagnostou, Ingenbeek & van Trijp (2015) find that the introduction of a new sustainable brand decreases perceptions of a brand which consumers regularly buy. Inspired by these findings, we suggest that the introduction of a new attribute (sustainability) by one product (e.g., with information on the packaging) decreases consumers attitudes towards brands competing in the same product category. Current understanding of the impact of spillover effects on consumers´ attitudes and choices rather follows the traditional attitude theorist approaching attitudes as self-reported cognitive processes (Ajzen & Fishben 1977). Following this logic, attitude should translate into a decrease in consumers´ actual choices for these competitors. However, dual-process theories suggest that there are two distinct mental processes underlying consumers attitudes; rational and intuitive (e.g., Epstein 1994; Fazio 1990; Kahneman 2003). Some even posit that most of real-life decision-making is dominated by automatic processes (Lindsey & Jacoby 1994; Kahneman 2011). Therefore, we propose that the spillover effect from the introduction of a new attribute on competing products has an underling intuitive mechanism. More specifically, we argue that when consumers notice the new attribute on one product, they will engage in a verification search to examine how competing brands perform on this new product attribute. As competing brands will not convey information about their performance concerning the new product attribute, consumers will subsequently draw negative inferences about the competing brands, thereby negatively affecting both attitude formation and product choice for competing brands.

In two eye-tracking studies, we demonstrate that the introduction of a new attribute (sustainability) by one product indeed negatively spills over to consumers´ choices for competing products, and we uncover the underlying cognitive and intuitive mechanism. The objective of the two future studies (study 3 and study 4) is to test alternative explanations for our core effects.

Study 1 (n=170) examined our basic premise combining eye-tracking with self-reported measures and explores the moderating role of price. We tested our predictions in a between-subject de-sign, in the context of one product category (pasta). Main dependent variables were choice, attention (in terms of fixation durations and fixation counts), and attitudes. Participants were randomly allocated to an assortment of eight products, with target product having an organic label, sold at regular price (Label-regular price), or having an organic label, sold at premium price, or having no label (Label-premium price), sold at regular price (control condition). Participants were first asked to choose one product from the assortment while their eye movements were recorded. Then, they evaluated target product next to one competing product. Consistent with our predictions, study 1 finds that the information about the new attribute increases visual attention towards competitors, decreases attitudes towards competitors, and decreases choice likelihood for competitors in the same product category. This effect weakens when the new attribute is introduced at the premium price (vs regular price).

The aim of study 2 (n=225) was to seek further evidence for the effect of the introduction of a new sustainability attribute to attention and choices for competing products and to extend findings from study 1 to more product categories. Due to a large variance in attention between individuals, the presence (vs absence) of the organic label was manipulated within-subjects. The evidence for the effect of introduction of the label on attention and choices for competing products in study 1 was limited to a relatively small sample, as only 37% in Label-regular price, and 36% in Label-premium price condition noticed the cue. To ensure enough data of consumers who processed the information about new attribute, the salience of this information was increased by adding a priming task, and by reducing the number of available products to six alternatives per product category. Results of study 2 replicated the findings from study 1 that noticing the information about the new attribute information increases visual search for competing products and decreases the choice likelihood for these competitors across six food product categories.

The present research makes essential contributions to the research on spillover effects, and generates practical knowledge for marketers, packaging designers, and new product developers. First, we identify a new source of competitive spillover effects that has not been considered before. An introduction of a new product attribute through product cues of may already affect attitudes and choices for competing products. This opens a new area of possible causes of spillover effects for future research. Second, we demonstrate new insights into the mental processes underlying spillover effects. It appears that competitive spillover effects on choice are mediated by attention. Thereby we show that the mechanism behind the spillover effects can operate in more autonomous manners, providing a new perspective to the research on spillovers in general. This perspective is especially important in times when limiting our understanding of constructs in consumer research to conscious processes is increasingly criticized and calls for more research beyond cognition are made (e.g. Williams & Poehlman 2016; Dijksterhuis, Knippenberg, Holland & Harm Veling 2014; Evans 2014).

Ask Formally: The Role of Formality on Charitable Giving

Aparna Sundar, University of Washington, USA
Edita Cao, University of Washington, USA
Bruce E. Pfeiffer, University of New Hampshire, USA

EXTENDED ABSTRACT

Advertising uses language in its messaging, which includes both content and style (Norton, 1978; Schindler & Bickart, 2012). In charitable advertising, the content of such messages remains relatively constant, generally consisting of information about the charity and a request of readers to donate. What can change about the message is the style. Style in language is that aspect of communication that is intended to state information with varied expression (Labov, 1972). Formal style includes word choice and structure that adheres carefully to standard grammatical form. Informal (or colloquial) style, on the other hand, includes characteristics that follow everyday conversational norms which differ based on social context (Grice, 1975; Heylighen & Dawaele, 1999). Given that people use different styles to communicate dependent on context (Joos, 1961), we expect that formality would not be received in the same way in every context. One aspect of social context which makes language style so critical is the social distance between individuals. This is because the information inherent in the style adopted by the communicator helps the audience infer meaning (Halliday, 1985; Poynton, 1985).

The purpose of a charitable ask is a sincere request to help others in need. Therefore, we would expect that when formal language is used, communication would focus on the core, informational content. This, we contend, would be more persuasive than colloquial language because it is more precise. We further posit that such a tactic would be contingent on the audience or the social context of communication. When individuals share contextual knowledge (i.e. when communicating to friends or family), they tend to use colloquial language (Grice, 1975; Heylighen & Dawaele, 1999). This is because such language can reinforce social closeness (Fitzsimons & Kay, 2004). However, when individuals share less contextual knowledge (i.e., when communicating to distant acquaintances or strangers), formal language is preferred (Joos, 1961). In two experiments, we provide evidence that the effectiveness of formality on donations depends on social distance. We operationalize formality by adapting real-world charitable appeals for wildfires (Study 1) and heart disease (Study 2) and show that formality is differentially persuasive based on the social distance of who prompts the charitable ask (Study 2).

Study 1 examined the differential effect of formal vs. colloquial language on willingness to donate. Participants ($N = 57$) completed a 2 (appeal language: formal vs. colloquial) between-subjects experiment. They were asked to evaluate a charitable appeal written in either a formal or colloquial language style. After viewing the appeals, participants indicated their charitable support (Greitemeyer & Sagioglou, 2018) and willingness to donate (in US dollars; Strahilevitz & Myers, 1998). A manipulation check indicated that the language style manipulation worked as intended ($p < .001$). As hypothesized, participants were more likely to demonstrate support for the charity when presented with the formal (vs. colloquial) appeal ($p < .05$). Participants also indicated a marginally greater willingness to donate when they viewed the formal appeal rather than the colloquial appeal ($p = .07$).

This study provides initial evidence that formality of appeal language increases participants' willingness to give to a charitable cause. In the next study, we investigate the role of social distance in how it could moderate the effect of language on intention to donate.

How formality is received is based on social context (Grice, 1975). Formality is a strategy used to maintain social distance (Levin, Giles, & Garrett, 1994). We therefore expect that a variation in language would influence donation intent based on the social context in which the donation is introduced.

Study 2 examined the role of social distance as a moderator of the effect of language on donation intentions. Participants ($N = 320$) completed a 2 (appeal language: formal vs. colloquial) × 3 (social distance: self vs. close other vs. distant other) between-subjects experiment. They were told that they were reviewing a cause either because they were considering donation (self), one of their friends had asked them to review information on the cause (close other), or a person named Alex, a distant connection on their favorite social media site, had asked them to review information on the cause (distant other). Manipulation checks indicated that the formality and social distance manipulations worked as intended ($ps < .002$). As predicted, there was a significant interaction ($p < .01$). Specifically, participants were more willing to donate when presented with the formal (vs. colloquial) appeal in both the self and close other conditions ($ps < .01$). However, for the distant other (Alex) condition, formality of language style made no difference on willingness to donate ($p = .89$).

This study provides further evidence that formality of appeal language increased participants' willingness to give to a charitable cause. Importantly, this effect occurs in socially close contexts (i.e., when an individual or close other prompts donation considerations). Contrary to prior research that suggests consumers are less likely to donate in socially distant contexts (Small & Simonson, 2008), we find that both formal and colloquial appeals are persuasive when a charitable ask comes from an organization recommended by a distant other.

The results of two studies suggest that formal language in a charitable ad appeal is more effective than colloquial language, which varies based on the social distance of who prompted the individual to review the appeal. Study 1 demonstrated that individuals who read an appeal written in a formal (vs. colloquial) style were more willing to donate to the charitable cause. Study 2 found the social distance of who is asking the individual to consider donating moderates the effect, such that formal (vs. colloquial) language is only effective when the ask comes from an organization recommended by someone socially close (i.e., the self or a friend). Importantly, both formal and colloquial language are equally persuasive when the ask is prompted by a distant other. Our findings provide an initial understanding of the role of formality in charitable appeals, but there is much space for future research. The first avenue is to investigate the underlying process for the effect of formality on donations.

Not All "Wins" Are Equal: The Effect of Unequally Attractive Prizes on Stimulus Appraisal

Arash Talebi, EDHEC Business School, France
Sonja Prokopec, ESSEC Business School, Singapore
Ayse Onculer, ESSEC Business School, France

EXTENDED ABSTRACT

As the proverb "to look a gift horse in the mouth," suggests, people might question the value of a gift. In a similar spirit, this research examines people's reaction toward the gains from *uncertain* promotions. Specifically, we investigate whether people question the value of the gained discount and transfer it to the promotional brand.

The perceived attractiveness of a risky outcome is dependent not only on the realized outcome, but also on other unattained but plausible outcomes, aka counterfactual comparison (McMullen, Markman, and Gavanski 1995). In certain situations, both upward and downward counterfactual comparisons are *simultaneously* plausible (e.g., a final gain of $10 when $5 and $20 gains were also plausible). Under these circumstances, i.e., when multiple reference points coexist, an outcome may be simultaneously perceived as a loss and a gain (Kahneman 1992). Note that two types of outcomes are plausible in uncertain promotions: the best outcome ("High win") and any other lower-magnitude outcome ("Low win"). We propose that the Low win recipients are likely to engage in simultaneous upward (versus High win) and downward (versus no-discount) counterfactual comparison; and hence, develop a concurrent gain and loss perception.

Simultaneous perception of gain and loss activates respectively positive and negative evaluative processes that engender attitude ambivalence (Larsen et al. 2004). Accordingly, we suggest an experience of attitude ambivalence in the recipients of the Low win.

Attitude ambivalence is a bothersome state (Cacioppo, Gardner, and Berntson 1997) that reduces the appraisal of the stimulus (Hong and Lee 2010; Williams and Aaker 2002). Therefore, we predict that an experience of attitude ambivalence in the recipients of a Low win results in a less favorable appraisal of the promotional brand.

Study 1 (a field study; N=59 Students), recruited research assistants (RAs) to sell lottery tickets on behalf of a fictitious casino ("El Royale") on the campus of a European school. Each lottery participant was randomly assigned to either the Low- (26 participants) or the High win (33 participants) condition. After participants received the prize, their Future Purchase Likelihood for El Royale's services was recorded (1-7 scale).

Study 2A (N=304 MTurkers) used a 4-group (Low-magnitude sure-discount vs. High-magnitude sure-discount vs. Low win vs. High win) between-subjects design and Chick-fil-A as the promotional brand. The participants of the sure-discount conditions received either a $2 or a $12 discount notice, respectively in the Low- and High-magnitude conditions. Participants of the uncertain conditions played a game to get either a Low- ($2) or a High-win ($12). Subsequently, all participants reported their Future Purchase Likelihood (slider bar: 0-100%).

Study 2B (N=106 Students) employed a 3-group (No discount vs. Low win frame vs. High win frame) between-subjects design where the offered discount magnitude in both Low and High win frame conditions was the same (€1.5) but framed against different counterfactuals to convey the discount as Low (€1.5 vs. €9) or High (€1.5 vs. 25¢). In addition, Study 2B included a no-discount baseline condition and used WIND, an e-scooter service, as the stimulus brand. The rest of the procedures paralleled those of Study 2A.

The results of the field study provide initial evidence for the main effect: receiving a Low win reduces consumers' stimulus ap-praisal. Studies 2A and 2B tested the effect in the controlled environment of the lab with including distinct control conditions. These studies replicated the main effect. Furthermore, Study 2A reveals that participants evaluated the brand less (more) favorably when they received a Low (High) *win* than when they received the same Low- (High-) magnitude of discount *directly*. This finding supports counterfactual comparison rather than discount magnitude in driving the results. Study 2B provides additional support for the role of counterfactual comparison in driving the results by holding the magnitude of the discounts constant between conditions. Further, Study 2B reveals that the unpleasantness of the Low win is so intense that it forces the Low win to underperform the zero-discount.

Studies 3A and 3B test the proposed mechanism through attitude ambivalence, as an affect-laden manifestation of counterfactual comparison, by direct measurement of the mediator. Study 3A (N=195 MTurkers) employed a 2-group (Low win vs. High win) between-subjects design. Respondents participated in the uncertain promotion campaign of CURB, a mobility service (Low win: $2 vs. High win: $10). After participants played the game, we measured their attitude ambivalence (Russel and Carroll's method, 1999) and Future Purchase Likelihood (slider bar: 0-100%).

Study 3B (N=246 MTurkers) was similar to Study 3A with the exception of counterbalancing the measurement order of the mediator and the dependent variable, employing different probabilities for the wins for robustness check, and using Pizza Hut as the stimulus brand.

Studies 3A and 3B replicated the main effect (i.e., the negative effect of the Low win on stimulus appraisal) and documented that attitude ambivalence mediates the effect of Promotion Outcome on Future Purchase Likelihood (Study 3A: indirect effect=-1.33, *SE*=.83, 95%CI=[-3.4245, -.1215]; Study 3B: indirect effect=-2.11, *SE*=.92, 95%CI=[-4.3150, -.7303]). Taken together, Studies 3A and 3B show that receiving a Low win elicits ambivalent feelings that negatively spill over into individuals' Future Purchase Likelihood of the target brand. In addition, Study 3B ruled out the role of measurement order in driving the results (Table 1).

This research investigates the effect of uncertain promotions on the promotional brand. We show that consumers who receive a Low outcome of an uncertain promotion engage in simultaneously comparing their attained outcome with the unattained outcomes. A comparison of the Low win with a no-discount situation induces positive emotions. However, a comparison with a High win results in negative emotions. Such a concurrent experience of emotions with opposite valences engenders attitude ambivalence. This bothersome state, in turn, reduces the brand evaluation.

This research contributes to the theory by documenting the role of attitude ambivalence (as a manifestation of simultaneous upward and downward counterfactual comparison) in determining appraisal of a promotional brand.

In sum, we suggest that marketers revisit the design of such promotions to ensure that consumer's perception of prizes is relatively uniform, preventing them from developing ambivalent feelings.

The Unresolved Uncertainty Effect: Do Brands Gain or Lose Stars When Consumers Have to Wait For Resolution of Brand-led Uncertainty?

Arash Talebi, EDHEC Business School, France
Sonja Prokopec, ESSEC Business School, Singapore
Ayse Onculer, ESSEC Business School, France

EXTENDED ABSTRACT

From the simplest decisions ("to get a Pepsi or a Coke with my meal"!) to the most complicated decisions ("to marry Emma or Louise!") are made in the presence of uncertainty. People generally express an inherent distaste for uncertainty (Tversky and Shafir 1992).

However, uncertainty associated with positive prospects may elicit, and prolong, positive feelings (Lee and Qiu 2009) because people could derive utility from savoring the expectation of the prospects (Loewenstein 1987).

Considering both views, how do people react toward a brand that led to an uncertain event? We investigate this question in the context of uncertain promotions.

Prior research has documented the benefits of uncertainty in a variety of domains: consumers' well-being (Clore and Colcombe 2003), romantic infatuations (Pennebaker 1997), and motivation (Shen, Fishbach, and Hsee 2014). We posit that the utility associated with the waiting period of uncertain promotions may induce positive emotions, specifically excitement, because excitement is an uncertainty-associated emotion in positive contexts (Lee and Andrade 2015). Highly intensified emotions (e.g., excitement) exert a strong impact on behavior (Loewenstein and Lerner 2003). Therefore, we expect the uncertainty-generated excitement to affect individuals' stimulus appraisal positively.

Note that two types of outcomes are plausible in uncertain promotions: the best outcome ("High win") and any other lower-magnitude outcome ("Low win"). People generally believe that larger prospects are less likely to happen than smaller outcomes (Pleskac and Hertwig 2014). This uniqueness is a driver of arousal (Ku, Malhotra, and Murnighan 2005), and hence, excitement. Therefore, we propose:

Hypothesis 1: *When people await the resolution of uncertainty or when they receive an immediate High win, they are more likely to evaluate the uncertainty-associated stimulus more favorably than when they receive an immediate Low outcome.*

Hypothesis 2: *The more favorable evaluations described in H1 is driven by heightened excitement of people during the waiting period or when they receive the immediate High win.*

Study 1 (N=214 MTurkers) employed a 3-group (Low vs. High win vs. Unresolved Uncertainty) between-subjects design. Participants played the promotional gamble of AppyFizz. Participants in the Low/High win conditions received the outcome immediately and indicated their Future Purchase Likelihood. Participants of the Unresolved Uncertainty condition went through the same procedure except that they filled the dependent variable measure before knowing the outcome.

Study 2 (N=113 Student) paralleled the design of study 1 with two changes: (1) The stimulus brand changed (CRAX), (2) The probabilities of Low/High win changed for robustness check.

Study 3 (N=405 MTurkers) was a conceptual replication of the previous studies with a familiar brand (Domino's). This study also ruled out several alternative accounts and collected a behavioral dependent variable: sharing personal email ID.

Studies 1-3 consistently found a positive effect of the waiting period (and the High win) on the brand evaluation (H1 supported; $F_{(2,211)}=5.20$, $p<.01$ Study 1; $F_{(2,110)}=4.88$, $p<.01$ Study 2; and $F_{(2,402)}=2.57$, $p<.08$ Study 3). In addition, mediation analysis in Studies 2 and 3 showed that excitement mediates the effect. Furthermore, Study 3 replicated the main effect and the mediation model with the behavioral dependent variables and ruled out the role of arousal and "feeling smart" in explaining the results (Table 1).

We also predict that the recipients of the Low win and those who wait for resolution of uncertainty experience mixed emotions because while on the one hand, people may detest receiving a low win or experiencing uncertainty (Gneezy, List, and Wu 2006); on the other hand, they may gain some positive feelings due to a gain or because of savoring the expectation of the prospects (Loewenstein and Elster 1992).

If not handled, mixed emotions make people experience discomfort, which in turn results in a less favorable stimulus appraisal (Williams and Aaker 2002). Nonetheless, people's ability in handling mixed emotions varies as a function of their construal level (Trope and Liberman 2000). Specifically, individuals with high-level construals handle their mixed emotions better than those with low-level construals (Hong and Lee 2010). Therefore, we propose:

Hypothesis 3: *Compared to those who gain a High win immediately, those who await the resolution of uncertainty and those who receive a Low win immediately may experience psychological discomfort, that in turn, negatively affects their stimulus evaluation. This mediating path happens only for individuals with low-level construals.*

On a related note, people's experience of happiness may also vary as a function of their construal level. Specifically, excitement, as one type of happiness, is a high-level construal emotion (Mogilner, Aaker, and Kamvar 2011). Thus:

Hypothesis 4: *The mediation path through excitement, H2, happens for individuals with high-level construals.*

Study 4 (N=305 MTurkers) used a 3 (Low vs. High win vs. Unresolved Uncertainty) × Construal level (measured) between-subjects design. Respondents participated in Uber's promotional game. Low/High win conditions saw the outcome immediately. Then, we measured their mixed emotions (Russel and Carroll's method, 1999), discomfort (Williams and Aaker 2002), excitement, Future Purchase Likelihood, and construal level (Vallacher and Wegner 1989). Participants of the Unresolved Uncertainty condition went through the same procedure except that the measures were collected from them before knowing the outcome.

The results show that only at high-level construals, the indirect effect through excitement was significant. For concrete mindset individuals, the indirect effect through psychological discomfort was significant. Further analysis demonstrated that the experience of mixed

emotions per se does not drive the results. Instead, a failure in handling mixed emotions (psychological discomfort) drives the results.

In this paper, we propose the unresolved uncertainty effect that suggests a *net* positive effect of the waiting period on consumers' appraisal of the stimulus. We find that individuals with high-level construals experience heightened excitement during the waiting period. Excitement, in turn, affects their evaluation of the uncertainty-associated stimulus positively. Those with low-level construals fail to handle their mixed emotions. This failure results in psychological discomfort and spills over into their stimulus appraisal negatively.

This research contributes to the theory by showing that people form an evaluation of the stimulus that created an uncertain event and by detailing how people feel during the period they live with the uncertainty: excited and/or uncomfortable depending on their construal level.

Circular Disposal Increases the Value of Products More Than Linear Disposal

Anna Tari, Boston University, USA
Remi Trudel, Boston University, USA

EXTENDED ABSTRACT

A viable alternative to a linear economy (i.e., where we take resources, produce, consume and ultimately waste), is a circular economy. A circular economy is a "closed loop" model where systems are designed so that products flow back into the cycle after use (i.e., through recycling, donating, and reselling) to minimize waste generation (Stahel 2016). A circular strategy presents a fundamental shift in thinking for firms and consumers, where consumers are required to think of disposal at acquisition and be active in "closing the loop". We suggest that considering disposal at point of purchase will influence consumers' valuation of products. We report four experiments demonstrating that a higher value is ascribed to products that will be disposed of through a circular means (i.e. recycling, donating, reselling) in comparison to a linear means (i.e. trashing).

Prior literature shows that people are strongly averse to creating waste (Arkes 1996; Donnelly, Lamberton, Reczek and Norton 2017; Trudel and Argo 2013; Winterich, Reczek and Irwin 2017) and that not being wasteful can also evoke positive self-conscious emotions (e.g. feelings of pride) (Sun and Trudel, 2017). We know that people may experience negative self-conscious emotions (e.g. guilt, shame, and embarrassment; Lewis 1997; Tracy and Robins 2004) when they purchase products that are not fully utilized (Bolton and Alba 2012). In particular, Arkes (1996) found that participants expressed negative emotion when paying for products that were not fully utilized (e.g. only using two of a three-pack). In line with these results, we propose that consumers will feel more pride in making a circular disposal decision and in turn less guilt in spending resources because they avoid being wasteful and are able to more fully utilize a product that is disposed through circular (recycle, donate or resell) vs. linear means (trash).

Studies 1A-1E *(N*=1,955) showed preliminary evidence of the main phenomenon. Participants read a scenario that contained information about a product they were about to purchase. In a 4-cell between-subject design, participants read information about how they thought they were going to dispose of the product when they no longer needed it, thinking they were either going to dispose it through a circular (i.e., recycle, donate, resell) or a linear means (i.e., trash). Participants stated their willingness to pay for the product. Across all studies, participants were willing to pay more for the product when they were going to dispose it of through circular vs. linear means (all ps < .05). This effect was robust across domains (i.e., table, sofa, jacket, hoodie) and in an incentive compatible experiment.

Study 2 (*N*=426) sought to provide further evidence of the hypothesized effect of anticipated disposal behavior on product valuation, and used an analysis of mediation to examine the role of pride in disposal and guilt in spending resources as the sequential path revealing the underlying psychological mechanism. The study design replicated that of studies 1A-1E. After participants gave their willingness to pay for the product, they rated how proud they felt about disposing the product and how guilty they felt about spending resources in the product. As predicted, circular disposal led to higher pride in disposal, which made participants feel less guilty about spending resources and be more willing to pay for products they thought they were going to dispose through circular vs. linear means ($\beta_{recycle}$ = 9.53, SE = 3.07, 95% CI = [4.32; 16.28]; (β_{donate} = 11.69, SE = 3.69, 95% CI = [5.39; 19.68]; β_{resell} = 9.29, SE = 2.98, 95% CI = [4.23; 15.86]). The next two studies sought to corroborate the mediating role of pride in disposal and guilt in spending through moderated mediation.

Study 3 (*N*=588) sought to provide further evidence for the role of pride in disposal in driving guilt in spending and therefore product valuation. We reasoned that, if pride in disposal drives product valuation, such effect should be eliminated when consumers' disposal decision is attributed to external circumstances that the consumer had to comply with rather than to the individual's goodwill. As predicted, results of the internal condition (i.e., when the disposal decision was attributed to the individual) replicated study 1A-1E, but product valuation was similar across disposal conditions in the external condition (i.e., when disposal means was determined by government regulations).

Study 4 (*N*=545) examined the role of guilt in spending as psychological mechanism underlying product valuation. We reasoned that guilt in spending should decrease when an individual has financial incentives to dispose the product in a certain way, such as receiving a government rebate for disposing a product. Participants were assigned to one of the conditions in a 3 (disposal: trash, recycle, donate) x 2 (no incentives vs. incentives). As predicted, the hypothesized effect only manifested when individuals had no economic incentives to dispose through a specific means but was eliminated when participants had incentives to dispose of the product.

Overall, this research contributes to the literature on product valuation (e.g. Atasoy and Morewedge 2018; Carmon and Ariely 2000; Dommer and Swaminathan 2013; Keinan, Kivetz, and Netzer 2016; Loewenstein and Kahneman, 1991), by showing what consumers expect to do with a product when they no longer want or need it can influence how much they value a product. Moreover, our results inform the growing literature on disposal decision making and on sustainability (Cialdini et al. 1990; Brough et al. 2016; Goldstein et al. 2008; Griskevicius et al. 2010; Luchs et al. 2010; White and Simpson 2013; Reczek et al. 2018), by pointing to an important outcome of disposal decisions (i.e., product valuation). Lastly, this research brings the circular economy into the fold. By doing so we hope to introduce some fruitful areas for future research. How does a circular strategy influence a brand, self-brand connection, product quality perceptions, price-fairness perceptions and other spillover sustainable behaviors? Because circular products or made of "others waste", it is possible, even likely to affect some the factors mentioned.

Food Sharing Reduces Perceived Consequences of Caloric Intake

Nükhet Taylor, York University, Canada
Theodore J. Noseworthy, York University, Canada

EXTENDED ABSTRACT

There has been a growing trend toward food sharing as means of portion control. Brands such as M&M's, Snickers, and Skittles released "*sharing size*" options, accompanied by overt claims promoting a healthier lifestyle (Mars Official Website 2017). This trend was not restricted to junk food. "Shared plate" options became some of the most popularized restaurant menu items (National Restaurant Association 2018). Yet, despite the popularity, obesity rates continued to climb (Trust for America's Health 2019). Far from a tool to promote portion control, food sharing may be promoting weight gain (Wurtman 2011). The goal of this research is to be the first to systematically explore why this may be happening.

In exploring the potential link between food sharing and weight gain, our first step was to probe whether consuming food shared by others was leading consumers to underestimate the caloric intake and/or fattening potential of the food item. The rationale was twofold. First, obesity research in diverse areas has pinpointed the underestimation of caloric content and fattening potential of food to be two of the prime drivers behind weight gain (Chernev 2011; Lansky and Brownell 1982). Second, testing caloric estimates alongside fattening judgments allowed us to simultaneously explore two possibilities. Fattening judgments, defined as the perceived potential for weight gain, is a possible outcome of caloric intake (Ilyuk et al. 2019). While caloric estimates often go hand in hand with fattening judgments, there are cases where people mentally decouple calories from fattening potential (cf. Oakes 2006). Thus, whereas one explanation is that people are downplaying their caloric intake, the other possibility is that people are downplaying the fattening potential of the consumption episode even though they understand their caloric intake. Three studies tested these possibilities. The data was analyzed using Bayesian analysis methods.

Study 1 (N=140) explored the core prediction that food sharing may be impacting caloric estimates and/or fattening judgments. Participants were randomly assigned to one of two between-subjects ownership conditions in a 2 (ownership: self, other) × 5 (categorical replication: grapes, pizza, M&M's, French fries, cookies) mixed factorial design. Participants were presented with a picture of each food item, and read that the item either belonged to them (self-ownership condition) or to their friend (other-ownership condition). Participants then imagined a consumption episode with this item. The questionnaire consisted of two randomized items, one capturing caloric estimates (open-ended), and the other capturing fattening judgments (1=*not fattening at all*, 9=*very fattening*). The task was repeated across five product categories.

A Bayesian repeated measures ANOVA yielded evidence against ownership having a reliable impact on caloric estimates ($BF_{10} = 0.48$). This suggested that food sharing was not altering caloric estimates. However, there is the possibility that people perceiving caloric intake to be less fattening when the food is shared by others. Our next analysis explored this possibility. A Bayesian repeated measures ANOVA supported the main effect of ownership ($BF_{10} = 2.93$), such that participants perceived their caloric intake to be less fattening when the food was shared by others ($M = 4.21$) than when it was owned by them ($M = 4.88$). The analysis also provided support against the full interaction model ($BF_{10} = .04$), suggesting that the food sharing reduced fattening judgments across all product categories. Overall, these results confirmed that participants judged their caloric intake to be less fattening when the food was shared by others.

Downplaying fattening potential of food can promote weight gain because it may reduce the likelihood that people will correct for the extra caloric intake in subsequent choices (cf. Dhar and Simonson 1999). Study 2 (N=206) tested this possibility. Participants imagined being at a restaurant with a friend, and were exposed to a picture of a plate of French fries. Participants read that this plate was either ordered by them (self-ownership condition) or by their friend (other-ownership condition). After imagining eating 5 individual French fries, participants were asked to select the desert alternative they preferred (1=*definitely the fruit salad*, 9=*definitely the chocolate cake*), followed by the same caloric estimate and perceived fattening measures as study 1. The caloric estimate and fattening judgments mirrored the findings of study 1, suggesting that people are downplaying the consequences of caloric intake when the food is shared by others. The critical question was whether this impacted subsequent choice. The analysis confirmed that the calorie-dense desert was preferred more in the other-ownership condition ($M = 6.93$) than in the self-ownership condition ($M = 6.13$; $BF_{10} = 2.68$). A frequentist mediation analysis confirmed a significant indirect effect of ownership through perceived fattening on desert choice (95% CI: .14, 1.11). Thus, consuming shared food reduced perceived fattening of the first consumption episode, which enhanced the preference for the calorie-dense desert.

The defining characteristic of food sharing, and the core manipulation in our studies, is the lack of ownership over the food item that one consumes. Thus, one possibility is that consumers are downplaying the consequences of caloric intake because they feel a lack of ownership over the food item. If true, then one may attenuate the bias by altering perceptions of ownership.

Study 3 (N=330) explored this possibility. All participants imagined being at McDonalds with a friend. Participants in the self-ownership (other-ownership) condition read that they (their friend) ordered Chicken McNuggets. The critical addition was the "other-with-psychological-ownership" condition. Like the other-ownership condition, participants in this condition read that their friend ordered the Chicken McNuggets. However, a classic psychological ownership manipulation was deployed to accentuate felt ownership over the food (Friedman 2010). The analysis showed a clear difference in fattening judgments ($BF_{10} = 20.24$). Fattening judgments were lower in in the other-ownership condition ($M = 5.34$) than in the psychological-ownership condition ($M = 5.86$; $BF_{10} = 1.56$), which was marginally lower than the self-ownership condition ($M = 6.29$; $BF_{10} = 1.35$). Thus, we were able to attenuate the biased fattening judgments by increasing felt ownership.

In contrast to the health benefits touted by companies, the current article shows that consumers are downplaying the fattening potential of consumption episodes when engaging in food sharing.

Firing Founders that Behave Badly: Effects of Morality versus Authenticity on Brand Evaluation

Lan Anh N. Ton, University of Georgia, USA
Rosanna Smith, University of Georgia, USA

EXTENDED ABSTRACT

When a company's founder engages in ethical misconduct, the company decides to fire the founder in hopes that the brand's reputation is maintained and that the company can recover from the financial losses. Specifically, 39% of the 89 cases of the CEO departures were due to ethical misconduct in 2018, an increase from the record of less than a quarter five years ago (McGregor 2019). For example, John Schnatter, founder of Papa John's Pizza, was forced out in the wake of his racist comment during a conference call in July 2018 (Neuman 2018). Jonathan Bush, co-founder and former CEO of Athenahealth, was also ousted amid past domestic assault and sexual misconduct allegations (Leaf 2018). Recently, McDonald's CEO stepped down after reports emerged that he violated company policy by engaging in a consensual relationship with an employee (Yaffe-Bellany 2019).

However, would the company's decision to fire an unethical founder improve the company's brand evaluation relative to the company's decision to retain him or her? Anecdotally, consumer reactions have been mixed. On the one hand, removing the founder can lead to positive reactions because the company has distanced itself from the moral violation. On the other hand, consumer reaction can be negative because firing the founder can lead consumers to see the company as no longer true to its origins. In this paper, we seek to provide an answer to the above question by proposing two parallel mechanisms (i.e., morality and authenticity) that explain the impact of the company's decision toward the unethical founder on its brand evaluation.

The company's perceived morality refers to the extent to which consumers perceive the company's intentions to be genuine or in service of a set of values (Beverland and Farrelly 2010; Morhart et al. 2015). Authenticity has been found to be subject to many meanings and has been classified into a variety of types (Newman and Smith 2016). In a recent article, authenticity is organized into three perspectives – authenticity as consistency between an entity's internal and external expressions, authenticity as conformity of an entity to the norms of its social category, and authenticity as connection between an entity and a person, place, or time as claimed (Lehman et al. 2019). The company's perceived authenticity is presented in the third perspective. Specifically, the company's perceived authenticity refers to the extent to which consumers perceive the company to be connected to its origin (i.e., the founder). The removal of an unethical founder could signal that the brand is committed to upholding a high ethical standard. Thus, firing (vs. retaining) the unethical founder should increase consumers' brand evaluation through enhanced company's perceived morality. However, the removal of the unethical founder could suggest that the company is no longer connected to its origin. Consumers tend to define what a product or brand is (i.e., its essence) in relation to its origins (Grayson and Martinec 2004; Newman and Dhar 2014). Hence, firing (vs. retaining) the founder could hurt the brand evaluation due to decreased company's perceived authenticity. In short, the company's decision to fire (vs. retain) the unethical founder could decrease and concurrently increase consumers' brand evaluation due to decreased company's perceived authenticity and increased company's perceived morality, respectively (See Figure 1). We tested our proposed relationship between the company's decision toward the unethical founder, the company's perceived morality and perceived authenticity, and brand evaluation across three experiments.

Empirical Evidence

Study 1. Study 1 tested whether firing an unethical founder had a positive effect on brand evaluation relative to retaining him or her. Participants first read about a coffee company whose current CEO was the founder. They either went on to rate their likelihood of purchasing a cup of coffee from the company (control condition) or learned that the CEO had physically assaulted someone and was either fired (fire condition) or not fired (retain condition) before evaluating the brand. Participants' brand evaluation in both the fire and retain conditions ($M = 4.00$, $SD = 1.34$) were significantly lower than the control condition ($M = 5.41$, $SD = 1.15$.; $t(363) = 9.63$, $p < .001$). Interestingly, there was no significant difference in brand evaluation between the fire ($M = 3.97$, $SD = 1.17$) and retain condition ($M = 4.03$, $SD = 1.50$; $t(363) = 0.33$, $p = .75$), suggesting that firing the unethical founder did not positively impact the company relative to retaining. Consistent with our predictions, consumer perceptions of the company's authenticity were directionally higher in the retain condition than in the fire condition, despite not being significant. In contrast, the company's perceived morality was significantly lower in the retain condition ($M = 3.43$, $SD = 1.51$) than in the fire condition ($M = 3.85$, $SD = 1.31$; $t(363) = 2.53$, $p = .01$, $d = 0.30$). These results were suggestive that the opposing forces of perceived morality and perceived authenticity might offset the overall positive effect of firing the unethical founder on consumers' brand evaluation compared to retaining. Hence, in the next two studies, we explored the boundary conditions under which one force drove the company's decision over the other.

Study 2. In study 2, we examined whether the effect of the company's decision toward the unethical CEO on consumers' brand evaluation, the firm's perceived authenticity, and the firm's perceived morality was moderated by the company's connection to its origin (i.e., CEO as a founder vs. CEO as a non-founder). We manipulated whether participants learned that the current CEO was the founder versus not the founder of the company, in addition to manipulating the company's decision toward the CEO (fire versus retain). Different from the previous study, a sexist comment at work was used as a moral violation. We expected that when the CEO was the non-founder, the company's decision to fire (vs. retain) him increased the company's perceived authenticity and perceived morality, which led to an increase in consumers' brand evaluation. In contrast, when the CEO was the founder, we would observe a competing effect of the two mediators. Specifically, the company's decision to fire (vs. retain) him decreased the firm's perceived authenticity and concurrently increased the firm's perceived morality, which led to a decrease and increase in consumers' brand evaluation, respectively.

A 2(decision: fire, retain) x 2(connection to origin: founder, non-founder) between-subjects ANOVA on consumers' brand evaluation revealed a main effect of decision, with brand evaluation rated higher in the fire condition ($M = 4.89$, $SD = 1.67$) than in the retain condition ($M = 4.34$, $SD = 1.79$; $F(1, 354) = 11.32$, $p = .001$, $d = 0.32$). There was no significant main effect of connection to origin on consumers' brand evaluation ($F(1, 354) = 0.43$, $p = .51$). Additionally, we observed a significant interaction between decision and

connection to origin ($F(1, 354) = 7.53$, $p = .006$). Consistent with the previous study, in the founder conditions, we observed no significant main effect of decision ($F(1, 354) = 0.22$, $p = .64$). In contrast, in the non-founder conditions, the brand was evaluated more positively in the fire condition ($M = 5.25$, $SD = 1.55$) than in the retain condition ($M = 4.34$, $SD = 1.79$; $F(1, 354) = 16.54$, $p < .001$, $d = 0.54$).

We also observed a significant interaction between decision and connection to origin on the firm's perceived authenticity ($F(1, 354) = 21.66$, $p < .001$). Consistent with our predictions, in the founder conditions, the company was perceived as more authentic in the retain condition than in the fire condition ($F(1, 354) = 4.81$, $p = .03$). In contrast, in the non-founder conditions, the company was perceived as more authentic when the non-founder was fired than when he was kept ($F(1, 354) = 18.23$, $p < .001$). There was also an interaction between decision and connection to origin on the firm's perceived morality ($F(1, 354) = 8.23$, $p = .004$). As expected, we observed that the company was perceived as more moral in the fire condition than in the retain condition across the non-founder ($F(1, 354) = 46.96$, $p < .001$) and founder conditions ($F(1, 354) = 11.87$, $p = .001$).

We then separately tested the proposed parallel mediation model when the CEO was the founder and when the CEO was the non-founder (Hayes 2013, model 4). When the CEO was the non-founder, we observed significant mediating effects of the firm's perceived authenticity and perceived morality (indirect effect = 0.41, $SE = 0.14$, 95% CI = [.16, .72]; indirect effect = 1.00, $SE = 0.25$, 95% CI = [.57, 1.54]). Specifically, firing the non-founder increased both the firm's perceived authenticity and perceived morality, leading to an increase in brand evaluation. In contrast, when the CEO was the founder, we found competing effects of the firm's perceived authenticity and perceived morality (indirect effect = -0.18, $SE = 0.09$, 95% CI = [-.37, -.02]; indirect effect = 0.46, $SE = 0.15$, 95% CI = [.19, .77]). That is, firing the founder increased the firm's perceived morality but at the same time decreased the firm's perceived authenticity, resulting in an increase and decrease in brand evaluation, respectively.

Study 3. Using the same moral violation as in study 2, we tested whether the effect of the company's decision on brand evaluation was moderated by the founder's engagement in moral restoration (i.e., apology vs. no apology). In addition to the manipulation of the company's decision, we manipulated whether the participants received information about the founder's apology (i.e., apology condition) or they received no additional information after reading about the company's decision (i.e., no apology condition). We anticipated that, given the information about the founder's apology, firing him decreased the firm's perceived authenticity relative to retaining him. That, in turn, resulted in a decrease in consumers' brand evaluation. In contrast, given no information about the founder's apology, firing the founder increased the firm's perceived morality relative to retaining him, which led to an increase in consumers' brand evaluation.

A 2(decision: fire, retain) x 2(moral restoration: apology, no apology) between-subjects ANOVA on consumers' brand evaluation revealed a main effect of decision, with brand evaluated higher in the retain condition ($M = 4.48$, $SD = 1.77$) than in the fire condition ($M = 4.06$, $SD = 1.67$; $F(1, 387) = 6.41$, $p = .01$, $d = 0.24$). There was also a main effect of moral restoration, with consumers' brand evaluation rated higher in the apology condition ($M = 4.46$, $SD = 1.82$) than in the no apology condition ($M = 4.11$, $SD = 1.64$; $F(1, 387) = 3.94$, $p = .05$, $d = 0.20$). Additionally, we observed a significant interaction between decision and moral restoration ($F(1, 387) = 6.29$, $p = .01$). Consistent with the results from the previous studies, when there was no additional information about the founder's apology, we found no significant effect of the company's decision on brand evaluation ($F(1, 387) = 0.00$, $p = .99$). In contrast, when the was information

about the founder's apology, retaining the founder increased consumer's brand evaluation relative to firing him ($M = 4.89$, $SD = 1.84$ vs. $M = 4.01$, $SD = 1.69$; $F(1, 387) = 11.99$, $p = .001$, $d = 0.50$).

We also observed a significant interaction between decision and moral restoration on the firm's perceived authenticity ($F(1, 387) = 5.60$, $p = .02$). Consistent with our predictions, in the apology conditions, retaining the founder increased the company's perceived authenticity relative to firing him ($F(1, 387) = 9.77$, $p = .002$). In contrast, in the no apology conditions, we observed no significant effect of decision on the company's perceived authenticity ($F(1, 387) = 0.02$, $p = .89$). We also found an interaction between decision and moral restoration on the firm's perceived morality ($F(1, 387) = 4.47$, $p = .04$). Specifically, in the no apology conditions, the company was perceived as more moral in the fire condition ($M = 4.72$, $SD = 1.47$) than in the retain condition ($M = 4.12$, $SD = 1.52$; $F(1, 387) = 7.64$, $p = .006$). However, in the apology conditions, there was no significant effect of the company's decision on the firm's perceived morality ($F(1, 387) = 0.09$, $p = .77$).

Similar to study 2, we then separately tested the proposed parallel mediation model when there was information about the founder's apology and when there was none (Hayes 2013, model 4). When there was information about the founder's apology, we observed only the mediating effect of the firm's perceived authenticity but not of the firm's perceived morality (indirect effect = -0.34, $SE = 0.15$, 95% CI = [-.68, -.11]; indirect effect = -0.03, $SE = 0.11$, 95% CI = [-.25, .20]). In contrast, when there was no information about the founder's apology, the effect of the firm's decision on brand evaluation was mediated by the firm's perceived morality but not by the firm's perceived authenticity (indirect effect = 0.26, $SE = 0.11$, 95% CI = [.07, .50]; indirect effect = 0.01, $SE = 0.11$, 95% CI = [-.20, .24]).

General Discussion

The current paper offers two theoretical contributions. First, we extend prior work that emphasizes the important role of authenticity on consumer behavior, by showing that when the origin (i.e., founder) of the company is tainted, the company's decision to fire or to retain the unethical founder evokes a tension between the company's perceived authenticity and morality. Second, we confirm the importance of apology in crisis communication in that an apology validates the morality of retaining the founder, who once committed a wrongful act. As a result, retaining the founder increases the firm's perceived authenticity relative to firing the founder, which, in turn, enhances consumers' evaluation of the brand.

Our findings provide consistent evidence across the three studies that firing an unethical founder did not enhance consumer evaluations of the brand relative to retaining the founder. This result was suggestive that the opposing effects of the firm's perceived authenticity and perceived morality might offset the positive impact of firing the unethical founder on consumers' brand evaluation relative to retaining. Given this finding, we proceeded to explore the boundary conditions in which one force drove the company's decision over the other. Specifically, we tested whether the effect of the company's decision on consumers' brand evaluation was moderated by the company's connection to its origin (study 2) and by the founder's engagement in moral restoration (Study 3). The results from these studies offered important implications for practitioners. When the unethical CEO was a non-founder, firing him improved both consumers' perceptions of the firm's authenticity and morality, leading to consumers' positive evaluation of the brand relative to retaining the non-founder. When the founder provides a sincere apology for his wrongful act, retaining him increased the firm's perceived au-

thenticity relative to firing, thereby enhancing consumers' evaluation of the brand. In future studies, we will continue to explore conditions under which companies can manage ethical violations by their leaders by improving either its perceived authenticity or its perceived morality.

Purity Packaging: How and When Simple Packaging Designs Enhance Product Evaluations and Choice

Lan Anh N. Ton, University of Georgia, USA
Rosanna Smith, University of Georgia, USA
Julio Sevilla, University of Georgia, USA

EXTENDED ABSTRACT

Packaging design is a common way for companies to enhance product appeal (Ampuero and Vila 2006; Underwood, Klein, and Burke 2001). Conventional marketing practice typically involves adding a set of design elements (e.g., graphics, images, illustrations) on packaging to communicate valued product attributes (Rundh 2009; Underwood and Klein 2002) such as product quality (Underwood and Klein 2002) or product healthiness (Vila and Ampuero 2007). Here, we examine when the use of less can lead to more. Specifically, this article examines the consumer response to products with simple (vs. complex) packaging designs.

Design simplicity often involves relatively minimal use of design elements (Agrawal 2019), whereas design complexity involves a relatively high number of design elements (Pieters, Wedel, and Batra 2010). Prior research has primarily examined the influence and benefits of general visual complexity on consumer attitudes (e.g., Orth, Campana, and Malkewitz 2010; Orth and Crouch 2014; Pieters et al. 2010). In this work, we focus on the contrast between overall package design simplicity (vs. complexity) on a set of consequential product inferences for both consumables and non-consumables in the context of consumer packaged goods. Holding constant all other information, we propose that a package with a simple (vs. complex) design will be more effective at conveying certain valued product attributes such as product quality and healthiness, which, in turn, will enhance product valuation and choice.

We theorize that these enhanced judgments primarily stem from the simplicity of the package design leading consumers to draw an implicit parallel connecting the design elements on the exterior package and the nature of the interior product. As simple packaging keeps visual features on the package to a minimum, we propose that consumers are likely to infer that the product's composition is similarly minimal or pure (i.e., has involved little processing or alteration) relative to that in complex packaging. We then posit that the enhanced perceptions of product purity with simple packaging design will increase product valuation and choice through enhancing dual inferences of product quality and healthiness.

To test the proposed processes, we first drew from four of the six design complexity principles of Pieters, Wedel, and Batra (2010) to create the simple (vs. complex) packaging designs: (1) the dissimilarity of objects, (2) the quantity of objects, (3) the irregularity of object arrangement, and (4) the detail of objects. We posit that design simplicity is the reduction of these principles. Thus, a simple design is one in which the objects used are similar to one another, are low in quantity, are regularly arranged, and possess little detail. Using their principles, we then developed a novel two-stage process to create the packaging designs for both consumable (trail mix) and non-consumable (hand lotion) products. To ensure the effectiveness of our design simplicity manipulation, we tested the two sets of created packaging designs for design simplicity perceptions (see table 1, pilot test). These created designs were then used as stimuli across five experiments (except for study 3 which used real packaging designs).

EMPIRICAL EVIDENCE

Study 1A. Study 1A tested our proposed processes using the created packaging designs for a consumable product (trail mix). Partici-

pants were randomly assigned to view a trail mix in either a simple or complex package. They were then asked to assess product valuation: How high-end do you think this product is? (1 = *Not at all High-end*, 9 = Very High-end); How expensive do you think this product is? (1 = *Not at all Expensive*, 9 = Very Expensive). Items were averaged to create a composite measure of product valuation (α = .87).

To capture product purity, participants rated: I think this product is pure; I think this product is made from unprocessed materials; I think this product is made from unprocessed ingredients; I think this product is made from natural materials; I think this product is made from natural ingredients (1 = *Strongly Disagree*; 9 = *Strongly Agree*). Items were averaged to create a composite measure of product purity (α = .93).

To measure perceptions of product quality, participants rated: To what extent do you think this product is of high quality? (1 = *Not at all*; 9 = *Very much*). To capture perceptions of product healthiness, participants rated: How healthy do you think this product is? (1 = *Not at all Healthy*; 9 = *Very Healthy*).

As a check for design simplicity, participants rated the same item from the pilot test (i.e., How complex do you think the packaging design of this product is? (1 = *Simple*; 9 = *Complex*)). To control for design attractiveness and brand familiarity, participants were asked: To what extent do you think the packaging design of this product is attractive? (1 = *Not at all Attractive*; 9 = Very Attractive); To what extent do you feel familiar with this product brand? (1 = *Not at all Familiar*; 9 = *Very Familiar*). Participants completed attention checks and demographics.

As expected, the simple package was perceived as less complex than the complex package (2.22 vs. 4.93; $t(177)$ = -8.80, $p < .001$, d = 1.33). Furthermore, we found no significant difference in design attractiveness ($p = .86$) or in brand familiarity ($p = .61$) across conditions.

We found that the trail mix in the simple (vs. complex) package was seen as higher in valuation (6.26 vs. 5.37; $t(177)$ = 3.34, $p = .001$, $d = .50$), purer (5.57 vs. 4.69; $t(177)$ = 3.59, $p < .001$, $d = .54$), higher in quality (6.10 vs. 5.29; $t(177)$ = 2.79, $p = .006$, $d = .42$), and healthier (6.04 vs. 5.08; $t(177)$ = 4.02, $p < .001$, $d = .61$). Moreover, we predicted that the trail mix in the simple (vs. complex) package would be perceived as purer, which, in turn, would increase perceived product quality and subsequent product valuation. Results from the serial mediation analysis (Model 6, Hayes 2018) revealed that the packaging design had a significant indirect effect on product valuation through sequential enhancement in perceived product purity and quality (β = .30, $SE = .11$, 95% CI = [.12, .55]). We also found support for our theorizing that the effect of packaging design on valuation was explained by the serial process from perceived product purity to healthiness (β = .13, $SE = .06$, 95% CI = [.03, .27]).

Study 1B. Study 1B extended the effects of simple versus complex packaging to a non-consumable product (hand lotion). Participants were randomly assigned to view a hand lotion in either a simple or complex package. They again rated the following: product valuation (α = .94), product purity (α = .94), product quality, and product healthiness. The product healthiness item was modified for a non-consumable product: To what extent do you think this product is good for your health? (1 = *Not at all*; 9 = *Very much*). Participants

rated the design simplicity of the package, design attractiveness, and brand familiarity. Lastly, they completed attention checks and demographics.

As expected, the simple package was perceived as less complex than the complex package (2.11 vs. 4.58; $t(333) = -11.61$, $p < .001$, $d = 1.28$). We again found no significant difference in design attractiveness ($p = .41$) and brand familiarity ($p = .22$) across conditions.

The hand lotion in the simple (vs. complex) package was seen as higher in valuation (5.79 vs. 5.04; $t(333) = 3.61$, $p < .001$, $d = .39$), purer (4.57 vs. 4.09; $t(333) = 2.74$, $p = .007$, $d = .30$), higher in quality (5.79 vs. 4.98; $t(333) = 3.98$, $p < .001$, $d = .43$), and healthier (4.85 vs. 4.33; $t(333) = 2.87$, $p = .004$, $d = .32$). Moreover, results from the serial mediation analysis (Model 6, Hayes 2018) revealed that the effect of packaging design on valuation was driven by the serial process both through purity and quality ($\beta = .26$, $SE = .09$, 95% CI = [.08, .45]) and through purity and healthiness ($\beta = .07$, $SE = .03$, 95% CI = [.02, .14])

Study 2. Study 2 tested our proposed process via both a mediation and a moderation approach by directly manipulating perceived product purity in addition to measuring the construct. We theorize that simple packaging increases perceived product valuation, quality, and healthiness because consumers draw an implicit visual parallel between the simplicity of the design and the purity of the product's composition. Thus, we reason that if consumers were given information about the product's composition that suggested the interior was altered from its original state, then we would expect the positive effect of simple packaging on perceived valuation, quality, and healthiness to attenuate. This is because providing this information about the product composition contradicts the implicit parallel made between the minimal features of the exterior simple design and the purity within.

A 2 (packaging design: simple vs. complex) by 2 (product interior: control vs. altered) between-subjects ANOVA on perceived product purity revealed a significant interaction between packaging design and product interior ($F(1, 463) = 7.91$, $p = .005$, $\eta_p^2 = .02$). In the control conditions, the trail mix in the simple package was seen as purer (5.76 vs. 5.00; $F(1, 463) = 11.23$, $p = .001$, $d = .45$). By contrast, in the altered conditions, we found no significant effect of packaging design (2.80 vs. 2.96; $F(1, 463) = .44$, $p = .51$, $d = .09$). There was a marginally significant main effect of packaging design ($F(1, 463) = 3.49$, $p = .06$, $d = .09$) and a main effect of product interior ($F(1, 463) = 238.06$, $p < .001$, $d = 1.40$). Of note, we also performed the same analysis on design simplicity manipulation check, product interior manipulation check, product valuation, quality, and healthiness and found support for our predictions (see table 1, study 2).

As expected, we observed significant moderated serial mediation (Model 83, Hayes 2018) by purity and quality ($\beta = -.45$, $SE = .17$, 95% CI = [-.77, -.14]) and by purity and healthiness ($\beta = -.20$, $SE = .09$, 95% CI = [-.40, -.05]). In the control conditions, participants thought the trail mix in the simple package was purer, which, in turn, increased quality and valuation ($\beta = .38$, $SE = .11$, 95% CI = [.17, .59]). These patterns were replicated in the sequential process through purity and healthiness ($\beta = .17$, $SE = .06$, 95% CI = [.06, .30]). However, in the altered conditions, perceived purity and quality/ healthiness no longer mediated the relationship between design simplicity and valuation ($\beta = -.08$, $SE = .12$, 95% CI = [-.31, .16]; $\beta = -.03$, $SE = .06$, 95% CI = [-.15, .07], respectively).

Study 3. Study 3 examined a potential boundary condition via another consequential consumer outcome: product choice. Since studies 1A-2 revealed that participants perceived products in simple packages to be higher in quality and, in turn, of higher valuation, we reasoned that people (less) concerned about product affordability would be (more) less likely to choose products in simple packages. To test this, participants were randomly assigned to one of two affordability conditions: low versus high concern about product affordability. They were then presented with a choice between two hand lotions, one in a simple package and the other in a complex package. As noted earlier, we used found product packaging designs as stimuli.

To test this, we ran a logistic regression with choice as the dependent measure and affordability concern as the independent variable. Consistent with our predictions, 74.5% chose the simple package in the low concern condition, whereas 64% chose the simple package in the high concern condition, revealing a significant attenuation in simple package choice by affordability concern (Wald = 4.93, $p = .03$; $X^2 (1) = 4.97$, $p = .03$). The effect of affordability concern on choice was significantly mediated by a serial process through purity and quality ($\beta = .05$, $SE = .03$, 95% CI = [.01, .12]) but not through purity and healthiness ($\beta = .04$, $SE = .03$, 95% CI = [-.01, .11]).

Study 4. Study 4 also examined another key boundary condition with choice as the dependent measure. Given that product healthiness is one key product inference attributed to simple designs, we reasoned that people would be (more) less likely to value products with simple designs if they had a (health) indulgence goal. To test this, participants were randomly assigned to either the health goal condition or the indulgence goal condition. They were then presented with a choice between the trail mix in the simple package and the trail mix in the complex package. Consistent with our expectations, 65% chose the simple package in the health goal condition, while only 41.4% chose the simple package in the indulgence goal condition (Wald = 17.48, $p < .001$; $X^2 (2) = 20.18$, $p < .001$, see figure 1). The difference in choice was mediated by the serial process between purity and healthiness ($\beta = .22$, $SE = .09$, 95% CI = [.08, .43]) but not between purity and quality ($\beta = .02$, $SE = .04$, 95% CI = [-.07, .10]).

General Discussion

Marketers typically add design elements to packages to signal valued product attributes. We find across a pilot test and five experiments that less can convey more. Using a theoretically grounded approach (Pieters et al. 2010), we created and tested simple (vs. complex) packaging designs across a consumable and non-consumable product. Studies 1A-1B provided support for our proposed processes across two product domains. Specifically, we found that the use of simple packaging enhanced product valuation. This enhanced valuation was explained through two paths—one through increased perceived product purity and quality and the other through increased perceived product purity and healthiness. Study 2 bolstered these results by providing moderation support for our proposed process by manipulating the perceived alteration of the product interior. Studies 3 and 4 tested two boundary conditions while also introducing a consequential dependent variable, product choice. Study 3 showed that the preference for simple packaging attenuated with high product affordability concerns. In Study 4, people with an indulgence goal were more likely to choose products with complex packaging.

This paper offers several theoretical contributions. First, this work enhances our understanding of how consumers evaluate design complexity by highlighting and providing conceptual grounding to the construct of design simplicity in the context of packaging designs for both consumable and non-consumable products. Second, this research introduces a theoretically and empirically driven conceptualization of product purity and shows that product purity can be signaled via subtle visual cues. Third, we establish a novel and effective way to convey product quality and healthiness through simple packaging signaling product purity. Our findings hold important manage-

rial implications. Simplifying packaging may be a win-win strategy for marketing managers in that simple packaging not only enhances valued product inferences but also may require less resource expenditure than complex packaging. Moreover, given that consumers are increasingly suspicious of artificial ingredients and processes, evoking product purity in packaging design is a key way managers can convey related product attributes like quality and healthiness.

Past Imperfect or Present Perfect: How Dynamic Ranks Influence Consumer Perceptions

Sanjeev Tripathi, Indian Institute of Management, Indore, India
Arpita Pandey, Indian Institute of Management Ahmedabad, India
Shailendra Pratap Jain, University of Washington, USA

EXTENDED ABSTRACT

Consumers evaluate market offerings based on their inclusion and their rank in the list (Sorensen 2007, Issac and Schindler 2014; Issac and Jain 2018). As such, firms can frame information about their relative standing in these lists to influence consumer perceptions (Sevilla, Issac and Bagchi 2018).

Ranking of firms in such lists can change over time. While it is known that consumers choose products based on their movement on a list (Pope 2009), there is little research on how such movement affects consumer perceptions (Petit et al. 2013).

We investigate how consumers evaluate firms based on historical rank information. We demonstrate that individuals rely on both, historical as well as current rank of the firm. For the same rank, consumers penalize firms if their ranks fall and reward them when they rise. Further, relying on Murphy and Dweck (2016), we show that for a given change, entity theorists who believe that world is stable/fixed are less malleable in their evaluations and do not penalize firms much when firms slide. However, incremental theorists who believe that the world is changeable penalize such firms more. Finally, we show that the effect of the direction of rank change on consumers' reactions is mediated by their evaluation of the firm and moderated by the degree of rank change. Formally,

Hypothesis 1:   *Consumers' evaluations of firms are dependent on current as well as past ranks of the firms in the list.*

Hypothesis 2:   *For the same rank, consumers reward firms for a rise in rank and penalize them for a fall.*

Hypothesis 3:   *The effect of rank change on consumers' reaction is mediated by the evaluation of the firm.*

Hypothesis 4:   *The effect of rank change will be attenuated for entity theorists and accentuated for incremental theorists.*

Hypothesis 5:   *Larger the change in rank magnitude, greater the impact on consumers' evaluations.*

In study 1, student participants (N = 102, 37% females) were randomly assigned to the three between-subjects rank change conditions in a 1 X 3 (rise 44→24, fall 2→24, remained stable 24→24) one-way design. The context of the study was the evaluation of a bank. Participants evaluated the quality of the bank on a three-item, 11-point scale (Isaac et al, 2016). A one-way ANOVA with quality perception as the dependent variable and rank change as the independent variable, indicated a significant effect ($F(2, 101) = 3.48$, $M_{Rise} = 6.16$, $M_{Drop} = 4.77$, $M_{Control} = 4.88$; $p = .035$). A pairwise comparison indicated that the quality perception associated with rise in rank was significantly different from drop in rank ($p = .046$) and marginally so from control ($p = .082$).

Study 2 replicated study 1 using a different context and different set of ranks. Participants (N = 68, 44% females) responded to a perception study about startups (Rise in rank 60→35/Drop in rank 5→35). An ANOVA showed a significant effect of rank change for both, evaluation, ($F(1, 67) = 6.29$, $M_{Rise} = 7.17$, $M_{Drop} = 6.06$; $p =$ .015) and investment worthiness ($F(1, 67) = 4.95$, $M_{Rise} = 6.77$, $M_{Drop} = 5.82$; $p = .03$).

Study 3 utilized a 1X2 (Belief systems: Incremental/Entity theorists) between subjects design. In the first part of a two-part study, participants (N = 117, 40% females) responded to an instrument (Implicit theory for general world order, Dweck and Legett 1988; Dweck 2013) to measure beliefs about changeability of the world order. In the second part, the subjects envisaged a scenario of planning a visit to a museum. Next, participants were informed that the museum had dropped from 2nd to 8th on a list of top 10 museums in Europe. They indicated their likelihood of visiting the museum on a three-item, 11-point scale (Goodall 1988; Summers and Kennedy 1995). An ANOVA based on median split on the implicit theory instrument revealed a significant main effect of belief system ($F(1, 116) = 7.04$, $M_{Incremental} = 4.83$, $M_{Entity} = 5.20$; $p = .009$) confirming that incremental theorists were less likely to visit the museum than entity theorists.

In Study 4, respondents (N = 129, 37% females) evaluated Football players for a fantasy league and considered them for drafting on the basis of their ranks in the top 100 list of players. The design was a 2 (Direction: Drop/Rise in rank) X 2 (Change: Large (20-ranks)/Small (5-ranks) between subjects. Participants evaluated the player on a four item, 11-point scale and their intention to select the player on a 3-item, 11-point scale. An ANOVA showed a significant effect of direction ($F(1, 128) = 12.607$, $M_{Rise} = 7.93$, $M_{Drop} = 6.90$; $p < 0.001$) on player evaluation. There was no effect of magnitude of rank change ($F(1, 128) = 0.112$, $M_{Small Change} = 7.40$, $M_{Large Change} = 7.43$; $p > 0.05$). However, this effect was qualified by a significant interaction ($F(1, 128) = 9.2$, $p = .003$). Similar results were observed for player selection. There was a significant effect of direction, no significant effect of magnitude of rank change and a significant interaction. The interaction indicated that while the selection likelihood was significantly different for large change in rank, there was no significant difference for small change in ranks.

A test of moderated mediation (Hayes process, model 7) indicated a significant mediation by evaluation ($p < 0.001$, 95%CI = [.83, 1.07]). The indirect effect of direction on evaluation and subsequently on DV was significant for drop in rank (95%CI = [-2.29, -.97]) but not for rise in rank (95%CI = [-.49, .24]).

This research contributes to the sparse literature on dynamic ranks and their consequences. We show that consumers' evaluations are impacted by historical ranks and bad past ranks may make the firm look good. While firms get penalized for falling ranks, entity theorists are less harsh in penalizing firms (vs. incremental theorists). Moreover, we find that the extent of rank change impacts consumer perceptions. Thus, firms may choose to provide information on past ranks depending on their movement in ranks. Further, if they know about consumers' implicit beliefs, they can frame information appropriately to manage consumer perceptions.

Stressed or Self-Importance? Intentions vs Perceptions When Communicating Busyness

Maria Giulia Trupia, IESE Business School, Spain
Cassie Mogilner, University of California Los Angeles, USA
Isabelle Engeler, IESE Business School, Spain

EXTENDED ABSTRACT

Polls show that people are feeling busier than ever (Carroll 2008; Hamermesh 2019). "Busyness" is commonly defined as the *feeling* of having a lot to do but not enough time to do it all (Gershuny 2005; Wilcox, Laran, Stephen, and Zubcsek 2016; Kim, Wadhwa, and Chattopadhyay 2019). Not only do busy people feel more stressed and less satisfied in life (Kasser and Sheldon 2009; Sharif, Mogilner, and Hershfield 2020), but they are also less likely to slow down and give time to others (Mogilner, Chance, and Norton 2012). An intuitive coping strategy is to communicate one's experience of busyness to others. Indeed, social media posts in which people complain about being busy are widespread (Alford 2012).

However, it is unclear what people are *intending* to convey when telling others they are busy versus what others perceive. Prior research has focused on identifying causes and consequences of people's feelings of busyness (Rudd 2019; Wilcox et al. 2016), as well as inferences that observers make about busy people (Bellezza, Paharia, and Keinan 2017). Still, little is known about what those *expressing* busyness want to convey. While research suggests that busyness is associated with feelings of stress (e.g., Etkin, Evangelidis, and Aaker 2015), recent findings suggest that through signaling status, busyness may instead be intended and perceived as conveying self-importance (Kim et al. 2019). Saying, "I am busy," to express stress versus self-importance would serve distinct interpersonal goals. While admitting feeling stressed might facilitate interpersonal connection (Alicke et al. 1992), highlighting one's importance might serve to impress the other (Sezer, Gino, and Norton 2018).

We examined what people ("expressers") are actually feeling and intending when they express being busy compared to what others ("receivers") perceive the person is feeling and intending. Four studies reveal a miscalibration, such that others over-perceive statements of busyness as expressing self-importance (vs. stress) and an intention to impress (vs. connect). That is, when told, "I am busy," receivers think that expressers feel more self-important than they actually do, and receivers believe expressers want to impress them more than they intend to. Importantly, we find that this miscalibration has interpersonal costs: receivers infer that expressers like them less than they actually do. Studies 1 and 2 identify and replicate the miscalibration using two different paradigms; Study 3 examines process and downstream consequences; and Study 4 shows that explaining this miscalibration can elicit expressions of busyness that are more accurately received.

Study 1 (*N* = 506) was a 2 (person: expresser vs. receiver, between) x 2 (expression: stress vs. self-importance, within) mixed design. Expressers were asked, "*In times when you have a lot to do and you tell someone (e.g., a friend, a colleague), "I am busy," what are you thinking and feeling?*", and receivers were asked, "*In times when they have a lot to do and someone (e.g., a friend, a colleague) tells you, "I am busy," what do you think they are thinking and feeling?*"). Expressers [receivers] then reported their own [the other's] feelings of stress and self-importance (1-7).

Overall, communicating busyness was associated more with feelings of stress than self-importance by both expressers and receivers (expression main effect: *p*<.001, *d*=.90). Importantly, there was a significant person x expression interaction (*p*=.021): receivers significantly overestimated expressers' feelings of self-importance (*p*=.004, *d*=.26); but not their feelings of stress (*p*=.867, *d*=.02).

Using the same mixed design as Study 1, Study 2 (*N* = 802) instructed participants to recall a particular situation. Expressers were instructed, "*Think of a time when you told someone (e.g., a friend, a colleague), 'I am busy'*", and receivers were instructed, "*Think of a time when someone (e.g., a friend, a colleague) told you, 'I am busy'*"). Expressers [receivers] then reported their own [the other's] feelings of stress and self-importance (1-7).

We again found a person x expression interaction (*p*<.001) based on receivers overestimating expressers' feelings of self-importance (*p*<.001, *d*=.44). In this study, receivers also marginally underestimated expressers' feelings of stress (*p* =.088, *d*=.14).

Making the recalled scenario even more specific, Study 3 (*N* = 1,006) specified the interaction partner (friend) and situation (in a conversation about how they are doing). In addition to measuring feelings of stress and self-importance, we also measured intentions to impress and connect (1-7), and liking (1-7).

We again found a person x expression interaction (*p*<.001) based on receivers overestimating expressers' feelings of self-importance (*p*<.001, *d*=.42). Receivers also underestimated expressers' feelings of stress (*p*=.021, *d*=.16). Consistent with this, receivers significantly overestimated expressers' intention to impress (*p* <.001, *d*=.38) and marginally underestimated expressers' intention to connect (*p*=.092, *d*=.12). Receivers' misperception of expressers' intention to impress (vs. connect) significantly mediated the receivers' misperception of expressers' feelings of self-importance (vs. stress) (95%CI=[-.43, -.16]). This all resulted in receivers inferring that expressers liked them less than expressers actually did (*p*<.001, *d*=.61).

To explore whether expressers of busyness can correct this misperception, Study 4 first informed a sample of MBA students (*N* = 89) about our observed effect and asked them to provide an alternative way to say *"I am busy"*—making it clear to the other that it is NOT their goal to impress them. We then randomly presented six of these generated alternatives (along with the sentence, "I am busy,") to a separate online sample of participants (*N* = 1,311). The participants were asked to imagine being told this by a friend and to rate their friend's stress, self-importance, intentions to connect and impress, and liking (1-7).

The results provided convergent evidence for the underlying process and, importantly, showed that—if people are made aware of the miscalibration—people can alter their expressions of busyness to more accurately convey their feelings, intentions, and liking.

In sum, this research identified a miscalibration between intentions and perceptions when people express busyness. Though others might see busyness as a status symbol that creates distance, our findings offer insight into the feelings that people actually want to convey and their reasons for telling others they are busy. The ultimate goal of communicating busyness is to connect, not impress.

I Will Get a Reward, Too: Disclosing the Referrer-Reward Increases Referring

Yanping Tu, University of Florida, USA
Zhihao Yu, University of South Florida, USA
Minzhe Xu, University of Florida, USA

EXTENDED ABSTRACT

Customer referral programs ("Refer a friend, reward yourself!") are prevalent nowadays because they can be a cost-effective way to acquire new customers (Berman 2016). While customer referral is an appealing idea to marketers, consumers are not enthusiastic—even among the most satisfied, only 29% participate (Decker 2018). One psychological barrier is that consumers view referral as a commercial activity, which conflicts with their communal relationship with friends (Grayson 2007), and worry that sending referral messages would make them look like salespersons.

How can companies alleviate the negative perception and increase referral rates? We propose a subtle change regarding the design of the referral message, which most companies automatically generate for customers to send to their friends. Interestingly, although referral programs may reward both customers and their friends (e.g., $10 for you, $10 for your friend), the referral messages usually mention referee-reward only but omit referrer-reward (only 10 out of the 50 brands we sampled disclosed).

Would disclosing referrer-reward in the referral message increase referrers' likelihood of sending the message? We hypothesize so, suggesting that disclosure enhances referrers' perception of the referral process as a communal/cooperative (vs. commercial) activity. This is because, first, disclosure is a gesture of cooperation (Baum and Critcher 2020). By being open and honest about their rewards, referrers make themselves vulnerable to their friends' judgment—an action that reflects trust, the foundation of cooperation. Second, disclosing referrer-reward weakens the "marketing message," which can reduce its sales-pitch feel (based on Attribution Theory; Kelley 1973). Third, in most cases, customers think of potential referees based on a genuine assessment of preferences/needs and pause only to worry that their friend may misread their intention. Disclosing referrer-reward helps customers "come clean" and steer clear of the ambiguity that may exist initially (John, Barasz, and Norton 2016).

Study 1a established the main effect in a field setting, using a 2 (referrer-reward: disclosed vs. undisclosed) between-participants design. Undergraduate students tried a coffee shop brand and received a referral opportunity—if their friend buys a coffee, both the self (i.e., the referrer) and the friend (i.e., the referee) will get a 20% discount for one cup of coffee. Participants then read a referral message that either mentioned the referee-reward only or both the referrer-reward and the referee-reward. We found that more people in the disclosed (vs. undisclosed) condition decided to send the message to their friends ($\chi^2(1) = 6.14$, $p = .01$). Study 1b replicated the main effect using a meal delivery service in a hypothetical setting ($\chi^2(1) = 5.31$, $p = .02$).

Study 2 tested the proposed mechanism by directly measuring perceptions of the referring action (communal vs. commercial). It also explored whether the main effect held in communal relationships with varying degrees of closeness. In a 2 (referrer-reward: disclosed vs. undisclosed) × 2 (referee: a close vs. new friend) between-participants design, participants first listed either a close friend or a new friend and indicated how close they felt to that person. They then imagined being a user of a music streaming service and learned about its referral program. Next, they read a referral message that disclosed their rewards or not and decided whether to send it to the listed person. Finally, participants rated whether they found the re-

ferral process a communal/cooperative activity in four questions (e.g., "This referral program offers a win-win opportunity for me and [the listed person]. (1 = strongly disagree, 7 = strongly agree)"). We found a main effect that disclosure increased the likelihood to refer ($\chi^2(1) = 4.66$, $p = .03$), and the effect was mediated by the communal perception of the referral process ($Z = 2.73$, $p = .01$; Iacobucci, 2012). Closeness did not moderate disclosure's effect on referral rate ($\beta = .02$, Wald = .02, $p = .90$), suggesting that this effect is generalizable to communal relationships that vary in closeness.

Study 3 tested a boundary condition—disclosure effect would be attenuated when the referral process already appears communal. In a 2 (referrer-reward: disclosed vs. undisclosed) × 2 (activity framing: control vs. communal) between-participants design, current players of Angry Birds 2 or Pokémon Go read an announcement from the game, asking them to invite their friends to join the game so that both can get some game currency. The announcement either emphasized the referrer's benefit (e.g., *"Want to earn gems in Angry Birds 2?"* control condition) or the communal benefit of friends playing the game together (e.g., *"Angry Birds 2 is more fun with friends!"* communal condition). Afterward, participants read a referral email, which either disclosed the referrer-reward or not, and indicated their willingness to refer to friends (1 = definitely No, 7 = definitely Yes). We found that disclosure increased willingness to refer in the control condition ($F(1, 157) = 5.78$, $p = .02$) but not in the communal condition (if anything, an unexpected marginal reversal; $F(1, 157) = 2.98$, $p = .09$).

Study 4 tested another boundary condition—disclosure would have a negative effect on referring when it signals a clear conflict-of-interest between the referrer and the referee. The study procedure was similar to that of study 1a, except that we orthogonally manipulated whether the referrer-reward came from the coffee company (no-conflict-of-interest) or from the referee's purchase (conflict-of-interest). We found that disclosure increased referring in the no-conflict-of-interest condition ($\chi^2(1) = 8.66$, $p < .01$) but marginally reduced referring in the conflict-of-interest condition ($\chi^2(1) = 3.25$, $p = .07$).

This research suggests an easy and costless way to improve the effectiveness of referral programs. It also demonstrates that disclosing the persuasion agent's benefit can enhance or diminish persuasion attempts, which complement the persuasion knowledge literature and the disclosure of conflict-of-interest literature that mainly focuses on the negative effect of disclosure (Campbell and Kirmani 2000; Sah and Loewenstein 2015).

What You Do Or What You Don't: The Impact of Framing on Goal Level Setting

Mirjam Tuk, Erasmus University Rotterdam, The Netherlands
Sonja Prokopec, ESSEC Business School, France
Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Goals are a key determinant of motivated consumer behavior, and previous research showed that ambitious, specific goal levels have a positive impact on performance (Latham and Locke 1991; Locke & Latham, 2002). While the relationship between goal levels and performance has been studied extensively, much less is known about the *determinants* of goal level setting. What leads a consumer to decide to work out twice or three times per week? Why does a student decide to attend 15 or 17 out of 20 lectures? The aim of the current work is to fill this gap and to examine how we can nudge consumers into setting more ambitious goal levels.

We propose that how the goal level decision is framed has a strong impact on the eventual goal level set. Specifically, when setting a goal level, one can think about how much of a certain goal one wants to undertake (e.g., work out 3 out of 7 days per week; attend 18 out of 20 lectures; "inclusion frame") but also about how much one wants to forego (e.g., forego working out 4 out of 7 days; skip 2 out of 20 lectures; "exclusion frame"). We expect that consumers consistently set more ambitious goal levels when they are considering how much of a certain goal to forgo (exclusion frame). We argue and show that this decision to forgo goal-directed activities is inconsistent with the actual goal and highlights a discrepancy between the current self and the ideal self (as someone who strives to achieve goals). Self-discrepancies are characterized by experiences of negative feelings such as guilt, stress, worry, tension and discomfort, and in turn can trigger a drive to compensate (Allard and White 2015; Higgins 1987; Mandel et al., 2017). A key way to compensate for these negative feelings is by 'direct resolution' – directly dealing with the source of the discrepancy. Setting more ambitious goal levels is a way to directly resolve a self-discrepancy. Thus, we expect that a consideration of how many goal-directed activities to forego will make consumers feel bad about themselves and that they will compensate for this negative feeling by setting higher goals.

In Study 1A, we examine the impact of goal-level framing across 6 different real-world contexts. Specifically, we find that sophomore students plan to study 5.3% more hours when setting their study goal in an exclusion frame (e.g., when asked how many study hours to skip vs. to work on the course). Master students aim to attend 12.5% more seminars when indicating their seminar plans in an exclusion frame (e.g., when asked how many of the scheduled 20 seminars they planned to skip vs. attend). Mturk participants decide to save 17% more of their discretionary income when setting a savings goal in an exclusion frame. They also aim to solve 10.6% more puzzles in order to earn raffle tickets when asked to set their goal level in an exclusion (vs. inclusion) frame, and subsequently solve more puzzles. Finally, students plan to eat 13.5% more vegetables when setting their consumption plan in an exclusion frame, and their performance closely follows their goal level (all *d*'s > .30, *p*'s < .05). In Study 1B, we show that participants who set their goal level in an exclusion frame plan to evaluate 35% more pictures in order to raise money for charity and that they in turn evaluate 20.7% more pictures as compared to participants in the inclusion frame or in a neutral baseline condition. This suggests that it is the exclusion frame that drives goal levels up, rather than that it is the inclusion frame that moves goal levels down.

In Study 2, we aim to rule out a variety of alternative explanations based on the usage of reference points. We show that the framing effect emerges ($F(1,300) = 21.10$, $p < .0001$, $\eta_p^2 = .066$) irrespective of whether people indicate their goal level on an open-ended scale, use a slider scale where the slider is either positioned at the highest or the lowest possible goal level, or when they are asked to indicate a range of acceptable goal levels (e.g., a minimum and a maximum goal level). The framing effect is not influenced by any of these manipulations, evidenced by no main effect of response format ($F(1,300) = 0.18$, $p = .839$, $\eta_p^2 = .001$) and no interaction effect between response format and frame ($F(1,300) = 0.40$, $p = .668$ $\eta_p^2 = .003$).

The aim of Study 3 is to show that the framing effect crucially depends on the emergence of a self-discrepancy. Specifically, while excluding goal-directed activities feels bad and should cause compensatory responses, the same should hold for the inclusion of goal-undermining activities. For example, both skipping healthy meals and having unhealthy meals should make participants feel bad. Hence, in Study 3 we manipulate both the framing (have. vs. skip) and the nature of the activity (healthy vs. unhealthy food). We exposed participants to a scenario in which they were asked to imagine having a goal to improve their health. Their work-place cafeteria offers a healthy-lunch program where healthy lunches are offered for the next 30 days in addition to the regular offerings. Participants were then asked to think and indicate how many (un)healthy lunches they would plan to have/ skip. Next, we recoded all responses to reflect the number of healthy foods participants wanted to have and we found a significant interaction effect $F(1,478) = 126.20$, $p < .0001$, $\eta_p^2 = .21$. Participants plan to have more healthy meals when they decide how many healthy meals they want to skip (M = 25.44) vs. have (M = 22.37), but they also plan to have more healthy meals when they decide how many unhealthy meals they want to have (M = 24.83) vs. skip (M = 13.92), all p's < .001. This study shows that the framing effect depends on the emergence of a self-discrepancy, which will arise both when including goal-inconsistent acts and excluding goal-consistent acts.

The aim of study 4 is to provide further evidence for a self-discrepancy as the key driver of the effect. If the framing effect is driven by a need to compensate for feeling bad about foregoing goal-directed opportunities, then we should find that this effect reduces if the activity for which the goal level is set is less instrumental towards goal achievement. In the end, it is less bad for goal-achievement to skip acts that are only of limited instrumental value to the goal, then it is to skip acts that are of high instrumental value. In study 4, all participants were recruited as being 'employed' and were asked to imagine that they planned to take a course aimed to improve their work performance. Half of the participants read that the course was of incremental value to improving their core work competencies, while the other half read that the course was of key importance to improve their core work competencies. Next they were asked to indicate how many of the 20 course sessions they would plan to attend / skip. We find that the framing effect crucially depends on the instrumentality manipulation, as indicated by a significant interaction effect between frame and instrumentality, $F(1,291) = 3.77$, $p = .053$, $\eta_p^2 = .013$. Specifically, while participants set higher goal levels in the exclusion frame (M = 17.13) than in the inclusion frame (M = 15.65) in the high instrumental condition, there is no difference between

exclusion frame (M = 15.75) and inclusion frame (M = 15.71) in the low instrumental condition.

In study 5 we aim to provide further evidence for a compensatory mechanism based on the experience of a self-discrepancy. Specifically, as Mandel et al. (2017) argue, a self-discrepancy can be resolved in different ways. Consumers can directly compensate for the experience of the self-discrepancy (e.g., through setting higher goal levels, as we consistently find), but they can also engage in other strategies. One effective strategy to cope with self-discrepancies is fluid compensation – the notion that affirming the self in an unrelated domain can nevertheless effectively reaffirm one's sense of the self as a capable, worthy individual. If the self is reaffirmed in an unrelated domain, then subsequently the need for other forms of compensation diminishes. This reasoning leads us to expect that confronting participants with a self-affirmation in an unrelated domain should reduce the need for compensatory responses and consequently reduce the impact of the exclusion frame on the goal level. We examined the impact of self-affirmation in Study 5. Specifically, participants read that they had the goal to improve their physical health and found a 30-session fitness course. However, they also realized that it might be difficult to attend to all the sessions [**as they occasionally engaged in charity activities for their local community**]. The latter part in bold was only included in the self-affirmation present condition. Next, half of the participants were asked to indicate how many sessions they planned to attend, while the other half were asked to indicate how many sessions they planned to skip.

Results show that the self-affirmation reduces the emergence of the framing manipulation, as evidenced by a marginally significant interaction effect, $F(1,191) = 3.56$, $p = .061$, $\eta_p^2 = .019$. Specifically, participants set more ambitious goal levels in the exclusion (M = 25.02) condition as compared to the inclusion condition (M = 20.52) in the self-affirmation absent condition. Contrary, goal levels were comparable in the exclusion (M = 22.85) and inclusion (M = 21.06) conditions in the self-affirmation present conditions. Hence, study 5 provides further evidence for the notion that a self-discrepancy drives the emergence of a framing effect, which is much less pronounced when the self is affirmed in a completely different context.

Finally, in Study 6, we aim to provide evidence for the process through mediation. However, we do not expect a traditional mediation pattern. Specifically, we expect that the impact of feelings on goal level crucially depends on the framing condition one is in. In the exclusion frame, consumers are expected to feel bad about skipping goal-directed activities. This experience of feeling bad in turn is expected to drive them to compensate and set higher goal levels. Hence, we expect a negative relationship between feelings and goal level in the exclusion frame. Contrary, people are generally expected to feel good in the inclusion frame, and not to experience a drive to compensate. Contrary, based on previous work (Cameron, Bertenshaw, and Sheeran 2018) we would expect that there is a positive relationship between feelings and goal level within the inclusion frame. In other words, we expect the impact of the mediator (feelings) on the DV (goal level) to depend crucially on the level of the IV (inclusion vs. exclusion frame). We tested for this effect in Study 6. Specifically, participants were again told that they had the goal to eat healthier and that their workplace cafeteria offered a 30-day healthy lunch program. Next, they read that they decided on how many healthy lunches to have or to skip, and were asked to indicate

how they felt about deciding to **skip / have** healthy meals (100-pt scale where 0 = very bad – 100 = very good). Then they were asked to indicate their goal level, and lastly evaluated how they felt about their plan. Results showed that people felt much worse about making an exclusion vs. inclusion decision, $t(121.45) = 8.23$, $p < .001$, $d = 1.43$ (corrected for inequalities in variance) but set higher goal levels in the exclusion vs. inclusion condition $t(111.45) = 1.88$, $p = .063$, $d = 0.33$ (corrected for inequalities in variance). Participants still felt slightly worse about their goal level after having made the decision in the exclusion frame, but this effect was much smaller than their feelings before making the decision, as evidenced by a significant repeated measures ANOVA, $F(1,130) = 36.19$, $p < .001$, $\eta_p^2 = .22$ (see Table 1 for all means).

Moreover, Process Model 74 (Preacher et al., 2007) confirms the existence of a positive indirect effect of the inclusion frame through feelings on goal level, and a negative indirect effect of the exclusion frame through feelings on goal level (see Figure 1).

Hence, this study shows that the exclusion frame makes people feel worse, which in turn prompts them to set higher goal levels.

In sum, the current work makes important contributions. First, where previous research studied the impact of (externally provided) goal levels on performance, we shed light on how consumers come to set their own goal levels. We show that a simple change in how the goal level decision is framed (as an exclusion rather than an inclusion decision) can lead to significantly higher goal levels, which in turn also lead to higher performance. Second, we contribute to the framing literature by showing that framing can influence goal level and trigger compensatory responses. Finally, we believe that our work has important and directly relevant practical implications. The framing manipulation we employed is easy to implement in various contexts where consumers set goal levels for themselves, such as when making savings decisions, setting exercise goals or setting goals to eat healthier. The current work suggests that simply prompting consumers to make an exclusion decision can significantly increase their goal levels, with direct downstream consequences on performance.

Alexa or Alex or Neither? Exploring Gender-Neutral
Voices, Gender Framing and Consumer Judgments of Synthetic Voices

Broderick Lee Turner, Virginia Tech, USA
Brett Christenson, Pennsylvania State University, USA

EXTENDED ABSTRACT

At any given time, more than a billion consumers are interacting with smart products, such as smart-phones and smart-speakers which are enabled with synthetic voice-prints, i.e., computer-generated voices unique to each device (Perez, 2019). These voice-prints are an aesthetic product characteristic which is made salient to the consumer through social interaction, similar to a human agent (Reeves and Nass, 1996). Similar to human characteristics which influence the perception of personality, a product's aesthetics are a major determinant of its personality (Aaker, 1997). For example, round shapes, curvy lines, and more colors indicate femininity, while angular shapes, straight lines, and darker tones are often categorized as masculine (Van Tilburg, Lieven, Herrmann, and Townsend 2015).

With regard to voice-prints, research indicates people very easily and accurately perceive information about a speaker, such as its gender (Whiteside, 1998). The pitch of a voice very reliably signals an individual's gender, with female voices being higher pitched than males (Kreiman & Sidtis, 2011). However, pitch can be manipulated and firms can create a synthetic voice with a pitch that sounds female or male. Moreover, firms can choose to refer to their voices with gendered pronouns (he and she) and names (Apple's Siri, Amazon's Alexa), which we define as gender-framing. However, given the societal recognition of non-binary gender identities, it is not necessary for firms to limit their synthetic voices to a gender binary in either pitch or framing.

Prior work on vocal communication indicates that when one hears a low-pitch voice, they tend to assume the voice is male whereas when one hears a high-pitch voice, they assume the speaker is female. However, with the control afforded in creating a synthetic voice-print, firms can generate voices with pitches which may not be perceived as male- or female-pitched. An as yet developed alternative would be a neutrally pitched, and therefore gender-neutral, voice.

Moreover, firms can decide to simply frame these voices as gender-neutral, such as Google choosing to refer to their synthetic voice as simply the Google Assistant.

The goal of this research is to provide the initial entrée into understanding the effect of gender neutral-pitch and gender neutral-framing on consumer judgments. We focus on consumer perceptions of both warmth and competence. These judgments are important because they are considered universal dimensions of social perception (Fiske, Cuddy, & Glick, 2007) and have been shown to explain more than 80 % of the variance of one's dispositional judgments of others (Wojciszke, Bazinska, & Jaworski, 1998). Warmth reflects perceived intent, i.e., the likelihood that another means one help or harm. Competence reflects one's ability to carry out this intent and is often measured in dominance, confidence and intelligence.

Prior research on voice pitch does not make strong predictions for how one might respond to a gender-neutral voice. This work does show speakers with lower pitch are typically perceived as being more warm *and* more competent than speakers with higher voice pitch (Klofstad, Anderson, & Nowicki, 2015; McAleer, Todorov, & Belin, 2014; Tigue, Borak, O'Connor, Schandl, & Feinberg, 2012; Tsantani, Belin, Paterson, & McAleer, 2016). However, female voices are seen as warmer in vocal quality than men, while males are often seen as more competent (Ko, Judd and Stapel 2009; Oleszkiewicz et al.

2017). Thus, this research makes two contributions. This is the first research in marketing, or related fields such as psychology, to explore gender-neutral voices. This is made possible by new developments in technology which make the creation of synthetic voices possible for testing. Indeed we create our own gender- neutral voice as original stimuli. Second, this research provides the first data to a novel question, what is the effect of gender-neutral pitch and gender-framing of synthetic voices on perceptions of warmth and competence?

Creating A Gender-Neutral Synthetic Voice

For humans, the pitch of a voice, or how high or low it sounds, is determined by the biological structure of the throat (Baken, 1987; Tusing & Dillard, 2000). The anatomy of the vocal cords limits a person's ability to modulate their voice pitch, creating fundamental acoustic differences between the male and female voices, most notably in its pitch (Childers and Wu, 1991). To create a gender-neutral synthetic voice we enlisted the help of a professionally trained audio technician who recorded a human female and a human male speaking the same prepared statements, matched for timing so that all phrases were spoken at the same rate and volume.

Next, the pitch of the recordings was manipulated by software to measure and adjust the fundamental frequency (Praat v5.3.56, Boersma & Weenink, 2013). In line with recommended settings for pitch analysis, typical male pitch range is 75-200 Hertz (Hz), with the male recording having a fundamental frequency inside this range (Mmale = 85.38 Hz). Typical female pitch range is 100-300Hz, with the female recording having a pitch inside this range (Mfemale = 142.85 Hz, Baken, 1987; Tusing & Dillard, 2000). Therefore, both recordings had a fundamental frequency within the acceptable range for a male and female voice, respectively. Additionally, the pitch shift tool was used to adjust the pitch of each recording to be on the border of their natural range, but overlapping with the opposing sex range. These overlapping recordings were then combined to form an average, or genderless recording which matched the speed and volume of the male and female voices while also being in a pitch range ambiguous in terms of gender (Mneutral = 107.54 Hz). In a pre-test using 104 participants from an online panel (mTurk), the voices were tested to ensure they were accurately perceived as male, female, and gender neutral. Participants were randomly assigned to listen to one of the prepared recordings and then rate the voice in terms of its pitch on a 7-point scale (1 = Very Low Pitched; 7 = Very High Pitched).

Comparison of the means between voices indicates each recording was accurately perceived along the desired gender lines. The female voice was rated highest in pitch (Mfemale = 5.37), and was significantly greater than the neutral voice (Mneutral = 3.66), which was significantly higher in pitch than the male voice (Mmale = 3.01, $F(2, 132) = 19.86$, $p = < .001$, $\eta^2 p = .231$). Important to the current study, the gender neutral voice was not rated significantly different from the midpoint of the 7-point scale for pitch, indicating it was rated equally as male and female.

Study 1: Gender Framing Effect On Gender Neutral-Pitch Voices

The goal of this pre-registered study is to test the effect of gender framing on the perception of warmth and competence. This study

employed a single factor (Framing: Male vs. Female) between-subject design. The outcome variables of interest are participants' perception of warmth and competence.

Method

Participants. We recruited one hundred and eight US-based consumers from an online panel who owned at least one product with a synthetic voice (45% Female; $M_{age} = 36.8$, $SD = 11.6$) participated in exchange for a nominal payment.

Materials and Procedures. We informed participants they would answer questions about a digital assistant. All participants were then played 4 short snippets of a gender-neutral synthetic voice (107MHZ). The voice was described as the voice of a male or female digital assistant.

After listening to the voices, participants answered their agreement with how they described the voice (1 = Strongly Disagree, 7 = Strongly Agree) on dimensions of warmth (Sociable, Caring, Unfriendly (reverse-scored), Insensitive (reverse-scored), Warm; $\alpha = .85$) and competence (Capable, Skilled, Lazy (reverse-scored), Disorganized (reverse-scored), Competent, $\alpha = .78$). Additionally, participants indicated their perception of the voice's femininity (1 = Very Feminine, 7 =Very Masculine), speed (1 = Very slow speaking, 7 = Very fast speaking), volume (1 = Very Quiet, 7 = Very Loud), and pitch (1 = Very low pitched, 7 = Very high pitched).

Results

Manipulation Checks. Regardless of framing, participants rated the voice as similar in femininity ($t(104) = 1.18$, $p = .24$), speed ($t(104) = 1.49$, $p = .14$), volume ($t(104) = .22$, $p = .82$). Importantly, when we ask people to consider the pitch, effectiveness of the gender framing manipulation should alter the perception of the voice. If participants are following the manipulation, then the perception of a voice with a pitch that falls lower then then the expected female pitch range, and higher than the expected male-pitch range should be malleable and dependent upon the gender-framing. Expectedly, when we describe the voice as male, participants indicate that the pitch is high ($M = 4.46$, $SD = 1.34$, one-sample t-test against the midpoint of the scale, $t(51) = 2.52$, $p = .014$) and the female voice is described as low ($M = 3.35$, $SD = 1.60$, one-sample t-test against the midpoint of the scale, $t(51) = 2.95$, $p = .005$). This difference in pitch perception indicates the effectiveness of our gender-framing manipulation.

Warmth and Competence. A repeated-measure ANOVA with gender framing (male vs. female) on measures of warmth and competence revealed no interaction with gender framing and the measurement of warmth or competence ($F(1, 104) = 2.66$, $p = .11$). However there was a main effect of the within-subject rating of warmth and competence ($F(1, 104) = 26.28$, $p < .001$, as participants rated the voices as more competent ($M = 4.52$, $SD = 1.32$) than warm ($M = 3.93$, $SD = 1.53$). Moreover, there was a main effect of the between-subject gender framing ($F(1, 104)= 9.77$, $p = .002$), such that the male-frame was rated more positively ($M = 4.59$, $SE = .17$), than the female-frame ($M = 3.84$, $SE = .17$). Indeed, when comparing the gender-framing on each measure individually, a male-frame leads to a higher warmth rating ($M = 4.39$, $SD = 1.50$) than the female frame ($M = 3.45$, $SD = 1.42$, $t(104) = 3.328$, $p = 0.001$) , and the male-frame ($M = 4.80$, $SD = 1.27$) also leads to higher competence rating than the female frame ($M = 4.23$, $SD = 1.33$, $t(104) = 2.26$, $p = 0.026$). The male-framing of a gender neutral voice leads to more positive evaluations of both warmth and competence. Given consumers do alter their perceptions of the voice's warmth and competence, the next study aims to both replicate this effect, and test it against gender-neutral framing and no framing.

Study 2: Gender Framing Effect Replication And Extension

The goal of this study is to test the effect of gender framing on the perception of warmth and competence. Importantly, it considers if the effect from Study 1 was simply a function of the male-framing, and if this can be extended to other terms. We included a framing of "gender neutral" and no framing control to establish a baseline. To test this study employed a single factor (Framing: Male vs. Female vs. Gender-Neutral vs. Control) between-subject design. The outcome variables of interest are participants' perception of warmth and competence.

Method

Participants. We recruited two hundred and seven US-based consumers from an online panel who owned at least one product with a synthetic voice. (46% Female; $M_{age} = 37.1$, $SD = 11.4$) participated in exchange for a nominal payment.

Materials and Procedures. We again informed participants they would answer questions about a digital assistant. All participants were then played 4 short snippets of a gender-neutral pitched synthetic voice (107 MHZ). The voice was presented as a male or female or gender- neutral digital assistant, or simply as a digital assistant (control). After listening to the voices, participants answered their agreement with how they described the voice using the same measures from Study 1 on dimensions of warmth ($\alpha = .83$) and competence ($\alpha = .88$). Again, participants indicated their perception of the voice's gender (1 = Very Feminine, 7 =Very Masculine), pitch (this voice is low pitched, this voice is high pitched, 1 = Strongly Disagree, 7 = Strongly Agree), speed (1 = Very slow speaking, 7 = Very fast speaking) and volume (1 = Very Quiet, 7 = Very Loud).

Manipulation Checks. Regardless of framing, participants rated the voice as similar in femininity ($F(3, 202) = .88$, $p = .45$), speed ($F(3, 202) = .39$, $p = .76$), volume ($F(3, 202) = .68$, $p= .57$). Again, when we ask people to consider the pitch the gender framing manipulation alters this perception of the voice. When we describe the voice as male, participants indicate that the pitch is higher-pitched ($M = 3.77$, $SD = 1.82$) than when it is described as gender-neutral ($M = 3.12$, $SD = 1.53$, $t(101) = 1.86$, $p = 0.05$, not labeled ($M = 2.94$, $SD = 1.65$, $t(101) = 1.86$, $p =0.05$), or described as female ($M = 2.56$, $SD = 1.80$, $t(102) = 3.41$, $p < 0.001$). The perception of pitch for the female described voice is not statistically different from the control condition ($t(101) = 1.11$, $p = .27$), nor the gender-neutral condition ($t(101) = 1.70$, $p = .09$), and the control condition and gender-neutral conditions do not differ from each other ($t(100) = .57$, $p = .57$).

This finding gives us some insight that male (vs. female, gender-neutral or control) gender- framing may change the perception of voice-pitch.

Warmth and Competence. A repeated-measure ANOVA with gender framing (male, female, gender-neutral or control) on measures of warmth and competence revealed no interaction with gender framing and the measurement of warmth or competence ($F(3, 410) =.29$, $p = .83$). However there was a main effect of the within-subject rating of warmth and competence ($F(1, 410) = 23.64$, $p < .001$, as participants rated voices, regardless of framing as more competent ($M = 4.94$, $SD = 1.21$) than warm ($M = 3.96$, $SD = 1.39$). Moreover, there was a main effect of the between-subject gender framing ($F(3, 410) = 6.86$, $p < .001$), such that the male-frame was rated more positively ($M = 4.99$, $SD = 1.11$), than the female-frame ($M = 4.15$, $SD = 1.07$, $t(102) = 3.50$, $p < .001$), the gender-neutral framing ($M = 4.49$, $SD = 1.16$, $t(101) = 1.85$, $p = .06$), or the control framing ($M = 4.27$, $SD = 1.23$, $t(103) = 2.75$, $p = .007$), whereas the female, gender-neutral, and control framing are not statistically different from each other (ps >.12, see figure 3 for a decomposition of the effects between warmth and competence).

General Discussion And An Invitation To Replication And Extension

The two preceding studies offer several contributions as well as invitations for future work. First, these studies build on prior work showing that the voice we hear impacts our perceptions of the person speaking. However, these studies seek to expand the literature to include the role gender perception may play in the attributes associated with a product. We produce evidence that both the gender, indicated by pitch, as well as gender framing can play a role in the attributes which are applied to a voice. Additionally, we provide initial evidence for the effect of a non-binary gender voice and framing. The pervasiveness of gender stereotypes has been extensively documented in the psychology literature (Nass, Moon, Green, 1997). In this work, we uncover that male gender framing raises both warmth and competence judgments for a gender-neutral voice. This novel finding provides a starting point for a new stream of research.

However, this work still leaves many questions to be answered. Primarily, what mechanism explains this effect? Instead of offering a speculative candidate mechanism, we want to invite other researchers to replicate this work. Would the effect hold up with populations outside of the US, under more relaxed criteria, or in a real-world setting and not in the confines of an online experiment? While we begin the current exploration, we invite collaboration. To help facilitate this work, all of our manipulations and data are public (https://osf.io/jezp5/).

Holding on for a Hero: Effects of Heroes in Mitigating
Mortality Threats on Unhealthy Consumption

Aulona Ulqinaku, Leeds University Business School, UK
Gulen Sarial Abi, Bocconi University, Italy
Elaine Louise Kinsella, University of Limerick, Ireland

EXTENDED ABSTRACT

We provide a novel avenue for mitigating the unhealthy effects of mortality threats on consumption. We investigated the possibility that heroes help people cope with mortality salience. We specifically tested the role of heroes in mitigating mortality salience (MS) threats by testing their effects on intentional and real compensatory consumption.

Meaning is "the expected relationships or associations that human beings construct and impose on their worlds" (Heine, Proulx, & Vohs, 2006, p. 90). Meaning can be disrupted by incoming information and by experiences that violate people's beliefs and values (Proulx & Inzlicht, 2012). According to the meaning maintenance model (MMM; Heine et al., 2006), Terror Management Theory (TMT; Greenberg, Pyszczynski, & Solomon, 1986), and Protection Motivation Theory (PMT; Rogers, 1975), when people's sense of meaning is threatened, they attempt to reestablish their existing mental structures. Some strategies to reestablish existing mental structures include reinforcing social connections (Wildschut, Sedikides, Arndt, & Routledge, 2006), including membership in enduring structures such as religions and nations (Arndt, Cook, & Routledge, 2004); connecting the past with the present and the future (Sarial-Abi, Vohs, Hamilton, & Ulqinaku, 2017); participating in mundane routines (Heintzelman & King, 2018); purchasing nostalgic (Routledge et al., 2011) and vintage products (Sarial-Abi et al., 2017); engaging in conspicuous consumption (Lee & Shrum, 2012); and believing in supernatural agents such as angels, devils, jinns, ancestor spirits, and God (Jong, Halberstadt, & Bluemke, 2012; Kay, Gaucher, Napier, Callan, & Laurin, 2008).

Despite the importance of psychological threats and extant research on how individuals cope when they are psychologically threatened, previous research lacks an understanding of how heroes may be used to cope with psychological threats. While previous research in psychology suggests that heroes help individuals to cope with threats (Kinsella, Igou, & Ritchie, 2017), research in psychology lacks empirical evidence on how heroes help individuals to cope with threats. In this research, we propose that heroes help individuals to cope with threats by bolstering personal power (i.e., the power to act in autonomy and to control one's own resources; Van Dijke & Poppe, 2006).

Heroes and Meaning in Life

The concept of heroes has existed since ancient times and remains important in modern society. In a survey conducted in 25 countries, 66% of people reported having at least one hero in their lives (Kinsella, Ritchie, & Igou, 2015a). Heroes are important for redefining individuals' well-being in contemporary culture (Franco, Efthimiou, & Zimbardo, 2016), and they have psychological importance to humankind (Sullivan & Venter, 2005).

While heroes are common in people's everyday lives, they are not easy to conceptualize theoretically (Franco, Blau, & Zimbardo, 2011; Kinsella et al., 2015a). Recent research identified the prototypical features of heroes (e.g., brave, fearless, selfless, self-sacrificing, honest, strong, and having moral integrity; Kinsella et al., 2015a) and their key peripherals (e.g., powerful, risk-taker, fearless, caring, exceptional, and strong).

Heroes provide psychological resources to people (e.g., helping individuals with self-identification, Veen & College, 1994; affecting self-perceptions, Sullivan & Venter, 2005; and reducing death thought accessibility; McCabe, Carpenter, & Arndt, 2016).

Thinking about heroes helps individuals identify with them more, thus reducing death-related thoughts (McCabe et al., 2016). Heroes can enhance meaning both in the presence and absence of a meaning threat (Kinsella et al., 2017).

The present research extends previous work in this domain (e.g., Coughlan, Igou, van Tilburg, Kinsella, & Ritchie, 2017; Kinsella et al., 2017), by examining one mechanism through which heroes provide psychological resources to people. Specifically, we examine whether heroes can serve to bolster *personal power* (i.e., the power to act in autonomy and to control your own resources; Van Dijke & Poppe, 2006), thus enhancing meaning in life or helping reestablish it when one's sense of meaning is threatened.

Heroes, Power, and Meaning in Life

We suggest power plays an important role in the relationship between heroes and individuals' meaning in life. This relationship exists for two main reasons: (1) heroes are perceived as figures vested with power (Becker, 1973; Kinsella et al., 2015a; Lash, 1995) and (2) power is an important psychological factor. Sense of power is defined as the ability to achieve what the individual desires without being influenced (Galinsky, Magee, Gruenfeld, Whitson, & Liljenquist, 2008; Van Dijke & Poppe, 2006). It is a need to act for yourself, to control the environment, to overcome resistance, to reach goals, and to pursue autonomy (Van Dijke & Poppe, 2006). We want to differentiate this from social power, which is defined as the ability to make others behave in a way they would not otherwise behave (e.g., a CEO over the employees; Van Dijke & Poppe, 2006). Although these two types of power can coexist in life (Lammers, Stoker, & Stapel, 2009), personal power is related to autonomy over one's own actions and resources, and social power is more linked to control of other people's actions and resources.

An enhanced sense of power can protect individuals from threats (Anderson & Berdahl, 2002; Kay et al., 2008). Individuals with a higher sense of power demonstrate a lower tendency to feel threatened (Anderson & Berdahl, 2002); they are less bothered about what happens in their social environments because they perceive themselves to be independent and free from others (Lammers et al., 2009). Perceptions of power increase meaning in life (Anderson & Berdahl, 2002; Galinsky, Rucker, & Magee, 2015; Keltner, Gruenfeld, & Anderson, 2003; Rousseau & Garcia-Retamero, 2007). Accordingly, when one's sense of personal control is threatened, people start believing in someone or something else (e.g., God or an institution) perceived to be vested with much power.

We suggest heroes also have power that helps individuals to enhance meaning in life. What kind of power do heroes have to help individuals enhance meaning in life?

While heroes are vested with power (Becker, 1973; Kinsella et al., 2015a; Lash, 1995), the type of power heroes are vested with must be specified. Research suggests two types of power: social and personal (Lammers et al., 2009). Heroes have a high degree of autonomy, which is the main feature of personal power, and they em-

ploy their power for independence over their actions rather than to push others to do something (Lash, 1995). Applying this logic here, we propose the personal power of heroes can help people enhance meaning in their lives. Hence, we refer to personal power when we discuss sense of power.

How can heroes' power help individuals enhance their meaning in life? During an interaction with a hero, the individual feels a strong connection leading to vicariously experienced attributes. These vicarious attributes lead to a change in behavior (Holt & Thompson, 2004). Simply by being reminded of a hero, some aspects of the hero are transferred to individuals. For example, reminders of heroes in product packages bring to mind safety and protection related to the product on which the hero label is placed (Masters & Mishra, 2019). The protective traits of heroes can be extended to the product if a hero label is attached to it; hence, the product is vested with heroic traits (i.e., protectiveness and safety). Applying this logic here, if heroes have personal power, even a mere association with the hero would be sufficient to enhance individuals' sense of power, analogous to the findings of Goldstein and Hays (2011) where mere associations with a powerful person (e.g., a CEO) would enhance someone's sense of power.

Pilot Study

In an observational pilot study on Twitter, after several terrorist attacks that have occurred in 2016-2017 (N = 154,390 tweets) we noticed that in tweets that used the hashtag #hero, the MS rating (measured with LIWC2015) was lower (β = -.999, p <.001). These results provided preliminary evidence that reminder of heroes might be related to lower MS.

Study 1

In Study 1, we tested our prediction that hero reminders affect individuals' meaning in life by investigating how individuals who are (vs. are not) reminded of heroes need to search less (vs. more) for meaning in life. Fifty-two undergraduate students participated in a European university laboratory session in exchange for course credit. participants were first randomly assigned to either the hero reminder or the non-hero reminder condition (Kinsella et al., 2015a). Then participants were asked to specify three people they knew who shared the characteristics of the person described in the text and to briefly describe them. In the second part of the study, to measure the search for meaning in life, we used the Search for Meaning in Life scale (Steger et al., 2006).

Results

As expected, participants in the hero reminder condition scored lower in Search for Meaning in Life compared to those in the non-hero reminder condition (M_{Hero} = 4.75, SD_{Hero} = 1.20 vs. $M_{Non-Hero}$ = 5.36, $SD_{Non-Hero}$ = .89, t(50) = 2.10, p = .04, Cohen's d = 0.63, r = .30).

Study 2

In this study, we tested the prediction that hero reminders positively influence individuals' sense of power. One hundred and ten students (27 male) participated in a university laboratory session in exchange for course credit. First, they were randomly assigned to either the hero reminder or the non-hero reminder condition as in Study 1. Then participants were told the first part of the study was over and they would begin a second part, unrelated to the former one. We administered the 8-item Sense of Power scale adapted from Anderson and Galinsky (2006). After that, participants indicated age and gender.

Results and Discussion

Purpose in life. We predicted participants in the hero reminder condition would score higher on purpose in life than participants in the non-hero reminder condition would. As expected, purpose in life was higher in the hero reminder condition than it was in the non-hero reminder condition (M_{Hero} = 3.56, SD_{Hero} = .69 vs. $M_{Non-Hero}$ = 3.20, $SD_{Non-Hero}$ = .93, t(108) = 2.35, p = .02, Cohen's d = 0.45, r = .22).

Perceived sense of power. As predicted, participants in the hero reminder condition scored higher on perceived sense of power than those in the non-hero reminder condition did (M_{Hero} = 3.82, SD_{Hero} = 0.60 vs. $M_{Non-Hero}$ = 3.55, $SD_{Non-Hero}$ = 0.84, t(108) = 1.99, p = .049, Cohen's d = 0.38, r = .19).

Perceived sense of power as the underlying mechanism. We next tested whether a perceived sense of power mediated the effect of the hero reminder (vs. the non-hero reminder) condition on purpose in life. The results of PROCESS revealed a significant indirect effect via perceived sense of power (β = 0.12, 95% CI: [.01, .28]). The results supported our prediction for the mediating effect of the perceived sense of power on purpose in life.

Study 3a

In study 3, we demonstrated that reminder of heroes (vs. acquaintances) helps individuals mitigate compensatory consumption during MS. This study used a four cells design: 2 (MS, control) x 2 (hero, acquaintance), where participants first wrote about MS (vs. dental pain; Burke et al., 2010). Next, participants described a hero (vs. acquaintance). To measure compensatory consumption, we used unhealthy food consumption (Ferraro et al., 2005; Mandel & Smeesters, 2008). Hence, we asked participants to imagine having a bowl of M&Ms (unhealthy) and one of grapes (healthy) in front of them and to take as many as they wanted (our dependent variable was the number of grapes minus M&Ms hypothetically consumed As predicted, results revealed a marginal two-way interaction effect of meaning threat (threat, control) and heroism (hero, no-hero) and on compensatory consumption, (F(1, 196) = 3.002, p = .08). Supporting our prediction, participants who were exposed to the meaning threat condition showed lower values of healthy compensatory consumption (and hence higher unhealthy compensatory consumption) when they were not reminded of heroes (i.e., acquaintance reminder; $M_{Threat-Hero}$ = 22.38, $SD_{Threat-Hero}$ = 156.22 versus $M_{Threat-No-hero}$ = -86.32, $SD_{Threat-No-hero}$ = 280.74, F(1, 196) = 7. 47, p = .007, Cohen's d = .48, r = .23). As predicted, participants who were exposed to the non-threatening conditions did not differ on their compensatory consumption values across hero and acquaintance conditions, suggesting this way that heroes mitigate the effects of meaning threats on compensatory consumption (p = .774). Had the hero not mitigated for the meaning threats, we would have observed a significantly lower value in healthy compensatory consumption in the threatening condition. In fact, the difference between the healthy compensatory consumption of threatened compared to non-threatened participants not reminded of heroes was significant ($M_{No-Hero-Threat}$ = -86.32, $SD_{No-Hero-Threat}$ = 280.74 vs. $M_{No-Hero-Control}$ = 23.59, $SD_{No-Hero-Control}$ = 153.99, F(1, 196) = 7.55, p = .007, Cohen's d = 0.49, r = .24). No differences were observed between the hero and no-hero (i.e., acquaintance) conditions when participants were not exposed to meaning threats (p = .798).

Study 3b

Study 3b tests our predictions in real life, in the field, in a natural setting with high MS, collecting our data on the Day of the Dead (MS), and then 3/4 days later (control).

Ninety-six participants (50 male) participated in our field study on the 1st, 2nd, 5th, and 6th of November. After writing about the festivity – enhanced MS – (vs. nothing) participants wrote about their hero (vs. nothing). To thank them for participating in our study, we offered candies from a bowl, our dependent variable. As predicted, an ANOVA on the number of candies consumed revealed the predicted interaction ($F(1, 93) = 10.609$, $p =$

.002). Those who were in the MS condition consumed a greater number of candies when they were not reminded of their hero ($M_{MS-Hero} = 0.79$, $SD_{MS-Hero} = 0.98$ vs. $M_{MS-NoHero} = 1.74$, $SD_{MS-Nohero} = 1.38$, $F(1, 93) = 8.98$, $p = .004$, Cohen's $d = 0.80$, effect size = .37). Again, the number of candies consumed in threat versus control conditions among those reminded of heroes did not differ ($p = .138$), suggesting that heroes might mitigate compensatory consumption.

Conclusions

The concept of heroes offers several important psychological benefits to individuals reminded of them. Heroes represent the "ideal self-image" (Sullivan & Venter, 2010, p. 437), they evoke moral and socially acceptable behavior (Goethals & Allison, 2012), they help reestablish meaning in life (Coughlan et al., 2017; Kinsella et al., 2017), they give people a sense of purpose in life and hopefulness when experiencing threats (Kinsella, Ritchie, & Igou, 2016), and they provide psychological protection and moral guidance (Kinsella et al., 2015a, 2015b). The present research adds to the previous literature by demonstrating that heroes can also enhance the sense of power of individuals reminded of heroes. Moreover, we demonstrate that due to this increased sense of power, individuals can enhance meaning in life more effectively than they would otherwise and this can block unhealthy overconsumption. We hope this research will inspire further research on the effects of hero reminders on meaning in life, showing their effect on other types of meaning threats as well (e.g., social exclusion or rejection, identity threats, etc.). Moreover, we hope this research will expand the field of research on heroes, from psychology to consumer behavior.

Market Radicalization: Exploring Reversed Co-optation in Far-Right Consumer Culture

Sofia Ulver, Lund University, Sweden
Tina Askanius, Malmö University, Sweden

EXTENDED ABSTRACT

With the global rise of populist right politics (Berman 2019; Krastev and Holmes 2019; Masood and Nasir 2020) consumer researchers have begun to pay more attention to consumer resistance leaning on far right ideologies (e.g. Cambefort and Pecot 2019; Castelló and Mihelj 2018; Luedicke, Thompson and Giesler 2010; Ulver and Laurell *forthcoming*). In tandem, a commercialization of extremist far-right consumer culture has nourished through an aesthetic mobilization of sophisticated marketing. Brands like German *Thor Steinar*, Ukrainian *Svastone*, Russian *White Rex*, Swedish *DFS*, Italian *CasaPound*, Kiev-based *MilitantZone*, and American *OfficialProudBoys*, have managed to successfully absorb the aesthetic branding techniques of mainstream brands and sell thier goods at sophisticated websites through ambiguously coded iconography. This market movement accompanies a larger shift where the embodied far-right has successively gravitated away from skin-head life style markers such as shaved heads, bomber jackets and military boots in favor of new, more ambiguous and subtle markers of belonging along with new and more lifestylish modes of community-building and strategic communication online. Not only do these brands mark affinity for the already converted, but according to research in cultural sociology they work systematically to normalize extreme right ideologies and recruit new young people by way of consumer culture (Miller-Idriss 2017). In this research, we aim to contribute to consumer culture theory (CCT) (Arnould & Thompson 2005) by shedding light on how a political movement mobilizes material goods to begin to radicalize consumers into extreme political activism. To better understand how market actors contribute to political radicalization of consumers, we explore these new forms of commercialization and aesthetization of extreme right movements online.

In consumer culture theory (CCT) (Arnould and Thompson 2005) researchers on consumer activism and resistance have long debated whether ideologically motivated consumption and market actors' political stances actually do have aimed political consequences (e.g. Gopaldas 2014; Thompson & Coskuner-Balli 2007ab; Thompson & Kumar 2018; Kozinets 2002) or instead lead to neoliberal *de*-politicization of citizens into mere consumers (e.g. Bertilsson 2015; Brunk, Giesler & Hartmann 2018; Giesler & Veresiu 2014; Holt 2002; Veresiu & Giesler 2018). The heart of the issue in these articles is the either destructive or potentially constructive relationship between consumption and capitalist ideology, where the critics argue that market expressed involvement in political issues is a co-opting, false veneer to cover their capitalist profit motives, and in the end only distracts from actual political activism. However, in our case of far-right commercialization, the heart of the issue is reversed; here the market actors use a capitalist market veneer to normalize and de-stigmatize their political past (Miller-Idriss 2017) to ultimately effectuate extreme political activism. Moreover, at this stage we focus on the market techniques of radicalization rather than on the consumers *per se*.

We position the phenomenon of far-right commercialization at the intersection of abovementioned body of literature in CCT on ideology and activism, and theoretical insights on radicalization, social movements, iconography and materiality/material culture in cultural and political sociology dovetailing on three major "turns:" (1) the *iconic turn* (Bartmanski & Alexander 2012), (2) the *material turn* (Miller 2010), and (3) the *affective turn* (Ahmed 2014).

To identify aesthetically radicalizing techniques in line with these turns, we use *visual methodologies* (Doerr 2017; Miller-Idriss 2019; Rose 2016) at a small selection of far-right webshops in Europe and the United States. These brands were selected based on searches for far-right brands through the media analysis tool *Retriever*. In line with Miller-Idriss' (2017) findings in far-right consumer culture, we analyze projected political branding techniques, coded symbols and iconography, and pay detailed attention to how the websites and their merchandise are explicitly or implicity laced with extremist, anti-Semitic, Islamophobic, homophobic and misogynist messages and symbols.

Our results indicate a flourishing commercialization of the far-right, by help of two main dimensions of simultaneous branding techniques; (1)*de-historicizing the past*, and (2) *politicizing the present*. In turn, these techniques include materialized techniques such as; using soft environments, situating models in contemporary lifestyle milieus to de-historicize, and combining argument with emotion, and using dark humour to politicize.

We situate our findings in the broader social, economic and political context and see the case of commercial far-right websites as *one* expression in a series of current efforts of re-branding/normalizing (Askanius 2020) and aestheticizing far-right ideology (see e.g. Kølvraa and Forchtner 2019) in ways that help normalize and banalize their underlying ideology and desensitize audiences to extremist messages. More specifically, besides contributing to CCT by empirically highlighting the nascent movement of far-right consumer culture, this research contributes conceptually to the stream on consumer activism (e.g. Gopaldas 2014; Kozinets and Handelman 2004; Sandlin and Callahan 2009) with insights on market-mediated political radicalization. In contrast to the previous main research focus on progressive, liberal, anti-capitalist movements conceptualizing consumerism as their adversary, we demonstrate how market actors actively give fodder to political extremism by aestheticizing their platform and offers in ways that distract consumers from the stigmatized past and at the same time amplify their political imperative. Furthermore, in contrast to research insights on the de-politicizing consequences of market actors' political involvement (e.g. Veresiu & Giesler 2018) we find that these actors rather politicize than *de*-politicize their consumers. Judging from our visual analysis of the far-rights' market space and offers, and in line with Miller-Idriss' (2017) insights on german youth, consumers may very well start out by "only" being attracted to the elaborate style, fairly unaware of the political messages behind, to then gradually be drawn into the extremist culture not only as consumers, but also as political activists.

Based on our findings and the status of extant research on political consumption and marketing, we encourage future research to further explore growing political radicalization (at all extremes) of consumers and market actors. Limitations with this present research is the lack of consumers as research objects, hence, we especially encourage longitudinal research which takes into account the interplay between market actors and consumers to better understand how this market-mediated radicalization actually plays out over time.

More Eggs in the Same Basket:
How Shopping Online Reduces Variety Seeking in Purchases

Julie Verstraeten, Ghent University, Belgium
Anneleen Van Kerckhove, Ghent University, Belgium
Jing Lei, University of Melbourne, Australia
Ye Zhao, Schulich Business School, Canada

EXTENDED ABSTRACT

In 2018, digital grocery sales in the US reached 23.9 billion dollars and these figures are bound to amount to 53.9 billion dollars in 2023. By 2022, 70 percent of US shoppers are expected to regularly shop for groceries online (eMarketer 2018; 2019). Other than the convenience factor (e.g., Chiang and Dholakia 2003; Wolfinbarger and Gilly 2001), a key reason why consumers shop online is that it allows them to choose from a wider, more varied assortment (The Food Industry Association 2018). Yet, it is unclear whether consumers actually reap the rewards of these (seemingly) wider assortments and seek more variety when shopping online versus offline.

In fact, despite its practical relevance, to date only little is known on how the composition of consumers' shopping baskets differs online and offline. Extant literature on how consumers shop online versus offline has examined the impact of shopping channel on consumers' price-sensitivity (Chu, Chintagunta and Cebollada 2008), reactions to price promotions (Degeratu et al. 2001), brand loyalty (Danaher, Wilson and Davis 2003), preference for package sizes (Andrews and Currim 2004), size of the basket and typical features of the purchased products such as product weight, size, and healthiness (Chu, Chintagunta, and Cebollada 2008; Pozzi 2013; Huyghe et al. 2017). Despite this research, literature remains silent on the variety of the items in consumers' shopping baskets online and offline. The current research addresses this question and investigates whether—and if so, why—the shopping channel through which consumers purchase groceries (i.e., online vs. offline) affects the variety of items in their shopping basket.

Variety seeking, as an important behavioral factor in formulating marketing strategies (e.g., Ratner and Kahn 2002; Seetharaman and Che 2009) has been researched extensively in the literature. In this research, we define variety seeking at the product level, measuring the number of unique products purchased in an online versus offline shopping basket. We hypothesize shopping baskets composed offline to exhibit more variety—that is, to contain more unique category items relative to the total number of category items—compared to shopping baskets composed online.

To build this proposition, we rely on the differential product presentation mode as a marked difference between online and offline shopping channels. Products are real and physically present in an offline store, whereas they are typically represented in visual forms such as pictures in online stores. We propose that, in comparison to the visual presentation of products in online shopping, the tangible and concrete presentation of products in an offline context (Huyghe et al. 2017) is likely to lead to a higher level of *anticipated satiation* (i.e., the extent to which a food is expected to deliver fullness; Brunstrom, 2011, Wilkinson et al, 2012). Past research has shown that expected satiation is significantly affected by the sensory characteristics of a food item such as viscosity and texture (e.g., Martin et al. 2015; McCrickerd et al. 2012) and its physical attributes (e.g., size, calorie density, Brunstrom and Rogers 2012). Importantly, this anticipated satiation can occur *prior to* the consumption, as consumers can rely on their past experience with a food item to estimate the degree of fullness that this food is likely to deliver (Keenan, Brunstrom, and Ferriday 2015). Research also shows that consumers may experience anticipated satiation if they simply simulate the consumption in their mind. For example, merely evaluating a food item repeatedly can result in satiation through mental simulation of the consumption (Larson, Redden, and Elder 2013). In the context of our research, we expect that the offline (versus online) presentation of a food item is more vivid and more likely to engender spontaneous mental simulation of the consumption, resulting a higher degree of anticipated satiation. Consumers feeling satiated are more likely to look for varieties in their purchase to maintain a desired level of stimulation.

Studies

In a first study we compared the online and offline purchases of 4,000 *mixed-channel customers*, who shopped online in some occasions and offline in others over a period of 6 months (from January until July 2018). To be considered as a *mixed-channel* customer, the percentage of a customer's online shopping trips needed to range between 25 and 75 percent. We focus on mixed-channel shoppers as this allows a better test of shopping channel effects (as in Huyghe et al. 2017, Chu et al. 2010, and Chu, Chintagunta, and Cebollada 2008) than a comparison of single channel shoppers (e.g., shoppers who only shop online or offline), as the latter comparison does not account for many of the inherent differences between the two groups of customers.

For this study we collaborated with a large Western-European retailer who operates both online and offline for many years and carries the same assortment in both channels. Specifically, this retailer offers a *click-and-collect service*, allowing customers to order their groceries online but pay and pick-up the groceries in one of the retailer's offline stores; the retailer does not provide a delivery at home service.

As shopping baskets generally contain more products online than offline (e.g., Chu, Chintagunta, and Cebollada 2008; Pozzi 2013) probably a result of convenience factor, we calculated the variety in a shopping basket as the total number of unique food items to the total number of food products purchased in a category (Levav and Zhu 2009). Every UPC (universal product code) is being counted as a unique item so that variety is calculated at the product level (e.g., a product with a new flavor within the same category is considered as a unique product). For instance, if on a given shopping trip a customer bought one raspberry and one strawberry yogurt, the degree of variety in this category would equal 2/2 or the maximum possible variety. The dataset encompasses multiple receipts per customers as we received all receipts of all selected customers over a time period of 6 months. Therefore, we run multilevel models to analyze these data as in previous studies (e.g., Chu, Chintagunta, and Cebollada 2008; Chu et al. 2010; Huyghe et al. 2017). In addition, we installed a cut-off of €500 on shopping baskets' total value, as basket values exceeding this cut-off likely do not reflect 'regular' household grocery shopping.

In line with our hypothesis, customers' shopping baskets were less varied when purchases were ordered online ($M_{Ratio\ online}$ = .52, SD = .20) compared to when they were bought offline ($M_{Ratio\ offline}$ = .62, SD = .25; $F(1, 37219.35)$ = 2441.20; $p <.001$). Furthermore, we

show the robustness of this effect by looking at the effect at (1) different levels of total spending and for (2) twenty-four different food categories (see Summarizing Results Table – Panel B and Panel C). With the exception of "alcoholic beverages" and "weight loss products and supplements" for which there were no differences in the variety chosen for online and offline purchases, our result show that the proposed effect of shopping channel holds for both the tempting and unhealthy product categories (e.g., cookies, candies, chips and salty snacks) and the less tempting, healthier categories (e.g., fruit and vegetables, fruit juices, bread, meat and flour products). It suggests that the tendency of variety seeking is higher offline than online. In an online shopping context, when purchasing from a product category, shoppers are likely to select multiple of the same items rather than spreading their choices across the available choice options. Nevertheless, real online and offline stores differ in many aspects, besides their presentation mode. For example, mixed-channel shoppers might have different motivations for shopping online versus offline, which may be reflected in their shopping baskets. If presentation mode contributes to the observed difference in variety seeking online versus offline, then a similar difference should be detected in a lab environment, where only the presentation mode differs.

The goal of **Study 2** was to replicate this effect in a controlled laboratory environment. Hereto, we set up a between-subjects design with two conditions (shopping channel: online vs. offline). For this study, we recruited 110 master students from a large Western-European University (38 men, M_{age} = 21.75 year) whom participated in return for partial course credit.

In this study, we told participants that we were interested in developing the ideal salty snack mix. In both the online and offline conditions, we presented them with five typical salty snacks and told them that they could compile their ideal snack mix. In total, they could fill five slots, one by one, with their preferred salty snack. In other words, they could choose five times the same salty snack if they wanted to. In the *online* condition, participants where shown five pictures, one for each of the available salty snacks, and were five times instructed to select one. After each choice, the same five pictures were shown along with the preceding choices they had made. In the *offline* condition, five boxes of each of the five salty snack mixes were placed in front of the participant. Participants could fill a five-compartment box by consecutively selecting five snacks and pouring them – one at a time – into the compartments.

We measured variety using the number of unique snacks each participant had chosen. The results support our hypothesis that participants' salted snack mix was less varied when it was composed online (M_{Online} = 3.80, SD = .91) compared to when it was composed offline ($M_{Offline}$ = 4.10, SD = .78; t(108) = 1.75; p = .08).

In **Study 3** we aim to replicate the results of Study 2. Moreover, we will test whether the effect replicates across *vice* and *virtue* assortments (Wertenbroch 1998; Milkman, Rogers and Bazerman 2010), as past research shows that the effect of presentation mode may differ between vice and virtue food products (Loewenstein 1996).

Seventy-seven participants (29 men, M_{age} = 25.86 year) whom were recruited through the Consumer Panel of a large European university, participated in this study in return for a small monetary compensation. Participants were randomly assigned to the online versus offline condition, which served as a between-subjects factor in this study. Participants were either consecutively exposed to four online assortments, each comprising six products, or were exposed to the same snack assortments depicted on a shelf in the lab. Of the four product assortments, we composed two *vice* assortments (e.g., candies, candy bars) and two *virtue* assortments (e.g., fruits and vegetables and cereal biscuits). In both conditions, participants selected six snack items from each assortment. It was explicitly indicated that they could select the same item multiple times.

Similar to Study 2, we calculated the number of unique snacks that each participant had chosen as the dependent variable in a multilevel model that accounts as each participant provided four datapoints. In line with our predictions, participants' choices were less varied when they were made online than when they were made offline (M_{Online} = 2.96, SD = 1.05 and $M_{Offline}$ = 3.40, SD = .98; F(1,75) = 7.89; p = .006). Importantly, when looking at the variation in participants' choices in the tempting (M_{Online} = 3.03, SD = 1.17 and $M_{Offline}$ = 3.58, SD = .93; F(1,75) = 7.86; p = .006) and non-tempting (M_{Online} = 2.89, SD = .92 and $M_{Offline}$ = 3.22, SD = 1.00; F(1,75) = 3.38; p = .07) assortments separately, the effect replicates.

In **Study 4**, we aim to replicate the finding while making participants' choices consequential. Hereto, we told participants that they had a 10% chance to receive the products they chose in this study two weeks after participation. This design also made sure that the products were available with a similar delay in both conditions ruling out differences in *order lead time* online and offline as an alternative account for the observed effect of shopping channel (Milkman, Rogers and Bazerman 2010).

In total, 75 participants (27 men, M_{age} = 23.69 year) from the Consumer Panel of a large European university participated this study in return for a small monetary compensation. We again manipulated whether participants made choices online versus offline and instructed participants to select snacks from the assortment in line with their preferences. All participants read this same scenario and were then asked to choose seven snacks from the available assortment. In the *online* condition, the snack assortment was displayed to the participants on the following page in the survey. For the *offline* condition, we constructed the snack assortment on a retail shelf in the consumer lab and participants were asked to look at this assortment and to indicate their choices on a separate paper, while seated in front of the assortment. The assortment consisted of 22 different snacks with both healthy and unhealthy snacks.

As in the previous studies, we calculated the number of unique snacks each participant had chosen. In line with our main hypothesis, participants' choices were less varied when they made their choices online compared to when they made choices offline (M_{Online} = 5.00, SD = 1.23 and $M_{Offline}$ = 5.60, SD = 1.30; t(73) = 2.00; p = .05).

General Discussion

In sum, this research demonstrates that consumers' food choices and purchases are less varied online than offline. We show that the effect holds for both tempting and non-tempting food products (Study 3) and rule out *order lead time* (Study 4) as an alternative account for the observed effect of shopping channel (Milkman, Rogers and Bazerman 2010).

This research responds to a recent call for research that compares consumers' purchases online and offline (Sevilla, Lu, and Khan 2019) and, as such, contributes to the stream of research comparing both shopping channels (e.g., Degeratu et al. 2001; Danaher et al. 2003; Chu, Chintagunta and Cebollada 2008; Chu et al. 2010;; Huyghe et al. 2017). Importantly, unlike many other studies that compared online versus offline customers using a between-subject design, in this research we analyzed mixed-channel customers— customers that purchased in both the online and offline stores of the same retailer. This is crucial as a between-subject comparison is difficult to rule out many of the potential confounds resulted from the inherent differences between customers who shop online and those shopping offline.

We propose that the shopping channel difference in variety seeking is the result of a difference in anticipated satiation online versus offline. Past research shows that vivid product presentations trigger more intense product desire and higher levels of temptation (Loewenstein 1996; Huyghe et al. 2017). We show, somewhat counterintuitively, that vivid product presentations (in offline stores) are not only more tempting, they also lead consumers to anticipate a more rapid decay in future consumption enjoyment and thus include more varieties in their purchases.

Our findings also provide important practical implications for retailers and product and brand managers which might help to improve their decision-making on their online and offline marketing and promotion strategies. Indeed, nowadays retailers strive to extend their offer online as well as offline to attract and please customers. Yet, the present findings suggest that consumers do not actually reap the variety they choose to have online; instead they do make more varied choices in brick-and-mortar stores.

Sociomaterial Performativity of the Surveillant Assemblage on Healthcare Platforms

Handan Vicdan, Emlyon Business School, France

EXTENDED ABSTRACT

This conceptual paper proposes a sociomaterial lens for understanding how surveillance functions and produces outcomes in platform organizations, and draws attention to this performative process of knowledge generation in healthcare. Platform organizations enable distant and asynchronous monitoring of people as assemblages of data (Zwick and Denegri-Knott, 2009). With this surveillant assemblage, purposes and hierarchies of begin to shift from one-sided power disparities (Foucault, 1979) to more complex surveillance networks (Haggerty and Ericson, 2000) because those who were once under surveillance, and thereby disciplined, now enact surveillance themselves. Questions emerge concerning how platform organizations constitute a surveillant assemblage that challenge the existing practices and power relations for medical knowledge constitution. Conventional theories of surveillance do not suffice to describe the complexity of the contours and effects of surveillance phenomena observed in the datafication of everyday life, as the effects of and responses to surveillance are much more complex than resistance and compliance (Brivot and Gendron, 2011). Hence a need to move beyond a dichotomous and reactive view of surveillance (Visser et al., 2017), and focus on how patients, the surveilled, can enact surveillance is warranted; a perspective often missing in surveillance literature (Visser et al., 2017).

With the emergence of participatory medicine, Web 2.0 technologies transform the ways patients manage their health by tracking health data in real-time and enabling big data generation. Hierarchies of knowledge production become leveled with increased access to medical knowledge (Rier and Indyk, 2006). Questions emerge concerning how platform organizations constitute a surveillant assemblage of humans and technology, and its outcomes, which challenge the existing practices and power relations for knowledge production. Sociomateriality is a useful lens for exploring the materiality and performativity (Jones, 2014) of surveillant assemblages and their outcomes as enacted in the practices and relations of human and nonhuman actors (Callon, 2008; Orlikowski and Scott, 2015). The inextricably related material, digital and social outcomes of surveillance in knowledge constitution (Barad, 2003; Orlikowski, 2007; Orlikowski and Scott, 2008) yield both material and social effects, which draws attention to the performativity of surveillance technologies, a key concept related to sociomateriality (Jones, 2014).

Sociomaterial lens in information systems and organizational research emphasizes the relationality and the constitutive entanglement of humans and technology (Barad, 2003; Orlikowski, 2007, 2010; Orlikowski and Scott, 2008, 2015) that enact performances via their practices (Barad, 2003), which is rarely studied (Gond et al., 2015) yet is critical for studying the constitution of knowledge as a sociomaterial practice (Barad, 2003; Orlikowski, 2007; Orlikowski and Scott, 2008). With advancement in digital technologies, wearable devices, and tracking tools, scholars may study the performativity of different sociomaterial arrangements and their consequences for a more distinct sociomaterial theorizing and understanding the change of power dynamics in these arrangements (Cecez-Kecmanovic, 2014). Furthermore, studies in marketing and consumer research focus on performativity by exploring how marketing tools and models shape markets (Kjellberg and Helgesson, 2006; Mason et al., 2015) as well as how consumer-enacted performativities (Martin and Schouten, 2014; Scaroboto, 2015) shape markets. However, less attention is given to the constitutive entanglement of humans and technologies (Orlikowski and Scott, 2008; Kjellberg and Helgesson, 2006) that enact performances (Barad, 2003) at micro/meso/macro levels, and how these outcomes reshape existing practices and transform power dynamics among market actors (Cecez-Kecmanovic et al., 2014; Orlikowski and Scott, 2015).

The emergence of alternative healthcare platforms (e.g., PatientsLikeMe, trackmystack, myhealthteams, 23andme, raremark) for medical knowledge generation is a good example to study the different performances and their related sociomaterial outcomes at micro/meso/macro levels. Surveillant assemblage on these platforms operates via different levels and involvement of multiple actors, human (e.g., patients, physicians, caregivers, platform operatives, pharmaceuticals, researchers, and state) and non-human (e.g., genetic reports, symptom tracking tools, mood maps, doctor visit sheets, disease rating scales, disease outcome measures). At the micro and meso levels, patient practices are configured by surveillance technologies and exist through material artefacts (e.g., doctor visit sheets produced on platforms and used in clinical settings, symptom trackers to track patient well-being), and their outcomes yield material (e.g., application of new treatments, patient self-tracked data influence his and others' bodily experiences), and social (tracking tools organize relations among patients and new forms of interaction between patients and doctors in clinical settings) effects. Patients use tracking tools to gain a deeper sense of self and others (Moore and Robinson, 2015) - a potential of surveillance and its reflexive nature (Iedema and Rhodes, 2010). Self-tracking is the result of a dynamic sociomaterial arrangement (Bode and Christensen, 2016). Digital tracking tools predict patient diagnostic/prognostic data as patients quantify and visualize their data, and shape their management of care and relations in material and social terms (Callon, 2008; Orlikowski and Scott, 2008). Outcome measures shared with other patients and healthcare stakeholders make surveillance more relational than ever. They improve communication on patient care with diverse stakeholders in clinical settings, influence patient embodied practices and organizing relations to others accordingly, prevent hospitalization or wrong treatments, hence producing both social and material outcomes in and beyond the platform. Institutional actors (pharmaceuticals) also track patient data, recruit patients for clinical trials, track drug effectiveness and side effects, and partner with patients for improving self-tracking tools. At the macro level, patient practices such as directly reporting drug side effects to government agencies using surveillance technologies further shape state pharmacovigilance of pharmaceuticals, and patient generated medical research via surveillance technologies inform scientific medical research. Hence, multiple performativities of the surveillant assemblage demonstrate the potential for shaping the practices of its actors, organizations and their markets (Callon, 2008; Orlikowski and Scott, 2008).

Sociomaterial performativity of a surveillant assemblage also draws attention to the performative struggles (Callon, 2007) or counterperformativities (Mackenzie, 2007) in the era of datafication. Micro/meso counterperformativities include the exclusion of illiterate patients in the surveillant assemblage. Platforms may also create a "technology of the self" via self-tracking, which may lead to manipulation of data by users. Data (il)literacy is also an important performative struggle, as it may obstruct decisions concerning patient care and scientific knowledge production, as well as power dynamics. Future research should work on to explore the impact of these counter-performativities in alternative markets.

Your Need Doesn't Appeal to Me: How Social Class Shapes Charitable Giving Across Causes

Yan Vieites, FGV-EBAPE, Brazil
Rafael Goldszmidt, FGV-EBAPE, Brazil
Eduardo B. Andrade, FGV-EBAPE, Brazil

EXTENDED ABSTRACT

Two recent tragedies received worldwide attention: the Cyclone Idai and the Notre-Dame Cathedral fire. While the former ranks as one of the deadliest tropical cyclones on record, the latter, though tragic for its cultural significance, did not affect people's access to pressing needs. Yet, members of the elite donated approximately ten times more to the rebuilding of the Notre-Dame Cathedral than to the victims of the cyclone (Martin 2019; Walsh 2019). Although celebrated by some, the enormous amounts donated to the Notre-Dame Cathedral have also triggered a massive public backlash (Sullivan 2019). At the center of the criticism was the question: which social causes are worthy of philanthropy for the rich? In this research, we shall demonstrate how a basic psychological process (i.e., sensitivity to need) may help explain this intriguing question.

Individual experiences have been shown to largely shape donation preferences (Radley and Kennedy 1995). Small and Simonsohn (2008), for instance, showed that past experiences with a friend's misfortune increases sympathy towards other victims from the same plight. However, since social class often shapes personal experiences in a relatively homogeneous way (Kraus et al. 2012), it may well mold people's relative sensitivity to particular sets of misfortunes and thereby influence their prosocial choices.

Given that lower-class individuals are embedded in contexts of generalized scarcity (Piff et al. 2012), we reasoned that they would present a greater sensitivity to the degree of need of social causes relative to their higher-class counterparts. Implicit in this reasoning is the idea that going from scarcity to abundance changes not only the amount of resources one has to give, but also the dimensions consumers are more sensitive to during the donation process. Among the poor, scarcity-based experiences should increase the donor's sensitivity to need. As a result, they should be more inclined to donate to more pressing causes (e.g., helping the homeless find shelter) than to relatively less pressing ones (e.g., promoting cultural activities). Among the wealthy, abundance-based experiences should reduce the donor's sensitivity to need and enhance the weight of other factors (e.g., social signaling; Sargeant and Woodliffe 2007). We test this possibility across 5 field studies with residents from extremely poor and wealthy areas of Brazil.

In study 1, participants received five R$2.00 bills in return for their participation. Upon completion of a filler questionnaire, respondents learned that research assistants were collecting resources for two campaigns, one to help the homeless find shelter (a pretested pressing need) and the other to help promote cultural activities (a pretested non-pressing need). Participants were then given two envelopes containing a pictorial depiction of each cause and instructed to deposit the money they were willing to donate (including any) in the designated envelope. As expected, higher-class consumers donated less than their lower-class counterparts to a cause concerned with the homeless but donated more when the cause concerned cultural activities.

Study 2 uses another combination of causes (food and culture) and provides initial process evidence. This study relies on the same procedure as study 1 except that half of the participants received an envelope containing a neutral pictorial appeal, whereas the other half received an envelope containing a visceral graphic appeal. If findings from study 1 are indeed explained by a sensitivity gap, then presenting the causes in a way that makes the degree of necessity emotionally/viscerally salient to *all* participants would make both higher- and lower-class consumers more likely to donate to the most pressing cause. That was indeed the case. When assigned to the neutral condition, higher-class participants donated more to culture than food, whereas the opposite held true for their lower-class counterparts. However, when assigned to the visceral condition, both groups became more charitable to the food-related cause.

Study 3 replicated the procedure of study 2 in a hypothetical scenario and asked participants to indicate not only the social cause they would contribute more money, but also the reason why they chose to donate more to one cause or the other (degree of need, affinity, or other motive). Beyond replicating findings from study 2, results also showed that the effect of the viscerality manipulation on patterns of giving was explained by the increase in the sensitivity to need among the wealthy in the visceral (vs. neutral) condition.

Study 4 relies on a distinct approach to examine the mechanism. Participants were offered the opportunity to donate to one of two causes in a hypothetical scenario. For half of the participants, the tradeoff hinged upon shelter and sports, whereas for the other half the options were safety and sports. A pretest showed that lower-class consumers experience much higher scarcity in the access to shelter than their higher-class counterparts, but both groups share similar scarcity experiences in terms of safety. Since our rationale predicts that higher scarcity experiences prompt a higher sensitivity to need, we reasoned that lower-class participants would donate more to the most pressing cause than their higher-class peers when the pair of available causes were shelter and sports but not when the pair of causes were safety and sports. This prediction was fully supported.

Our final study adopts a framing strategy to provide further evidence for the proposed mechanism. Participants were offered the opportunity to donate to a shelter-related cause and/or a sports-related cause in a hypothetical scenario. Whereas for half of the participants, the shelter-related appeal emphasized the benefits inherently connected to having access to adequate shelter (e.g., well-being), for the other half the appeal centered on the idea that reducing homelessness might help promote safety in the city. As expected, emphasizing the safety-related benefits of helping homeless people increased sensitivity to need, and thereby donation amounts, among the higher-class more than among the lower-class.

This research offers two main contributions. First, we move beyond the question of who behaves more prosocially to assess when and why members of contrasting socioeconomic backgrounds act the most on behalf of others. Second, we extend the finding that personal experiences shape sympathy towards specific causes by showing how it can reflect a group-based phenomenon.
