A mother's autonomous status has a substantial influence on a child's educational attainment (Korupp, Ganzeboom and Lippe 2002), survival (Fantahun et al. 2007), and health condition (Senarath and Gunawardena 2009). However, scant research has been done to investigate the impact of mothers on their children's educational spending. Research in economics and psychology addressing this topic suggests that a mother's autonomous status is a critical determinant of investment made for their children's future (Mencher 1988). In this paper, we (a) consider the impact of a mother's level of empowerment on educational issues, (b) explain how access and use of social media influences a mother's empowerment and thus children's outcomes (Figure 1) and (c) test our hypotheses with mothers in both India and the United States.

Study 1- Mother's Empowerment In India

Educational spending was measured by summing up the expenditures on education (₹) for the oldest child between the ages of 11 and 17. The expenses include tuition, school fees, books, transportation to school, other school materials, and test preparatory services. According to Zimmerman (1995), to fully understand empowerment, both forms of empowerment, intrapersonal empowerment, and interactional components, should be considered. We used a developed scale to capture this (Liu 2016). We recorded mother's use of social media on Yes, Sometimes or No. Other relevant background control variables were captured, including the self (wife) and husband's income, the number of children, work status of the mother, and wife and husband's education level.

The average age of the 301 respondents was 38.5 years (SD = 6.23). Majority of the children (78.7%) were enrolled in a private school. Forty-two percent of the surveyed women stated that WhatsApp was their primary social media option. About 70% of the WhatsApp users are a part of their child's school group or other educational related online communities, and 34% of these women reported either "always" or "mostly" use WhatsApp for this purpose.

A confirmatory factor analysis (CFA) was conducted with a bootstrap resampling procedure with 2000 samples and 95% bias-corrected confidence interval. Our model presented a good fit ($\chi 2$ (26) = 53.11, p < .05; CFI = .98; RMSEA = .06, NFI = .96; Hu and Bentler 1999; Jöreskog and Sörbom 1993). The results suggest that less social media use had a significantly reduced effect on the latent variable, interactional empowerment (-.48; p < .05), but not intrapersonal empowerment. Children's school grades decreased (.96; p < .05; reverse-scored) as their mother's intrapersonal empowerment levels increased, and they also spent less on educational expenditures (-.99; p < .05). Meanwhile, higher levels of interactional empowerment significantly increased educational expenditures (.21; p < .05) while not significantly affecting their child's school grades. There were no indirect effects of media use. The control variable school type had a significant effect on expenditure, while the gender of the child had a significant impact on grades.

Study 2- Mother's Empowerment In The United States

To understand how the use of social media impacts empowerment in the US, we captured active or passive usage of Facebook, Instagram, Twitter or other social media sites (Li 2016). Educational expenditure was captured using the question- "Please consider the following educational expenses: tuition, private tutoring, books, and other school materials, test prep services, transportation to school" on a scale with 1 = < $250 to 9 = $2000+ with increments of $250. An individual's social needs, recognition needs, and cognitive needs were also captured to understand the motivation of seeking social media (Leung 2009) and children's grades in school. Out of the 182 participants, 98% of the mothers owned a smartphone, and all participants had access to some form of social media. Ninety percent of the participants used social media regularly, while others used social media occasionally.

Our CFA model had a good fit ($\chi 2$ (40) = 66.66, p < .05; CFI = .94; RMSEA = .06, NFI = .86). The results suggest that the mother's active social media use had a significant effect on the latent variable, intrapersonal empowerment (.26; p < .05), but not interactional empowerment, as we had expected. Our results show that passive social media use had a significant and positive effect on the latent variable, interactional empowerment (.17; p < .05). Increased intrapersonal empowerment reduced their child's school grades (.73; p < .05; reverse-scored) while interactional empowerment increased educational expenditures (1.81; p < .05). We also find that recognition (.28; p < .05) and social needs (.36; p < .05) significantly impact active social media use while cognitive needs (.36; p < .05) leads to passive media use.

Discussion

By having a mere presence on social media (via passive use) helps women develop interpersonal relations and propel collective action (related to interactional empowerment). These outcomes positively influence children's future since with increase in interactional empowerment, more expenditures are spent related to children's education. Also, it is worth noting that cognitive needs drive passive use of social media, possibly relying on social media as a critical source of information. However, mothers relying on active use of social media without the relational bonds (created through interactional empowerment), may negatively result in (a) reduced expenditures on children's education in India, and (b) their children performing more poorly in school (lower school grades), which was revealed in both in India and US. Our paper is informed by traditional marketing theories of consumer and media socialization and psychological theories of empowerment and places the family, especially the mother and her media use, central to a child's welfare.

The Interplay of Religious Discrimination/Segregation with Consumption and Production Activities

Akshaya Vijayalakshmi, Indian Institute of Management Ahmedabad, Ahmedabad, India
Nitisha Tomar, University of Wisconsin-Madison, Madison, USA
Ankur Kapoor, Indian Institute of Management Udaipur, Udaipur, India

EXTENDED ABSTRACT

This research focuses on the interplay of consumption and production practices with religious discrimination/segregation. Although works of Izberk-Bilgin (2012) and Sandikci and Ger (2010) consider religion as an ideological tool for consumers' identity projects, we analyze a context where a pernicious, discriminating structural order prevents the use of religion as an ideological tool. Instead, the neoliberal market discourses are implicated, which, ironically leads to reproduction of discrimination. We situate this work in prior research on marketplace exclusion (Scaraboto and Fischer 2012), redlining (D'Rozario and Williams 2005), spatial exclusion (Castilhos 2019), and stigmatization (Sandikci and Ger 2009). Our central research questions are: (a) How does religious discrimination shape consumption and production practices of the discriminated? (b) How do these consumption and production practices, in turn, influence segregation and discrimination?

The study is set in Ahmedabad (India), which has history of several interreligious conflicts, and majority of its population lives in religiously homogeneous neighborhoods (Field et al. 2009). As the context deals with aspects of distinction (between Hindus and Muslims) and spatial segregation, Bourdieu's 'thinking tools,' such as capital, doxa, interest, and symbolic violence, and Wacquant's analyses of territorial stigmatization, are useful in analyzing the data (Grenfell 2014; Wacquant, Slater and Pereira 2014).

Data. Using QGIS application, public/private amenities were mapped onto each of 48 wards of Ahmedabad (Figure 1). This mapping helped us analyze the peripheralization that extends beyond the well-researched residential segregation - to that of access to mainstream marketplaces. We also interviewed 16 Muslims who have been living in Ahmedabad since the 2000s. Participants provided in-depth details on the marketplace discrimination experienced in their everyday lives - segregated housing, schooling, employment, bank loans, and public facilities. Furthermore, the authors gained a richer understanding by participating in several inter-community events, thus traveling to otherwise invisible parts of the city. The analyses followed a hermeneutic approach (Thompson 1997) by identifying themes within and between interviews and connecting these themes with theory.

Findings. Marketing is suggested to favor the in-group through marketing mix, store location, delivery modes, etc. (Bennett et al. 2016). The GIS map and interviews illuminate redlining (paucity of retail stores, restaurants, and banks) in Muslim majority areas, leading to significant differences in amenities between Hindu and Muslim majority areas. Participants also mentioned being underserved by public or private schools and paying higher prices for electricity. Markets become a tool for expressing the religious doxa and reproducing field positions through spatial segregation (Bourdieu 1986, Wacquant et al. 2014). Such structuring influences production/consumption opportunities of the dominated. Interestingly, such a process not only leads to inferior outcomes for Muslim consumers, but also hurts businesses that accommodate inefficiency/losses to maintain social legitimacy (by not serving Muslim dominant areas). Thus, markets forego ideals of profit maximization and customer satisfaction to align with discriminating structural forces.

To redress their dominated positions, stigmatized Muslim producers rely on neoliberal logics of entrepreneurship, individual effort, and market-mediated solutions for overcoming discrimination. "Forced entrepreneurs" (in the words of a participant) emerge as they develop alternative markets for schools, supermarkets, and real estate, among others. Participants worked in their 'interest' to improve their field positions by relying on 'market doxa' to redress the inferior position imposed through 'religious doxa'. Thus markets, and not religion, provide necessary ideological and material resources to subvert structural discrimination.

We find that even if our informants had the economic means to out-migrate, they found it difficult, if not impossible. Barriers to mobility were either institutionally sanctioned or culturally legitimized (prohibition of meat consumption in many residential localities). A participant running a food business could not expand his business as he was denied a larger commercial space in Hindu majority area. Likewise, participants mention about not being granted loans easily because they live in 'negative areas', along with issues in school admissions. Bourdieu (1986) argues that the value of one form of capital lies in its ease of conversion to other forms of capital. We find that location (physical capital) inhibits the conversion of economic capital into symbolic capital. This non-conversion of capital 'freezes' the position of the dominated in the field, thus aggravating distinction and symbolic violence.

Success stories of a few entrepreneurs provided inspiration to rely on one's effort to overcome discrimination. This valorization and internalization of market logic (individuality, self-reliance) made participants feel responsible for their condition. Thus, market logic promoted the consideration of structural and arbitrary as natural and self-inflicted, thereby precluding any collective action against systemic disadvantages. In doing so, market logic becomes complicit in reproducing discrimination by replacing collective efforts towards structural change with individual efforts towards personal change.

The struggle of the participants to redress the stigmatization resulted in entrepreneurial initiatives enveloped in an "identity dance" (Weinberger 2015) of selective fore-/back-grounding of religious markers. Some Muslim entrepreneurs navigated inter-communal boundaries by keeping non-Muslim names for their businesses (e.g., Ruby/Best-Mart) to "pass for normal" (Goffman 1963). Unlike Crockett and Wallendorf (2004), some entrepreneurs assigned Muslim names to their businesses (e.g. Bismillah) to reinforce collective Muslim identity, but only when catering to a Muslim clientele.

Discussion. Our work contributes to theory in the following ways. First, we uncover how lack of legitimate physical capital inhibits the conversion of economic capital into symbolic capital. Thus, we address the limited attention Bourdieu (1986) accords to physical space. Second, we uncover the dual role of markets, in the way they help survive discrimination by enabling means of living but foreclose opportunities of collective action and structural changes, through individualization and responsibilization. By foreclosing collective action, the market's neoliberal ethos appears to reproduce distinction and segregation.

Our work also informs contexts wherein spatial segregation is institutionally or culturally legitimized (refugee camps, gated communities, redlining, etc.). Often, it is believed that market logic will

eventually resolve underlying segregation/discrimination. We found that without efforts through other collective means, the market may aggravate the conditions it is meant to alleviate. We attempt to uncover the complex interplay between marketplace activities of individuals and structural aspects of discrimination/segregation, thus informing theory and public discourse on these issues.

Frequent Consumption of the Sharing Services

Racheal Louis Vincent, Sunway University, Malaysia
Sanjaya Singh Gaur, New York University, USA

EXTENDED ABSTRACT

Introduction

The concept of the sharing economy is more than just a buzz-word. By 2025, the sharing economy is expected to be valued at *$335 billion* (Kindergan 2015). The term 'shared services' in our study is with regards to the services provided in the sharing economy such as ride-sharing (e.g., Uber and Lyft), accommodation sharing (e.g., Airbnb and Couchsurfing), task-sharing (e.g., Taskrabbit and Airtasker), closet-sharing (e.g., Rent the Runway and Style Lend) and many more. These types of services are labelled as 'shared services' because they provide access without ownership (Eckhardt et al. 2019, Kumar, Lahiri, and Dogan 2018).

With the support of digital and mobile technology, these shared services apps (mobile applications) offer consumers an easier access to a variety of on-demand goods, services and underutilized assets for monetary gains. We know that consumers will repeat their service usage if they find that the company provides some sort of value (intrinsic and/or extrinsic) to them. For example, Uber reported their "Monthly Active Platform Consumers" (MAPCs) of 91 million in the fourth quarter of 2018. These are users who were found to take at least one ride on Uber or buy at least one meal on Uber Eats (Salinas and Feiner 2019). For explaining individual's frequent usage of such shared services, we posit that the difficulty (or ease) of use and the overall experience of using shared services plays a major role in influencing their usage behavior.

To date, little is known about individual's shared services frequent usage behavior. The focus of the extant literature seems to be more inclined towards the motivations and barriers for using shared services and overlooks the importance of understanding individual's frequent usage behavior of these services. Past scholarly work done on understanding of human behavior seem to emphasize on the intention-behavior relationship (Ajzen 1991, Godin and Kok 1996, Sheeran and Orbell 1998, 2000b, Warshaw and Davis 1985, Sheeran and Orbell 2000a) and have yet to consider actual frequent usage behavior. The more frequent and recent an individual's usage behavior (Bagozzi and Dholakia 2002), the more likely he/she will repeat their usage behavior again in the future.

With regards to adoption of technology, many studies have primarily focused on perceived ease of use (PEOU) (Fagan, Neill, and Wooldridge 2008, Luarn and Lin 2005, Saadé and Bahli 2005, Venkatesh 1999, Gefen, Karahanna, and Straub 2003, Hansen, Saridakis, and Benson 2018) and limited studies have considered perceived difficulty of use (PDOU) in terms of understanding consumer's usage behavior (Trafimow et al. 2002, Barnard et al. 2013, Venkatesh 2000). However, in actual reality, it is the perceived difficulty of use (PDOU) that influences frequent usage of the adopted services. This is because we postulate that it is much easier for individuals to express their difficulty in using shared services rather than the ease in using these services. Besides, it was found that consumers showed higher intentions to purchase when they had favorable past purchasing experiences (Weisberg, Te'eni, and Arman 2011). Thus, we also examine the role of the experience in making consumers use the same services frequently.

Based on the above backdrop, the aim of our research is to understand individual's consumption of shared services particularly their frequent usage behavior, and the role of perceived difficulty of use (PDOU) and their experience of using shared services. Therefore, to address these research gaps, our study is guided by four research questions. These questions are: What influences people to frequently consume shared services? How the perception of difficulty in using the shared services affects frequent usage behavior? What is the role of past experience in consumption of shared services? How social norms affect intention to participate or not to participate in the sharing economy?

Conceptual Framework

According to Ajzen and Fishbein (2005), human behavior is guided by attitudes and therefore, attitudinal theories are needed to understand and explain individual's consumption of shared services. Our research framework draws advances from attitudinal theories explaining individuals' frequent usage behavior together with extant knowledge of shared consumption. We grounded our research framework on Theory of Trying (TT) by Bagozzi and Warshaw (1990) and Extended Model of Goal-Directed Behavior (EMGB) by Perugini and Corner (2000) together with frequent usage behavior, perceived difficulty of use (PDOU) and experience of using shared services to explain individual's shared services behavior. Applying one theory to the domain of the other has potential to generate novel insights. According to Mayer and Sparrowe (2013) in order for integration to be successful, it is important for a clearly articulated link between the theory and the new domain to be present as it allows for productive dialogue. We propose an integration of both mentioned theories as they complement each other. TT's three determinants: attitude toward success, attitude toward failure and attitude toward the process also known as the pre-factual attitudes allow a better understanding of individual's shared services frequent user behavior when integrated with EMGB. Individuals using shared service may experience impediments and that could drastically affect their shared services usage frequency. On the other hand, EMGB is said to have outperformed the TPB and has shown substantial predictive power (Perugini and Corner 2000, Lee et al. 2012). To the best of our knowledge, this is a first empirical study to integrate two attitudinal theories: Theory of Trying (TT) and Extended Model of Goal-Directed Behavior (EMGB) to further explain individual's frequent usage of shared services.

Method

Data for the study were collected using a mall-intercept survey using structured questionnaire. Measures for all the variables used in this study were drawn from well-established literature and were modified to suit the present study. Out of *500* respondents participated in the mall-intercept survey, *393* responses were found to be usable. Partial Least Squares based Structural Equation Modelling (PLS-SEM) was used to test all the hypotheses in the conceptual framework. The SmartPLS 3.0 software was used for the testing of both measurement model and structural model. PLS based SEM technique was used mainly because it provides a useful estimate for a complex framework with many constructs and many indicators (Chin 1998, Hair et al. 2011, Ringle, Sarstedt, and Straub 2012). Moreover, Hair et al. (2011), Hair et al. (2014), Henseler, Ringle, and Sinkovics (2009), highlighted that PLS-SEM has been widely used in marketing research and also been used in many top-tier and other leading journal publications.

Discussion

Our findings offer new insights for understanding individual's consumption of shared services particularly their frequent usage behavior, the role of perceived difficulty of use (PDOU) and experience of using shared services. Consequently, our research augments the Theory of Trying (TT) and Extended Model of Goal-Directed Behavior (EMGB) in several ways. Empirical findings of the study prove to show the proposed framework of the study developed by integration of theories was successful in explaining individual's shared services frequent behavior.

Pre-factual attitudes towards success (feelings towards success, expectation of success and evaluation of success), attitude towards failure (feelings towards failure), attitude towards the process (feelings towards process) were found to influence individual's attitude towards using shared services. Similarly, we found attitude towards use, subjective norms and group norms significantly influence individual's desire for using shared services. Desire to use shared services and perceived behavioural control were found to influence individual's intention for using shared services. Besides that, we also found intention to use and subjective norms significantly influence individual's frequent usage of shared services. Perceived difficulty of use (PDOU) on the other hand, was found to be negatively associated with individual's frequent usage behaviour of shared services and experience of using shared services was found to be negatively associated with PDOU.

Conclusions

As mentioned earlier, the primary objective of this study was to understand individual's consumption of shared services particularly their frequent usage behavior, and the role of perceived difficulty of use (PDOU) and experience of using shared services. Our findings show that individual's pre-factual thought process influences their attitudes towards using the sharing services. How individual's feel, expect, evaluate success or failure and their overall thought process of using shared services highly depends on the sharing service providers'. Moreover, perceived difficulty of use (PDOU) and experience of using shared services were found to play an important role in terms of influencing individual's frequent consumption of the sharing services.

There are three main contributions of our study from the perspective of academia. The first contribution is in terms of the explanation for the frequent consumption (usage) of shared services. Second contribution is in terms of the inclusion of perceived difficulty of use (PDOU) variable in the existing behavioral models which have primarily considered perceived ease of use (PEOU). The third contribution comes from explaining the role of experience of using shared services in the frequent usage behavior.

This study also provides several practical implications for the key stakeholder of the shared economy, such as shared service providers (operators). It is imperative for the sharing service providers to create a positive brand experience and minimize service failures. This is vital because experience of using shared services not only affects individual's perceived difficulty of use (PDOU) but also their frequent usage behavior.

It is important for the sharing service providers to educate consumers on using the features of their mobile apps such as by including step-by step video of use in the app itself especially for the older consumers who often have anxiety towards technology adoption. The findings of our study are indeed valuable not only for future scholars who are keen to study similar technology adoption but also provide useful guidelines for the sharing economy practitioners.

Deriving Mental Energy from Task Completion

EXTENDED ABSTRACT

People often complain that they have plenty to do, but not enough time to do it. Yet, time is not the only resource that limits daily productivity. People also have limited mental energy. Approximately 20% of Western adults experience mental fatigue on a regular basis (Lerdal et al., 2005; Pawlikowska et al., 1994). Despite the importance of mental energy, and the fact that many daily tasks are naturally depleting, consumer research on how to replenish mental energy is limited.

Mental energy is defined as *momentary feelings* of alertness that supports the ability to remain focused on and complete ongoing *cognitive* tasks (O'Connor 2006; Ryan and Frederick 1997). Existing research investigates the *exogenous* source of energy replenishment (i.e., a source that is independent of the energy-consuming task) such as taking a rest (Helton and Russell 2017) and engaging in intrinsically interesting activities (e.g., leisure activities) (Reis et al., 2000). We suggest an *endogenous* source of energy replenishment – the completion of a goal-directed task – and propose that energy replenishment at task completion depends on the value of task rewards. People's energy level increases compared to *pre-completion* levels when completing high-reward tasks, but not low-reward tasks. We argue that task completion is the time when people obtain and reflect upon task rewards (Gollwitzer 2012; Heckhausen and Gollwitzer 1987), which creates mental energy. As suppression of one's needs, or regulation of the behavior that meets one's needs, consumes mental energy (Baumeister et al. 1998; Vohs and Faber 2007), it is possible that satisfying one's needs (e.g., rewards) boosts mental energy.

We further suggest two moderators of the effect of reward value on energy replenishment: task effort and task focus (reward vs. mere completion). Reward is a consequence of cognitive control during goal pursuit, which is subjectively costly and influences people's responses toward the rewards (Botvinick and Braver 2015; Inzlicht et al. 2018). When task effort is high, task completion should generate mental energy only when reward value is high because the investment of energy was worthwhile. When effort is low, energy replenishment should be less sensitive to reward value and will occur at the completion of both high-reward and low-reward tasks because both tasks were worthwhile given the minimal investment of effort.

Finally, we propose that there are two sources of the reward experienced at completion: the act of completing the task itself and the rewards associated with completing the task. If this is true, mental energy replenishment should be a function of reward value when people focus on the rewards associated with task completion; when people focus on the mere act of task completion, mental energy should be replenished as long as the task is completed, regardless of task reward.

Study 1 demonstrated that mental energy is replenished upon completion of a high-reward task, but not a low-reward task. The task involved finding the best deals (i.e., lowest price) for five products. Task reward was manipulated by whether or not participants learned that they would get a $0.1 bonus for each best deal they found. Participants reported higher mental energy post-completion than pre-completion (i.e., before searching for the 5th product) when reward value was high ($p<.001$) but not when reward value was low ($p=.88$; interaction: $p=.011$). Felt achievement and competence did not differ across conditions.

Study 2 showed behavioral implications of energy replenishment – persistence in a subsequent task. Participants completed the same deal-finding task, except that task completion was manipulated between-subjects by whether or not telling participants that the deal-finding task was completed after they finished the 5th deal-finding task. Then all participants were directed to a book-evaluation task where they could choose to quit at any time. Task persistence was measured by the number of books participants evaluated before they quit. Participants who were informed of task completion evaluated more books than those who were not when reward value was high ($p=.031$) but not when reward value was low ($p=.31$; interaction: $p=.025$).

Study 3 tested moderation by task effort. The task involved learning good sources of six micro-nutrients among five groups of food. Within each group, participants saw six food items and their nutrition facts and needed to identify items that were good sources of each nutrient. Nutrition facts of different foods were listed in % daily value *per serving* that can be directly compared (low-effort) or *in different serving sizes* that required additional calculation (high-effort). The food was either easy to find in grocery stores (e.g., watermelon, blueberries; high-reward) or not (e.g., Kiwano, Loquat; low-reward). In the high-effort condition, mental energy was higher post-completion than pre-completion (i.e., before working on the 5th group) in the high-reward task ($p=.001$) but not in the low-reward task ($p=.914$; interaction: $p=.016$). In the low effort condition, however, mental energy was replenished regardless of reward value (main effect of completion: $p=.043$; interaction: $p=.561$). Study 3 also ruled out alternative explanations of positive affect, felt achievement, and competence.

Study 4 tested moderation by task focus. Participants were asked to 5 hand-written ship logs into digital texts. Reward value was manipulated by framing the task as helping scientists input important historical data (high-reward) or as digitizing logs that were not very useful (low-reward). Task focus was manipulated by adding visual cues that emphasized task completion (an arrow pointing to an icon signaling the end of the task), or not adding such cues, so that task reward was more salient (similar to prior studies). In the reward-focus condition, mental energy was higher post-completion than pre-completion in the high-reward task ($p=.011$) but not in the low-reward task ($p=.511$; interaction: $p=.023$). However, in the completion-focus condition, mental energy was replenished regardless of reward value (main effect of completion: $p=.058$; interaction: $p=.536$).

Our findings suggest that mental energy can be replenished in accordance with the reward experienced at task completion. This energy replenishment strategy could be conceptualized as an evolutionary advantage, as it is an endogenous source that sustains the completion of a sequence of tasks. These insights suggest the need for a broader conceptualization of the generation of mental energy.

The Looking-Glass Self: Low Self-Concept Clarity Increases Appearance Management

Jiaqian (Jane) Wang, Kellogg School of Management, Northwestern University, USA
Yiqi Yu, Guanghua School of Management, Peking University, China

EXTENDED ABSTRACT

Recent years have witnessed the rapid expansion of beauty industries. Yet, limited research has shed light on when and why consumers are motivated to manage their appearance. The current research examines how self-concept clarity, a structural feature of self-concept, shapes appearance management.

Self-Concept clarity is defined as the possession of "clearly defined, temporally stable, and internally consistent self-views" (Campbell et al. 1996). Maintaining a clear self-concept is an essential psychological need and can guide how consumers behave. Thus, when lacking self-concept clarity, consumers strive to understand who they are and what to do. Because social standards and evaluations can serve as a reference (Cooley 1902), low self-concept clarity increases consumers' sensitivity to social information. Indeed, when experiencing low self-concept clarity, consumers are more likely to engage in social comparisons, adopt social standards and ideals, and conform to others' expectations to seek social approval (e.g. Mittal 2015). These behaviors manifest the tendency to view the self as embedded in social contexts, which is termed as public self-consciousness (Fenigstein, Scheier and Buss 1975). It triggers the self-presentation motive which drives consumers to build and exhibit a positive self-image to others (Schlenker and Weigold 1990). To the extent that physical attractiveness is one of the most observable, explicit factors in social judgment (Freeman and Ambaby 2011), consumers with strong public self-consciousness tend to be highly involved in appearance management to obtain social approvals.

Taken together, we predict that low-concept clarity increases appearance management by heightening public self-consciousness. This effect will be attenuated when appearance management entails negative self-presentational value (i.e. brings unfavorable social judgments).

Five studies using a survey, archival data, and experiments tested these propositions. Study 1 (N = 300; Mturk) showed that dispositional low self-concept clarity was associated with more frequent appearance management behaviors (e.g. tanning; B = .117, $p < .001$) and stronger preferences for three appearance-improving products (ps < .001).

Study 2 (N = 113; Chinese college students) used a two-condition (self-concept clarity: low vs. high), between-subject design to test the causal effect of self-concept clarity on interest in getting information regarding appearance management. We also explored the role of global self-esteem. Results showed that low self-concept clarity increased interest in learning more about appearance management (M_{low} = 6.00, SD = 1.02 vs. M_{high} = 5.46, SD = 1.22; $F(1,112)$ = 6.43, p = .013, d = .48) without affecting self-esteem (M_{low} = 4.58, SD = 1.01 vs. M_{high} = 4.74, SD = .97; $F(1,112)$ = .73, p = .394, d = .16). Also, the effect of self-concept clarity on appearance management held when controlling for global self-esteem (p = .011), suggesting that self-esteem was not a likely mediator.

We then investigated the underlying mechanisms of the effect. Using a secondary data set (the Midlife in the United States survey), Study 3 examined the link between low self-concept clarity, public self-consciousness, and appearance management. Regression results showed that dispositional low self-concept clarity was associated with greater public self-consciousness (N = 2651; B = .608, SE = .033; $p < .001$). Among female respondents who indicated how much they worried about being less attractive (N = 1413), we found that low self-concept clarity predicted greater concerns about physical attractiveness (B = .143, SE = .022; $p < .001$). More importantly, mediation analysis using SPSS PROCESS macro Model 4 revealed that the indirect effect of public self-consciousness did not contain zero (95% CI = [.04, .07]), suggesting that public self-consciousness mediated the association between low self-concept clarity and concerns about physical attractiveness.

Next, Study 4 (N = 219; Mturk) causally tested the mediating role of public self-consciousness. We manipulated self-concept clarity using a typing task which ostensibly assessed typing speed and accuracy. Participants typed in six sentences describing high or low self-concept clarity word by word. After completing the manipulation check and measures on public self-consciousness, participants read an introduction to cosmetic procedures and indicated their interest in cosmetic procedures (Henderson-King and Henderson-King 2005). Then, they responded to items on private self-consciousness and global self-esteem. As predicted, low self-concept clarity led to greater interest in cosmetic procedures (M_{low} = 2.47, SD = 1.82 vs. M_{high} = 2.06, SD = 1.54; p = .072, d = .24). Mediation analysis using PROCESS macro Model 4 suggested that this effect was mediated by heightened public self-consciousness (indirect effect: 95% CI = [.01, .31]) but not global self-esteem (95% CI = [–.12, .05]) or private self-consciousness (95% CI = [–.12, .08]).

Finally, Study 5 (N = 394; Mturk) employed a process-by-moderation approach to further test the proposed mechanism. Participants were randomly assigned to one of four conditions in a 2 (self-concept clarity: low vs. high) × 2 (self-presentational value: positive vs. negative), between-subject design. Participants first completed a writing task which manipulated self-concept clarity. Then, those in the positive (negative) self-presentational value group read about how Botox could lead to "more compliments" ("being judged as inauthentic"). Next, participants indicated their interest in Botox. Results revealed a significant main effect of self-concept clarity ($F(1, 390)$ = 4.35, p = .038, η_p^2 = .011), no main effect of self-presentational value ($F(1, 390)$ = .95, p = .329, η_p^2 =.002), and a significant interaction ($F(1, 390)$ = 5.84, p = .016, η_p^2 = .015). A planned contrast suggested that when Botox led to positive social evaluations, participants in the low self-concept clarity condition showed greater interest in Botox (M_{low} = 2.62, SD = 1.98 vs. M_{high} = 1.85, SD = 1.61; p = .002). However, when negative social evaluations were highlighted, self-concept clarity had no effect (M_{low} = 2.04, SD = 1.61 vs. M_{high} = 2.09, SD = 1.62; p = .810).

Theoretically, the current work extends research on self-concept, public self-consciousness, and appearance management. Practically, our findings suggest that beauty industries could benefit from combating stereotypes and stigma associated with beauty striving. Moreover, to tackle consumers' beauty obsession, it is vital to eliminate the overemphasis on physical attractiveness and promote more inclusive and diverse beauty in society.

Loss Aversion: The Impact of Uncertainty on Experiential Product Preference

Lili Wang, Zhejiang University, China
Xuan Zhang, Zhejiang University, China
Wei Lyu, Shanghai Jiao Tong University, China

EXTEND ABSTRACT

Individuals experience uncertain at a high frequency for all ages. It seems that people make almost all of the key decisions with various kinds of uncertainty, such as investment and life planning. Uncertainty has a great influence on consumers' emotion, judgement, decision making and behavior. How does uncertainty influence consumers' product preference, particularly for experiential vs. material preference?

Uncertainty increases reliance on emotional attachment when making decisions (Faraji-Rad and Pham 2017), repetition behavior for uncertain reward (Shen, Hsee and Talloen 2019), resource investment (Shen, Fishbach and Hsee 2015), and motivations to maintain a stable self-concept (Savary and Dahr 2019). Building on these findings, we propose that uncertainty leads to a loss of psychological ownership by impairing belonging, self-identity and self-efficacy (Elstak et al., 2015; Pierce et al., 2001). Compared to material product, experiential product provides shorter longevity (Tully, Hershfield, and Meyvis 2015; Weidman and Dunn 2016), lower identity association (Dommer and Swaminathan 2013; Morewedge and Giblin 2015; Weiss and Johar 2013, 2016) and is unalterable (Rosenzweig and Gilovich 2012). Thus, to some extent, experiential product would have lower psychological ownership than material product. Therefore, for experiential vs. material product preference under uncertainty, there might be two competitive accounts:

1) From loss aversion perspective, sense of uncertainty should reduce experiential (vs. material) product preference to avoid further loss of psychological ownership.

2) For complementary consumption perspective, sense of uncertainty might increase material (vs. experiential) product preference to restore lost psychological ownership.

Across five studies, we attempt to examine how sense of uncertainty influences experiential vs. material product preference and which account driven this effect.

Study 1 examined the relationships between participants' general sense of uncertainty and experiential (vs. material) product preference. Students (N = 260) completed different kinds of insecurity (Wittkowski 2001) as a proxy of uncertainty perception. Then, experiential product preference (Ryan, Paulina and Ravi 2012). Results showed that general sense of uncertainty was negatively related to preference for experiential product (b = -.29 (.09), $t(258)$ = -3.18, p = .002). Study 2 tested the main effect of uncertainty on experiential (vs. material) product preference. Participants (N = 226) firstly completed the certainty manipulation task (Faraji-Rad and Pham 2017). Then participants read descriptions of experiential or material grills (Tully and Sharma 2018) depended on which condition they were in and then evaluated the grill. A 2 (state) x 2 (product type) ANOVA revealed predicted significant interaction between state and product type ($F(1, 222)$ = 4.38, p = .037, η_p^2 = .02). When the product was experiential-oriented, compared to certainty condition (M = 5.56, SD = 1.49), uncertainty lead to a marginally more negative attitude toward the outdoor grill (M = 5.10, SD = 1.29, $t(222)$ = 1.89, p = .060, d = .33). However, when the product was material-oriented, product evaluation did not differ between certainty (M = 5.43, SD = 1.29) and uncertainty condition (M = 5.69, SD = 1.07, $t(222)$ = 1.07, p = .287, d = .22). These findings provide direct evidence that uncertainty decreases experiential product preference rather than increases material product preference.

To further confirm this effect is driven by uncertainty' aversion effect rather than certainty's complementary effect, the next study added a pure control condition to further examine these two competitive accounts and tested the mediating role of psychological ownership. Participants (N = 308) were randomly assigned to one of the three certainty manipulation conditions and then made a choice from a laptop and a travel. After that, they completed the psychological ownership measure. Results showed that participants in uncertainty condition (M = 44.33%) were marginally less likely to choose travel than participants in certainty-condition (M = 57.43%; b = -. 53 (.29), z = 1.84; p = .066) and in control condition (M = 61.26%, b = .69 (.28), z = 2.43; p = .015). There was no significant difference between certainty (57.43%) and control condition (61.26%, b = -.16 (.28), z = 0.57; p = .570). In addition, the impact of uncertainty on experiential product aversion is driven by relative sense of psychological ownership from experiential vs. material product. We ran two process model and in support of our hypothesis, relative perceived psychological ownership mediated the effect of sense of uncertainty on experiential product preference.

Study 4 investigated the moderator of perceived psychological ownership. Participants (N = 290) completed certainty manipulation, gift choice and perceived relative psychological ownership. Results showed a significant interaction between state and relative psychological ownership (b = .33(.17), z = 1.96, p = .051). Floodlight analysis showed that those perceived experiential product had lower psychological ownership compared to material product (relative psychological ownership score of 2.86 or lower) were more likely avoid to choose travel as the gift under uncertainty condition. Once perceived relative psychological ownership of experiential product increases, this negative effect would disappear.

Study 5 directly manipulated psychological ownership in a real choice context. Students (N = 231) completed certainty manipulation task, psychological ownership manipulation task, and then made a real choice between an umbrella (material product) and motive ticket (experiential product, pretested). Logistic regression showed a marginally significant interaction between state and relative perceived psychological ownership (b = 1.05(.54), z = 1.93, p = .054, η_p^2 = .02). Decomposing this interaction showed in the control condition, participants were less likely to choose a film ticket as a bonus when they were uncertain (34.55%) than when they were certain (M = 50.85%; z = -1.75, p = .081). However, in the high psychological ownership condition, participants showed no preference difference for the film ticket and the umbrella when they were certain (33.33%) and when they were uncertain (M = 42.11%; z = .98, p = .328).

Taken together, these studies provide consistent and convincing evidence that sense of uncertainty leads people to less prefer experiential product because experiential product is associated with lower psychological ownership compared to material product.

Time Machine to the Future The Potentials and Risks of Using Virtual Reality to Stimulate Saving Behavior

Andrea Weihrauch, University of Amsterdam, Netherlands
Tobias Schlager, HEC Lausanne, Switzerland

EXTENDED ABSTRACT

Every consumer faces the risk to experience (unexpected) negative life event (i.e., job loss, divorce). Such negative events often come with financial consequences, and can significantly affect the financial situation of consumers (McKay and Kempson 2003). The best way to (financially) prepare would be to create a "safety buffer". However, evidence suggest that many consumers are financially unprepared (Macrae et al. 2017; Peetz and Buehler 2009). One of the main reasons for this "lack of preparation" is that they are unable or unmotivated to imagine their future (Gilbert and Ebert 2002).

One strategy to help consumers to prepare for negative life events is to expose them to simulations of the future. Loewenstein (1996) theorized that a vivid impression of a future situation can substantially affect people's current behavior. Exposing consumers to a simulation of a future event should enable them to better imagine its occurrence, and may eventually motivate them to (financially) prepare for that event. Traditionally, firms used videos to simulate those events. However, the development of new technologies provides different opportunities to immerse people. There are many examples for VR use to simulate negative life events (i.e., an UK insurance company exposes consumers to a house fire to encourage the purchase of an insurance).

Initial evidence suggests that Virtual Reality (VR) can indeed effectively simulate future events and encourage people to adapt their behavior. For instance, Hershfield et al. (2011) showed that exposing people to an age-progressed avatar of their future selves in VR increases their willingness to save money for retirement.

While such findings shed a positive light on the ability of using VR simulations to motivate and enable saving behavior, using VR could have downsides: Not only is creating VR stimuli costly, but the high level of immersion such simulations produce could lead to some unexpected risks. Increased immersion entails that the experience is more confronting. For instance, experiencing an extremely realistic simulation of being laid off, is likely perceived to be painful and uncomfortable. Imaging a very negative life event might trigger cognitive defenses (Miceli and Castelfranchi 1998), with the result that consumers underestimate the likelihood of the event or deny its impact (Parfit 1984; Taylor 1991). Thoughts such as "this would never happen to me" could in the worst case even be demotivating.

This leads us to the following three hypotheses:

Hypothesis 1:   *Exposure to more immersive simulations (VR vs. video) of negative future events decreases saving motivation.*

Hypothesis 2:   *Exposure to more immersive simulations (VR vs. video) of negative future events triggers cognitive defenses, which in turn lead to a decrease in saving motivation.*

Hypothesis 3:   *Framing the negative life event as more positive can attenuate the negative effect of immersion on saving motivation.*

We conducted a series of stimuli pretests and two laboratory experiments to examine whether and how using VR to simulate life events affects saving behavior. Together with a professional VR company and an actor with many years of industry experience, we designed a simulation of a negative live event, namely the temporarily loss of employment. We used this negative life event as it 1) has the strongest negative impact on consumers financial situation (compared to e.g., parenthood, divorce, or bereavement), 2) is a negative life event that many consumers experience at some point in their life, 3) can occur in different stages of one's life. During the simulation, consumers "walked" into an office, took a seat across from their boss, and were informed that their work contract would be changed, and that they would experience a significant decrease in income for a six-month period.

In study 1, we exposed participants (n = 237, 48.1% female, M_{age} = 19.98) to that stimulus in high immersion (VR) and low immersion video (video). We assessed their self-reported saving motivation, and an incentive-conform measure of saving behavior. We also tested an intervention to provide some evidence of the suggested process of activated cognitive defenses, and included a negatively-framed version of the life event, as well as a positively-framed version.

In study 2 (n = 333, 52.9% female, M_{age} = 20.18), we replicated the procedure of Study 1 and further included an additional condition: a negative scenario (both in video and VR) with an intervention aimed to remove possible cognitive defenses. As argued, participants likely use arguments such as "this will never happen to me". To mitigate this, we asked participants after exposure to the negative scenario to provide one or more reasons why such a temporary unemployment is likely to occur to them.

Our results show that the prevailing notion "the more immersion is always better" might not always be true. For negative life event, less immersive technologies than VR (such as video simulations) can be more efficient to stimulate saving behavior. The underlying reason is that a too realistic simulation of a negative event triggers cognitive defenses in consumers. Should the use of VR still be considered, accompanying the simulation with a task to remove these cognitive defenses is advised to attenuate the negative effect of immersion on saving motivation. This seems to be a more effective strategy than framing the negative event as more positive.

This manuscript makes important contributions to 1) the literature examining the potential of VR to change consumer behavior; 2) research aiming to better (financially) prepare consumers for their future; 3) research on positive versus negative information, and 4) literature on cognitive defenses. In sum, it supports the growing literature on the intersection of financial, technological and behavioral sciences.

The insights of our studies should inform both companies and public policy makers, and ultimately consumers. Our results provide concrete guidelines in designing the best instrument to better prepare customers for the financial implications of (negative) life events.

The Environmental Consequences of People's Moods: Positive Moods and Disposal Behavior

Sarah Whitley, University of Georgia, USA
Remi Trudel, Boston University, USA
Weston Baxter, Imperial College London, UK

EXTENDED ABSTRACT

Recycling presents a real way to combat climate change, but can something as simple as your mood influence your likelihood to recycle? We suggest that positive moods increase one's likelihood to recycle with behavioral evidence observed both in the lab and on an aggregate level in the community.

Every day people are faced with disposal decisions: whether to keep, trash, or recycle an object. The US EPA concludes that recycling provides a real way to help address climate change. Unfortunately, much of what ends up in landfills could have been recycled (US EPA 2012). Prior research has shown a number of cognitive factors that influence one's decision to trash versus recycle (product form, Trudel and Argo 2013; identity-relevance, Trudel, Argo, and Meng et al. 2016a; proximity, Catlin and Wang 2013), but what about affective factors? Research has seldom explored affective influences on sustainable behaviors. Ad/image-induced negative emotions (sadness/guilt) from environmental campaigns have been shown to increase environmental concern (Schwartz and Loewenstein 2017; Sevillano, Aragonés, and Schultz 2007), other work has shown that people are waste averse and consume less resources to avoid negative emotions from wasting (Sun and Trudel 2017), but research has yet to explore the influence of incidental affect on disposal decisions. In this work, we examine whether affect, specifically mood, influences consumers' disposal decisions: the choice to trash vs. recycle an object.

Across four studies, we examine if and in what manner mood may influence recycling behavior. In our first two studies, using historical recycling collection data (i.e., community refuse pickup amounts), we test for evidence of a relationship between macroeconomic events that influence mood (e.g., sporting event outcomes, weather) and observed/measured recycling behavior. Next, we explore the causal direction of this hypothesized relationship in the lab by observing participants' decision to recycle versus trash a piece of scrap paper after being induced into a positive, negative, or neutral mood state. Lastly, we propose that one of the mechanisms driving the effect of mood on recycling behavior is consumers' ability to correctly categorize products at the point of disposal decision (i.e., deciding if the object should go into the recycle vs. trash bin), as positive moods engender more flexible cognitive categorizations (Isen and Daubman 1986).

STUDY 1

Recycling is a highly observable behavior in that it is quantified on both an individual and aggregate level. Consumers in charge of their own recycling collections deposit it at a recycling facility and pay fees according to the weight of the recycled content, while community

collections do this on an aggregate scale, keeping records of daily, weekly, and monthly recycled content. Provided this wide-scale quantification of recycling behavior, we first examined whether it is possible to observe a relationship between mood and observed recycling collection amounts. While it is not possible to measure each individual's mood when considering wide-scale community collection observations, there are certain types of events that can impact the general mood of a community. Prior research suggests that sporting event outcomes significantly impact mood (Edmans, Garcia, and

Norli 2007), and thus we examine the impact of sporting event outcomes on a community highly invested in the outcomes of a specific sport: college basketball. Using collegiate basketball game results as a proxy for mood, we examine the effect of historical basketball game outcomes on observed college campus recycling collections.

Method

We collected daily recycling collection amounts (lbs), spanning 2012-2016, from four U.S. universities whose men's basketball teams were ranked in the top 30 of the 2016 pre-season NCAA Division 1 Men's College Basketball Rankings. Looking at the first recycling collection date following each historical basketball game from 2012-2016, school-specific campus recycling collections were regressed on basketball game outcomes (wins vs. losses/ties) to test for any relationship between mood and recycling behavior.

Data and Variables. Each university had a different recycling collection schedule (e.g., Monday/Thursday, Tuesday/Friday, etc.), resulting in each collection date (i.e., the day recycling was collected from the bin and weighed by the city) representing the amount collected over a varied period of days. To create a dependent variable comparable across schools at the collection date level, we calculated the average daily recycling amount for each collection date by simply dividing the total weight (lbs) of recycling content collected on each school-specific collection date by the number of days content accumulated in the recycling bin (i.e., # of days since last collection date). This resulted in our dependent variable of average daily recycling (lbs/day) for each collection date. Our final dataset included 373 collection day observations.

Historical game outcomes (win, loss, tie) were matched to the first recycling collection date immediately following the date of the game. In some cases, more than one basketball game occurred before a single recycling collection date; to account for this, we calculated a "Majority Wins" independent variable characterizing whether the majority of games occurring before the collection date were wins (Majority Wins=1) or losses/neutral (Majority Wins=0).

Results and Discussion

We used a linear mixed effects model (ML estimation) with game wins (Majority Wins) as the fixed effect predictor and both school and season (i.e., 2012-2013) as random effects to analyze their association with daily average recycling. Basketball game wins were associated with a significant increase in average daily recycling (b=1,096.14, SE=523.25, t=2.10, p=.037), suggesting a positive correlation between mood and recycling behavior.

STUDY 2

We next sought to replicate the results of the prior study using another historical data analysis employing a different macro-level proxy for mood: weather. Weather has been shown to influence people's moods, with good weather bringing about positive moods and inclement weather prompting negative moods (Hirshleifer and Shumway 2003; Schwarz and Clore 1983). Using precipitation as a proxy for negative mood, we examine the effect of historical precipitation levels on neighborhood recycling collection amounts. Lastly, unlike Study 1, we were able to obtain data about trash collection

amounts from our source and thus incorporate the effects of trashing behavior in our analysis of recycling.

Method

One year (4/1/2015-3/31/2016) of daily curbside trash and recycling collection amounts (metric tons) were obtained for 14 neighborhoods in a London suburb, resulting in a total of 2,831 curbside collection date observations across 203 individual collection dates. These daily collection amounts were regressed upon daily precipitation (mm) data for the London area for the same dates.

Data and Variables. Since the neighborhoods operated according to different collection schedules (e.g., Monday/Thursday, Tuesday/Friday, etc.), in the same vein as Study 1, a dependent variable of average daily recycling (metric tons/day) was created to allow for comparisons across neighborhoods by collection date. We created an average daily trash (metric tons/day) variable in the same manner. Trash served as a covariate in our analysis to evaluate the independent effect of precipitation on recycling absent any effects from trash. Daily precipitation (mm) was averaged over the days contained within each collection period (i.e., period between prior collection date and current collection date – days over which content accumulated in the bin) and served as our independent variable of average daily precipitation (mm/day).

Results and Discussion

We used a linear mixed effects model (ML estimation) with average daily precipitation as a fixed effect predictor and neighborhood as a random effect. We also controlled for average daily trash collected, holiday occurrence, and collection pickup schedule (Monday/Thursday vs. Tuesday/Friday) by adding them as fixed effects in the model. Our analysis revealed that increases in precipitation (i.e., a proxy for increased negative mood) was associated with a significant decrease in the amount of recycled content collected (b=-.001, SE=.0003, t=-3.36, p=.001). This suggest that negative mood has a negative impact on recycling, supporting the same conclusion from Study 1 that mood is positively correlated with recycling (i.e., recycling moves in the same direction as mood).

While the covariate of average daily trash had a significant positive relationship with recycling (b=.214, SE=.006, t=34.88, p<.001), a separate analysis with trash as the dependent variable revealed that precipitation had a negative effect on average daily trash collected (b=.004, SE=.001, t=-4.75, p<.001). Together, these results suggest that the negative association of precipitation and recycling holds over and above precipitation's influence on trash collected.

Additionally, an analysis using standardized variables confirmed that the negative effect of precipitation on recycling (β=-.074) was greater in magnitude than that of precipitation on trash (β=-.064).

STUDY 3

While Studies 1 and 2 provide correlational evidence of the relationship between mood and recycling behavior in the real-world, in this study we use a controlled lab environment to show that mood directly causes changes in recycling. Additionally, it is not clear if the positive correlation between mood and recycling is due to positive moods increasing recycling or negative moods decreasing recycling. By adding a neutral mood condition, we can disentangle the effect of positive versus negative moods on recycling.

Method

Participants and design. Undergraduate participants (N=234) were randomly induced with either a positive (n=69), negative (n=74), or neutral (n=69) mood and their disposal behavior of a piece of scrap paper was recorded.

Procedure. Participants sat at a lab computer and were provided with a small piece of paper (3x1.5 inch) with a 3-digit code. This small paper was used because although paper is recyclable, small prices of paper have been shown in prior research to often be trashed rather than recycled (Trudel & Argo 2013), providing a refuse object that is capable of being either recycled or trashed and for which people show inherent variance in their disposal behavior. Depending on their assigned condition, participants were asked to read a positive, negative, or neutral online news article (Fishbach and Labroo 2007) and then asked to reflect on their own experiences and write a short news-like article detailing one of the saddest, happiest, or a typical day in their life, respectively. Upon finishing the mood manipulation task, participants were told to "dispose of their paper on the way out." Directly outside the lab were two disposal bins, labeled "Trash" and "Recycle." Data was collected at the end of the day by a research assistant who counted the number of pieces of paper in the trash versus recycling bins. The codes on each disposed paper was used to link participant disposal behavior with assigned condition.

Results and Discussion

Twenty-two participants left with the paper, leaving 212 observations (59.4% female; M_{age}=19.84 years). A binary logistic regression (Trash=0, Recycle=1) revealed that mood influenced recycling (χ^2(2)=9.83, p=.007). Participants recycled significantly more when in a positive mood (44.9%) than in a negative (25.7%; β=.86, p=.017) or neutral mood (21.7%; β=1.08, p=.004; See Figure). Disposal behavior between the negative and neutral mood conditions did not differ (β=.22, p=.581). These results provide causal support for the positive relationship between mood and recycling and suggest this effect is driven by a positive mood increasing recycling, rather than a negative mood discouraging recycling.

STUDY 4

Various affective, motivational, and cognitive mechanisms may underlie the observed effect of mood on recycling behavior. Since recycling and trashing are associated with positive and negative affect, respectively (Sun and Trudel 2017), people in positive moods may be more likely to recycle in order to maintain their positive mood state (Wegener and Petty 1994).

Additionally, as recycling is often a more effortful task than trashing, since positive moods have been shown to increase effort (Erez and Isen 2002; Fishbach and Labroo 2007), this suggests people with positive moods may be more likely to recycle. We suggest that despite these affective and motivational mechanisms, we believe part of the reason positive mood increases one's likelihood to recycle is cognitive. The decision to recycle, itself, is a cognitive one: when faced with an article of refuse, a consumer must decide to either recycle or trash the object.

However, consumers often erroneously categorize recyclable items as trash and throw them in the trash bin rather than the recycling bin (Trudel, Argo, and Meng 2016b). Positive moods lead to more flexible categorizations (Isen and Daubman 1986) and we suggest that consumers in positive moods will be more likely to categorize fringe exemplars (e.g., smashed cans, scrap paper; Trudel and Argo 2013) correctly as something to be recycled rather than trashed. In this study, we evaluate whether mood influences how consumers categorize fringe exemplars of recyclable products (i.e., scrap paper), as correct categorization should theoretically drive correct disposal.

Method

Participants and design. Undergraduate participants (N=166) were randomly induced with either a positive (n=56), negative (n=55), or neutral (n=55) mood and asked about their categorization of a piece of scrap paper.

Procedure. Analogous to Study 3, participants sat at a lab computer and were provided with a small piece of paper (3 x 1.5 in) with a 3-digit code before being induced with a positive, negative, or neutral mood. The same mood manipulation from Study 3 was used. Participants were then asked to focus on piece of paper and indicate "how much is the paper like trash?" (1=Not at all like Trash; 5 = Exactly like Trash), a measure used to investigate the categorization of recyclable material (Trudel et al. 2016b).

Results and Discussion

ANOVA results revealed differences in categorization between mood conditions ($F(2, 163) = 4.78$, $p = .010$). Specifically, participants in a positive mood ($M = 2.59$, $SD = 1.33$) were less likely to rate the scrap paper as typical of trash compared to participants in a negative mood ($M = 3.27$, $SD = 1.18$; $p = .003$) or neutral mood ($M = 3.04$, $SD = 1.02$, $p = .048$). There was no difference in categorization of the scrap paper between participants in the negative and neutral mood conditions ($p = .297$). Supporting our claim, these results show that people in positive moods are more integrative in their categorization and less likely to erroneously categorize a small piece of paper as trash. This proper categorization (as not trash) should theoretically lead to proper subsequent disposal (i.e., recycling), suggesting that positive moods should drive an increase in one's likelihood to recycle.

GENERAL DISCUSSION

Overall, we show that mood significantly impacts recycling behavior, both on an individual and aggregate level, with positive moods increasing recycling both among experimental induced moods and naturally occurring mood states from macro-level events. We find that positive moods make consumers more likely to recycle a recyclable object (Study 3), and believe this greater likelihood to properly recycle objects (rather than trash them) underlie the positive relationship between mood and recycled content observed in Studies 1 and 2 (i.e., recycled content can only increase by more recycling-capable content being placed in the bin). While affect regulation and motivational mechanisms may certainly play a role in the impact of positive moods on recycling, we suggest that reduced improper categorization of recyclable products as trash under a positive mood (Study 4) underlies the observed increase in recycling associated with positive mood.

This work adds to prior research noting the mixed effects of mood on traditional prosocial behaviors focused on helping others (e.g., donating, volunteering, helping with a task; Salovey and Rosenhan 1989; Carlson, Charlin, and Miller 1988), by exploring the impact of mood on a sustainable behavior (i.e., recycling), a decidedly both self- and other-helping behavior. Lastly, in addition to the more cognitive (Jenkins et al. 2003; Reschovsky and Stone 1994; White, MacDonnell, and Dahl 2011), social (Goldstein, Cialdini, and Griskevicius 2008) and convenience-based (Halvorsen 2008) antecedents of disposal decisions, we find that affect, specifically incidental mood influences one's decision to recycle.

Examining the Ongoing Process of 'Hegemonic Legitimacy' of Meat: a *Discursive* Institutional Perspective on Market Maintenance

Lucie Wiart, Université de Lille, France
Deirdre Shaw, University of Glasgow, Scotland, UK
Nil Özçaglar-Toulouse, Université de Lille, France

EXTENDED ABSTRACT

In marketing, the study of how markets evolve through different dynamics or logics has been well developed (Ertimur and Coskuner-Balli, 2015). In most of these studies, institutional perspectives have been adopted for examining processes of market legitimacy creation, evolution, and maintenance (see Humphreys and LaTour, 2013; Humphreys, 2010; Kates, 2004; Scaraboto and Fischer, 2012). However, the process of legitimacy maintenance has been neglected. Also, while the process of legitimacy across the three areas of market creation, evolution and maintenance has been conceptualized, the relationships between these processes have not been empirically examined. Such an omission is important as markets are not static, thus, we would expect movement between and within these concepts. Furthermore, market maintenance requires ongoing effort over time, suggesting a process of evolution which may require elements of market creation. Therefore, in highlighting the need to examine market maintenance we also highlight the need to examine the process of legitimacy as a whole to understand the role of market maintenance within this process not in isolation from it.

To achieve this we focus on discursive aspects of legitimacy to consider power relations and struggles (Vaara and al, 2006; Vaara and Tienari, 2008; Vaara and Monin, 2010; Johnson, 2017). Indeed, some research understands legitimacy as a process of *discursive struggle* through which discourses both attempt to either resist or reproduce and reinforce legitimacy (Laine and Vaara, 2017). We specifically draw on Critical Discourse Studies (CDS) considering discourse as a practice of constructing the social world and meanings (Fairclough and Wodak, 1997; Jorgensens and Phillips, 2002). From this perspective, the market could be considered as an entirely discursive formation: it provides concepts, objects, and subject positions (Fairclough, 1992; Phillips and Hardy, 1997). The three processes of market creation, evolution and maintenance would necessarily be linked to the discursive constructions of concepts, objects and subject positions. The context of discursive struggles over these three differing constructs will shed light on the market as dynamic across the processes of legitimacy. Such an approach will reveal how market as a discourse is (re)created and evolving and the resultant relationship and impact on market maintenance.

To examine these discursive processes, we focus on the context of meat consumption, which has a long history of critique (Spencer, 2000) right up to present day links between meat consumption and climate change (Springmann et al, 2018). Although consumers have been converting to vegan, vegetarian and flexitarian diets in increasing numbers, demand for meat is increasing globally (Godfray et al, 2018). In this paper we ask how a food source that has been challenged over a significant time period has managed to maintain its legitimacy.

We draw on a 'discourse-historical approach' (Wodak, 2001; Reisgl, 2018; Reisgl and Wodak, 2015) that puts emphasis on historical anchoring and how discourses are subject to diachronic change. We conducted a historical discourse analysis from 1944 to 2019, gathering media articles on meat consumption from two French newspapers. The specific perspective of Laclau and Mouffe (1985) regarding hegemony and discourses is used to analyze the data and for developing theoretical insights.

We outline our findings across three key time periods representing points of discursive struggle between opposing ideologies in relation to meat (non)consumption and resulting challenges to legitimacy maintenance:

1944-1980: Meat as an industrial product

During this period we observe the creation, evolution and maintenance of meat as a legitimate industrial farm product articulated by commodity and scientific signifiers. Counter-hegemonic resistance is lacking and economic discourse is dominant, indeed, meat consumption is considered vital to support economic development.

1980-2019: Safe to eat?

The period from 1980 represented a '*period of dislocation*' (Laclau and Mouffe, 1985*)* where two major events, namely, 'hormonal veal' (1980) and 'mad cow disease' (1996) resulted in legitimacy threats in relation to the conceptualization of farm animals as objectified and industrialized. To maintain market legitimacy we observe the creation of a new discourse of 'Happy Meat', countering animal suffering while maintaining the position of meat as a food source. Accordingly, the subject position of 'Compassionate Carnivore' is created affording a humane identity to meat consumers.

2000-2019: Climate crisis

The mainstreaming of discourse around climate change position overconsumption of meat as unsustainable and unhealthy. From this we observe the creation of 'flexitarian' as a new moral and dominant subject-position enabling the construction of a responsible identity. Here the market created 'meat substitutes', offering a 'fake meat' product. In doing so, the concept of farm animal is gradually disarticulated from the concept of meat, the new meat-substitute market completely erases the animal signifier. Through this new market, negative signifiers associated with farm animals and livestock sectors are, therefore, not co-opted, rather erased. Such a creation, maintains the position of 'meat' as food while shifting what the object of meat is in terms of what it comprises, either as plant based meat substitutes or lab meat grown from animal cells.

Our findings reveal that the process of legitimacy is dynamic across market creation, evolution and maintenance and that to maintain legitimacy requires engagement with creation and evolution in a non-linear circling between concepts. In this process we see discursive struggles forcing market creation and the evolution of meaning and relevance. Thus, to maintain hegemonic legitimacy necessities a continuously crafted discourse embedded within cultural and historical contexts, constantly arranging and recreating legitimacy through new articulations or reinforced processes of differentiation and chains of opposition.

We also develop a post-structural institutional understanding of individual resistance and agency toward a hegemonic market that could direct future research. Indeed where discourse is studied in research on market evolution, it is constructed by researchers as an instrument for actors to impact markets (see e.g., Giesler, 2012; Thompson, 2004; Kates, 2004; Press et al, 2014) or conceptualized as a reflector of underlying normative change (see Humphreys,

2010). This ignores the role of discourse as a vehicle for change in itself and as constitutive of social reality (Larsson, 2019). Here, we find that individual actors convey either dominant or alternative discourse through performing subject positions and could, therefore, be seen as instruments for market maintenance.

Counting Calories: How Calorie Perceptions and Estimates Diverge

Kaitlin Woolley, Cornell University, USA
Peggy Liu, University of Pittsburgh, USA

EXTENDED ABSTRACT

To manage calorie intake and achieve weight-related health goals, consumers often monitor calories expended and consumed (Campbell and Warren 2015; Jia et al. 2020). We identify a novel factor biasing calorie assessments and subsequent food choice: the estimation mode consumers use to evaluate calories burned during exercise or contained in a food portion.

We distinguish between two modes consumers use to estimate caloric consumption and expenditure—forming ordinal calorie estimates (i.e., "very few" to "very many" calories) versus forming absolute calorie estimates (i.e., numeric response). We propose that calorie estimates systematically diverge as a function of estimation mode, with important consequences for consumers' choices aimed at managing caloric intake. In addition, because both approaches are used interchangeably by researchers (Carels et al. 2006; Chernev, 2011; Liu et al. 2019), some conclusions based on prior findings may be moderated by estimation mode.

Type and Quantity as Inputs to Caloric Judgments

Calorie estimates are a function of both what a stimulus is in terms of its "type" (e.g., healthy vs. unhealthy food; easy vs. difficult exercise) and its "quantity" (e.g., food portion size; exercise duration). Prior research has found that information on type is "primary" in that it is processed before information on quantity (Liu et al. 2019).

We propose that consumers differentially rely on type versus quantity depending on whether they form ordinal or absolute estimates. First, we theorize that ordinal estimates involve categorical thinking driven by scale compatibility (Tversky et al. 1988; Fischer et al. 1999). That is, ordinal estimates anchor on type (more vs. less healthy food), and as this information is compatible with the ordinal estimate response scale (few vs. many calories), information on type is incorporated into their estimate (i.e., healthier food = fewer calories; less healthy food = more calories). After spontaneously considering type, we suggest that ordinal estimates then fail to adjust much for quantity. By contrast, we suggest that absolute estimates involve continuous thinking. Specifically, although type information is primary, this information is not compatible with the absolute estimate response scale (i.e., number of calories), and thus we suggest that forming absolute estimates prompts people to consider other information beyond type, leading them to incorporate quantity into their calorie estimate.

When Will Ordinal and Absolute Calorie Estimates Reverse?

If ordinal and absolute calorie estimates are differentially sensitive to type versus quantity information, these estimation modes should lead to calorie estimate reversals when type and quantity diverge. That is, estimates should diverge when considering calories burned by difficult, shorter (vs. easier, longer) workouts, or when considering calories contained in smaller, healthier food portions (vs. larger, less healthy portions). We test this theory across six studies (five pre-registered; see table 1a) by examining whether the effect of estimation mode (ordinal vs. absolute) diverges as a function of type/quantity.

Study 1 examined divergence in ordinal versus absolute estimates of calories burned for different exercises. Participants indicat-ed both ordinal estimates ("very few" to "a lot of" calories burned) or absolute estimates (numeric response). Ordinal estimates were greater for more intense, shorter exercises (e.g., 10-minutes of moderate biking) than for less intense, longer exercises (e.g., 30-minutes of slow biking) ($F(1, 395) = 52.75$, $p < .001$), which reversed when forming absolute estimates ($F(1, 395) = 5.18$, $p = .023$), despite equivalent objective calories burned across intensity/duration. Studies 2-6 examined this prediction within the food domain.

Study 2 assessed calories in a larger portion of healthier food (200-calorie almond snack plate) and a smaller portion of less healthy food (100-calorie chocolate covered almond snack plate). Participants indicated either ordinal estimates ("very few" to "many" calories) or absolute estimates (numeric response). Ordinal estimates of almonds (vs. chocolate covered almonds) were significantly lower ($t(121) = 6.50$, $p < .001$); this pattern attenuated for absolute estimates ($t(120) = .99$, $p = .325$). This divergence affected actual food choice: when choosing a snack plate with fewer calories to eat in the lab, more participants chose the larger portion of almonds when forming ordinal (vs. absolute) estimates (59.8% vs. 46.3%; $\chi^2(1, 243) = 4.48$, $p = .034$).

Study 3 replicated this effect and demonstrated consequences for consumer research by testing for moderation of an existing finding in the literature. First, we replicated a previous finding (study 2 in Chandon and Wansink 2007) that people forming absolute estimates estimate more calories in a Subway 12-inch turkey sub (larger, healthier) than in a McDonald's cheeseburger (smaller, less healthy) ($t(136) = 1.90$, $p = .059$). However, this pattern reversed when assessing ordinal calorie estimates, wherein people estimated fewer calories in the Subway's sandwich (vs. McDonald's cheeseburger) ($t(139) = -9.27$, $p < .001$).

Studies 4-6 demonstrate evidence for our underlying process. First, study 4 fully crossed type (almonds vs. chocolate covered almonds) and quantity (small vs. large portion), demonstrating that ordinal estimates are more sensitive to type ($F(1, 586) = 14.36$, $p < .001$), whereas absolute estimates are more sensitive to quantity ($F(1, 586) = 28.12$, $p < .001$).

Study 5 examined moderation within ordinal estimates by quantity primacy. Increasing the primacy of quantity information led those forming ordinal and absolute estimates to both estimate more calories in a larger portion of healthier food (vs. smaller portion of less healthy food). Lastly, study 6 examined moderation within absolute estimates by intuitive (vs. deliberative) mindset (e.g., Woolley and Risen 2018). Adopting an intuitive mindset (quick, immediate response) led those forming absolute and ordinal estimates to both estimate fewer calories in a larger portion of healthier food (vs. smaller portion of less healthy food).

Overall, six studies identified a novel bias in consumers' calorie estimates as a function of whether they made ordinal or absolute estimates. Depending on calorie estimate mode, we document predictable divergences between ordinal and absolute calorie estimates when evaluating stimuli that tradeoff on type and quantity. These findings are of consequence to consumers, as whether consumers use ordinal versus absolute estimates can affect their food choices, and for researchers, as the method of evaluating calories matters in terms of how consumers incorporate type and quantity.

EXTENDED ABSTRACT

From Kraft's creation of "the smile noodle" to Herta's promotion of the "Herta makes a meal happy" campaign, smile is an essential marketing tactic for firms to better engage consumers. Indeed, smile is widely believed to activate positive emotions and generate favorable feedback in service and promotion contexts (e.g. Bugental 1986; Cheng, Mukhopadhyay, and Williams 2020; Mueser, Grau, Sussman, and Rosen 1984).

Smiles are not expressed in a vacuum. Consumers decode emotional expressions based on a set of emotion decoding rules in the communication context. While burgeoning research has explored how emotional expressions may elicit consumers' reactions in a variety of domains (Barger and Grandey 2006; Small and Verrochi 2009; Wang, Mao, Li, and Liu 2017), little is known about how the interplay of emotional expressions, displayer characteristics, and contextual factors collectively impact consumer inference. This research addresses this gap by highlighting the important roles of the displayer's social rank and consumers' decision time in consumers' interpretation of smiles.

Study 1 (N = 294) provides initial evidence of the proposed role of social rank in the interpretation of smiles. This study uses a 2 (smile type: slight vs. big) x 2 (rank: lower vs. higher) between-subjects design. To manipulate smile type, we showed participants a photo featuring a male employee's slight or big smile. To manipulate rank, the job position of the employee was either an office assistant or a manager. The rank manipulation was confirmed by a pretest with the same subject pool ($p = .02$). As expected, there was an interactive effect between smile type and rank ($F = 6.93$, $p = .01$), such that when the employee was an office assistant (lower rank), participants liked him more if he had a big rather than slight smile ($p = .04$). When the employee was a manager (higher rank), nevertheless, participants liked him less if he had a bigger smile ($p = .06$).

Study 2 (N = 229) replicates the proposed effects in an advertising context and extends the investigation to purchase intentions. We also investigate the moderating role of processing time. Consumers often make decisions under time pressure (Cristol and Sealey 1996; Dhar and Nowlis 1999). Consistent with the heuristic-systematic dual-processing model, consumers focus on fewer informational cues when they have limited time (Dhar and Nowlis 1999). When the processing time is shorter, we propose that consumers should focus on the overall communications and be less likely to process peripheral informational cues, such as social expectations for emotional displays.

This study has a 2 (smile type: slight vs. big) x 2 (rank: lower vs. higher) between-subjects design. Participants were shown one of four ads with a female displayer promoting a black tea. The female had either a big or a slight smile (confirmed by a manipulation check) and was titled as either doctor (pretested to have higher rank) or first name (pretested to have lower rank). We also measured processing time as a continuous variable by recording the time that participants spent on viewing the ad.

The three-way interaction effect (smile type x rank x processing time) on consumers' choice was significant (Wald's $\chi^2(1) = 5.11$, $p = .02$). Specifically, when participants spent longer time (1 SD above the mean) viewing the ad, they chose to buy the tea more often if the displayer addressed by her first name had a bigger smile ($p = .01$) but less often if the displayer addressed by her doctor title showed a bigger smile ($p = .03$). When participants spent less time (1 SD below the mean) viewing the ad, the smile type x rank interaction was not significant ($p = .66$). Additional analyses also revealed a significant three-way interaction (processing time x rank x smile) on consumers' purchase likelihood ($p = .04$). Similar patterns of results were observed.

Study 3 (N = 166) directly tests the mediation path and extends our investigation to emoji characters and brand rank. This study uses a 2 (smile type: slight vs. big) x 2 (rank: lower vs. higher) between-subjects design. We operationalize the rank by brand names and confirmed the effectiveness of this manipulation by pretests. Consistent with our main proposition, the analysis of liking as a function of rank and smile type yielded an interaction effect $(F = 10.02$, $p = .002)$. For the lower-rank brand, participants liked the design better if the emoji had a big smile ($p = .014$). For the higher-rank brand, participants liked the design more if the emoji had a slight smile ($p = .051$). More importantly, a mediation analysis (Model 8; Hayes 2013) directly supported our hypothesis about the mediating role of expectations for emotion displays concerning rank and smile type.

Study 4 (N = 214) extends our proposed effects to a field setting. This study has a 3 (smile type: slight vs. big vs. no smile) x 2 (rank: lower vs. higher) between-subjects design. Amazon Mechanic turkers were approached after they finished a paid task. We then pleaded them to participate in another task without extra payment. Following the same manipulations of smile type and rank in Study 3, we tracked the percentage of participants who accepted our request to finish the voluntary survey. In particular, when we introduced ourselves by a first name along with a big (vs. slight or no) smiley face at the end of the request description, participants had a higher compliance likelihood. However, when we introduced ourselves as a Ph.D. researcher, a slight smile led to a higher compliance rate (Wald's $\chi^2(1) = 6.64$, $p = .01$ for the interaction).

In conclusion, when a big (slight) smile is displayed matching the displayer's low (high) rank, consumers perceive a higher level of consistency with social expectations for emotion displays. Therefore, they like the displayer better and are more likely to purchase the associated product or service. As important evidence supporting this proposed conscious process, these results hold only when consumers have enough time to decode the emotional expression cues (smiles) in the communication process.

The Effect of Product Evaluations on Consumer Recycling Behavior

Vivian (Jieru) Xie, Virginia Tech, USA
Rajesh Bagchi, Virginia Tech, USA

EXTENDED ABSTRACT

While the industrial revolution has heralded an age of unprecedented affluence and choice abundance, it has also unfortunately increased wastefulness. Trashing products mean that not only did we not utilize the full potential of the raw material, but that we will be imposing further stress on our landfills and incineration facilities. Thus, it is of critical importance to understand how consumers can be encouraged to recycle more.

Consumers' decisions to recycle (vs. trash) a product are subject to a variety of influences, which range from consumer-centric to societal-level factors. Consumer factors, such as knowledge (e.g., Andrew et al. 2013) and concerns for the environment (Schultz and Oskamp, 1996), product-level factors, such as product form distortion (Trudel and Argo 2013) and identity-relevance (Trudel et al. 2016), and finally, social-class and cultural variables (e.g., Laidley 2013) have all been shown to affect consumers' decisions to trash or recycle.

We explore how a specific post-ownership experience, evaluations (positive vs. negative), influences consumers' disposal decisions. We evaluate products all the time and even share our evaluations. While our evaluations play a fundamental role in affecting our future engagement with products, these evaluations could also affect our disposal decisions—whether we trash or recycle a product? For example, while the evaluation of a drink's taste is likely to affect consumers' propensity to repurchase the drink, would it also impact their decision to recycle the container?

From a material-value perspective, there should be no reason to expect any difference in disposal propensity. If consumers are aware that a product (e.g., a drink's bottle) is recyclable, then, normatively, their disposal decisions should be independent of the product's evaluation (tastes good or bad). However, we argue that consumers will be more likely to recycle products that they evaluate positively (vs. negatively), and, thus, will be more likely to recycle a bottle when they evaluate the drink's taste positively.

We propose that this effect emerges because people are more likely to respect a product with positive (vs. negative) evaluations, and it is this respect that drives them to recycle (vs. trash). Respect is earned and is often based on reasons (Dillon 2007). We propose that a product associated with positive (vs. negative) evaluations will also be accorded greater respect by consumers. Furthermore, we believe that products that are respected more will also be given a more respectful burial—recycling (vs. trashing) may be a more respectful way to dispose of a recyclable product. In summary, we propose that people are more likely to respect a product associated with positive (vs. negative) evaluations, which would increase likelihood of recycling (vs. trashing).

In study 1 (N = 173), participants were randomly assigned to one of two conditions. In the positive (negative) evaluation condition, participants were informed that a brand of bottled water was very well (poorly) rated with an evaluation score of 4.8/5 (2.2/5) because most consumers liked the taste (did not like the taste). In both cases the product was priced the same. Participants then indicated how would they dispose of the bottle if they received a free sample and finished it. As shown in Table 1, consumers were more likely to recycle the bottle, and believed the bottle was more worthy of recycling when its taste was evaluated positively.

To investigate whether respect mediated the effect, we used an Implicit Association Test (iatgen via *Qualtrics*, Carpenter et al. 2018) to examine the positive association between the concepts of *respect* and *recycling (vs. trashing)* in study 2. The goal of this study was to assess if respondents associate "Recyclable materials" with "Respect" and "Non-recyclable materials" with "Disrespect." We provided participants (N = 208) with 5 words belonging to each of the four categories and ask them to categorize stimuli. In the "compatible" block, "Recyclable material" and "Respect" were on the one side, while "Non-recyclable material" and "Disrespect" were on the other side. In the "incompatible" block, the combinations were switched. As shown in Table 1, the association occurred more quickly in the compatible than in the incompatible block therefore, confirming our predictions.

In study 3, we replicate these effects in a context with real recycling behaviors, demonstrating external validity. We recruited 153 undergraduates to complete this study in an individual lab room to avoid distractions. We provided each participant with a piece of origami paper and asked them to make an origami fox following a tutorial. Then they were required to take their finished origami fox to the lab assistant. The lab assistant took pictures of their work and told them that an auto-grading system would score their work (but in fact the grade was assigned randomly). Thus, half the participants received a positive grade (8.5/10), while the other half received a negative grade (4.5/10). We then asked them to dispose of their work in the bins (a recycling bin and a trash bin) in the individual lab room. After that, they indicated their respect level toward the origami work. Unbeknownst to participants, after they left, the lab assistant recorded whether they recycled or trashed their fox and removed it to retain the same presets for each participant. As shown in Table 1, more of the participants who received a manipulated positive (vs. negative) evaluation score recycled (vs. trashed) their origami work, and respect toward their origami work mediated these effects.

We introduce a novel effect of product evaluations on consumer recycling behavior—consumers are more likely to recycle a product when it is positively evaluated. Overall, we believe this research makes important contributions from both theoretical and practical perspectives. From a theoretical perspective, this research explores the impact of intangible characteristics related to the product itself—product evaluations. We expand the literature on disposal decision making by demonstrating how a novel product-level characteristic — product evaluations — impact disposal decisions to trash or recycle. From a practical perspective, we believe it is of great importance to understand what drives consumers to recycle more. Our research adds to the growing discourse on environmental issues.

Was the Past Heavier? The Impact of Product Temporal Orientation on Perceived Heaviness and Product Purchase

Lan Xu, Wuhan University, China
June Cotte, Western University, Canada
Nan Cui, Wuhan University, China
Yiran Jiang, Wuhan University, China

EXTENDED ABSTRACT

Consumers may use perceived heaviness as a clue to diagnose the durability and quality of a tangible product (Krishna, 2006; Lin, 2013; Togawa, Park, and Ishii, 2016). Extant research has found that product-related attributes such as size (Murray et al., 1891), color lightness (Hagtvedt, 2019), or location of the product image on a package (Deng & Kahn, 2009) affect individuals' perception of product weight. In this research, we theorize and demonstrate a new aspect- the temporal orientation of a product (the perception of it as being from the past or the future)-that influences consumers' perception of product weight, and ultimate product choice.

Our theory about how product temporal orientation affects perceptions of heaviness is a processing-based one. Compared to the future, consumers can think of many more specific events that have happened in the past. Hence, one's memories and the facts related to one's past are specific and detailed (Muehling, Sprott, & Sprott,2004). Thinking about the past will inevitably trigger recollection and reflection on these specific facts and experiences (Van Boven, Kane, & McGraw, 2010). However, thinking about the future, no matter the extent of imagination or planning involved, is more uncertain and less specific (Epley & Dunning, 2000; Wilson et al., 2000). The different temporal orientation of products may trigger us to retrieve our experiences (past versus future) and we recollect more specific facts from the past, which we argue feels heavier, and may influence how we perceive the heaviness of a product we are considering.

When consumers are considering a product that is temporally oriented to the past, they are more likely to retrieval their sensory experiences and memories about events that happened in the past (Deng, Han, and Wang, 2019). The immediate experience of recalling details of events evokes simultaneously muscular thinking, which renders inner experience felt to be heavy (Winnicotti, 1971). The more details consumers consider, the heavier they will feel during this thinking/processing. The feeling of heaviness will be projected to the object which leads to thinking (Jostmann, Lakens, & Schubert, 2009). In contrast, when exposed to a more futuristic product, consumers are less likely to perceive heaviness because less processing of details happens when thinking about the future.

Hypothesis 1: *Compared to the product with a future temporal orientation, consumers will perceive a product with a past temporal orientation as heavier.*

Hypothesis 2: *The specificity of thinking related to product temporal orientation mediates the influence of the product's temporal orientation on perceived weight.*

Based on processing fluency theory, consumers will be more fluent in processing a weight-related stimulus that matches their current state of thinking of based on temporal orientation (Labroo et al., 2008).

Hypothesis 3: *Consumers are more likely to buy a product with a past (future) temporal orientation when it is designed to be heavier (lighter).*

We tested our hypotheses through three lab experiments and a field experiment. Study 1 examined the impact of the product's temporal orientation (past vs. future) on perceived product weight. A total of 75 undergraduates participated in this experiment. The experiment followed a two-cell (product temporal orientation: past vs. future) between-subjects design. We manipulated the temporal orientation, informing participants that a newly-designed notebook either "was launched in the market six months ago" (past) or "will be launched in the market in six months" (future). Then participants rated their perceived weight of the notebook using 9-point scales (1 = relatively light and 9 = relatively heavy). The results revealed a significant effect of product temporal orientation on perceived weight ($F(1,73)=37.62$, $p<0.001$). Participants in the past condition perceived the product to be heavier than those in the future condition ($M_{past} = 5.72$, $SD_{past} = 2.08$, $M_{future} = 3.03$, $SD_{future} = 1.68$).

Study 2 examined the robustness of H1 and the mediating role of specificity of thinking in the impact of product temporal orientation on perceived weight. A total of 114 undergraduates participated in this experiment. The experiment followed a two-cell (product temporal orientation: past vs. future) between-subjects design. As predicted, participants in the past condition perceived the product to be heavier. Mediation analysis showed that the indirect path of temporal orientation on perceived weight via specificity of thinking was significant.

Study 3 was to verify the impact of the match of temporal orientation and product weight on purchase intention (H3). A total of 148 undergraduates participated in this experiment. The experiment followed a 2 (product temporal orientation: past vs. future) × 2 (product weight: heavy vs. light) between-subjects design. Participants were asked to imagine a scenario of lamp purchase. Temporal orientation was manipulated by asking participants to look for either an antique lamp or a futuristic lamp. The product description was designed for the manipulation of the product weight (2500g net weight vs. 500g net weight). As predicted, an ANOVA revealed a significant interaction of temporal orientation and product weight on purchase intention ($F(1,144)=13.57$, $p<0.01$).

Study 4, a field experiment, was designed to examine H3 in a real shopping situation. We examined consumers' actual purchase by cooperating with a university souvenir shop selling bookmarks for four weeks. The experiment was a two-way mixed design, with a two-level between-subjects factor (temporal orientation: past vs. future) and a two-level within-subjects factor (product weight: heavy vs. light). The dependent variable was the real purchase of the bookmarks. Our results revealed a significant effect of the interaction of temporal orientation and product weight ($\chi2 = 6.23$, $p<0.05$) on product purchase. Specifically, in the past condition, a majority of the shoppers preferred the heavy bookmark (68.6%, [35/51]), whereas in the future condition, a majority of the shoppers chose the light bookmark (55.8% [29/52]), thus supporting H3.

In summary, four studies support the predicted relationship between product temporal orientation and perceived weight. Specifically, compared to a product with a future temporal orientation, consumers perceive a product with a past temporal orientation to be heavier, which was mediated by the specificity of thinking related to temporal orientation. Furthermore, consumers had higher purchase intention, and more actual purchases, when the product's temporal orientation matched its actual weight.

How do Consumers React to Company Moral Transgressions?
The Role of Power Distance Belief and Empathy for Victims

Haiyue (Felix) Xu, The Pennsylvania State University, USA
Lisa E. Bolton, Pennsylvania State University, USA
Karen Page Winterich, Pennsylvania State University, USA

EXTENDED ABSTRACT

Company moral transgressions are prevalent in today's marketplace (e.g., Nike's poor labor practices, Volkswagen's emission scandal). With the Internet and social media, such company moral transgressions rapidly receive public scrutiny (Crockett 2017), which can cause considerable damage to transgressing firms (e.g., Frooman 1997).

However, not all consumers have the same level of concern toward company moral transgressions. Moral norms are often subjectively determined by one's moral system (Trevino and Nelson 2016) with moral judgments varying substantially across individuals and cultures (Haidt and Joseph 2004; Schein and Gray 2018). The current research examines how, when, and why power distance belief (hereafter, PDB), which is the extent to which people accept and endorse inequality and hierarchy in society (Hofstede 1980), influences consumer response following company moral transgressions. Equality is a prominent moral principle, and a moral transgression can be conceptualized as a powerful transgressor (corporations) harming vulnerable victims (Gray and Wegner 2009). Hence, we propose that PDB will affect how individuals react to company moral transgressions with empathy toward the transgression victims as the underlying mechanism.

Empathy is an other-oriented emotion that arises from witnessing someone in distress that subsequently motivates an effort to help (Batson 2011; DeSteno 2015). We theorize that i) low-PDB individuals are motivated to minimize social inequality and tend to feel empathy for the vulnerable in society (Winterich and Zhang 2014), such as transgression victims, whereas high-PDB individuals tend to defend social hierarchy and status quo (Jost, Banaji, and Nosek 2004) and hence may perceive transgression victims as less warranting of care and empathy (Lee, Winterich, and Ross 2014), and ii) the experience (or lack) of empathy further influences how negatively consumers evaluate transgressing companies. Thus, low- (versus high-) PDB consumers, due to their greater empathy for transgression victims, will have less favorable evaluations of transgressing companies.

Consistent with this theorizing, we propose that the effect of PDB is attenuated when the company moral transgression does not have a salient victim as even low-PDB consumers do not focus on victims, thereby suppressing empathy. We also investigate company response strategies and propose that neither an apology nor remedy alone dampens the PDB effect but a combined apology and remedy can attenuate the effect by signaling the company's empathy for victims.

In study 1, we examine search data regarding the Volkswagen emission scandal together with country-level cultural values (Hofstede 2018) to test the impact of PDB on consumer response to the scandal. Using Google Trends, we performed the topic search of "Volkswagen emission scandal" across all global regions. The PDB scores along with other cultural values were obtained from Hofstede's (2018) website and matched to the search data along with other controls (e.g., political freedom, GDP). Based on a one-year event window following the scandal, PDB had a negative effect on the search index (b=-.41, t(54)=-3.93, $p < .001$); that is, people from lower PDB countries were more likely to search for the scandal, consistent with greater concern for the moral transgression. This pattern remained when including control variables and conducting robustness checks with different event windows.

In Study 2, participants completed a PDB manipulation (Zhang, Winterich, and Mittal 2010) and read about two fitness brands, one with a moral transgression (poor labor practice), and the other with a non-moral transgression (poor product quality) and indicated their response. Consistent with our prediction, low PDB consumers made less favorable evaluations ($M_{\text{low PDB}}$=4.94 vs. $M_{\text{high PDB}}$=5.47, F(1, 245)=5.41, p=.021). Participants also had a chance to win a \$25 gift card to the brand of their choice: low PDB consumers were marginally less likely to choose the morally transgressing brand ($M_{\text{low PDB}}$=68.6% vs. $M_{\text{high PDB}}$=79.0%, χ^2(1)=3.12, p=.077).

Study 3 tests the empathy mechanism. Participants completed the same PDB manipulation as study 2 and then read about a different moral transgression (environmental harm), followed by measurement of their response and empathy toward victims (Batson 1987). As expected, low-PDB participants responded less favorably ($M_{\text{low PDB}}$=1.93 vs. $M_{\text{high PDB}}$=2.34, F(1, 207)=4.53, p=.035) and expressed greater empathy ($M_{\text{low PDB}}$=5.67 vs. $M_{\text{high PDB}}$=5.15, F(1, 207)=4.47, p=.036), and the effect of PDB on consumer response was mediated by empathy.

Study 4 uses an established empathy manipulation (high vs. control) to demonstrate moderation-of-process (Spencer, Zanna, and Fong 2005). Participants read about a company moral transgression (poor labor practice), with an empathy manipulation embedded, and then indicated their response and PDB (measured with Yoo et al. 2011). Results revealed the expected interaction between measured PDB and manipulated empathy (b=-.16, t(198)=-1.98, p=.049): lower PDB participants responded less favorably in the control condition (b=.33, t(198)=2.80, p=.006) but, as expected, the PDB effect was attenuated in the high empathy condition (b=.01, t(198) =.07, p>.05).

Study 5 manipulates victim salience by using two transgressions that vary naturally in victim salience: mistreating employees (high) vs. disrespecting traditions (low). Consumer response and PDB were measured as in study 4. We found the expected interaction (b=.21, t(305)=2.67, p=.008): lower PDB participants responded less favorably when victim salience was high (b=.49, t(305)=5.20, $p < .001$) but not when victim salience was low (b=.08, t(305)=.67, p>.05).

In Study 6, participants read about the a moral transgression (environmental harm) and were randomly assigned to either no response, an apology, a remedy, or a combined apology and remedy, with consumer response and PDB measured as in studies 4-5. Results revealed the expected interaction between PDB and firm response (F(3, 397)=7.73, p<.001): an effect of PDB following no response (b=.73, t(397)=7.73, p<.001), an apology (b=.74, t(397)=7.89, p<.001), or a remedy (b=.58, t(397)=5.73, p<.001), but not after a combined apology and remedy (b=.16, t(397)=1.65, p>.05).

In six studies, we find robust support for our theorizing across various consumer samples, operationalizations of PDB, and transgression contexts. In doing so, this research makes important contributions to the literature on corporate social (ir)responsibility and consumer/marketplace morality in a cross-cultural context. This research also has implications for marketers to understand when and why consumers have negative reactions to company moral transgressions, as well as guidance for company response strategies.

Getting Nothing Feels Fairer Than Getting Something: How Allocation Outcomes Invoke Different Allocation Rules

Minzhe Xu, University of Florida, USA
Bowen Ruan, University of Iowa, USA

EXTENDED ABSTRACT

Most resources are limited, which is presumably why most social systems evolve mechanisms for resource allocation (Cook and Hegtvedt 1983). A primary goal of an effective allocation mechanism concerns how fair people perceive the allocation of resource to be. Indeed, people care about fairness so much that they would sacrifice their own interests (and punish others) for the sake of fairness (Dawes et al. 2007).

A common practice to achieve fairness is to proportionally allocate resource based on the performances of the entities involved (Adams 1963; Hatfield et al. 1978; Ma and Roese 2013). Consider a sales contest in which two salespersons—A and B—compete for a total bonus of $1,000. A has sold 9,000 units in the contest, and B has sold 10,000 units. Based on the proportion rule, the fairest allocation of the bonus is A receiving $474 (9/19 of $1,000) and B receiving $526 (10/19 of $1,000), and the less an allocation deviates from the fairest allocation, the fairer people should perceive it to be. Therefore, it can be inferred that people perceive A receiving a small compensation amount (e.g., A receives $100 and B receives $900, a small-large allocation) to be fairer than A receiving no compensation (e.g., A receives $0 and B receives $1,000, a none-all allocation).

However, we find that the opposite is true: in a study (N=130), participants perceived A receiving no compensation ($0) to be fairer than A receiving a small compensation amount ($100; 4.02 vs. 3.08, $F(1, 128) = 8.05$, $p = .01$). Study 2 replicated this finding with an incentive-compatible design. Participants (N=147) were invited to compete with another participant in a math-addition task to win an extra bonus. They also learned, before the competition started, that the person who answered more questions correctly would receive 50 cents, whereas the other person would receive 0 cents (the none-all-allocation condition) or 1 cent (the small-large-allocation condition). Participants were not really in a competition—they were all told at end of the task that they lost (by 1-3 questions, randomly determined) and thus received a bonus of 0 cents or 1 cent. Supporting our hypothesis, participants in the none-all-allocation (vs. small-large-allocation) condition rated the allocation rule as fairer (4.28 vs. 3.57, $F(1, 145)=5.13$, $p=.03$) and were more likely to do the task one more time with the same participant and the same allocation rule (71% vs. 53%; $\chi^2(1)=4.99$, $p=.03$).

We argue the reason is that a small-lage allocation (e.g., $100-$900) invokes the proportion rule, and prompts people to calculate the proportion of the allocation (e.g., $100/$900=1/9) and compare it to the proportion of performance (e.g., 9,000 units/10,000 units=9/10). Because of the drastic difference between these two proportions, people likely infer that the small-large allocation violates the proportion rule to a large extent and thus perceive it as unfair. In contrast, when the low performer receives no compensation, people tend to infer the allocation rule is binary (e.g., the winner takes all) and are less likely to pay attention to the proportion of performance. Because the actual allocation is binary and thus consistent with the inferred allocation rule, people perceive the none-all allocation as fair.

Study 3 (N=573) had two goals. First, to test the proposed mechanism, we added another condition in which the resource allocation perfectly followed the proportion rule. Although in both this and the none-all-allocation condition, the allocation aligned with the inferred allocation rule, because the proportion rule ensures equity and is perceived to be fairer than the binary rule in most cases (Cook and Hegtvedt 1983; Berkowitz et al. 1987), we predicted that participants would perceive the perfectly proportional allocation as even fairer than the none-all allocation. Second, we tested a boundary condition: if people are prompted to use the binary rule regardless of the actual resource allocation (e.g., performance itself is evaluated in a binary way, such as pass/fail), those faced with a small-large allocation tend not to calculate or compare the proportions. We predicted that in such case, the difference between the none-all-allocation and the small-large-allocation conditions would be smaller. Study 3 represented a 3 (allocation: none-all vs. small-large vs. proportional) × 2 (performance: binary vs. control) between-subjects design. Supporting our hypotheses, in the control condition, participants perceived the small-large allocation to be less fair than the none-all allocation (2.47 vs. 4.34, $F(1, 567)=56.51$, $p<.001$), which was less fair than the proportional allocation (4.34 vs. 6.33, $F(1, 567)=66.95$, $p<.001$). Critically, in the binary-performance condition, the difference between the small-large-allocation and the none-all-allocation conditions became smaller (4.37 vs. 4.95, $F(1, 567)=5.60$, $p=.02$; partial interaction: $F(1, 567)=13.61$, $p<.001$).

Study 4 examined another boundary condition. In a non-competitive setting where individuals collaborate rather than compete with each other, the binary allocation rule may not be applicable, attenuating our effect. In a 2 (allocation: none-all vs. small-large) × 2 (context: competition vs. non-competition) between-subjects design, participants (N=342) imagined that they submitted a research proposal to either a competition where researchers competed against each other for research grant or a symposium where researchers interacted with each other. They learned that proposals with 80 or more votes (out of 100) would receive a grant of $500,000, while those with fewer than 80 votes would receive either no grant (none-all) or $10,000 (small-large). They then learned that their own proposal received 78 votes and received no grant or $10,000. We found that in the competition condition, participants perceived the none-all allocation to be fairer than the small-large allocation (4.36 vs. 3.78, $F(1, 338)=4.58$, $p=.03$), while in the non-competition condition, the effect disappeared (3.76 vs. 4.18, $F(1, 338)=2.32$, $p=.13$; interaction: $F(1, 338) = 6.66$, $p = .01$).

This research presents a novel effect regarding resource allocation that a small compensation amount (vs. no compensation) may backfire. It contributes to the literature on fairness perception by demonstrating that people may infer different allocation rules from the actual allocations of resource, which can have important consequences on fairness perception and behavior.

Social Media Magnetism and Marketplace Pilgrimage

Haibo Xue, East China Normal University, China
Xin Zhao, Lancaster University Management School, UK

EXTENDED ABSTRACT

In this paper, we investigate why certain quintessential tourist spots, shops, and retailing outlets become an instant magnetic site on social media and attract a large number of pious followers. Within the urban consumptionscape in Shanghai and many other metropolis in China, huge groups of consumers may spend an average of over 5 hours, and as long as 7 hours waiting in line in order to purchase a cup of bubble tea, a snack, a Chinese pancake, or even a piece of cookie. The zeal for such retail outlets is often fueled by Chinese social media such as Tiktok, the Little Redbook, WeChat, Weibo, and online forums. Such avid desire can only be matched by the devotions of religious pilgrimage (e.g., Turner and Turner 1978).

In particular, we examine consumption rituals at these places and discuss implications for understanding pilgrimage in the marketplace as a simulated form of consumer deceleration (e.g., Husemann and Eckhardt 2019; Rosa 2013). We seek to understand: whether or not the perceived slowed-down temporal experience can be achieved in the marketplace and without the expected detachment from one's social worlds as have been previously suggested.

Pilgrimage is a journey to the sacred place containing the actual sacred relics from the past, which has the power to contaminate pilgrims with magical cure or positive energy (Turner and Turner 1978). Consumers seek spirituality and self-transformation through religious pilgrimages (Hamilton and Higgans 2011; Higgans and Hamilton 2016). More importantly, these physically demanding and sacred journeys allow consumers to escape from their accelerated social life (Rosa 2013) and to engage in consumption practices that help them to slow down (Husemann and Eckhardt 2019). Such deceleration is a temporal consumption experience that is achieved through immersing in extended geographic journeys far away from home and ideally from the market. In this paper, we argue that such temporal experiences of slowing down may be achieved through the simulation of deceleration in marketplace pilgrimage.

In this study, we adopted both ethnographic and ethnographic approaches (Kozinets, 2015), to understand marketplace pilgrimage. We used emergent design, multiple sites, purposive sampling, and field interviews in the process of data collection. Our data collection started in Spring 2017 and continued into Summer 2019. The research team visited various cult food shops in Shanghai and participated in the waiting. This helped them to reflect upon the observations and to develop a better understanding of consumer experiences. We observed different waiting lines outside different cult food stores. Pictures and interviews were combined with detailed observation notes. Our total dataset consists of 35 depth interviews, 120 pages of fieldnotes, 257 images from our fieldwork, and over 300 social media accounts that describe consumption experiences of these cult food stores. Our data analysis proceeded in an iterative process (Spiggle 1994). We focus on consumers' experiences and seek to understand why consumers spent prolonged periods of time waiting in line.

The experiences of prolonged waiting in line at the shops are commonly understood and interpreted by our informants as a "*pilgrimage*". Many come with friends and collectively participate in the pilgrimage. We found that similar to religious pilgrimage, marketplace pilgrimage is structured by varied rituals, including anticipation, participation, evaluation, and dissemination. Marketplace pilgrimage involves efforts and bodily labor that transform consumer desire and consumption experience into an ephemeral form of social capital that can then be competed and displayed in social media space. It gives visual forms to consumers' formless and exhausting labor of waiting. In this case, consumers do not deliberately seek to slow down and to escape from the accelerated social life. It is oriented toward social media conspicuity and is an extrinsic form of deceleration that does not aim at introspection and reflection. The cult shops that attract pilgrims are characterized by scarcity, difficulty of access, ability of being traced on social media, or their potential for visual transportation and transformation, as well as endorsement of social media celebrity. We refer to the quintessential qualities of such pilgrimage space as social media magnetism.

In this paper, we extend previous literature on consumer deceleration by highlighting the *simulation* of consumer deceleration through pilgrimage in the marketplace. Our notion of social media magnetism explains why certain retailing space becomes an instant spot of such devotion. Together, we contribute to consumer culture theories on the sacralization of commercial spaces by highlighting the transient value of marketplace pilgrimage on social media in the era of assess-based consumption (e.g., Bardhi and Eckhardt 2017).

Stigma and Taint in Advertising

Cagri Yalkin, Middle Eastern Technical University, North Cyprus Campus, Turkey
Finola Kerrigan, University of Birmingham, USA

EXTENDED ABSTRACT

Advertising sustains the contemporary system and people's desire to consume despite recurring financial crises and the ongoing climate crisis (e.g. Pradham 2009, UNFCC 2019). Advertisers remain key cultural intermediaries and taste makers (Cronin 2004, Cayla and Eckhardt 2008). The conduct of *Cambridge Analytica*, widely covered in the press and through the documentary *The Great Hack* (2019), have highlighted the ability of advertising in manipulating all areas of public life. Corporate scandals have been blamed on the advertising industry and its professionals (e.g. Business Insider 2016). Consumption's direct link with climate crisis (see Carlson-Kanyama and Gonzalez 2014), stereotyping and racism (see Thomas and Jones, 2019) thus require to further critical engagement with the advertising industry.

Previous literature has often focused on creativitiy in advertising (e.g. Nyilasy, Kreshel, and Reid 2012), creative identities (Hirschman 1989, McLeod et al. 2009), gender in advertising practice (Nixon and Crewe 2004, Windels and Lee 2012), advertisers' perceptions of gender portrayals in advertisements and ethics (Zayer et al. 2015) and managing creatives (Gotsi et al. 2010, Hackley and Kover 2007, Hirschman 1989). In particular, Nixon and Crewe (2004) and Hackley and Kover (2007) illustrate how advertisers negotiate competing identities. Here, we study how advertisers view their own jobs in light of the recent global state of affairs.

Stigma and taint are associated with tasks of dubious virtue (e.g., exotic dancer, bill collector, pawnbroker) or with jobs that are "deceptive, intrusive, confrontational, or that otherwise defy norms of civility" (Ashforth & Kreiner, 1999, p.415) (e.g., paparazzo, telemarketer). As such, advertising can easily be classified as a stigmatized job as it is about managing sometimes deceptive perceptions that may not necessarily be based on the actual properties and benefits of products/services/brands. There is limited literature related to how the occupation holders themselves who are in morally stigmatized jobs view their jobs (see Zayer et. Al 2015 and Drumwright and Kamal 2016 for exceptions). If stigma and taint reduce occupational prestige (see Ashforth & Kreiner 2014), *what are the ways in which advertisers view their profession and themselves?*

This on-going qualitative study draws on data from Turkey, an emerging economy with a workforce of 28 million. The studies on the advertising industry in the Global South are still limited. Exceptions are Kaptan (2013), Cayla and Eckhardt (2008), and Drumwright and Kamal (2016). Here, in-depth interviews with 20 advertisers are completed. A maximum variation purposeful sampling is used, where age, department within the agency, tenure and type of agency (network vs. local boutique) is varied. The data are analysed by the authors using a hermeneutic approach (Thompson 1989) and interpretation followed the guidelines of Miles and Huberman (1994) and Spiggle (1994).

Our emergent findings point to a nuanced understanding of advertisers' own work as stigmatized and precarious, and the emerging circumstances under which they may or may not feel the pressure this brings. In particular, the advertisers view their jobs as stigmatized and precarious. They view their job to be stigmatized to the degree of being immmoral because they create artificial needs. Dar, a 40 year old senior creative, says: "*afterall it is about selling people crap they do not need... people look at me like I am evil*". Do, 40, is of a similar opinion "*..it is what it is. It is not helping anyone in any real sense*". On the other hand, excessive working hours express themselves as precarity: Goz, 41, account manager, illuminates the precarious aspect of her job "*..i'm trying to manage the feelings of everybody... trying to write emails that will not damage the relationship with the client*" and Fah, creative, seconds: "*we do the ugly job... so many people's feelings and irrelevant and irrational thoughts to manage 24/7, via email, via whatsapp, via everything else that I feel like I am just wasting the time*". Do also explains "*you can't just not take part in a tender, although it may not lead anywhere, you work on it for months, concurrently with other tenders too*".

The preliminary data analysis reveals that the advertisers from various ages and job specialisms view their job as stigmatized. In particular, they have a dual view of their job as stigmatized and precarious; where precariousness feeds into their perceptions of taint. This study extends the previous literature on creative identities (e.g. Hackley and Kover 2007, Gotsi 2010) by focusing on a middle to high income morally tainted line of work – advertising. Previous studies focused on physically and socially stigmatized jobs (e.g. Dick 2005, Simpson et al. 2014), here, we extend the inquiry into the moral arena. Limitations of this study are that it is a snapshot in time and it is bound by its context. For example, in light of the Covid-19 crisis, have the advertisers view of their jobs worsened? Future work could seek to investigate whether this perception also holds across other settings in the Global south and in the Global North and what coping strategies advertisers cultivate to manage taint.

Time in the Past is Real and Honest: The Role of Nostalgia in Enhancing Authenticity

Shiyu Yang, University of Illinois at Urbana-Champaign, USA
Jia Chen, University of Illinois at Chicago, USA
Yu-Wei Lin, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Authenticity, typically defined as being "real", "genuine", or "true" (Dutton 2003; Sharpley 1994; Taylor 1991; Vannini and Franzese 2008), is a desirable state for individuals (Gino, Kouchaki, and Galinsky 2015) and a cherished attribute of products (Newman and Dhar 2014). Many recent social criticisms argue that our society is experiencing an authenticity deficit because of the overflow of meaningless market offerings (Boyle 2004). To overcome this deficit, people increasingly search for authenticity in brands, products, and experiences (Arnould and Price 2000; Beverland 2005; Morhart et al. 2015). As a result, authenticity has "…overtaken quality as the prevailing purchasing criterion" (Gilmore and Pine 2007, 5) and become "one of the cornerstones of contemporary marketing . . ." (Brown, Kozinets, and Sherry 2003, 21). In response to consumers' craving for authenticity, marketers are enthusiastic in cultivating products and services that are experienced as authentic (Goldman and Papson 1996; Grayson and Shulman 2000).

It is therefore important to ask the following questions: From consumers' perspective, what kind of products can connect them with a real, honest and genuine self-view (i.e., self-authenticity)? From marketers' perspective, how to make their products experienced by consumers as real, honest, and genuine (i.e., product authenticity)? These two questions are interrelated, as prior research has shown that consuming authentic products can increase self-authenticity (Hahl, Zuckerman, and Kim 2017); also, a product that connects consumers with their true self is perceived to be symbolically authentic (Morhart et al. 2015). We therefore ask the following question encompassing both self and product authenticity: how to increase *experienced* authenticity in consumptions? We posit that inducing nostalgia in consumptions can lead consumers to experience a greater level of authenticity.

A plethora of research has documented the benefits of nostalgia, such as social connectedness (Wildschut et al. 2010), meaningfulness (Routledge et al. 2012), empathy (Zhou et al. 2011), and patience (Huang, Huang, and Wyer Jr 2016). A majority of consumer research has shown that nostalgia toward a brand could increase brand preference, respect, trust (Merchant and Rose 2013; Muehling and Sprott 2004), and the likelihood of purchase and recommendation (Nam et al. 2016). However, as far as we know, there is limited research on how nostalgia may influence consumers' experience of authenticity.

Drawing upon research linking past autobiographical memories with intrinsic self-focus (Baldwin, Biernat, and Landau 2015) and pure self-view (Gino and Desai 2012), we argue that nostalgic consumptions will offer a window to one's original self, a self that is real, honest and true, a self that preserves one's intrinsic nature as a person that is not yet tainted by any external constraints. The recollection of past experiences can set the tone for understanding and anchoring individual identity. Following these arguments, we predict that consumptions that have been woven into consumers' personal histories are likely to be perceived as embodiment of their true self (i.e., self-authenticity); a logical corollary is that, products that can elicit nostalgic feelings are likely to be perceived as real, honest, and genuine (i.e., product authenticity). We therefore posit that inducing nostalgia in consumptions (e.g., nostalgic descriptions or advertisements) can potentially enhance experienced authenticity.

Across six studies, we examined how nostalgic consumptions enhanced experienced authenticity. We first demonstrated that products that made consumers feel authentic (vs. products that consumers liked) were more nostalgic (Study 1 N=63). Building on this finding, we further tested the causal effect of nostalgia on experienced authenticity using both controlled (Study 2 N=107) and freely recalled consumptions (Study 3 N=190). Moreover, we identified the underlying mechanism by showing that nostalgic consumptions could remind consumers of their intrinsic nature, which in turn led to increased experienced authenticity (Study 3). We also found that self-concept clarity moderated the effect, such that the positive relationship between nostalgia and experienced authenticity was stronger among consumers with ambiguous self-views (Study 4 N=51). We then applied the findings to a purchase decision context and showed that highlighting the importance of authenticity would lead consumers to favor nostalgic products over novel ones (Study 5 N=159). Finally, applying natural language processing to analyzing over 5000 real-world products on Kickstarter, we showed that invoking nostalgia when pitching for a product could potentially make the product appear more authentic (Study 6 N=52997).

Taken together, our research contributed to the literature on authenticity and nostalgia by unveiling the relationship between them, the underlying mechanism, and the boundary condition. Moreover, our findings have implications for marketers who want to appeal to consumers with authentic market offerings and consumers who are in search for authenticity. Also, to the extent that authenticity is a positively valenced psychological state, the current research also contributes to the literature on consumer well-being.

The Moderating Effect of Regulatory Effect on Consumer Preferences for Price Discounts and Bonus Packs

Jun Yao, Macquarie University, Australia
Di Wang, Queensland University of Technology, Australia
Brett A.S. Martin, Queensland University of Technology, Australia

EXTENDED ABSTRACT

In today's increasingly competitive marketplace, firms deploy a range of sales promotion tactics to encourage purchases by providing consumers with extra benefits or incentives. The sales promotion literature suggests that monetary tactics, such as price discounts, and non-monetary tactics, such as bonus packs, distinctively influence consumers' purchase behaviors. Bonus packs which offer more product volumes are generally preferred by consumers over price discounts which offer lower prices (Diamond and Sanyal 1990; Mishra and Mishra 2011), because the former tend to be framed as pure gains while the latter tend to be framed as reductions in losses according to prospect theory's value function (Kahneman and Tversky 1979).

We propose that regulatory orientation (Higgins 2000) plays a moderating role in consumers' preferences between bonus packs and price discounts. Specifically, the default preference for a bonus pack does not hold for individuals with a prevention orientation. A price discount provides an opportunity to reduce the economic cost and thus aligns with a prevention orientation to minimize losses. In turn, individuals with a prevention orientation are expected to experience a regulatory fit between the prevention orientation and the price discount, resulting in a preference for a price discount over a bonus pack.

In contrast, a bonus pack provides incremental product benefits and thus aligns with a promotion orientation to maximize gains, individuals with a promotion orientation are expected to experience a regulatory fit between the promotion orientation and the bonus pack, resulting in a preference for a bonus pack over a price discount. Such a preference is in line with the default preference in favor of a bonus back based on differential framing (i.e., a bonus pack is framed as a pure gain while a price discount is framed as a reduction in loss). However, we argue the regulatory fit cue may not be as accessible as the differential framing cue to influence the preference.

We present two studies, including a field study, to test the proposed effects. Study 1 investigates the joint effect of regulatory orientation and promotion format on purchase intention and the mediating role of regulatory fit. We recruited 387 participants on Mturk. The study adopted a 2 (promotion format: discount vs. bonus pack) × 2 (regulatory orientation: promotion vs. prevention) between-participants design, with two product replicates to enhance generalizability.

Results demonstrated that neither promotion format nor regulatory orientation had main effects, but there was a significant interaction effect. Participants in the prevention-orientation condition were more likely to purchase the product when the promotion was in the discount format than in the bonus pack format. Participants in the promotion-orientation condition were more likely to purchase the product when the promotion was in the bonus pack than in the discount format. The analysis of regulatory fit revealed a significant interaction effect such that participants in the prevention-orientation condition felt the discount was more "right" than the bonus pack. There was no difference in regulatory fit between the discount and bonus pack in the promotion-orientation condition. Results of the mediation analysis showed a significant moderated mediation effect. Specifically, the indirect effect was significant while the direct effect was not significant in the prevention-orientation condition. The indirect effect was not significant, but the direct effect was significant

in the promotion-orientation condition. These results indicate that regulatory fit mediates only the effect of prevention orientation on preference for promotion format, but not the effect of promotion orientation on preference. The direct effect in the promotion-orientation condition can be explained by consumers' inherent preference for a bonus pack over a price discount, due to the prospect theory-based framing conceptualization.

Study 2 was designed to replicate the findings shown in Study 1 in a field setting. In addition, instead of using percentages, we used an equivalent absolute value in the two promotion formats. The study adopted a 2 (promotion format: discount vs. bonus pack) × 2 (regulatory orientation: promotion vs. prevention) between-participants design. We collaborated with a medium-sized supermarket to conduct this study over a one-week period. We set up a table in the entrance/exit area of the supermarket and put a sign on the table reading, "By completing our marketing survey, you can receive a $5 voucher." Participants were asked to read three sentences either related to their hopes and aspirations (i.e. "I want to do grocery shopping," "It is enjoyable to do grocery shopping," "Doing grocery shopping is interesting.") or to their duties and obligations (i.e. "I ought to do grocery shopping," "It is an obligation to do grocery shopping," "Doing grocery shopping involves a feeling of duty."). Participants were then told that today the supermarket was running an in-store promotion for a store gift voucher. The promotion was framed as either a discount (i.e. "you buy a $12 gift voucher and get $2 off, you pay $10 cash") or a bonus pack (i.e. "you pay $10 cash to get $2 bonus, you get a $12 gift voucher"). Participants indicated their choice of whether to purchase the gift voucher.

Results showed an interaction effect. In the prevention-orientation condition, 58.5% of participants in the discount condition and 40.0% of participants in the bonus pack condition chose to purchase the gift voucher. In contrast, in the promotion-orientation condition, 40.6% of participants in the discount condition and 58.5% of participants in the bonus pack condition chose to purchase the gift voucher. Again, participants in the prevention-orientation condition felt the discount promotion was right more than the bonus pack. Those in the promotion-orientation condition felt no difference in terms of how right participants felt in the discount and bonus pack conditions. Similar to Study 1, results indicate that regulatory fit mediates only the effect of prevention orientation on preference for promotion format, but not the effect of promotion orientation on preference.

One limitation of our research is that regulatory orientation was primed across two studies. To enhance the robustness of our findings, further research could assess consumers' chronic regulatory orientation to see whether the moderating effect of regulatory orientation on consumer preferences for promotion tactics still hold.

The Devil You Know: The Problem of Equilibrium Goals

Siyuan Yin, The Wharton School, University of Pennsylvania, USA
Cait Lamberton, The Wharton School, University of Pennsylvania, USA

EXTENDED ABSTRACT

Why do we stay in unsatisfying relationships with brands (Erdem and Keane 1996, Erdem, Keane, and Sun 2008), hold onto losing stocks even when they have little likelihood of improving (Odean 1998, Shefrin and Statman,1985), take extra flights to stay with airlines that delay us regularly, or remain in frustrating jobs or interpersonal relationships? We conceptualize such "devil you know" situations as *equilibrium goals*, in which we prioritize status quo maintenance even when changing our state would be more likely to offer positive utility than remaining.

Three studies have been completed to substantiate the unique nature of equilibrium goals. We first identify consistent characteristics of equilibrium goals across domains. Study 1 (n = 460) followed a five (scenario: job, relationship, diet, budget, cancer treatment) by two (goal: equilibrium vs. disequilibrium) between-subject design. For example, participants in the equilibrium job condition read: "Suppose that your current job is boring and involves tedious work and you have been working in the position for 5 years. You could change jobs, but you choose to continue to go to work and do well enough to stay in this job." By contrast, participants in the disequilibrium job condition read the same information with reversed actions.

Participants reported that in both goal conditions they were pursuing a goal to an equivalent extent and had a similar level of past investment in pursuit of that goal. However, disequilibrium goals (e.g. changing jobs) involved a higher focus on change, stronger motivation, and higher anticipated utility than equilibrium goals ($b_{focus on change}$ = -.023, $p < .001$; $b_{motivation}$ = -.026, $p = .002$; $b_{utility}$ = -.033, $p < .001$). By contrast, remaining in equilibrium as opposed to disequilibrium goals required greater self-control ($b_{self-control}$ = .039, $p < .001$). Thus, it appears that equilibrium goals create an undesirable situation for consumers: while their self-control costs are high, their motivation and utility are low.

To prompt consumers to release their equilibrium goals, we examined literature on maintenance goals (Yang, Stamatogiannakis, and Chattopadhyay 2015) and consumer lock-in (Johnson and Russo 1984, Johnson, Bellman, and Lohse 2003, Zauberman 2003). This literature suggested that consumers in equilibrium goals may perceive higher switching costs than necessary. If this is the case, lowering perceptions of social and cognitive switching costs should weaken consumers' hold on equilibrium goals.

Study 2 (n = 1782) tested this prediction using a three (cognitive cost: control, high, low) by three (social cost: control, high, low) by three (scenario: airline, retailer, partner relationship) between-subject design. For example, in the airline scenario, the equilibrium goal related to staying in an airline reward program that regularly provided less-than-optimal service. We manipulated the perceived social and cognitive switching costs as high or low via cost-related messages. No cost information was provided in the control conditions. Participants reported how likely they would be to end their relationship and start over with another airline or do what it takes to maintain their relationship from 0 (definitely keep status) to 100 (definitely end the relationship).

A mixed-effects model predicting this likelihood with cognitive- and social-cost conditions as predictors and scenarios as random effects revealed significant main effects of cognitive costs ($F(2, 1771)$ = 14.17, $p < 0.001$) and social costs ($F(2, 1771) = 32.65, p < .001$), but no significant interaction ($F(4, 1771) = .47, p = .75$). Compared to control conditions, people in the high social- and cognitive-cost conditions were less likely to switch away from equilibrium goals ($b_{high social cost}$ = -7.41, $p < .001$; $b_{high cognitive cost}$ = -3.04, $p = .038$) and people in the low social- and cognitive-cost conditions were more likely to do so ($b_{low social cost}$ = 4.13, $p = .005$; $b_{low cognitive cost}$ = 5.19, $p < .001$). Thus, manipulating both types of switching costs can independently shift individuals' likelihood to persist in equilibrium goals.

To replicate this finding in a more consequential setting, Study 3 (n = 228) established a "work partnership" with cost-related interventions in the lab. The experiment followed a two (cognitive cost: high vs. low) by two (social cost: high vs. low) between-subject design. Participants worked together in "teams" to obtain points, such that they could maximize their final bonus that would be determined by their own points and their team points. All participants were assigned the role of "receiver" and received points allocated by their paired deciders who was ostensibly on the same team. We held constant point allocations across conditions such that an equilibrium goal situation was created for all participants: the decider was systematically underallocating to participants, such that little utility could be gained by staying in the partnership. After three rounds of point allocations, participants read, in the high (low) cognitive (social) cost condition, "The average rating of cognitive (social) costs of switching from previous surveys was 7 (3) out of 10." Participants then had the opportunity to switch partners who were on an opposing (the same) team in the high (low) social cost conditions.

Despite the fact that participants had evidence that their decider was unlikely to offer a high chance to maximize their outcomes, only 58.7% decided to switch partners, leaving 41.3% pursuing the equilibrium goal. Participants in the low social-cost conditions were significantly more likely to switch partners, thus releasing an equilibrium goal, than those in the high social-cost conditions ($b_{low social cost}$ = 1.85, $p < .001$). Participants in the low cognitive-cost conditions were marginally more likely to switch partners than those in the high cognitive-cost conditions ($b_{low cognitive cost}$ = .91, $p = .08$). As before, no interaction was observed ($b_{interaction}$ = -.70, $p = .30$).

We show that manipulating perceived goal-switching costs effectively shifted people away from equilibrium goals in both marketplace and collaboration contexts. Our findings contribute to traditional goal and motivation literature with a new framework that helps understand the mechanisms of equilibrium goal-pursuit behavior. Future research will extend these findings to other consequential equilibrium goals, in the hope that we can learn more about ways to enhance consumers' goal pursuit and overall well-being.

The Effect of Social Identity Conflict on Consumers' Planning Time Horizons

Yiqi Yu, Guanghua School of Management, Peking University, China
Ying Zhang, Guanghua School and Management, Peking University, China

EXTENDED ABSTRACT

Consumers often hold multiple social identities (Crisp and Hewstone 2007). For example, immigrants are simultaneously identified with their country of origin and the new country; students may hold identities associated with the multiple schools that they have attended. When these identities are simultaneously activated and the contents of these identities are perceived incompatible, consumers experience social identity conflict (Hirsh and Kang 2016).

Despite the ubiquity and importance of consumers experiencing such conflict, research that examines whether and how this experience may affect consumer choices remain relatively scarce. In this research, we explore how social identity conflict might alter one's perception of self, and in turn affect his/her planning time horizon in consumption decisions. Specifically, we predict that experiencing social identity conflict leads consumers to focus more on here and now, thus showing greater preference for short-term products and service plans. This preference shift occurs because experiencing social identity conflict undermines a clear sense of self (Campbell et al. 1996), which lays the foundation of a temporally stable self (Dunlop 2017; Jiang, Chen, and Sedikides 2019). A less enduring sense of self in the temporal dimension, in turn, leads to less willingness to plan for the distant future.

Study 1 surveyed 225 Mturkers to directly test the relationship between social identity conflict and planning horizon. Participants indicated the extent to which and how often they felt that their multiple social identities were in conflict, after we introduced what was social identity conflict. We then used three items to measure participants' planning time horizons (e.g. "I focus more on the proximate future when I am making the decisions") and found that social identity conflict was positively correlated with shorter planning time horizons ($b = 0.128$, $p = .001$), controlling for demographic variables.

Study 2 employed a lab study where 94 participants first read a diary written by a college student about her experience after moving to a different city from her hometown and imagined themselves being the student. Participants were randomly assigned to a conflict condition where the diary described that the college student often experienced identity conflict because of the different norms of the two places, or a no conflict condition, where the diary described that the student comfortably navigated between the two identities and no conflict experience was mentioned. Next, in an ostensibly unrelated task, participants were told to write down their future plans. We intentionally kept the instructions vague and did not specify any time period for the "future". Their answers were coded based on the time frame and we found that, participants in the conflict condition wrote down more plans about proximate future than did those in the no conflict condition: 71.8% vs. 47.6%, $p < 0.001$.

Study 3 moved to school identity. A total of 104 graduate students were randomly assigned to either a social identity conflict condition where they imagined that they were watching a championship match between their undergraduate alma mater and their current school, or a friendly exhibition match between the two teams. Then, participants were asked to indicate their preferences between two financial products: a one-year CD offering 1.12% APY and a three-year CD offering 1.28%. Results showed that participants in the conflict condition were less likely to choose the three-year product ($M_{Conflict} = 2.14$ vs. $M_{No conflict} = 3.09$, $p = .018$; higher value denoted preference for the long-term product).

Using the Midlife in the United States survey, study 4 found that a less clear sense of self was associated with shorter planning horizons among 2654 respondents. Further, study 5 directly measured our proposed mechanism, after the using the same manipulation of conflict as Study 2. Results suggested that experiencing social identity conflict increased participants' preferences for a short-term video streaming membership ($M_{Conflict} = 3.05$ (1.50) vs. $M_{No conflict} = 3.79$ (1.59), $p = .011$). Furthermore, bootstrapping analyses revealed that an unclear sense of self mediated this effect (95% CI = [-0.6973, -0.0031]).

In study 6, we employed a 2 (social identity conflict: conflict vs. no conflict) ×2 (bolstering a clear sense of self: yes vs. no) between-subject design and randomly assigned 231 participants to one of the four conditions. We manipulated identity conflict as study 5. Participants were then asked to describe a personal possession (Morrison and Johnson 2011). Specifically, to bolster a clear sense of self, participants were asked to describe a possession that reflects one of his/her important social identities. In the control condition, participants were asked to describe a possession which they found useful. We then recorded their choice of financial products. We found that when a clear sense of self was not bolstered, participants who experienced social identity conflict showed greater preference for the short-term financial products than did those who experienced no such conflict ($M_{Conflict} = 2.98$ (2.05) vs. $M_{No conflict} = 3.92$ (2.06), $p = .019$). However, when participants experienced a clear sense of self, the difference disappeared ($M_{Conflict} = 3.83$ (2.05) vs. $M_{No conflict} = 3.75$ (1.39), $p = .642$).

To summarize, by showing consumers who experience social identity conflict are more likely to adopt short planning time horizons, our work makes important theoretical contributions and yields practical implications for consumer decision-making and well-being.

How Mere Manager Response Influences Product Evaluations

Vincentia Yuen, University of Miami, USA
Michael Tsiros, University of Miami, USA

EXTENDED ABSTRACT

As firms gradually notice the impact of electronic word of mouth (eWOM) on business performance, online review management has become more prominent in marketing practice. Rather than subtly intervene in eWOM by promotional reviewing (Mayzlin, Dover, and Chevalier 2014), firms start to actively engage in eWOM conversations by responding to customer reviews to restore customer satisfaction (Gu and Ye 2014) and influence future reviews (Proserpio and Zervas 2017) via a manager response (MR) feature.

While MRs are, in theory, directed at reviewers, Murphy (2019) finds that 97% of review readers also attend to MRs when they evaluate products online. For this reason, even if managers are responding to prior failures, the impact of such highly observable MRs should no longer be confined to the focal recipients who wrote the initial reviews but should also extend to all customers who observe such responses. In the current research, we build on service recovery literature and hypothesize that the mere presence of MR —with no knowledge of the actual content—can positively shape consumer responses.

It is well-established that a successful recovery from service failure could restore customer satisfaction and enhance repurchase intentions (Grewal, Roggeveen, and Tsiros 2008). When firms recover in a way that builds customer trust, customers are more likely to make confident predictions about the firms' future recovery behaviors and thus commit themselves to ongoing relationships (Kim, Kim, and Kim 2009). As trust could also be acquired by observing or learning from previous interactions (e.g., conflicts) that the firm has had with others in similar situations (Holmes 1991; Tax et al. 1998), we argue that previous recovery episodes should enhance prospective customer trust and enhance product evaluations on the basis of a positive expectation of solving any potential future failures. Formally, we hypothesize:

Hypothesis 1: *The mere presence (vs. absence) of manager response to negative reviews enhances product evaluations.*

Hypothesis 2: *The effect of the presence of manager response on product evaluations in H1 is mediated by the increase in perceived recovery and subsequent customer trust toward the firm.*

Three studies examine the hypotheses and the proposed psychological mechanism. In all studies, participants first read identical product information along with actual hotel or restaurant reviews (where we only manipulated the presence of MR) and responded to measures on seven-point Likert scales. It is worth noting that we examine the impact of the *mere* presence of MR, rather than the effects driven by the MR content itself.

Study 1 (N= 258) tested the central hypothesis that the mere presence of MR enhances product evaluations with a 3(MR: mere presence vs. with content vs. control) between-subjects design. As one might question how our findings might compare to the more popular practice of having MR response present publicly, we also examine a condition in which (a widely used) response content (acknowledgment and apology) is shown in this study. After reading the stimulus, participants indicated their product evaluations (α = .940). Results supported our prediction (H1). Product evaluations in the two MR presence conditions (Mmere = 4.70, F(1, 255) =2.431, p=.016 and Mcontent = 4.75, F(1, 255)=2.776, p=.006) were significantly higher than that in the control condition (Mcontrol = 4.34). As expected, we found no significant difference in product evaluations between the two MR presence conditions (F(1, 255)=.351, p = .726).

Study 2 (N= 273) tested the hypothesized mechanism (H2) with a 2(MR: presence vs. control) between-subjects design. We measured product evaluations (α = .969), trust (α= .960), and perceived recovery (e.g., "I expect the [firm] to try to make up for any negative issues mentioned in the reviews," α = .843) respectively. As predicted, the presence of MR increased product evaluations (4.08 vs. 3.79; t(271) = 1.94, p =.053). A serial mediation analysis (PROCESS model 6; Hayes 2018) confirmed our hypothesized process (b = .24; 95% CI from .0611 to .4273) that the presence of MR made consumers perceive the firm will address the issues mentioned in the review (b = .48, t = 2.65, *p* <.01), which enhanced customer trust toward the firm (b = .64, t = 18.73, *p* < .001) and thus boosted product evaluations (b = .78, t = 19.87, *p*< .001).

Lastly, study 3 (N= 231) further examined the hypothesized underlying process by directly manipulating perceived recovery through review valence with a 3 (MR presence: negative reviews vs. both positive and negative reviews vs. control) between-subjects design. If, as we suggest, MR increases product evaluations by making the firm seem more likely to address the negative issues raised in reviews and lead to higher trust, then having managers also reply to positive reviews should weaken this positive effect from the MR. We measured product evaluations (α = .898), trust (α= .916), and perceived recovery (α = .836) in a randomized order. As predicted, planned contrasts revealed that product evaluations in the condition with MRs to negative reviews (M = 4.94) were significantly higher than that in the condition with MRs to both positive and negative reviews (M = 4.45; F(1, 228) = 2.573, p=.011) and the control condition (M = 4.43; F(1, 228) = 2.618, p=.009). We found no significant difference in product evaluations between the latter two conditions (F(1, 228)= .104, p = .917). The serial mediation analysis (PROCESS model 6) again confirmed that perceived recovery and customer trust mediated the effect of MR on product evaluations (b = .27; 95% CI from .0902 to .4711). Overall, H1 and H2 were supported.

In sum, this research contributes to the eWOM literature by showing how firms could proactively intervene in the impact of online reviews on consumer responses. To date, no research has examined the psychological processes underlying the impact of MRs on prospective customer evaluations. Hence, by extending key findings in the service recovery literature, this research yields important insight into the process explanation and shows how the mere signal of response to a negative prior review could influence product evaluations. From a substantive perspective, this research offers clear implications to practitioners, particularly those under pressure to manage their online reputation.

Does Space Speak Quantities? The Impact of Interspace on Product Size Estimates

Yuli Zhang, Stockton University, USA
Hyokjin Kwak, Drexel University, USA
Marina Puzakova, Lehigh University, USA
Charles R. Taylor, Villanova University, USA

EXTENDED ABSTRACT

Academic research has recognized the general significance of space in a retail setting and marketing communications by devoting attention to the study of the downstream consequences of the amount of space allocated to products in a display (e.g., shelf display, POP/advertising display) (Dreze, Hoch, and Purk 1994; Parker and Lehmann 2011). However, this past streams of work have primarily focused on either variation in the amount of space dedicated to a product display itself (e.g., more or less amount of display space) or the alteration in the space-to-product ratio (e.g., high or low interstitial space) in a display. Our research significantly differs from these prior investigations in that we examine the impact of the *existence* of space *between* products (hereafter referred to as "interspace") as opposed to the overall space *surrounding* products. In our research, we hold the amount of display space constant and demonstrate that the existence or nonexistence of interspace in a product display has unique consequences for judgments of product size. We posit that an interspatial (vs. a non-interspatial) product display is likely to increase consumers' perceived product size.

Prior research on visual processing demonstrates that space between entities facilitates an entity's recognition or increases its delineation from the background (Qiu, Sugihara, and von der Heydt 2007; Rayner 2011). In this regard, prior research points out that objects are more readily recognizable when they are separated by background space than when they are connected to each other or overlapping (Qiu et al. 2007). In situations where distinction from the background is enhanced, this causes increased salience of the target stimulus (Nothdurft 2000), which in turn affects the allocation of attention to that stimulus (Bacon and Egeth 1994). Overall, prior research suggests that when space isolates objects in a visual field from the background they are more salient and, thus, attract more attention. We further theorize that such increased attention to products in an interspatial (vs. a non-interspatial) product display subsequently results in greater size perceptions. According to prior research, an object appears to be larger and/or of greater quantity when people's attention is automatically directed to this object (Folkes and Matta 2004). Hagtvedt and Brasel (2017) also show that objects with highly saturated colors attract more attention and, thus, are perceived to be larger. Taken together, these findings point out that increased attention devoted to an object prioritizes processing mental resources to make size estimation better.

Study 1 examines the core effect of interspace on product size estimates and the underlying mechanism. Participants (n = 103) were instructed to view a print ad which included an image of three cans of a fictitious brand of wafers. In the interspatial (non-interspatial) display condition, the cans were presented with a perceptually recognizable space (vs. no space) between them. Participants then reported their perceived product size. As predicted, participants in the interspatial (vs. non-interspatial) display condition estimated a greater quantity of wafer rolls per product package ($M_{interspatial}$ = 23.06 vs. $M_{non-interspatial}$ = 17.21; t(101) = 2.21, $p < .05$). Mediation analysis revealed a significant indirect path from interspatial product display to product size estimates through attention (95% CI = [.2317, 3.9667]). The effect of interspatial product display on product size estimates through product popularity and quality were not significant.

Study 2 aims to replicate the findings of Study 1. Participants were asked to imagine going to a store and considering buying mixed nuts and then were presented with a shelf image displaying the fictitious brand of mixed nuts. We manipulated interspatial (non-interspatial) product display similar to that of Study 1, with only slight modifications. Study 2A (n = 160) kept the number of products and the amount of white space between conditions constant. Study 2B (n = 87) held the size of the display between conditions constant. As expected, participants estimated that one product package contained a higher number of servings of mixed nuts in the interspatial (vs. non-interspatial) display condition (Study 2A: $M_{interspatial}$ = 11.38 vs. $M_{non-interspatial}$ = 9.26; t(158) = 1.99, $p < .05$; Study 2B: $M_{interspatial}$ = 6.54 vs. $M_{non-interspatial}$ = 5.28; t(85) = 2.09, $p < .05$). Mediation analysis revealed a significant indirect path from interspatial product display to product size estimates through attention (Study 2A: 95% CI = [.0525, 1.0726]; Study 2B: 95% CI = [.0319, .8221]).

Study 3 provides further process evidence by manipulating individuals' attention level. Participants (n = 155) first viewed a one-tier shelf image displaying HK shampoo. Interspatial (non-interspatial) product display was manipulated in a manner similar to that of Study 1. At the same time, participants' level of attention was manipulated via a distraction task. In the distraction (no distraction) condition, a popular song was played (no music was played) while participants were exposed to the HK shampoo display. After viewing the image, participants then indicated their perceived product size. As expected, when participants were not distracted, they estimated the product to contain more quantity in the interspatial (vs. non-interspatial) display condition (how many washes per bottle: $M_{interspatial}$ = 58.55 vs. $M_{non-interspatial}$ = 37.71; F(1, 150) = 9.15, $p < .01$; how long to use up (days): $M_{interspatial}$ = 68.81 vs. $M_{non-interspatial}$ = 47.97; F(1, 150) = 6.74, $p < .02$). However, when participants were distracted, there was no significant difference in perceived product size between the two conditions (Fs < 1).

From a theoretical point of view, our research contributes to the literature by identifying a novel spatial factor, the mere existence of interspace in a display, that has unique consequences for judgments of product size. Our work also provides significant managerial guidelines for the use of space between products in a product display.

The Pursuit of Pragmatic Truth at the Cost of Literal Truth

Charles Y. Zhang, University of California, Riverside, USA
Norbert Schwarz, University of Southern California, USA

EXTENDED ABSTRACT

In communication, listeners expect speakers' utterances to be truthful and speakers expect their utterances to be accepted as true. Philosophers and linguists consider it a core principle of cooperative conversation that speakers should only say what they believe to be true (Grice, 1975). Grice (1989) noted that his other maxims of conversation (relation, quantity, and manner) "come into operation only on the assumption that this maxim of quality is satisfied" (p. 27).

In the present research, we challenge this view and introduce a distinction between literal and pragmatic truth. To tell a *literal truth*, a speaker should avoid saying anything she does not believe to be part of the fact. To tell a *pragmatic truth*, a speaker should provide information that is as close to the fact as possible on the variable that is most relevant to the audience. Although the goals of achieving literal and pragmatic truth are often aligned, they can conflict in contexts where the fact cannot be entirely and precisely communicated, e.g., e.g., due to a lack of time, technical difficulties, or the recipient's lack of background knowledge. We propose that, in these cases, speakers will, and will be expected to, form utterances that maximize the pragmatic truth, even at the cost of literal truth. In the present research, we pitch statements that are literally true but pragmatically false against statements that are literally false but pragmatically true. We demonstrate the existence of situations in which pragmatically true statements are considered more appropriate than literally true statements and discuss the implications of the findings for marketing contexts.

In study 1, participants were told that a medicine was recently found to have side effects, including *dry mouth* and *heart attack*. An official misspoke in a radio interview that "the medicine may cause side effects such as dry mouth and liver failure." The editor's only choices were to either broadcast this interview or a trimmed version of it: "the medicine may cause side effects such as dry mouth." The original statement is literally false but pragmatically truer because liver failure and heart attack are comparable in terms of their severity. As predicted, the majority of participants considered that the trimmed version better reflected the facts, but chose the full version to broadcast.

In study 2, participants imagined being a burglar whose task it is to warn a partner of any approaching cops. They had agreed to position their arms horizontally if no cop is in sight and vertically if a cop is approaching. Participants were told that, although no cop was approaching, they spotted a hidden surveillance camera when their partner was about to commit the crime. In this situation, the gesture that indicates an approaching cop could serve as a warning even though no cop was seen; it would hence serve the pragmatic purpose while being literally false. As expected, most participants chose to hold the arms vertically, thus conveying a warning, while also agreeing that the explicit prerequisite for this signal (cop approaching) was not met.

An utterance can be relevant to different listeners in different ways. Statements that are pragmatically true to some listeners may not be pragmatically true to others, which should affect speakers' choice of utterances. In study 3, participants learned that a typhoon hit a Pacific island and destroyed a warehouse and the only seaport. Two local officials were interviewed. One stated that a warehouse was destroyed and the other stated that a warehouse and the only airport were destroyed. Half of the participants were told that the interview would be used as part of a call for international charity donations; the other half were told that the interview would be used to inform the coordinators of international rescue teams. All participants were asked to 1) choose which interview should be issued, and 2) identify which statement was more accurate. For donors, it is irrelevant if the damage pertains to the seaport or airport as long as the severity of damage is comparable. In contrast, whether the seaport or the airport is destroyed is crucial for rescue teams, who need to approach the island. Accordingly, while most participants in both conditions considered "a warehouse and the airport were destructed" less accurate, they chose to issue this statement to potential donors but not to rescue teams.

Study 4 provides process evidence that a speaker's choice of utterance is driven by the extent to which she believes that the utterance is pragmatically true. Participants learned that a medicine could lead to side effects such as dry mouth and heart attack. The official misspoke the side effects either as "dry mouth and liver failure," "heart attack and itchy skin," or "dry mouth and itchy skin." All participants were given a choice of broadcasting the original version or to trim off the second side effect of the corresponding statement. They also rated the severity of the four side-effects. When the speaker mentioned dry mouth and liver failure, most participants chose to broadcast this (literally false) statement over the trimmed version. Their decision to do so was mediated by their perceived severity of the side effect. In contrast, significantly fewer participants chose to broadcast one of the other literally false statements (heart attack and itchy skin or dry mouth and itchy skin).

In sum, the present research highlights the distinction between pragmatic and literal truth. When literal truth conflicts with pragmatic truth under conditions of communication constraints, speakers choose the pragmatically true statement over the literally true statement.

Maximizing Strengths or Fixing Weaknesses?
Evaluatees Tend to Fix Weaknesses More Than Evaluators Appreciate

Xiaoying Zheng, Nankai University, China
Yanping Tu, University of Florida, USA
Jingting Yuan, China Construction Bank, China
Jing Xu, Peking University, China

EXTENDED ABSTRACT

Everything has its strengths and weaknesses. For instance, a restaurant may receive an above average rating on food quality, but an average rating on service; a job candidate may have better analytical skills than writing skills. When given an opportunity to improve, do people (e.g., the restaurant manager, the job candidate) prioritize maximizing strengths (e.g., food quality, analytical skills) or fixing weaknesses (e.g., service, writing skills)? Moreover, often times, these decisions are made to cater to others' preferences. For instance, the restaurant manager would like to win consumers' heart; the job candidate hopes to get recruiters' vote. Do the restaurant manager and the job candidate make improvement decisions optimally?

We examine decision contexts like these, which involve an evaluatee/seller who provides products for others to evaluate or select, and an evaluator/buyer who evaluates or selects among products provided by evaluatees. Evaluatees often make decisions to improve an original product (P_O) that has strengths and weaknesses. Should they prioritize maximizing strengths (MS) or fixing weaknesses (FW)? Sometimes the answer is obvious: if the weakness falls below the acceptable threshold, then FW will be imperative; if the return for improving a certain attribute is higher, then effort should be devoted to that attribute. However, in situations where the original product (1) is reasonably good such that the weakness is not alarmingly unacceptable and (2) the return of improving either the strength and the weakness is similar, what should evaluatees do? To illustrate (figure 1), consider, in a 5-star evaluation system, a product at the original state P_O (4.3, 4.0), scoring 4.3 on attribute A (i.e., the strength) and 4.0 on attribute B (i.e., the weakness). Suppose the evaluatee can improve the rating of one (and only one) attribute by 0.3. Should they improve attribute A or B?

To answer this question, our empirical approach is to present the final products of the two strategies to evaluators, ask evaluators to choose, and assess the match. Specifically, maximizing strengths will lead to a product with more polarized attributes, some extremely strong and some relatively weak (P_{MS}); fixing weaknesses will lead to a product with more balanced attributes, all moderately strong (P_{FW}). We measure whether evaluators prefer P_{MS} or P_{FW}, as a proxy of their appreciation of evaluatees' effort of MS or FW.

Evaluatees Prefer Fixing Weaknesses More Than Evaluators Appreciate

We propose that evaluatees may choose FW more than evaluators appreciate, for the following reasons. To begin with, it is well documented that people feel apprehensive (also described as anxious, uneasy, or worried in literature) when being judged by others (i.e., evaluation apprehension; Rosenber 1969). Feeling apprehensive, evaluatees may consider more about the negative prospects of their decision (e.g., being rejected or disliked by evaluators), rather than the positive prospects (e.g., being selected or favored by evaluators). Our proposition is informed by two streams of research. First, mood alters cognition (Mayer et al. 1992; Johnson and Tversky 1983): people attend to mood-congruent information, generate mood-congruent thoughts, and expect mood-congruent event to be more likely to happen. More specifically, apprehension heightens

sensitivity to potentially threatening information and negative outcomes: apprehensive individuals detect negative information faster (Bradley, Mogg and Lee 1997), interpret ambiguous stimuli in a more negative way (Calvo and Castillo 1997; Eysencket al. 1991), and perceive higher risks of negative events (e.g., failing an exam, catching a disease) (Butler and Mathews 1987; Mitte 2007). Another stream of research that informs our proposition is about how motivational orientation (prevention vs. promotion focus; Higgins 1997) changes thinking. Specifically, apprehension is associated with a prevention-focus (Klenk, Strauman, and Higgins 2011), a "vigilant, negative-outcome-focused motivational state," which makes people attend to negative information and work towards avoiding negative outcomes (rather than achieving positive outcomes).

Thinking guides action. If follows that, when evaluatees worry about the negative prospects of being rejected or disliked, they act on the aspect that is more likely to cause it. Because weaknesses (rather than strengths) are the more likely causes of the negative prospects, evaluatees will act on weaknesses to ensure that they provide no grounds for rejection.

However, evaluators, the other party in the evaluatee-evaluator dyad, do not experience such apprehension and are less likely to adopt a negative focus when choosing a product. Compared to evaluatees, their attention is less likely to be drawn to the weakness attribute, and, consequently, they would not appreciate evaluatees' effort of FW as much.

In sum, our central hypothesis is that, when making improvement decisions, evaluatees tend to fix weaknesses more than evaluators appreciate, because they are in a more apprehensive state and engage in more negative thinking.

Study 1: Job Candidate vs. Recruiter

Study 1 (N = 173) tests our basic hypothesis in the job market context, using a one-factor two-level (evaluatee vs. evaluator) between-participants design.

In the evaluatee condition, participants imagined themselves hunting for a job and preparing for two equally important job entrance tests (A and B). They learned that the total score of each test was 150, and that, in a mock test, they scored 120 for test A and 100 for test B. Participants further supposed that they could improve the score on either test by 20 points, and indicated whether they would like to improve test A (the strength) or test B (the weakness).

In the evaluator condition, participants imagined being a recruiter and choosing between two candidates. They learned that the total score of each test was 150, and that, candidate 1 scored 140 on test A and 100 on test B (i.e., the end state of the evaluatee had they chosen to improve test A), whereas candidate 2 scored 120 on both tests (i.e., the end state of the evaluatee had they chosen to improve test B). Evaluators indicated which candidate they would like to recruit.

Evaluatees who chose to work on test A [test B] were coded as preferring MS [FW]; evaluators who selected candidate 1 [candidate 2] were coded as preferring MS [FW]. A Chi-Square test showed that evaluatees preferred FW (63%; 53 out of 84) more than evaluators

(45%; 40 out of 89; $\chi^2(1) = 5.73$, $p = .017$, odds ratio = 2.09), lending support to our basic hypothesis.

Study 2: Vacation Spot Manger vs. Consumer

Study 2 (N = 402) aimed to explore the main effect in a marketer-consumer setting. We also examined whether (1) the importance of the weakness attribute and (2) whether P_{FW} received perfectly balanced scores on both attributes had an impact. It used a 2 (evaluatee vs. evaluator) x 2 (P_{FW} has perfectly balanced attribute scores: yes vs. no; conceptual replication factor) x 2 (importance of the weakness attribute: high [food]vs. low [entertainment]; conceptual replication factor) between-participants design.

In the evaluatee conditions, participants imagined themselves being a manager of a vacation spot with food and entertainment (abbreviated to entmt.) as the two major attributes. They can improve the rating of one dimension by 0.2. In the evaluator conditions, participants imagined themselves making a choice between two vacation spots which differed in ratings on food and entertainment. Information on attribute values shown to evaluatees and evaluators respectively is in appendix A.

We coded participants' preferences for MS/FW. The choice share for FW broken by cells is shown in appendix B. A 2 (evaluatee vs. evaluator) x 2 (P_{FW} has perfectly balanced attribute scores: yes vs. no) x 2 (importance of the weakness attribute: high [food]vs. low [entertainment]) logistic regression with choice (0 = MS, 1 = FW) as the dependent variable yielded neither a three-way interaction nor any two-way interactions (all $ps > .350$). Thus, we collapsed data on the latter two factors and ran a chi-square test, finding that evaluatees preferred FW (72%, 149 out of 208) marginally more than evaluators (63%, 122 out of 194; $\chi^2(1) = 3.50$, $p = .061$, odds ratio = 1.49).

Collectively, studies 1 and 2 established the main effect, as well as demonstrated its generalizability.

Study 3: Testing the Underlying Mechanism

Study 3 (N = 401) aimed to test the proposed mechanism: evaluatees consider more about the negative prospects of their decisions, leading them to act on the more likely cause (i.e., weakness). In addition, we generalized the effect to a new domain: Airbnb, with a host and a guest as the seller-buyer dyad. This study used a one-factor two-level (evaluator vs. evaluatee) between-participants design.

In the evaluator condition, participants assumed the role of an Airbnb host who was considering whether to improve the amenities or the interior design (i.e., two focal attributes of their apartment). Participants learned that their apartment was currently rated 4.0 and 4.3 on interior design and amenities, respectively, on Airbnb's 5-star rating system. They further learned that they had the resources to improve the customer rating of one, and only one, attribute by 0.3. Participants then chose one attribute to improve. In the evaluatee condition, participants assumed the role of an Airbnb guest who was choosing between two apartments. Apartment A was rated 4.0 on interior design and 4.6 on amenities (i.e., P_{MS}). Apartment B was rated 4.3 on both interior design and amenities (i.e., P_{FW}).

Afterward, participants indicated (1) whether they experienced a negative mentality ("I was worried that guests may not like my apartment" and "I felt uncertain about what kind of apartment would be preferred by guests." in the evaluatee condition; "I was worried that I may not like the apartment I chose" and "I felt uncertain about what kind of apartment I prefer." In the evaluator condition) and (2) whether they adopted a negative focus ("I was worried that guests may focus more on the lower rated aspect of my apartment" and "I was worried that guests may not choose my apartment because of its lower rated aspect." in the evaluatee condition; "I focused more on

the lower rated aspect of these apartments" and "I made the decision based on the lower rated aspect of these apartments." in the evaluator condition). (1 = *completely disagree*, 7 = *completely agree*).

Replicating the findings in Studies 1 and 2, the results showed that evaluatees (hosts) preferred FW (49%, 98 out of 201) more than evaluators (guests) (30%, 60 out of 200; $\chi^2(1) = 14.77$, $p < .001$; odd ratio = 2.22). Evaluatees (M = 4.11, SD = 1.40) experienced a more negative mentality than evaluators (M = 3.31, SD = 1.31) (t(399) = 5.94, $p < .001$), and adopted a more negative focus (M = 4.36, SD = 1.77) than buyers (M = 3.39, SD = 1.55) (t(399) = 5.84, $p < .001$). The planned serial mediation (PROCESS Model 6; Hayes 2013) confirmed that negative mentality and negative focus mediated the impact of role (evaluatee vs. evaluator) on preference for FW (95% CI = [.1185, .3355]).

Study 4: Car Manufacturers vs. Car Buyers

Although for simplicity and clarity, we conducted our analysis and most empirical work in a two-products and two-attributes context where evaluatees choose to improve one attribute, our theory could make predictions in multiple-products and multiple-attributes contexts where evaluatees can choose to improve multiple attributes. In such contexts, MS means increasing the variance across attributes (i.e., making attribute values more polarized), whereas FW means reducing the variance across attributes (i.e., making attribute values more balanced).

Study 4 offered such an empirical test, modeling real decisions by car manufactures (evaluatees) and buyers (evaluators). We linked (1) a unique proprietary data set of multi-attribute rating information (fuel consumption, handling, horsepower, exterior styling, interior design, comfort, and space), scraped from a leading customer review website, of the top 20% major cars and (2) their corresponding monthly sales volumes in the Chinese market, between January 2014 and October 2019 (70 months).

Car manufacturers make decisions to improve car models on a yearly basis, and thus we coded attribute rating at year-level. Their choice of FW [MS] would manifest as a decrease [an increase] of variance across attributes (Var) from time t-1 to time t. We note the possibility that the whole industry might be shifting to produce cars with more balanced (or more polarized) attributes due to external factors, and thus standardized Var based on the average variance of all the car models in the given year (SVar). We reason that, if car manufacturers adopt a FW strategy, then a car with an above-average variance last year should have a larger decrease in variance this year. Put formally, our dependent variable was the difference of standardized variance between year t and year t-1 for car i (), and our main predictor was standardized variance of car i in year t-1 (). We included rating valence (), sales volume (), and price () of car i in year t as control variables. We also incorporated fix effects for car () and for time (). Equation is shown below.

$$SVar_{it} - SVar_{it-1} = \beta_0 + \beta_1 SVar_{it-1} + \beta_2 Valence_{it} + \beta_3 Volume_{it} + \beta_4 Price_{it} + \alpha_i + f_t + \varepsilon$$

If manufacturers choose FW [MS], then should be negative [positive]. Our theory predicts that should be negative. Regression results supported our theory (see appendix C).

Car buyers make purchase decisions based on customer review information. Because we obtained monthly sales data, we coded attribute rating data at monthly level. Our dependent variable was *sales volume* of car i at month t (), and our main predictor was the accumulative variance at month t-1 of car i (). Note that we used accumulative reviews, because when a buyer reads reviews at time t, she gets reviews from time 1 to time t. Our control variables included accumulated valence from time 1 to time t (), accumulated volume

from time 1 to time t (), and price at time t of car i (). In addition, to control for the impact of the change in the entire industry, we factored in accumulated industry-level variance (Var_industry$_{it}$) by averaging variances in all the accumulated reviews for all cars from time 1 to time t. We also incorporated fix effects for car () and for time (). Equation is shown below.

$$SalesVolume_{it} = \gamma_0 + \gamma_1 Var\_review_{it-1} + \gamma_2 Valence_{it} + \gamma_3 Volume_{it} + \gamma_4 Price_{it} + \gamma_5 Var\_industry_{it} + \alpha_i + f_t + \varepsilon$$

If consumers appreciate FW [MS], then should be negative [positive]. Our theory predicts that should be positive. Regression results supported our theory (see appendix D).

General Discussion

Across three lab studies and two secondary data sets collected in both the US and China, we document a robust effect that evaluatees choose to fix weaknesses more than evaluators appreciate. We further identify the underlying psychological process: evaluatees experience apprehension and focus more on negative prospects.

Our research adds to literature on improvement decision, which previously only focused on establishing methods to calculate financial returns post hoc (Rust, Zahorik and Keiningham 1995). It enriches literature on how roles shape preferences and decisions (Weaver, Garcia and Schwarz 2012; Woolley and Fishbach 2018). Last but not the least, our research offers clear recommendations for managers that they should give prioritize maximizing strengths rather than fixing weaknesses.

Donating Cash or Donating Objects? How Donation Type Determines Donation Likelihood

Xiaozhou (Zoe) Zhou, IE Business School, Spain
Dilney Gonçalves, IE Business School, Spain

EXTENDED ABSTRACT

Charities have been concerned about in-kind donations (vs. cash donations) shipped to disaster-affected areas displacing more urgent shipments and incurring high logistic costs (Brooks 2018; Piper 2019). However, a pre-test (30 participants) revealed that more than half of the participants believed that making in-kind donations (i.e., food/supplies) was a better way to help disaster-affected area. In this research, we sought to provide evidence for and explain the underlying mechanism of donors' preference for in-kind donations.

Research of imagery has recognized that stimulus plays an important role in eliciting imagination (MacInnis and Price 1987; Spears and Yazdanparast 2014). Moreover, researchers demonstrate that stimulus with higher concreteness is better at inducing imagination (Burns, Biswas, and Babin 1993; Yoo and Kim 2014). Drawing on previous findings, we propose that in-kind donations, which are both tangible and concrete, are more likely to induce donors' imagination about how their donation can be used. Since people have higher confidence about the likelihood of an event happening if they have previously imagined the same situation (Anderson 1983; Carroll 1978), we hypothesize that asking for in-kind donations will increase donors' contribution confidence about their donation's helpfulness, thus increasing donation intention.

Consumers vary in their imaginal processing ability (Ernest 1977). Studies that examined the effect of imagery-eliciting strategies on advertising found that advertisements that instructed consumers to imagine were more effective to participants with high imaginal ability (Burns et al. 1993). We thus predict that donors with high imaginal ability will show a stronger preference for in-kind donations by better using the stimulus (the in-kind donations) to imagine an end result. Low imaginal ability donors, in contrast, have limited ability to use stimulus to imagine a similar situation. Consequently, we hypothesize that donors' imaginal ability will moderate the effect of donation type on donors' perceived contribution confidence.

According to construal-level theory, low-level construal leads people to construe events in a more concrete manner (Trope and Liberman 2010). Since the ease of imagination increases as concreteness increases (Sherman et al. 1985), we expect that the ease of imagination increases as mental construal decreases. Thus, we hypothesize that the effect of donation type on contribution confidence will be attenuated by low construal because low construal encourages imagination regardless of donation type.

In studies 1a and 1b participants were told to evaluate a situation where a charity, which was collecting donations for people who just suffered an earthquake, approached them at a supermarket. We employed a between-subjects design in study 1a and an independent-samples t-test revealed that donation likelihood was significantly higher for in-kind donations ($M_{physical}$ = 3.94, SD = 1.11; M_{cash} = 3.43, SD = 1.35; $t(159)$ = -2.60, p = .01). Study 1b used a within-subjects design. A paired-samples t-test showed that participants still preferred in-kind donations ($M_{physical}$ = 3.78, SD = 1.27; M_{cash} = 2.98, SD = 1.30; $t(79)$ = - 4.05, p < .001).

Study 2 examined how people react to nonprofits' ads that requested either cash or in-kind donation by using Google Adwords to post charity advertisements. Two advertisements were created to raise donations for Chinese residents living in the epidemic area during COVID-19 and the advertisements differed only in the first headline where we manipulated the donation request as either in cash or in in-kind. A third ad was created which instructed people in its description to imagine how their cash donation could be used to get face masks. Chi-square tests revealed that the likelihood of clicking on the in-kind advertisement was higher than the cash advertisement (χ^2 = 16.89, p < .01). People were also more likely to click the cash advertisement that encouraged imagination (χ^2 = 6.13, p < .02) compared to that which simply requested cash. We did not observe any difference between in-kind and cash advertisement with imagination (χ^2 = 1.07, p = .30).

Study 3 examined the moderated mediation with mental imaginal ability as a moderator. Participants were presented with a mostly identical charitable advertisement. The only difference was the type of donation the charity sought (in-kind or cash). We measured participants donation likelihood, contribution confidence (Macdonnell and White 2015), and imaginal ability (α = .73, scale developed by Childers, Houston, and Heckler (1985)). A regression with donation type, imaginal ability, and their interaction on contribution confidence (the mediator) revealed a significant interaction effect (β = 1.31, p = .01). The moderated mediation through contribution confidence was also significant (indirect effect = .99, SE = .42; 95% CI [.2172, 1.8927]). Participants with high imaginal ability indicated higher donation likelihood for in-kind donation as these increased their contribution confidence.

Study 4 examined moderated mediation with construal-level as a moderator. Mental construals were manipulated by social distance. The charity was either collecting donations (cash or in-kind) for people in the participants' hometown (low construal) or Indonesia (high construal). A regression with donation type, construal level, and their interaction on contribution confidence revealed a significant interaction effect (β = .96, p = .01). The overall moderated mediation was also supported (indirect effect = .71, SE = .27; 95% CI [.1929, 1.2589]). Participants with high mental construal indicated higher contribution confidence and donation intention for in-kind donation. We did not observe differences in contribution confidence between donation types when participants use low construal.

Past research mostly focused on the difference between cash donation and volunteering (Liu and Aaker 2008). Our research fills the gap by examining the difference between cash and in-kind donation. Moreover, our work adds to consumer imagination literature, particularly in the area of donation. We also provide practical implications. Our studies suggest that nonprofits can create advertisements that elicit imagination about how cash donations can be used to encourage cash donations. The results that construal levels can influence people's preferred donation type also provide guidance to nonprofits who target a wide range of donors. There are situations where nonprofits would prefer physical donations, and sometimes nonprofits might want to collect in-kind donations from nearby donors and cash donation from long-distance donors. In this case, different advertisements could be designed.

Can a Single Digit Make Consumers Eat Less? The Influence of Calorie Presentation Format on Consumers' Unhealthy Food Consumption

Li Zhou, Hunan Normal University, China
Leilei Gao, Chinese University of Hong Kong, China
Guowei Zhu, Hunan University, China

EXTENDED ABSTRACT

To alleviate the problem of obesity and promote consumers' well-being, many countries require food companies to provide nutritional information on food packages (FDA 2016; European (EU) No 1169/2011). Yet, with regard to information on calorie content in particular, different countries have different regulations (Appendix A). Take the original flavored Pringles potato chips as an example, companies selling in the EU market are required to present the calorie content of Pringles as a precise integer (154 calories per serving), whereas companies in the US market have to round the number of calories to the nearest multiple of 10 (150 calories per serving). An interesting question that arises is, does this tiny difference in the presentation of calorie information affect consumers' food consumption intentions and actual behavior?

A round number is defined as any integer that is a multiple of 10 (where numbers that end in more zeroes are considered to be "rounder" than numbers that end in fewer zeroes). Consumers perceive numbers that end with non-zero digits to be more precise than round numbers (Thomas, Simon, and Kaidiyali 2010; Pena-Marin and Bhargave 2016). Research suggests that people process round numbers more easily (or fluently) than they process precise numbers (Kettle and Häubl 2010; King and Janiszewski 2011; Wadhwa and Zhang 2014, 2019). The heightened processing fluency associated with round numbers is commonly attributed to the high frequency of usage of round numbers in daily life (Dehaene and Mehler 1992; Fassbender et al. 2014.

Prior research does not provide an obvious indication of whether round (vs. precise) presentation of calorie content is likely to positively or negatively affect consumers' perceptions of a particular food item. On the one hand, some studies suggest that processing fluency can evoke positive affective reactions, which individuals might misattribute to the target stimulus, leading them to evaluate it more favorably (Winkielman and Cacioppo 2001; Winkielman et al. 2003; Schwarz 2004). This account would suggest that presenting calorie information in round (vs. precise) numbers might elicit more positive affect, leading to more positive evaluations of the food item. Yet, other researchers downplay the role of positive affect triggered by processing fluency, and instead emphasize the general capacity of processing fluency to magnify one's judgment of a stimulus, whatever that judgment might be (Jacoby and Dallas 1981; Jacoby, Kelley, and Dywan 1989; Witherspoon and Allan 1985). This stream of research (Albrecht and Carbon 2014; Carbon and Albrecht 2016) suggests that a higher level of processing fluency can activate a clearer interpretation of the most salient source of the stimulus that is task-relevant at the time of judgment, thus intensifying one's original evaluations of that stimulus. In other words, under heightened processing fluency, an individual will evaluate positive attributes of the stimulus even more positively, and negative attributes more negatively (King and Janiszewski 2011; Wadhwa and Zhang 2014).

In the case of unhealthy foods, consumers usually have mixed evaluations. Such foods offer immediate hedonic enjoyment, but also high numbers of calories that conflict with long-term goals of staying healthy or losing weight (e.g., Read, Loewenstein, and Kalyanaraman 1999; Wertenbroch 1998). When processing calorie information of unhealthy foods, we suggest that consumers are likely to treat it as

negative information. Thus, for a given vice food item, we would expect a round-number presentation of caloric information (as opposed to precise presentation) to intensify consumers' negative evaluations.

Finally, we expect people's evaluative judgment of food items to have a direct impact on their consumption intention such that negative (positive) evaluation of a given food item will decrease (increase) consumption (e.g., Kivetz and Simonson 2002; Wertenbroch 1998). Therefore, it is expected that a round-number presentation of caloric information (as opposed to precise presentation) will intensify consumers' negative evaluations of unhealthy food items, and subsequently decrease consumption intention. We examined this proposition in four studies.

Study 1a

Method

Participants (N=114, 45.6% female, M_{age}=36.65, SD=10.19) recruited on Amazon M-Turk were randomly assigned to one of two conditions (round vs. precise calorie information) in a between-subject design.

All participants were shown the front and back package views of a brand of peanut butter flavored sandwich crackers, with either round (200 calories) or precise (202 calories) calorie information displayed on the back-pack nutrition facts label (Appendix B). Participants were then asked to estimate the number of crackers they would like to eat (between 0 and 30). As hunger has been reliably shown to affect people's food consumption level (Garg, Wansink, and Inman 2007; Tangari et al. 2019), in all studies we also recorded participants' hunger level ("How hungry are you at the moment?"; 1= *not at all*, 7= *extremely hungry*), and included hunger as a covariate in all the related analyses.

Results

Consistent with our expectation, participants indicated that they would eat fewer crackers when calorie information was presented as a round number (*M*=8.67, SD=6.37) than as a precise number (*M*=11.12, SD=8.8; $F(1, 111)$=4.37, p=.039, η^2=.04).).

Study 1b

Study 1B sought to replicate the findings of Study 1A using a different product and a different presentation method of calorie information. To assure that the effect was not only observed when the precise number was bigger than the round number, Study 1B adopted two precise presentation conditions where the precise numbers were either slightly higher or slightly lower than the round number. Finally, in Study 1B, we measured the perceived healthiness and perceived calorie level of the unhealthy food item and examined whether it was these judgments that were magnified by the round presentation of calorie numbers and subsequently caused the effect.

Method

Participants recruited via Amazon M-Turk (N=201, 46.8% female, M_{age}=36.79, SD=11.13) were randomly assigned to one of three conditions (round, precise-low, and precise-high) in a between-subject design.

They were told to look at the package design of a newly launched ice cream brand and indicate how much ice cream they would like to

eat at the moment (between 0 to 250 grams). The per-serving calorie content was 200 calories, 196 calories, and 204 calories for the round, precise-low, and precise-high conditions respectively (Appendix C). Next, they evaluated the perceived healthiness of the food item ("*In your opinion, how healthy is the ice cream?*"; 1=*Not at all healthy*, 7=*Very healthy*)" and the perceived calorie level of the ice cream ("*How do you perceive the calorie level of the ice cream?*"; 1=*Extremely low*, 7=*Extremely high*).

Results and Discussion

As expected, there was a significant difference in consumption intention across the three conditions ($F_{(2, 197)}$=3.48, p=.03, η^2= .033). Participants in the round-number condition intended to consume less ice cream (M=101.46, SD=75.38) than those in the precise-high condition (M=138.06, SD=80.88; $F_{(1, 197)}$= 5.07, p= .025, η^2= .03) and those in the precise-low condition (M=128.36, SD= 73.68; $F_{(1, 197)}$=5.33, p= .022, η^2= .03). Participants in the two precise-number conditions, however, did not differ in terms of their intended consumption level (F < .01, p = .966).

In addition, calorie presentation format did not affect the healthiness perception of the ice cream (p= .163), nor the perceived calorie level of the ice cream (p= .431).

In summary, Study 1A and Study 1B provide convergent evidence that a round-number presentation of caloric information (as opposed to precise presentation) decreased consumption intention. However, the lack of between-condition difference in perceived unhealthiness and perceived calorie level of the ice cream suggests that the effect was not caused by the amplification of these judgments. It is possible that they may not be the primary consideration when consumers process calorie information on nutrition labels.

Study 2

Study 2 was designed to replicate the findings of Study 1 with real consumption behavior. In addition, we continued to examine the underlying mechanism of the effect by measuring participants' risk perception and guilt associated with eating unhealthy foods.

Method

Students from a large university (N=124, 51.6% female, M_{age}=21.34, SD=2.01) participated in the lab study and were randomly assigned to two conditions (round vs. precise). As a cover story, participants were asked to taste a brand of newly launched potato chips and provided their evaluations. Each participant was provided a cup of water to rinse their mouth, a plate containing 20 original flavored potato chips, and a food label that presented the calorie information either as a round (2000 KJ/100g) or precise (2021KJ/100g) number. Participants were given five minutes to taste the chips and fill out a short questionnaire measuring their food evaluations (e.g., taste, saltiness, crispiness). After the food-tasting task, all participants returned the questionnaire and any leftover food to the experimenter and answered some additional questions.

Specifically, participants' risk perceptions were assessed ("Will eating chips on a regular basis increase the risk of weight gain?" and "Will eating chips on a regular basis increase the risk of long-term health problems?" 1= *not at all*, 7= *definitely*). The two measures were highly correlated and were combined for later analyses (r = .77). Participants were also asked, "How guilty do you feel to eat the chips in today's study?" (1= *not at all guilty*, 7= *extremely guilty*). After the participant left the lab, the experimenter counted each participant's leftover potato chip pieces and recorded their consumption amount to the nearest half chip.

Results and Discussion

Replicating the findings of Studies 1A and 1B, we found an effect of calorie information roundness ($F_{(1, 121)}$=5.03, p= .027, η^2= .04). Participants ate significantly fewer chips when the calorie information was presented in a round number (M=5.33, SD=3.53) than a precise number (M=7.2, SD=4.73).

In addition, there was no difference in self-reported guilt associated with eating chips (p = .332). Nonetheless, analysis on risk perception revealed an effect of calorie presentation condition ($F_{(1, 122)}$= 10.06, p= .002, η^2= .08). Specifically, compared to presenting the potato chip's calorie content in a precise number (M=4.30, SD=1.46), participants perceived greater health-related risks when the calorie content was presented in a round number (M=5.14, SD=1.49).

We also conducted a mediation analysis following the PROCESS macro (calorie presentation format à risk perception à consumption volume; model 4, Hayes, 2018). The effect of calorie presentation on risk perception was significant (b=.65, SE= .17, t= 3.76, p = .001, 95% CI= [.31, 1.00]), so was the effect of risk perception on food consumption (b= -.31, SE= .10, t=-3.18, p =.001, 95% CI= [-.50, -.12]). Participants' subjective judgment of risk factor fully mediated the effect of calorie presentation on food consumption (b= -.20, SE= .08, p = .017, 95% CI= [-.41, -.08]).

In summary, Study 2 replicated the findings of Study 1 with consumers' actual consumption behavior. In addition, Study 2 found that it was the risk judgment associated with consuming unhealthy food that was magnified when calorie information was presented as a round (vs. precise) number, and subsequently decreased consumption volume.

STUDY 3

Thus far, our findings are consistent with the conceptualization that processing fluency increases attention paid to calorie information, which allows consumers to form a more negative interpretation of the information, and subsequently decreases consumption intention. If this is the case, then the effect should be prominent among those who do not habitually pay attention to food calorie information, but attenuated when consumers' default attention to food calorie information is high. We tested this hypothesis in Study 3.

Method

Participants (N=211, 49.3% Female, M_{age}= 30.01, SD= 7.23) were randomly assigned to two conditions (calorie presentation: round vs. precise). We also measured participants'' default attention paid to food calorie information and treated as an individual difference moderator.

Participants were presented the front package view of a fictitious brand of potato chips with calorie information presented either as a round (800 KJ) or precise number (813KJ). Next, they indicated the amount of potato chips they felt like to eat (0 ~ 70 grams). Then, participants' default attention levels were measured with three questions, "How often do you check calorie information when choosing food items?" (1= *never*, 7= *always*); "How sensitive are you to calorie information when choosing food items?" (1= *not at all sensitive*, 7= *extremely sensitive*); "To what extent do you base your snack purchase decision on the calorie information?" (1= *not at all*, 7= *totally*). These three measures were combined for later analyses considering the high correlation among them (r = .93).

Results and Discussion

A bootstrapping method with PROCESS macro (Model 1, Hayes 2013) was conducted with food consumption as DV, calorie presentation format (0=precise, 1=round) and attention to calorie

information as the IV. Results showed a significant main effect of caloric number roundness on food consumption (b=-6.82, SE=3.01, t=-2.26, p= .025, 95% CI= [-12.75, - .88]) such that participants indicated that they would eat fewer potato chips when the calorie information was presented as a round than precise number. In addition, there was a significant interaction between calorie number roundness and default attention level (b=4.75, SE=1.80, t=2.63, p= .009, 95% CI= [1.19, 8.31]). For participants whose default attention level to food calorie information was low (b=-14.95, SE=4.42, t=-3.38, p= .001, 95% CI= [-23.66, -6.23]) or median (b=-6.82, SE=3.01, t=-2.26, p= .025, 95% CI= [-12.75, - .88]), presenting the calorie number in round (vs. precise) number decreased their consumption intention. However, for participants whose default attention level to calorie information was already high, presenting calorie information as a round or precise number did not cause any difference in consumption intention (b=-1.32, SE=4.21, t=.31, p= .754, 95% CI= [-6.97, 9.61]).

In summary, Study 3 provides strong support to our theory and suggest that the effect is primarily driven by consumers who are habitually inattentive to food calorie information.

General Discussion

In recent years, considerable attention has been paid to the efficient presentation of nutrition information on food packages. For example, research has suggested presenting nutrition labels on front (vs. back) packages (Van Kleef et al. 2008), and informing consumers of the duration of exercises needed to burn out the calories (Dowray et al. 2013; Kim et al. 2018). The current research shows that simply presenting calorie information in round (vs. precise) numbers can nudge consumers to reduce their unhealthy food consumption, especially for those who do not habitually pay attention to calorie information on food packages.

Our studies also show that the calorie roundedness effect is triggered by greater processing fluency associated with round (vs. precise) calorie numbers, which in turn magnifies perceived health risks of unhealthy foods, and subsequently reduces consumers' consumption intention and actual consumption volume.

Digital Nudging to Reduce Screen Time Consumption

Laura Zimmermann, IE University, Spain
Michael Sobolev, Cornell University, USA

EXTENDED ABSTRACT

Mobile phones are our constant companions and an integral part of our daily lives. Despite the huge advantages of mobile devices, research has started to uncover negative effects on behavior, including performance (Felisoni & Godoi, 2018; Lanaj, Johnson, & Barnes, 2014), emotional health (Lee, Chang, Lin, & Cheng, 2014), sleep patterns (Thomée, Härenstam, & Hagberg, 2011) as well as cognitive capacity (Ward, Duke, Gneezy, & Bos, 2017). A significant proportion of people want to reduce their screen time, yet they are not able to achieve the goal. As a solution, both Apple and Google released time management applications with the goal of helping consumers understand and change their mobile phone habits.

Despite recent controversies regarding the correlational nature of studies investigating screen time consumption, there is a lack of systematic experimentation of interventions to reduce screen. Although a plethora of possible solutions are suggested in the popular press to reduce screen time, almost none have been examined in a randomized fashion. One approach to help consumers lower their screen time is altering the choice architecture by manipulating existing features on mobile devices, for example, by incorporating frictions in the usage process which disrupt habitual, automatic behavior and stimulate a more mindful interaction with the phone (Cox, Gould, Cecchinato, Iacovides, & Renfree, 2016). Such digital nudges do not eliminate consumers' freedom of choice to use their phone (as opposed to blocking applications) but nevertheless lead individuals in a particular direction (Okeke, Sobolev, Dell, & Estrin, 2018; Thaler & Sunstein, 2009).

This research addresses the question of whether screen time tracking apps effectively educate consumers about their digital behavior on mobile, and whether this leads to a reduction of screen time (study 1: longitudinal field study). Second, we investigate consumers' attitudes towards app designs varying in terms of their coerciveness (study 2: experimental survey). Third, we study digital nudges that alter the choice architecture as a method to reduce screen time consumption (study 3: longitudinal randomized trial). Finally, we examine to what extent reducing objectively measured smartphone usage is linked to wellbeing and academic performance.

Study 1 investigated the effect of mobile phone screen time tracking apps on users' self-awareness, their actual time spent on mobile, and long-term consequences for grade point average (GPA). Participating students (N=246) completed two screen time estimation surveys before and after (T1 & T2) a mobile phone tracking project which was part of a university workshop. Students downloaded a tracking app and submitted screenshots of their usage indicators. At T1, before the tracking project, estimated screen time was not correlated with actual screen time (r=.018, p=.783). At T2, after tracking, participants' estimates of mobile screen time were highly correlated with their actual screen time (r=0.691, p<.001). Longer tracking durations led to better calibration (β=1.63, SE=.46, t=3.55, p<.001). However, this did not lead to a reduction of overall screen time. In fact, the findings suggest the opposite (β=1.56, CI [-.22, 3.35], t=1.71, p=.087), an increase in screen time. Higher mobile phone screen time was linked to lower GPA (β=-0.0004, SE=0.0002, p=.031).

Study 2 investigated consumers' attitudes towards app design idea varying in terms of coerciveness (Thaler & Sunstein, 2009). We hypothesized that consumers evaluate app designs, which limit free-dom of choice directly or nudge consumers to reduce screen time *less favorably* than apps, which only provide information. We investigated consumer perceptions of three app design ideas (within-subjects: tracking vs. blocking vs. greyscale) in terms of overall preference, knowledge efficacy and reduction efficacy (scales from 0-100). Participants (N=139; Prolific Academic) evaluated three app design ideas with the goal of helping consumers spend less unproductive time on their phones. Within-subjects ANOVA showed that participants had a clear preference for the purely informational tracking app (F(2, 276)=15.74, p<.001), and thought it was most effective in increasing self-awareness (F(2, 276)=50.98, p<.001). However, in terms of reduction efficacy, the blocking app was perceived as most effective (F(2, 276)=18.55, p<.001).

Study 3 employs systematic experimentation of interventions to reduce screen time as well as potential consequences for GPA and wellbeing. We conducted an RCT with three conditions among a student population (N=112) over three weeks and altered the choice architecture of mobile consumption by manipulating existing mobile features to help consumers lower their screen time. In the control condition subjects simply tracked their screen time with the help of an app. Additionally, we examined two commonly proposed digital nudges varying along a spectrum of coerciveness: (1) greyscale: altering the color of the screen, and (2) self-commitment: setting goals to limit time spent on addictive apps. Objectively measured screen time was obtained through screenshots.

As hypothesized, simply tracking phone usage had no effect on screen time (M=283 min). However, the greyscale (M=233 min) and, to a lesser extent, self-commitment (M=268 min) digital nudges led to significant reduction in daily screen time (F(2,109)=3.21, p=.044). Subjects in the greyscale condition reported lower enjoyment of social media activities during the intervention (F(2,131)=3.35, p=.038), suggesting a process mechanisms through which greyscale is effective.

While our intervention was effective in reducing screen time, it did not have any immediate causal effects on sleep quality, happiness and stress level (all ps=ns). We also found no difference for GPA (F(2,109)=0.15, p=.858). Nevertheless, average daily screen time was correlated with GPA (r=-0.263, p<.0.001).

Our findings offer insights for consumer researchers and practitioners interested in curbing mobile phone overload. By showing that screen time is linked to GPA we add to the growing literature on consequences of mobile phone overuse. This research further contributes to the 'quantified self' literature (Lupton, 2016) by showing that the quantification of mobile phone usage with the help of tracking app has benefits for self-awareness, but no impact on behavior change. Finally, we add to the literature on digital nudges, by showing that greyscale mode can be a viable technique to reduce mobile use. Taken together, our research advances knowledge about effective solutions to curb digital overload and potential consequences of screen time reduction.

Engagement with Virtue and Vice Information Through the Day

Ozum Zor, Rutgers University, USA
Kihyun Hannah Kim, Rutgers University, USA
Ashwani Monga, Rutgers University, USA

EXTENDED ABSTRACT

A growing number of consumers access information using social media platforms, such as Twitter. These platforms have become the dominant locations to engage with new information. Consumers spend more than two hours per day on social media (Bayindir and Kavanagh 2018). Users mostly engaged with frivolous information in the early days of social media, but it is now a source of news for 68% of U.S. adults (Matsa and Shearer 2018). Thus, it is critical to understand how different types of information are driving engagement. We specifically focus on vice (i.e., tempting, but with few later benefits) versus virtue information (i.e., not tempting, but offering later benefits).

We draw from research on self-control. Similar to muscles weakening after physical exertion, self-control weakens after subsequent efforts (Muraven and Baumeister 2000). Individuals are faced with multiple self-control challenges through the day, as they try to avoid tempting activities and foods. Such behavior is depleting (Vohs et al. 2008), weakening self-control as the day progresses. For instance, individuals are more likely to disregard professionalism rules or engage in unethical behavior later in the day (Dai et al. 2015; Kouchaki and Smith 2014). What is not yet understood is how self-control depletion may manifest for online information engagement. One exception is Hofmann et al.'s (2012) examination of a broad set of activities, including TV watching and web surfing. They observed an increased desire to engage in several media activities in the evening hours. Will such a pattern emerge similarly for engagement with online information, specifically, tweets on Twitter? We argue that the outcome will depend on what the tweet is about. That is, the type of information will matter.

Specifically, we discover an asymmetry in the engagement with vice versus virtue information. A relative vice offers immediate pleasure at the moment of consumption but may have negative consequences later on; in contrast, consumption of a relative virtue may not be pleasurable at the moment but provides benefits in the long-term (Khan and Dhar 2007; Khan, Dhar, and Wertenbroch 2005; Siddiqui, May, and Monga 2017). While a bulk of the vice-virtue research has been conducted on foods, this distinction can apply equally to information content. Thus, a salacious gossip in the *Cosmopolitan* could be considered vice information by many who are tickled by the instantaneous pleasure of reading the article but know that there is no long-term benefit from it. However, an article on financial markets in *Forbes* could be considered virtue information by many who find it hard to understand but appreciate the long-term benefit of becoming more knowledgeable on the topic. We argue that the self-control depletion arising at the end of the day is likely to reduce the resources needed to process the *Forbes* article, but makes one more likely to succumb to the immediate gratification from reading the *Cosmopolitan* article. Thus, we expect that as the day wears on, consumers will engage more with vice content and less with virtue content.

We observe such a pattern across six studies—four experiments and two studies using large-scale Twitter datasets. In study 1, we find initial evidence of engagement shifting away from virtue and toward vice as morning turns to evening. Studies 2 and 3 replicate this result with student participants in a lab setting, where we simply measure the time at which participants complete the survey considering vice versus virtue magazines and websites. Study 4 also shows the same vice-virtue asymmetry for tweets from CNN when we randomly assign participants to morning and evening time periods. We observe the same asymmetry in study 5 where we measure actual engagement of Twitter users with several magazines through likes (Study 5A) and followers (Study 5B). Finally, in study 6, we measure actual engagement through likes by using vice versus virtue information from the Twitter account of a newspaper. In addition, we observed that this asymmetry becomes stronger when day temperatures are higher, providing evidence for depletion as the underlying reason.

Our results add to the findings from social media research. To our knowledge, we are the first to demonstrate asymmetric engagement with vice versus virtue content throughout the day on social media. By examining vice versus virtue content online, we also contribute to research on self-control. We believe that our study is the first to show depletion effects using large-scale social media datasets.

The current research has implications for consumers and practitioners. Our findings can help consumers, and public policy makers understand how the time of day changes sensitivity to different kinds of information. On the flip side, our results are helpful for companies trying to decide when to release which type of information to best capture consumers' attention.

SESSION OVERVIEW

In today's world, consumers leave unprecedented amounts of digitized footprints every day when they use social media platforms, review a movie on IMDb, make purchases using their credit cards, or decide to help fund a new project on Kickstarter. The availability of digitized 'Big Data' and the recent advances in data science created numerous novel opportunities to ask many consumer-related questions. Our session concentrates on multiple different kinds of digitized 'Big Data' and applies cutting-edge machine learning techniques to gain insights about various aspects of consumer cognition and behavior.

Aka, Olivola, Bhatia, and Nave shed light on the relationship between consumer personality and brand liking as revealed in large online datasets. Using machine learning models trained on large-scale digitized language data and Facebook 'likes' data, they predict consumer personality profiles for brands above and beyond demographic variables, or other objective and subjective brand characteristics. They show how these 'black box' models can be interpreted in terms of the images associated with brands liked by particular consumer personality segments. Finally, they also demonstrate self-congruity effects in consumer liking of brands.

Nave, Rentfrow, and Bhatia combine data from Facebook and IMDb to investigate associations between movie characteristics and consumer personalities. They find that key features of movies' plots predict the personality profiles of consumers who are fans of those movies, above-and-beyond demographic variables, movie genre, and movie metadata. Their findings thus reveal robust links between personality and movie preferences, with implications for media marketing recommendation systems.

Goetz, Ebert, Mueller, Gladstone, and Matz examine how the personality of consumers' social context (i.e. the personality of those around them) shape their spending decisions above and beyond their own individual traits. Using spending records of 111,336 participants across 374 Local Authority Districts (LAD), she finds a congruency between geographic regions' aggregate scores on a given personality trait and the collective spending on categories associated with that trait. Furthermore, individual-level analyses demonstrate that regional personality of a participant's home LAD predicts individual spending above and beyond individual personality.

Wang, Lu, Li, Khamitov, and Bendle investigate the relationship between vocal tones of persuaders and online persuasion using Kickstarter videos. Applying a novel audio mining technology, they find that concentration, lack of stress, and stable emotions influence funding success. Next, they conduct a controlled experiment to show how greater signs of stress or extreme emotion hurt while greater signs of concentration help persuasion success. Lastly, they identify perceptions of competence as a mediator in this relationship between vocal tones and persuasion success.

Altogether, the papers presented in this session demonstrate how novel machine learning approaches applied to digitized big data can provide important new insights to consumer behavior. More specifically, each of the papers use a unique digitized data platform and apply varying novel quantitative techniques to answer consumer-relevant research questions. This session will appeal to a broad audience who are interested in learning about novel approaches to studying consumer behavior, and will also be relevant to all researchers as well as practitioners interested in consumer personality, cognition, and decision-making.

Computational Consumer Segmentation and Brand Management

EXTENDED ABSTRACT

The emergence of social media has fundamentally changed the way consumers interact with brands and, as a result, how brands are managed (e.g., Appel et al. 2020; Batra and Keller 2016). For example, every day, millions of social media users (e.g., on Facebook, Instagram, and Twitter) express their attitudes towards branded content through 'likes' (De Vries et al. 2012; John et al. 2017). These indicators are often viewable to their friends, family, colleagues, and acquaintances, and are available to brand managers in real-time. As a consequence, firms can efficiently monitor the favorability of their brands and how this favorability evolves over time. In this paper, we use several recently assembled datasets drawn from social media and news media. We analyze these data using techniques from machine learning, to study how consumer psychographic characteristics (their

personality) relate to brand image and brand liking. In particular, we analyze a unique dataset of Facebook users who rated their (own) personality characteristics and examine the relationships between different brands and the personality of social media users who "liked" those brands. This allows us to determine how personality traits are associated with brand liking. We go further by utilizing a word embeddings model built using large scale language data (Mikolov et al. 2013; see reviews in Bhatia et al. 2019) and an established semantic dictionary (the LIWC) (Pennebaker and Graybeal 2001; Pennebaker et al. 2003) to predict consumer personality and to identify the main concepts and themes that each brand is associated with, in the mind of consumers. This, in turn, allows us to analyze the relationships between consumer characteristics and brand liking, for hundreds of brands, both within and across different product categories. We present three studies. The goal of Study 1 was to evaluate our machine learning approach for predicting consumer personality. Specifically, we tested how well we could predict the average personality profiles of Facebook users who 'liked' different brands. We call this 5-dimensional personality profile "Brand Consumer Personality Profile" (BCPP). We used high-dimensional embedding representations for those brands (i.e., brand embeddings), derived from large-scale natural language data. The brand embeddings served as predictor variables in five Ridge regression models (one for each personality dimension) that attempted to predict (out-of-sample) the BCPPs of the brands. Due to the flexibility inherent in machine learning modeling, we evaluated all our models in terms of their out-of-sample predictive power—i.e., their ability to predict Facebook user personalities for novel brands, not previously shown to the model. The results of this analysis plots observed vs. predicted BCPPs for each brand and for the five personality dimensions. Our approach achieves high accuracy rates, with an average out-of-sample correlation of 0.62 across the five personality dimensions. To evaluate our approach against other established methods, we tested competitor models that used various quantified brand characteristics (e.g., brand age, brand personality trait ratings) as predictor variables (Lovett et al. 2014). Additional analyses of the robustness of our approach involved models based on user demographics and brand categories. Our results showed that these methods predict BCPPs above-and-beyond brand category information, consumer demographics, and brand-level characteristics (including both In Study 2, we sought to examine and interpret the information contained in brand embeddings that gives rise to these successful predictions. Embedding vectors quantify the extent to which words and concepts are associated with each other in language, and thus by extension, in the minds of consumers. In this way, embedding vectors provide an approach to measuring brand associations and images automatically from natural language data. By studying the words and concepts that make up these images, we can try to characterize the variability in BCPPs across different brands, and understand how this variability relates to brand images. That is, we can "dig into" our brand embeddings data in order to determine which attributes, traits, concepts, and constructs are most associated with brands that are 'liked' by consumers who are high (vs. low) on a particular personality dimension.

We identified a number of distinct associations between psychological constructs and BCPPs. For example, the BCPP for Openness correlated with brand construct associations (BCA) and brand word associations for experiences, creativity and art (in other words, brands whose consumers were higher in Openness were closer in the word embedding space to words and constructs related to experiences, creativity and art). Likewise, Agreeableness correlated with pro-sociality and Extraversion with apparel and parties. While not all of the associations we identified have simple explanations, many

of them were consistent with the notion that consumers 'like' brands that reflect their personality. We test this conjecture more formally in the next study.

In Study 3, we carried out a similar analysis, but with personality words instead of the LIWC constructs, in order to directly examine whether brand personality dimensions relate to consumer personality traits. Doing so allows us to evaluate the extent to which consumers tend to like brands that "fit" (i.e., are congruent with) their own personality traits. Our analyses using dimensions of human personality found evidence for congruity between BCAs and BCPPs for three of the Big Five dimensions: Openness, Agreeableness and Emotional Stability (thus, for example, brands strongly associated with Openness adjectives were also liked by individuals high in Openness).

In sum, this paper showcases, through three studies, the power and promise of combining big data and machine learning methods to examine three important topics in consumer research: consumer psychographic segmentation, brand image, and consumer-brand self-congruity. The capacity to accurately and inexpensively assess the BCPP of brands, using publicly available word embedding representations, not only has important practical managerial applications for marketing strategy, but also enhances our theoretical understanding.

We Are What We Watch: Movies Contents Predicts The Personality Of Their Social Media Fans

EXTENDED ABSTRACT

With the growing prevalence of on-demand video streaming services, the volume of personalized media consumption is rapidly increasing. Despite the ubiquity of personalized video consumption, and although understanding the psychological characteristics of media audiences is fundamental to many aspects of marketing, relatively little is known about the associations between movie preferences and individual differences in psychological traits. The current work addresses this gap in knowledge by systematically studying the personality profiles of movie fans.

Our analysis uses data collected via *myPersonality*, a Facebook app through which roughly 3.5 million users took personality questionnaires and consented to share their Facebook data with researchers. Using the myPersonality database, we created personality profiles for 854 movies, by averaging the Big Five personality scores of all users who "liked" these movies on Facebook (we included all of the movies in the myPersonality dataset that were liked by at least 250 people). Similarly, we estimated the fans' demographic profiles by calculating their average age, percentage of females, and the percentage of individuals who reported being in a relationship.

We obtained rich representations of movies from *IMDb* (www. imdb.com), an online database that contains information about over 5 million titles of movies and TV episodes . Each IMDb entry represents a title, and includes genre information (a total of 21 genres), and user-generated plot keywords that describe *"any notable object, concept, style or action that takes place during a title".* IMDb also includes additional information about the movies, such as box office income and critics ratings, to which we refer as "metadata".

Our primary objective was to test whether movies' characteristics (genre, metadata and content, as captured by plot keywords), contain information about the personality of their Facebook fans. To this end, we conducted "leave one out" cross validated predictions (Stone, 1978; Zhang, 1993) to predict the Big Five profiles associated with each movie, using different combinations of the following variables: (1) the movie keywords (2) the demographic profiles of the movies' fans; (3) the movies' IMDb metadata variables; (4) the movies' genre. Personality predictions for each movie were carried

out by fitting regularized linear regressions with the least absolute shrinkage and selection operator (LASSO (Tibshirani, 1996) to the data of all other movies, and recording the out-of-sample predictions under different model specifications. The results reported here were obtained using a LASSO with regularization parameter value of λ = 0.001. Similar results were obtained using different λ values. Predictive accuracy was calculated as the part of the variance in personality that could be explained by the independent variables.

Our results indicate that all of the Big Five traits could be predicted from the keywords (all p-values <0.001), and that the variance in fans personalities that was predicted by plot keywords was significantly greater than what could be explained by metadata and genre in all of the Big Five traits. Furthermore, adding plot keywords significantly improved the predictive accuracy incrementally above all of the other variables, for all of the Big Five traits.

Our findings provide marketers means for reaching audiences of specific personality profiles via cinema advertising (Phillips & Noble, 2007), branded entertainment (Hudson & Hudson, 2006) or product placement (Gupta & Lord, 1998). While personality has been shown to be indicative of consumer's attitudes and behavior (Arbuthnot, 1977; Matz, Kosinski, Nave, & Stillwell, 2017; Moon, 2002; Wheeler, Petty, & Bizer, 2005), its use in marketing has been limited due to the questionnaire-based nature of personality assessment. Although recent research has shown that personality can be approximated from individual's digital footprints (e.g., Facebook Likes, Instagram photos and Twitter language), marketers seldom have access to dataset that contain both individual-level digital footprints and personality measures. Our approach overcomes this barrier by allowing marketers to assess the personality profiles of movies' audiences based on the movies' attributes alone (as measured using plot keywords), and without having to collect data about individuals.

Our work also contributes to the literature of content recommendation and prediction of viewing behaviors. Typical individual-level recommendation systems (or prediction models) requires observing each consumer's past behavior (i.e., using panel data). However, such data may not be available in the particularly important application of making recommendations to new consumers. However, in some cases it is possible to approximate the personalities of new consumers (e.g., from their tweeter language), and provide them with personality-based recommendations.

Our study has several limitations, which provide a fertile ground for future investigations. First, while our findings suggest that part of the variance in movie preferences is linked to stable personality traits, movie preferences are likely also influenced by environmental context. For example, the movie industry is highly seasonal (Einav, 2007), and people were shown to prefer romantic movies when it is colder (Hong & Sun, 2012). Continuous investigation of how context variables affects dynamic aspects of movie preferences may benefit from studying interactions between context variables and personality.

A second limitation concerns our use of Facebook Likes is proxies for movie preferences. While Likes are active, ecologically valid expressions of preferences, they do not necessarily reflect what people de facto watch, and they might be affected by social and cultural factors that do not immediately reflect the content of movies, such as signalling and impression management. Our reliance on Facebook likes might also bias our study because specific types of people may be more disposed to sharing their Facebook data with the *MyPersonality* app, or to liking movie-related contents on Facebook. However, such selection bias would be expected, in general, to attenuate the associations we observed, because it would restrict the range of personalities that we observe and thus constrain the amount of

personality variance that could potentially be explained by the other factors (Sackett & Yang, 2000). We hope that the growing availability of video-streaming services (e.g., Netflix, Hulu, Amazon Prime) will facilitate the generation of datasets that would allow exploring the associations between personality and preferences for movies using actual watching behavior and with less selection bias.

Spending Reflects Not Only *Who We Are* But Also *Who We Are Around*: The Joint Effects of Individual and Geographic Personality on Spending

EXTENDED ABSTRACT

Research shows that people's personality traits play and important role in their spending decisions. Previous research has shown that people tend to spend money in a way that is aligned with their personality (Aaker, 1999, Govers & Schoormans, 2005; Matz, Gladstone, & Stillwell, 2016) and personal values (Hill & Howell, 2014). An extraverted person, for example, is more likely to spend money on social activities such as going to bars and restaurants, while an introverted person is more likely to spend money on books (Gladstone et al., 2019; Matz et al., 2016). This is because spending not only reflects functional need-fulfillment but also reflects who we are as individuals (self-congruity theory, Sirgy, 1985): We buy products not only for what they can do, but also for what they mean to us (Levy, 1959). Consistent with this idea, individuals high in extraversion, agreeableness and openness prefer to spend money on experiences (Howell, Pchelin, & Iyer, 2012; Mehmetoglu, 2012), whereas individuals low in agreeableness, conscientiousness and emotional stability prefer to spend money on possessions (Zhang, Howell, Caprariello, & Guevarra, 2014).

At the same time spending is also an inherently interpersonal, social behavior and--at least in part--performative. What people buy is not only guided by their own preferences, but also by cultural norms (de Mooij & Hofstede, 2002; Henry, 1967; Kacen & Lee, 2002), social expectations (Martineau, 1958; Mathews & Slocum, 1969; Rook & Fisher, 1995; van Kempen, 2004), status concerns (Brown, Bulte & Zhang, 2011; Martineau, 1958; Veblen, 1899), and people's social networks (Gärling, Kirchler, Lewis, & van Raaj, 2009; Sheth, 1967; Wang & Xiao, 2009). Spending can be used to satisfy social needs, such as reinforcing and expressing self-identity to others, and allowing one to differentiate oneself and to assert one's individuality (Ball & Tasaki, 1992; Belk, 1988; Fournier, 1998; Richins & Rudmin, 1994). Consequently, what people buy is not only determined by their own preferences, but also their socio-cultural context.

In this work, we integrate these separate research streams by investigating the extent to which the personality of consumers' social context (i.e. the personality of those around them) influence their spending decisions above-and-beyond their own individual traits. Specifically, we test the impact of individual and regional personality as drivers of spending behavior in two steps. First, we analyze spending records from 111,336 participants (over 31 million unique transactions) to test whether spending behaviors (i.e., what people spend their money on) are regionally clustered and whether these regional clusters of spending are reliably predicted by regionally aggregated personality traits (H1). This step is necessary as examining the relationship between regional personality and spending behavior is only meaningful if people in different areas actually spend money differently. Second, we analyze individual personality and spending of 1,716 participants, to test whether regionally aggregated personality predicts individual spending behavior above-and-beyond individual personality (H2).

Our findings show that personality-related spending is meaningfully clustered on the geographic level. The effects are strongest for the traits of extraversion and openness, for which we find strong geographical clusters of highly prototypical spending in and around Metropolitan London, while low (i.e., introverted and less open) spending clusters North of London, in the Southwest, Wales and the North of England. For agreeableness, we find significant hotspots of prototypical agreeable spending in the very Southwest of England, Southern Wales as well as in pockets of Northern England and Scotland, while low, disagreeable spending clusters in Metropolitan London and North of London. For conscientiousness, high prototypical spending clusters in the very South and North of England and the English Midlands, while low, unconscientious spending strongly cluster in Southern Wales and parts of Scotland. For neuroticism, high prototypical spending clusters in pockets of Scotland, Southern Wales and the English Midlands, while low, emotionally stable spending primarily clusters around London. Importantly, those spending clusters map onto clusters found for the regional personality of participant. We capture this relationship more objectively by calculating the zero- order correlations between the two variables on the aggregated LAD level ($N = 374$). We find a significant positive relationship for all Big Five personality traits. These correlations were medium-sized for openness ($r = .34$, $p < .001$), extraversion ($r = .47$, $p < .001$), agreeableness ($r = .33$, $p < .001$) and neuroticism ($r = .34$, $p < .001$) and small for conscientiousness ($r = .17$, $p < .01$).

To test whether regionally aggregated personality scores predict prototypical individual level spending above-and-beyond individual personality, we used a subset of 1,716 participants for which individual spending and personality information was available. Specifically, we employed multilevel analyses (individuals nested in 374 LADs) to regress prototypical individual level spending on individual personality, gender, age and total spending amount (level 1 predictors) and aggregated personality (level 2 predictor). We z-standardized all non-binary predictors (i.e., all except gender) and specified random intercepts and random slopes for individual personality.

As hypothesized, regional personality positively predicted prototypical spending above all individual level predictors for all Big Five traits. For conscientiousness ($\beta = .06$, $p < .01$) and neuroticism ($\beta = .06$, $p < .05$) effect sizes reached roughly one third of the effect size of individual personality. For openness ($\beta = .08$, $p < .001$) and agreeableness ($\beta = .10$, $p < .001$), the regional level effect approached half the size of the individual level effect. Finally, for extraversion, the regional level effect ($\beta = .17$, $p < .001$) even reached the same size as the individual level effect. In other words, prototypically extraverted spending to the same extent reflects the personality of the regional context as the personality of the individuals themselves. These results provide support for our second hypothesis that regionally aggregated personality scores predict individual spending on associated purchase categories above-and-beyond individual level personality for all of the Big Five personality traits.

Taken together, our findings empirically support the proposition that spending behavior is a reflection of personality traits as both a personal and environmental characteristic.

The Role of Vocal Tone in Online Persuasion: A Crowdfunding Enquiry

EXTENDED ABSTRACT

A major stream within consumer research involves understanding persuasion attempts and reactions to these (Campbell and Kirmani 2000; Friestad and Wright 1994; Petty and Cacioppo 1986). The profusion of online interactions provides additional observations to studying this important consumer-relevant phenomenon but also somewhat changes the process. Online those making persuasion attempts (who we will call persuaders) cannot be assessed through such things as handshakes and eye contact. Yet as technology progresses this gives access to more cues that allow for intuitive assessment (Nisbett and Wilson 1977) by those subject to a persuasion attempt (who we will call receivers). Receivers tend to use assessments beyond the message content (Hall 1980) to judge whether persuaders are worthy of their support. Since online videos allow receivers of a persuasion attempt to hear the vocal tones that the persuader uses, these vocal tones are likely to give cues that are used by the receivers to inform the persuasion attempt success.

Prior work has examined how certain vocal characteristics, such as speech rate, pitch, volume, and tone, can influence individuals' perceptions of speaker traits and character (Apple et al. 1979; Chattopadhyay et al. 2003; Cheng et al. 2016; Klofstad et al. 2012, 2015; Oleszkiewicz et al. 2017; Street et al. 1983; Signorello 2019; Tigue et al. 2012; Wiener and Chartrand 2014). A vast majority of this important work has been conducted in traditional, face-to-face contexts. This precludes understanding all the nuances and intricacies of the now prevalent online and digital persuasion attempts. Second, virtually all relevant prior research did not venture beyond assessing attitudes and behavioral intentions to systematically tap into real-world funding outcomes that are more relevant to ultimate persuasion success. Third, prior work has predominantly employed labor-intensive and/or semi-automated approaches to coding and interpreting vocal characteristics which limited scalability and researchers' ability to consider fine-grained detail. These benefits are now afforded by advanced machine learning techniques and computational methods.

We first used novel audio mining technology to investigate Kickstarter videos, looking for indications related to the receiver's assessment of the persuader's concentration, stress, and lack of extreme emotion. These indications were assessed for connections to successful persuasion, i.e. funding of the project. We collaborated with Nemesysco Ltd., an Israel based high-tech firm whose QA5 system (Nemesysco 2015) was commercially applied in call centers and sold as "the most sophisticated, flexible, cutting edge voice analysis technology available today" (Nemesysco 2016). The software not only allows analysis of many more audio files than could be achieved using human coders, it also uses standardized signal processing algorithms to extract and combine attributes from voices identifying, amongst other things, stress, cognitive processes, and emotional reactions. Taken together, the study showed a significant relationship between concentration, lack of stress, and lack of excessive emotionality on funding success.

Next, we conducted a controlled experiment to validate our findings from the secondary data and to extend them by investigating if perceptions of competence mediate the differential relationship between vocal tones and persuasion attempt success. We used a pretested "Coolest cooler brand" actual Kickstarter pitch recorded by a research assistant that was made to sound either concentrated, stressed, extremely emotional, or neutral (control). Overall, we found that a funding request was less likely to succeed when the voice of a persuader requesting funds in a pitch shows greater signs of stress or extreme emotion compared to a control. In contrast, a funding request was more likely to succeed when the voice of the requestor shows greater signs of concentration (vs. control). The findings of study 2 also support our theorizing regarding a focal mechanism. Specifically, we documented that a concentrated vocal tone (vs. control) generates greater perceptions of persuader competence, thus, leading to increased willingness to fund and improved brand

evaluations. Conversely, a stressed or extremely emotional vocal tone (vs. control) reduced perceived persuader competence, thereby lowering willingness to fund and brand evaluations. Lastly, study 2 also explored the possibility that given trust and processing fluency are central considerations in consumer decision-making in the marketplace (Chaudhuri and Holbrook 2001; Graf et al. 2018; Khamitov et al. 2019; Morgan and Hunt 1994; Reber et al. 1998; Winkielman and Cacioppo 2001), the resulting levels of trust or distrust in a persuader might have guided a particular peer-to-peer funding decision. Since vocal tone dimensions did not seem to foster different levels of processing fluency or persuader trust, the latter are unlikely to drive our findings.

Our findings offer insight to the persuasion literature, reinforcing that speaker characteristics matter (Crowley and Hoyer 1994; Eisend 2006; Rucker et al. 2014; Tormala and Petty 2004; Swartz 1984; Wilson and Sherrell 1993). Our enquiry documents that speaker characteristics in online persuasion attempts can not only be readily inferred from the voice heard but, more importantly, matter so much in first impressions as to exert influence on real world financial outcomes. In doing this our work speaks to persuasion in the online world which is an increasingly fruitful topic given the profusion of online interactions and how they provide additional opportunities to studying persuasion (Grewal and Stephen 2019; Kupor and Tormala 2018). In contrast to the work focused on offline persuasion environments, another key contribution of our research is to provide an early illustration that the effectiveness of online persuasion efforts can be computationally mined and captured at a much larger scale with more fine-grained detail using an automatic novel method. Here, we provide one of the pioneering accounts of how computers can precisely predict the general effectiveness of online persuasion attempts based on automatically extracted vocal tone characteristics and their interplay with the extent of video stimulation and brightness. In doing this we contribute by highlighting audio-mining's potential in academic consumer research (Hobson et al. 2012; Mayew and Venkatachalam 2012). We, using technology now available to marketers, have fascinating new methods of quantifying key elements of the human voice. Using these could benefit numerous academic fields with consumer research taking the lead.

SESSION OVERVIEW

In a recent paper, Proserpio and colleagues (2019) highlight how advances in machine learning research help marketing researchers estimate models that predict extremely well and that are able to leverage the power of new data sources such as images, text, audio, and video. At the same time, they raise how machine learning research needs a "soul" which should capture competitors' reactions in complex markets as well as consumer theories to be able to capture the complexity of consumer behaviors, their needs and preferences.

The papers in this special session "Consumer Behavior Meets Machine Learning" aim at improving our understanding of consumer behavior and attitudes by combining advanced machine learning techniques with behavioral theories. The papers contribute to answering the following high-level questions:

- How can machine learning enhance our understanding of consumer attitudes and behaviors?
- How can behavioral theories help machine learning researchers open the prediction black-box and generate more interpretable features?

Using Natural Language Processing to Investigate the Role of Syntactic Structure in Persuasive Communication

EXTENDED ABSTRACT

How to use language, that is, how to formulate marketing communications so that they are persuasive, is a decision problem most marketers face. Language, spoken and written alike, is a fundamental element of marketing messages. Language is used in various contexts such as political debates, product reviews, product descriptions and brand communications with the goal of persuading the recipi-
ent. Today, the use of email, social media posts, live chats and blogs provides unprecedented opportunities to reach consumers with verbal messages in addition to existing channels such as TV, radio or newspaper ads.

Extant literature in marketing suggests that the language used influences the persuasive outcomes in various marketing contexts. For instance, language used in news articles reflects the emotions and legitimacy of the article, and influences consumers' attitudes toward the article as well as their likelihood of reading or sharing the article (Berger and Milkman 2012; Humphreys and LaTour 2013; Berger, Moe, and Schweidel 2019). Language used in movie scripts reflects the theme, scenes, and emotion in the movie and thus predicts the box office success (Eliashberg, Hui, and Zhang 2007). Language used in songs impacts the songs' success on the market as the typicality of the lyrics impacts the popularity of a song (Berger and Packard 2018). Elaborateness and the emotionality of tweets about political debates influences which topics get consumers' attention and are shared with others (Berman et al. 2019). Even though a large stream of recent literature is dedicated to understanding the role of language used in marketing contexts (see Berger et al. 2020 for an overview), most of this research is dedicated to the content of the message communicated (i.e., choice of words). Tools for understanding what makes the language used in marketing messages persuasive independently of the content are still missing.

In the current research, we seek to understand what makes marketing messages persuasive independently of the message content. In that, our focus is on the impact of the syntax of the language used (i.e., grammar) on the persuasiveness of the message communicated. Following a natural language processing (NLP) approach, we posit that the syntactic structure of a message influences its persuasiveness (Gibson 1998). We develop and test a novel approach to measuring syntactic structure in a series of three studies, and identify the specific syntactic elements, referred to as dependencies, which impact the persuasiveness of a marketing message. In our main study, using a dataset consisting of 134 debates with 129,480 sentences, we develop an NLP-based measure of syntactic structure. In this study, we show that the syntactic structure of the language used in the debates impacts the attitude change caused by the debates. Using our measure, we identify the specific syntactic elements that affect the persuasiveness of a marketing message. Our measure captures syntactic structure more systematically and better in terms of predicting the persuasiveness of a message than past measures of syntax.

We validate our measure of syntactic structure and the impact of the specific syntactic elements that affect the persuasiveness of a marketing message in two experiments that follow the main study: First, we conduct a laboratory experiment where we manipulate the syntactic structure of a marketing message using the specific syntactic elements identified in our main study. The context is a persuasive message about the benefits of wearing a bike helmet. We show that when the syntactic structure of the message is changed according to our findings, the persuasiveness of the message is increased. Second, we conduct a field experiment on Facebook, where we improve the syntactic structure in the copy of an advertisement designed by a marketing agency using the specific syntactic elements identified in our main study, and measure click through rates for the ad. We show that when the syntactic structure of the ad language is improved using the specific syntactic elements we identified, the persuasiveness

of the ad is increased: The click-through rate for the ad increased significantly by 40% compared to the baseline ad version, which was designed by the marketing agency. This experiment also demonstrates how marketers can use our method to improve their marketing messages to make them more persuasive.

Our work contributes to marketing research by developing a novel approach of measuring and modifying syntactic structure, allowing for a more precise way of formulating persuasive marketing communications. Additionally, our work contributes to marketing practice by providing a tool that marketers can use to efficiently improve the persuasiveness of their messages as well as any other communication that uses language as a medium.

Scalable Content Curation: Learning from Human Effort

EXTENDED ABSTRACT

Many firms rely on the crowdsourcing platforms to generate new product and advertising ideas. For example, Colgate-Palmolive, a large consumer products firm, collaborated with a digital creative agency to generate ideas for one of its most visible advertising campaigns. The firm organized an ideation contest - members of the agency's innovation platform submitted ad ideas, and the winning ideas were used to develop an ad that was shown to over 109 million viewers of the Super Bowl - one of the world's most popular television events. Major advertisers such as P&G and Unilever generate ideas for new products and advertising campaigns either using internal crowdsourcing platforms or through specialized creative agencies. Crowdsourced ideas can be more creative than internal solutions. The firm may uncover an unexpected extreme-value solution thanks to a large number of opinions from diverse participants. Crowds can also identify niche consumer interests which can lead to valuable innovations that the firm would not have considered otherwise.

Crowdsourcing campaigns can yield thousands of submissions that firms cannot exhaustively and carefully evaluate. For example, our data provider attracted 74,436 ideas over 153 ideation contests. The scale of these campaigns raises the important question of how to identify the best ideas efficiently. Current approaches involve using either the crowd itself or a set of internal employees to prescreen ideas. However, the crowd-based approach is infeasible if the firm prefers to keep submissions confidential. In this research, we focus on the case where the firm uses internal evaluators to maintain submission confidentiality and thereby abide with data protection laws or withhold the submissions it receives as a competitive advantage. In our field setting, each idea was evaluated once by several employees of the crowdsourcing platform in a prescreening stage, which resulted in a total of 186,111 evaluations and consumed about 14 workdays per month of human effort in the median month.

Our research aims to develop an efficient approach to identify the best ideas from crowdsourcing contests using data on the behavior of internal evaluators, whom we refer to as "voters", idea characteristics and text, and the selection of winning ideas by the clients, whom we refer to as "sponsors". We develop a model to reconcile the difference between the sponsor's selection of finalist ideas and the evaluations of voters who prescreen the ideas. In our field setting, the platform sorts ideas based on their average voter score before presenting them to the sponsor. A model that transforms voter scores and incorporates idea characteristics and text can yield a better score to sort ideas, thereby reducing the number of ideas that a sponsor must review to identify all finalists by 7-18%, depending on the specific evaluation approach. Equivalently, the platform can reduce the workload of its employees by 8-25% while maintaining the same quality of the idea ranking for the sponsor.

We find that voters exhibit persistent differences in their "importance", or the extent to which their votes help identify finalists. As a result, a model trained on one set of contests can extend to future contests even if ideation topics differ across contests. We define a metric for measuring the importance of a voter as the deterioration in the quality of the idea ranking when we remove this voter. Interestingly, voter importance may differ depending on whether a model is used or not. We call this phenomenon "predictable inaccuracy" – a voter may be more predictive of the sponsor's choice if her votes are properly transformed. Moreover, two voters who are similarly important when the platform uses average score to rank ideas may differ significantly in their importance when a model is used, suggesting that different voters can exhibit different levels of predictable inaccuracy. Voter "redundancy", or the extent to which voters are correlated with each other, can also lead to varying levels of predictably inaccuracy. Our results suggest that a firm interested in identifying its most valuable voters may arrive at different conclusions depending on whether it assesses voter performance jointly with a statistical model or independently of a model based on the initial ranking criteria.

We complement our findings with a survey based on a product design contest organized by an open innovation platform called Lego Ideas. The survey allows us to design simulations to study the generalizability of our findings, recover ground-truth measures of idea quality that are not available in the field data, and study how voter characteristics may relate to voter importance. We capture voter heterogeneity through differences in brand appreciation and generate a sponsor score from a subset of the available votes. We find that even if voters do not influence sponsor choices, and sponsor preferences are representative of voter preferences, certain types of voters still emerge as more important than others. A statistical model with text data yields improvements in the survey setting as well, but there is only subtle evidence of predictable inaccuracy in the particular simulation we study because of limited nonlinearities in the relationship between voter and sponsor scores. The survey confirms that a statistical model can exploit varying voter importance and redundancy, thereby reducing evaluation effort in this alternative setting, even when there are no significant preference differences between voters and the sponsor.

Overall, our findings suggest that firms can enhance their content curation processes, even if they crowdsource ideas on different topics over time. In assessing the performance of different voters, firms must consider how the voters perform in conjunction with a model as opposed to independently. The "predictable inaccuracy" of certain voters, if it is present, can alter their relative importance.

The Power of Brand Selfies in Consumer-Generated Brand Images

EXTENDED ABSTRACT

Every day more than 5 billion images are shared on social media networks such as Facebook, Twitter, or Instagram. Of particular interest to marketers are images that feature brands and consumption experiences that contribute approximately 1% of all social media images, resulting in 50 million social media images featured with brand logos daily. At the same time, one of the biggest trends introduced by smartphone cameras and social media are selfies. Today, more than 383 million images with the hashtag #selfie exist on a single photo-sharing platform such as Instagram. The emergence of selfies merits

the question of how brands appear in selfie images and how observers respond to this type of social media brand images.

In fact, recent marketing practice attempts to capitalize on the selfie phenomenon, mainly by actively encouraging consumers to post selfies of their product encounters. Brand images are also of interest to managers when passively listening in to social media posts. Among other things, companies track brand logo presence on social media to understand social media popularity, rank consumer-generated images on their social media brand page, or use such images as part of their own marketing campaigns.

However, not all brand logo appearances are created equal. Some may generate more valuable consumer-brand engagement than others. Accordingly, the objective of this research is to investigate how brands appear in consumer-generated images and to examine the effectiveness of different types of social media brand images on generating engagement among consumers. Specifically, we investigate both sender engagement objectives in terms of how brand images may generate image engagement (i.e., likes or comments) and brand engagement objectives in terms of how brand images may generate brand engagement (i.e., brand-related comments such as expressed purchase intent).

Academic research provides ample evidence for the effectiveness of images in advertising (e.g., Hanssens and Weitz 1980; Xiao and Ding 2014). Recent studies have also explored the motivations to share content and take photos and how this affects subsequent sender behavior (e.g., Barasch, Zauberman and Diehl 2018; Grewal, Stephen and Coleman 2019). However, little is known about how observers respond to brand images in social media.

Using both manual annotations of a sample of images and convolutional neural networks (CNN) for automated image classification of nearly half a million brand images related to 185 different brands that were posted on Twitter and Instagram, we identify three types of user-generated brand images that differ in terms of human and facial presence. Consumers post either images of products in isolation or holding products themselves (i.e., selfies). We find that these brand-related selfies exist in two forms with consumers either visible (their face) or invisible to the viewer (e.g., first-person point of view of the product). We name the former consumer selfie and the latter brand selfie to indicate the focus in brand selfies is exclusively on the product and differentiate it from consumer selfies where the face of the sender is visible[1]. This results in the following typology of brand images:

1. Brand Selfies: branded products held by an invisible consumer,
2. Consumer Selfies: visible consumer faces together with a branded product,
3. Packshots: standalone images of branded products.

The CNN algorithm accurately classified images into these three categories with a hold-out accuracy level of > 80%. In both datasets, we find that consumer selfies have the lowest fraction of all types, suggesting that consumers are reluctant to post photos of themselves with the brand on their own accord. At the same time, consumer selfies are the image type most often encouraged by corporate communication campaigns, and face images, akin to consumer selfies, are ubiquitous in print advertising (Xiao and Ding 2014).

---

[1] Note, we distinguish brand and consumer selfies based on the visibility of consumer faces. Conceptually, the term selfie suggests the person on the image took the photo herself. Yet, in some cases, a third person may have photographed the sender (e.g., < 3% of brand selfies and < 39% of consumer selfies in our Twitter data). This can be difficult to distinguish empirically for both the human eye and an automated image classifier.

Whether consumer selfies are well suited as a user-generated media content is an open question, which we attempt to answer in this research.

Analyzing consumers' response to the different types of brand images in terms of likes and comments, we find that consumer selfies, in which a person appears with the brand, generate the highest level of engagement towards the image or the sender in terms of the number of likes and comments on the image. However, these simple engagement measures, while encouraging for brands in terms of user potential, may be misleading. Examining the content of the user comments, using both dictionary-based and machine learning text mining tools, we find that consumer selfies generate fewer self-brand mentions and stated purchase intentions of receivers in response to the original image post. These results are consistent with research from traditional advertising and information systems, which indicate that, on the one hand, images with faces catch more attention than those without faces (Bakhshi, Shamma and Gilbert 2014; Xiao and Ding 2014), but, on the other hand, may detract attention away from the brand itself (Erfgen, Zenker and Sattler 2015).

These results are consistent for both the Twitter and Instagram dataset, suggesting that the effects are not driven by different consumer motives of the respective platforms. We complement these results with a lab experiment, which allows us to control for the prominence of the brand in the image and collect purchase intent ratings, as well as to

test the underlying potential psychological mechanism that may trigger consumers' varying reaction to different brand image types. The results of the experiment further suggest that brand selfies have a superior impact on perceived purchase intent compared to consumer selfies. In addition, it suggests the differential impact of brand selfies is related to easier and more accessible self-reference and mental simulation offered by these image types.

Black-Box Emotion Detection:
On the Variability and Predictive Accuracy
of Automated Emotion Detection Algorithms

EXTENDED ABSTRACT

Automated emotion detection from facial expressions refers to the use of algorithms that detect facial landmarks in pictures to classify people's discrete emotions (Liu et al. 2014; Wood et al. 2016). These automated emotion detection systems classify discrete positive emotions such as happiness or surprise to negative emotions such as anger and fear. A computer vision algorithm first identifies facial landmarks in a picture and then assigns each picture a discrete emotion label based on the features or composition of the existing facial landmarks (Fox et al. 2000; Pantic and Rothkrantz 2000) development of an automated system that accomplishes this task is rather difficult. There are several related problems: detection of an image segment as a face, extraction of the facial expression information, and classification of the expression (e.g., in emotion categories. Companies such as Microsoft, Google, or GfK provide platforms to perform such automated emotion detection with recent industry reports suggesting a CAGR of 32.7% and a market size of 25 billion by 2020, highlighting the importance and dominance of these AI-powered technologies for the future of marketing. Despite the increasing availability of automated emotion detection systems, fundamental methodological questions arise. Are automated emotion detection systems valid? Is the same picture classified correctly across emotion detection systems? These questions are important as emotion detection systems are using pre-trained algorithms to classify discrete emotions from facial expressions in a way that is unknown to

the user of these systems. Thus, it is likely that the same picture is assigned a different discrete emotion conditional on the type of emotion detection system being used. To the best of our knowledge, both a formal test of this hypothesis is non-existent as is a formal analysis that unravels under which conditions emotion detection algorithms would increase in predictive accuracy. The current paper fills this gap by providing a tightly controlled validation study comparing the effectiveness (i.e., in terms of predictive accuracy) of major automated emotion detection systems across discrete emotions, dependencies on the modelling technique being used, the stimuli set, and ways to improve predictive accuracy by combining feature sets or using ensemble methods.

We used a standardized picture set with objective ground truth, i.e. knowledge about the discrete emotion that is displayed by actors in a standardized picture set. Specifically, we used the Chicago face database (Ma, Correll, and Wittenbrink 2015) to evaluate automated emotion detection systems. The Chicago face database contains photos from 597 male and female targets of varying ethnicity between 18 and 40 years under standardized conditions. For a subset of 158 targets, images display either a neutral, angry, fearful, or two positive emotional states (happy face with either an open or closed mouth). Each of these images of the 158 subjects displaying various emotions was classified using five major automated emotion detection systems via an Application Programming Interface (API): Microsoft Cognitive Services, Google ML, Sightcorp, Kairos, and the GfK EmoScan. The data was normalized across emotion detection systems to provide meaningful comparisons in the following analyses.

To set a baseline, we evaluated the effectiveness of the different emotion detection systems by predicting each image emotion label via the corresponding emotion measure (i.e., predicting happy faces using the happiness feature of each emotion detection system). A multinomial logit model revealed substantial variation across emotion detection systems with the highest, cross-validated (CV) prediction accuracy for Google ML with a test accuracy of 58.94% and a test Kappa of 40.25%, compared to the lowest prediction accuracy for GfK EmoScan with a test sample accuracy of 49.81% and a test Kappa of 36.88%. Positive emotions were predicted consistently better compared to the substantial variation across negative emotion labels (variability across emotion detection systems: $\sigma_{happy\ open}$ = 3.81, $\sigma_{neutral}$ = 6.89 σ_{fear} = 14.98, σ_{anger} = 30.9) and overall lower predictive power for negative emotions than for positive and neutral emotions (average balanced accuracy for the different emotion classes: $\mu_{happy\ open}$ = 78.97, $\mu_{neutral}$ = 79.97 μ_{fear} = 65.45, μ_{anger} = 44.3). These findings were robust even after controlling for all other emotion features.

Next, we aimed at further improving prediction accuracy in two ways. First, by increasing the feature space through combining the entire set of features across all emotion detection systems. Second, by using more flexible model estimation and machine learning techniques. Specifically, recent advances in deep learning might further improve predictive accuracy by increasing the number of layers and / or boosting a model by aiming at predicting misclassified cases. In short, increasing the feature space resulted in a greater test accuracy with an averaged accuracy of 85.73% and a Kappa of 81.02%.

Next, we aimed at further improving prediction accuracy by using more flexible machine learning techniques. Parameters were selected through grid search in the parameter space. Lowest performance was achieved by Support Vector Machines with radial basis kernel resulting in a test accuracy of 84.41% and a test Kappa of 79.33%. Highest performance was achieved by using Random Forests and LogitBoost achieving 92.02% test accuracy, 89.25% test kappa and 93.60% accuracy, 91.34% kappa, respectively. These changes led to a significant increase in predictive power also for neg-

ative discrete emotions and substantially reduced variation across positive, neutral and also negative emotion labels ($\sigma_{happy\ open}$ = 2.71, $\sigma_{neutral}$ = 1.36, σ_{fear} = 5.32, σ_{anger} = 4.61).

To the best of our knowledge, this is the first systematic study demonstrating the striking variability in automated emotion detection systems across discrete emotions and we provide two easy to implement modelling strategies to improve prediction accuracy across automated emotion detection systems.

Paper #4: AI Service Agents, Figurative Language, and Conversational Cooperativeness

Marat Bakpayev, University of Minnesota Duluth, USA
Ann Kronrod, University of Massachusetts Lowell, USA

SESSION OVERVIEW

Consumers are increasingly interacting with AI agents, asking for suggestions from chatbots, talking to service robots at hotels or restaurants, and telling their AI assistants - be it Alexa, Siri, or Cortana – "I love you" (Belk 2019; Belk, Humayun, and Gopaldas 2020; Novak and Hoffman 2018; van Doorn et al. 2017; Mende et al. 2019). The nature of these interactions is not yet fully explored. Therefore, this session is aimed to bring together works that explore interactions with AI agents from a multifaceted, multimethod point of view.

We see AI agents from the perspective of slaves, masters, friends, partners, or tools (Elder 2017; Breazeal et al. 2004; Grudin 2017; Schweitzer et al. 2019). The consumer research literature mostly examines AI agents as tools, as well as the tendency of people to humanize/anthropomorphize machines. The papers in this session explore a broader range of roles and perspectives that consumers take toward intelligent machines. In line with the spirit of the conference, the four papers integrate multiple perspectives and methods, examining aspects of interactions with AI agents via a historical lens, a socially responsible business lens, a medical lens, and a linguistic lens. Together, these papers illustrate how robots and AI agents take on different roles in the lives of consumers – as tools or as partners.

Bakpayev and Belk open the session with a historical overview of interactions with robots and AI. The authors conceptualize types of interactions that people have or would have with machines, and discuss the changing landscape of seeing machines as servants, masters, monsters, or friends. Next, Puzakova and Grinstein focus on robots in socially responsible business practices. Across three experiments, the authors demonstrate and explain the negative effect of employing service robots (vs. humans) on consumers' willingness to engage with the brand in socially responsible practices, as well as consumers' perceptions of the brand as being socially responsible. Third, Shanks, Mende, Scott, van Doorn, and Grewal focus on robots as partners in a medical context and examine the effect of a robot taking more or less prominent roles in medical environments. This research examines the underlying mechanisms that impact consumer

behavioral intentions, as robots shift away from operating as tools to being partners in decision making. Finally, Bakpayev and Kronrod take a linguistic perspective on conversations with AI agents. Looking at the use of figurative language (humor, metaphor) by AI/human service agents and perceptions of conversational cooperativeness, the authors find that while human agents are expected to use figurative language because they are perceived as cooperative speakers, AI agents are harmed when they employ figurative language.

Taken together, the papers in this session will examine the same topic of AI agents as tools or partners but from different perspectives. They collectively contribute to the discussion about the role of AI in consumer service from a historical, CSR, medical, and linguistic perspectives. We, therefore, expect the session to attract a wide variety of attendees interested in the integration of artificial machines in consumer service in various contexts.

Consumer Interactions with Artificial Intelligence Agents – a Historical Perspective

EXTENDED ABSTRACT

"Replicants are like any other machine. They're either a benefit or a hazard. If they're a benefit, it's not my problem."

Rick Deckard, *Blade Runner*.

Historically, whether in fiction or fact, humans were captivated by the idea of creating human-like entities (Belk 2016; Kang 2011; Mayor 2018; Nocks 2008; Riskin 2016). Replicants, as depicted in the movie *Blade Runner* (1982), are just one example of artificial beings that appear identical to human beings. Philip Dick (1968) in his novel *Do Androids Dream of Electric Sheep?* – which serves as a primary source for the film – refers to them as "andys" or androids (Greek root "man-like"). Both the novel and the film portray a future circa 2020; that is, now.

While machines in our time are not yet the replicants or androids imagined in Dick's science-fiction, some of them are remarkably human-like and engage us in interactions that are increasingly human in nature. For example, consumers voice commands to their digital assistants like Alexa; consumers chat with AI friends like Replika; consumers look into the "eyes" of the robot Pepper, who greets them in service environment, and reply "Hello!"

Overall, across multiple studies, consumer researchers highlight anthropomorphic aspects of technology when these nonhumans are endowed with human-like traits (Epley 2018). *But what are the origins and consequences of humanizing AI?* While the literature provides various scenarios and results, there is still a great deal to be learned as science fiction becomes science fact. Taking a historical perspective, we look at the nature of our relationships with human-like machines and the consequences of humanizing them.

The term "robot" comes from a science-fiction stage play. Karel Čapek (1920/2004) wrote R.U.R. (*Rossum's Universal Robots*) one-hundred years ago. In the play, robots and robotesses are artificial people, forced into labor as secretaries, postmen, and workers. "Robot" derived from Old Slavic "rab" or slave. The serving purpose was quite prevalent in the early history of artificial life. While not referred to as "robots" yet, humans were developing figurines, statues, mechanical knights, stone giants, and automatons that served more as tools (Belk 2016; Kang 2011; Mayor 2018; Nocks 2008; Riskin 2016). Researchers have traced other perspectives as well.

Belk, Humayun, and Gopaldas (2020) explore the history of Artificial Life (AL) and connect it to four cultural myths: Pygmalion (AL as a product of human desire), Golem (AL as a product of human survival), Frankenstein (AL as a product of human curiosity), and Metropolis (AL as a product of human politics). These myths show deeper insights into our fears and fascinations with artificial beings. While there is a degree of tool-oriented practicality in these visions, there are also deeper orientations toward perfection and immortality.

The idea of the creation of human-like machines took a new turn with the development of computers. During a nearer period in history referred to as the "AI Spring" in the 1940s and 1950s, machines for the first time seemed intelligent. Drawing on early computing and Norbert Weiner's cybernetics, Alan Turing proposed a test (the Turing Test) that could determine when human-like AI was able to pass for being human. The field of Human-Computer Interaction started to develop (Grudin 2017; Haenlein and Kaplan 2019). Machines - and technology in general - were stills tools, more like extensions of our arms, eyes, and minds. However, as AI went into "Summer" and "Winter" (the 1960s and 1970s), consumers realized that their grand expectations for the machines failed.

Similarly, in recent years, with the second "AI Spring" and the threat of a second "AI Winter," reactions to computers started to change. Arguably, we are in the stage of Human-Computer Symbiosis, where machines are seen more like partners (Breazeal et al. 2004; Grudin 2017). Designed to facilitate social interactions, they can be our companions and friends (Elder 2017; Schweitzer et al. 2019). Nevertheless, at the end of his career, Weiner warned that like the Golem of the Rabbi of Prague, we might be creating machines that threaten our continued existence. Slaves could become masters (Schweitzer et al. 2019). Ideological tensions develop as we increasingly humanize AI. As depicted in the opening quote from *Blade Runner*, further development of AI agents could indeed lead to potential benefits for humankind (Markoff 2015), as well as hazards, noted by some visionaries like Bill Gates, Stephen Hawking, and Elon Musk. Huang and Rust (2018; 2020) specify types of service jobs that AI can take on – mechanical, analytical, intuitive, and empathetic – leading to mechanical AI, thinking AI, and feeling AI. Indeed, despite significant accomplishments and progress in AI, or perhaps *due to* the progress, research confirms concerns regarding AI, finding that reactions to humanoid service robots can be discomforting (Mende et al. 2019) and uncanny (Kim, Schmitt, and Thalmann 2019). It appears that consumers resist automation, especially if it threatens their identity (Leung, Paolacci, and Puntoni 2018).

In sum, while past perspectives toward human-like machines focused on ways in which they serve to boost humanity, existential fears about AI seem to be rising in recent years. We worry that algorithms threaten our privacy, security, wealth, and opportunity. We fear that robots will displace us in the workforce and that our machines will become smarter and stronger than us – in the end, taking over, and even extinguishing the human species. Based on historical perspectives and scenarios involving AI agents, the authors consider the possible implications of current transformations in consumer interactions with artificially intelligent agents. Consumers are apt to regard these machines as servants, friends, monsters, or masters. As a result, interactions may be functional or social, calming or frightening, successful or failed. Such developments contribute to further discussions on ethical, moral, legal, and existential questions that are critically important for future consumer research.

Are Robots in Service of the Environment? The Role of Service Robots in Socially Responsible Business Practices

EXTENDED ABSTRACT

Two of the most meaningful societal trends today involve the introduction of robots in services (Mende et al. 2019) and brands' increased engagement with socially responsible practices (i.e., CSR; Mishra and Modi 2016). Importantly, the two trends have not been studied jointly but we argue that they are intertwined and can alter consumption. Here, we aim to fill this gap and address multiple unanswered research questions: How the introduction of a service robot (vs. human) impact: (a) consumer perception of and (b) consumer engagement with the brand's socially responsible practices? What is the underlying mechanism that drives consumer response to a service robot?

Research on consumer reactions to service robot providers is an emerging inquiry and has discussed, for example, the impact of service robots on consumers' social surroundings and service outcomes (e.g., van Doorn et al. 2017), and consumption patterns (e.g., Mende et al. 2019). In turn, the literature on consumers' reactions to brands' CSR practices suggests that consumers believe that business bears responsibility for driving positive social change, and they encourage firms to improve society and the environment while achieving firm goals (Porter and Kramer 2011). Supporting this trend, research shows that in general consumers perceive brands' CSR efforts positively (Luo and Bhattacharya 2006). Relatedly, some research studies situations where brands wish to engage consumers in socially responsible behavior (e.g., recycle, donate; Goldstein et al. 2008, Lichtenstein et al. 2004) and the conditions under which consumers are more likely follow the brand's requests (Romani and Grappi 2014). Overall, how would consumers be influenced by service robots in the context of brands' social responsibility?

Relatively to humans, robots are perceived as more efficient, productive, and generally less warm. Although technological developments imbue robots with increasing automated social presence and humanness (van Doorn et al. 2017), robots are still perceived only as partial social actors and less warm than humans (Heerink et al. 2010). Here, we argue that introduction of service robots can lead to a greater experience of psychological coldness compared to situations when customers are served by humans. Given service robots represent and reflect on the brand, brands that use service robots (vs. humans) will be perceived as colder. This process can have unintended consequences for consumers' perceptions of socially responsible business practices. That is, prior work establishes the negative relationship between psychological experience of coldness and prosocial behaviors (Zhong and Leonardelli 2008). Thus, we postulate that a "colder" experience will result in consumers' less positive views on a brand's social responsibility practices and their own willingness to engage with the brand on social responsibility.

H1: Brands' use of service robots (relatively to humans) is negatively related to consumer (a) perception of the brand's social responsibility, and (b) engagement with the brand's socially responsible practices.

H2: The influence of service robots (relatively to humans) on consumer reaction is mediated by lower brand warmth perceptions.

We test these hypotheses in three studies. Study 1 (N=226, students) used the context of a hotel bellman service. Participants were prompted to imagine that upon their check-in, they were greeted by a hotel bellman (by a service robot) that assisted carrying their luggage and accompanied them to their rooms. After respondents were assisted by a hotel's bellman (robot), they further imagined finding a card on their desk describing that the Ario hotel (a fictitious brand)

partnered together with a local charity organization "the Feed the Hungry Foundation", after which respondents indicated their inferences about the sincerity of the company's motives for pursuing the CSR activity (Yoon et al. 2006), rated brand warmth (Aaker et al. 2010), and the service novelty.

The results of study 1 (a one-way (robot vs. human service) ANCOVA with the novelty of service experience as the covariate) revealed that experiencing a robot (vs. human) service decreased consumers' perceptions of the sincerity of the hotel's motives to engage in CSR (M_{robot}=4.88 vs. M_{human}=5.54; $F(1,223)$ = 7.45, p = .007). The decrease in the sincerity of the motives was driven by lowered perceptions of brand warmth (b=–.46, 95% CI[–.77, –.17]).

Next, study 2 (N=206, MTurk participants) replicates the effect with a different social responsibility domain (environmental concerns) and examines whether robot (human) service also decreases consumer engagement with the brand's socially responsible practices (i.e., willingness to pay an extra-fee for sustainable breakfast). The results of this study revealed that being assisted by a service (human) robot decreased consumers' own desire to engage in sustainable behavior (M_{robot}=3.62 vs. M_{human}=4.28; $F(1,203)$ = 4.47, p < .036). We also found that consumers perceived the motives as less sincere for a service robot (M_{robot}=4.95 vs. M_{human}=5.57; $F(1,203)$ = 7.29, p < .008). Both of these effects were driven by lower brand warmth (lower desire to engage in sustainable consumption: b=–.23, 95% CI [–.50, –.004]); sincerity of the motives: b=–.60, 95% CI [–.94, –.34]).

Study 3 (N=196, MTurk participants) rules out alternative processes through perceived self-efficacy and uncertainty (Chen 2016; van der Wal et al. 2018). Replicating results of studies 1 and 2, the findings revealed that being assisted by a service (human) robot led to lower inferences of the motive sincerity (M_{robot}=4.69 vs. M_{human}=5.78; $F(1,193)$ = 19.28, p < .007) and reduced consumer engagement with a brand's socially responsible practices (M_{robot}=4.01 vs. M_{human}=4.71; $F(1,193)$ = 7.48, p < .007). Next, testing parallel mediators (i.e., brand warmth, self-efficacy, uncertainty; model 4; Hayes 2013) revealed a significant indirect path through brand warmth (sincerity of the motives: b=–.73, 95% CI [–1.08, –.46]; consumer engagement with CSR: b=–.41, 95% CI [–.69, –.18]), with both self-efficacy and uncertainty being nonsignificant.

Overall, this research identifies important consequences of introducing robots into service contexts. In particular, three studies demonstrate that a robot (vs. human) service lowers consumers' perceptions of the sincerity of the motives for the CSR activity and reduces consumers' own engagement with the brand's CSR practices. Our work sheds light on the underlying process through reduced attributions of brand warmth, while also ruling out alternative explanations through self-efficacy and uncertainty.

The Impact of Humans and Robots on Consumer Behavioral Intentions in Medical Contexts

EXTENDED ABSTRACT

As the use of robots in the marketplace increases, both the marketing and robotics literatures have examined how consumers will respond. The literature has mostly examined this phenomenon from the lens of a robot in the position of a tool. However, technological advances are resulting in robots that can begin to assume an increased variety of roles in marketing settings. As robots shift away from being merely tools that assist consumers, it is important to understand how consumers will respond.

We examine this phenomenon in a medical context, as research suggests positive outcomes of the increased use of robots including a decrease in post-surgical complications and shorter hospital stays (Kalis, Collier, and Fu 2018; Marr 2018). Previous research has proposed several mechanisms that may impact consumer response including anxiety (Broadbent et al. 2011; Mende et al. 2019; Mori 1970), social dimensions (van Doorn et al. 2017; Wirtz et al. 2018), and various dimensions of robotic threat (Stein, Liebold, and Ohler 2019; Złotowski, Yogeeswaran, and Bartneck 2017). The use of advanced technology, such as artificial intelligence (AI), in healthcare settings similarly results in adverse consumer reactions due to a belief that AI is less able to adjust for individual situations (Longoni, Bonezzi, and Morewedge 2019). Moreover, this research examines the underlying mechanisms that impact consumer behavioral intentions as robots shift away from operating as tools. An examination of boundary conditions investigates various effects of risk acceptance, power, and anthropomorphism on consumer behavioral intentions.

Nine studies examine the effect of a robot in a more or less prominent role in medical environments; two studies involve live interactions with an actual robot. Study 1A examines the effectiveness of a human-robot team. Patients at an elderly care facility participated in exercise sessions with either a robot with a human physical therapist or a human physical therapist alone. Participants had an unfavorable reaction to the human-robot team (vs. human), rating the exercises as less favorable (p < .01) and reporting lower behavioral responses (p = .04). Study 1B replicates these findings. Participants imagined going to a doctor for an examination while viewing a picture of a human or a human-robot medical team. Participants again had an unfavorable reaction to the human-robot team, and lower ratings of loyalty intentions (p < .001), warmth (p < .001), and competence (p = .02).

Study 2 examines the effect of a human-robot team on a consumer's response to a robot-led team. Participants received a nutritional counseling session from a live, in-person human-robot team with either the human or the robot as the team leader. The results revealed that loyalty intentions (p < .001), and perceptions of warmth (p < .001) and competence (p = .03) were lower when the team was led by a robot (vs. a human).

Study 3 examines the moderating role of risk acceptance (measured) using a video of a human-robot team. The results revealed that participants with low levels of risk acceptance showed a decrease in loyalty intentions and ratings of warmth and competence to the robot-led team (vs. human). The effects were attenuated for participants high in risk acceptance.

Study 4 examines the moderating role of power distance belief (PDB). Power distance belief was measured. Participants watched the same video as in Study 3. The results revealed an increase in unfavorability to a robot-led team for participants low in PDB and an attenuation for participants high in PDB.

Studies 5A and 5B examine the role of perceived choice on response to a human-robot team. In Study 5A, participants chose the robot used in the medical team in the choice condition and were unable to choose the robot used in the control condition. In the control condition, participants had lower loyalty intentions to the robot-led (vs. human-led) team. This was attenuated in the choice condition. Study 5B examined the role of choice on upgrading behavior, finding greater interest in paying to upgrade to a human-human team when the initial team was led by a robot.

Studies 6A and 6B generalize the effect to anthropomorphized robots. Although the results did not reveal effects of anthropomorphism, participants had lower loyalty intentions and ratings of warmth and competence to the robot-led team (vs. human-led), consistent with our previous studies.

The current research uncovers insights into how consumers respond to robots as they move away from the role of tools. Our findings have implications for marketing strategy as we demonstrate that this shift results in an unfavorable consumer response and strategies to mitigate this negative response.

AI Service Agents, Figurative Language, and Conversational Cooperativeness

EXTENDED ABSTRACT

Firms are improving AI service agents' conversational capacities, striving to make their language more natural and more similar to that of humans (e.g., Google's Meena, the open-domain chatbot, Adiwardana et al. 2020). But how do consumers react to this human-like conversational ability? Previous research examined reactions to AI with external similarity to humans (Davenport et al. 2020; van Doorn et al. 2017; Huang and Rust 2020; Mende et al. 2019). To date, research has not inquired into the effect of conversational similarity – one of the most distinctive human capacities – on perceptions of AI agents, and their effects on service.

Addressing this question, we examine reactions to AI service agents employing human-like conversation. Specifically, we compare reactions to the use of figurative language (metaphor, humor) – a distinctly human capacity - by human and AI service agents.

Figurative language requires the speaker to be conversationally cooperative, making assumptions about the other person's understanding (Grice 1975). We suggest that consumers expect human service agents to be conversationally cooperative, but not AI service agents. These conversational expectations, in turn, attenuate the positive effect of using figurative language by AI service agents, compared to literal language, and compared to human agents. Formally, we suggest that:

Hypothesis 1:   *AI service agents who use figurative language evoke less positive reactions than human service agents who use figurative language.*

Hypothesis 2:   *AI service agents who use figurative language evoke less positive reactions than when they use literal language.*

Hypothesis 3:   *These differences are driven by perceptions of the agents' conversational cooperativeness: AI service agents are perceived as significantly less conversationally cooperative than human service agents.*

We explore this effect via four studies. In Study 1, a preliminary test, we compared reactions to human and artificial service agent humorous response to a customer's inquiry. 205 MTurk participants read a brief dialogue between the customer (themselves) and a human/AI hotel booking agent, which ended with the agent making a joke. Participants then reported intentions to book a room with the agent, their comfortableness with and trust towards the agent, and how funny was the joke. T-tests comparing the two groups on the different variables revealed no significant differences in booking intention ($p=.103$), but overall participants were more likely to book with the human (M=5.64) rather than the artificial agent (M = 5.33). We found marginal differences in trust ($p=.098$), comfort ($p=.099$) and satisfaction with the conversation ($p=.083$). Across all variables, the human agent was rated higher than the artificial agent.

The purpose of Study 2 was to compare reactions to serious or humorous answers by human or artificial agents. 427 MTurk participants were randomly assigned to one of 4 conditions in a 2 (human/artificial agent) by 2 (serious/humorous answer) between-subjects design. 2-way ANOVA revealed a significant interaction of agent (human/artificial) and answer (humorous/serious) on booking intention ($F(1,423)=7.47$, $p=.007$), and on answer humorousness ($F(1,423)=8.7$, $p=.003$). Planned contrasts showed that while for human agents there was no significant difference in booking intention whether the agent was joking (M=5.66) or serious (M=5.78, $F(1,423)=.35$, $p=.55$), when the agent was artificial, booking intention was significantly lower when the agent was joking (M=4.77) than when the agent was serious (M=5.65, $F(1,423)=19.9$, $p<.001$). These results support H1 and H2.

In Study 3, we aimed to measure the mediation of conversational cooperativeness expectations. 202 MTurk participants imagined interacting with a human(artificial) service agent, for example, calling a company to book a hotel, or having an online chat to solve a technical problem with a product (e.g., kitchen appliance) and rated their expectations about the agent's behavior in the conversation. Respondents expected human agents to be more cooperative (M=5.58) than artificial agents (M=5.09, $F(1,200)=7.389$, $p=.007$). They also had significantly higher expectations from human agents than artificial agents on Communication Openness ($F(1,200)=6.145$, $p=.014$) and General Cooperativeness ($F(1,200)=4.288$, $p=.040$). To explore the effect of agent type (human/artificial) and cooperativeness expectations on language expectations, a multiple regression was executed. The overall model was significant ($F(3,198)=10.297$, $p<.001$; $R^2=13.5\%$, adjusted $R^2=12.2\%$), suggesting that AI agents are expected to be less cooperative than human agents.

Finally, Study 4 introduces a boundary condition: in a situation of negative service conversations (e.g., complaints), the differences between human and AI service agents are attenuated. 809 MTurk participants were randomly assigned to one of 8 conditions in a 2(human/artificial agent) by 2(metaphorical/literal language) by 2(positive/negative conversation) between-subjects design. Participants read a conversation excerpt where they (the consumer) were talking with a human (AI) customer service agent who used literal language/metaphor in a positive/negative context (choosing a free t-shirt/replacing a wrong t-shirt). They then indicated a likelihood to shop again, rated the retailer and agent's cooperativeness. We found a three-way interaction on likelihood to shop again ($F(1,801)=8.337$, $p=004$), retailer rating ($F(1,801)=10.162$, p=.001) and conversation cooperativeness ($F(1,801)=6.047$, $p=.014$). Contrast analyses within the positive interaction condition showed, as before, that while for human agents language did not influence behavior intentions, retailer evaluation and cooperativeness, for AI agents behavior intentions, and retailer evaluation were significantly lower when they used metaphor versus literal language However in the negative condition this effect disappeared. Mediation analyses showed that agent conversational cooperativeness mediates this effect ($B=.289$, $SE=.064$, $t=4.56$, $p=.0001$, 95%CI: [.165,.414]).

To sum, research on conversational norms in consumer research suggests that adherence to conversational norms, and specifically using figurative language, is positively perceived (e.g., Kronrod and Danziger 2013; Xu and Wyer 2010; Zhang and Schwarz 2012). We discover that when it comes to AI service agents – this relation is moderated. We also find that the negative effect of using figurative language by AI agents is at least partially due to consumers not perceiving them as cooperative conversation partners. Future work can further explore AI agents as conversation partners in various consumer service situations and inform marketers on the way to avoid

unwelcome outcomes of the race towards human-like AI conversation.

Drazen Prelec, Massachusetts Institute of Technology, USA

SESSION OVERVIEW

Consumer behavior, and marketing more generally, is increasingly driven by collective beliefs regarding the popularity of brands, the quality of products, etc. The growing availability of product reviews and rapid dissemination of opinions about brands via social media have created more opportunities than ever before, for both consumers and marketers, to aggregate information about products and brands. Whereas recent research has emphasized the benefits of trusting aggregate opinions (the 'wisdom of crowds'), this session provides a more nuanced perspective on collective beliefs, by also showcasing their limitations. The four papers in this session reveal novel insights into the strengths and weaknesses of collective beliefs, while addressing important questions: How are erroneous beliefs formed and why are they maintained? When are collective beliefs more (vs. less) accurate? How can we leverage consumers' social networks to improve predictions?

The first two papers examine how consumer social networks and market selection processes can bias consumer beliefs.

The authors of **Paper #1** demonstrate an important limitation of social belief aggregation (e.g., the revision of beliefs through word-of-mouth information transmission). In particular, they show that, whereas social (e.g., word-of-mouth) information transmission can improve the accuracy of beliefs regarding continuous numerical values ("how long will this product last?"), it often fails to improve beliefs regarding binary choice decisions ("should I purchase?").

The authors of **Paper #2** identify an important, yet previously unrecognized, marketplace source of erroneous belief maintenance and propagation: the *statistical self-fulfilling selection fallacy*. They show how multi-stage market selection processes (e.g., the decisions to first purchase, and later return, a product) that are inadvertently biased by erroneous beliefs can produce evidence that seems to support those beliefs, thereby reinforcing them. Critically, this fallacy occurs even without motivations to maintain those beliefs.

The next two papers consider the relative benefits of relying on groups (vs. markets) and social networks to improve predictions.

The authors of **Paper #3** compare the ability of groups versus information markets to aggregate information effectively. They show that groups outperform markets in the absence of conflicts of interest, whereas markets outperform groups when conflicts of interest are present. Moreover, they show that people do not anticipate these results and generally trust groups more than markets, unless they have acquired experience with information markets.

The authors of **Paper #4** propose a new variant of conjoint analysis: Instead of eliciting consumers' personal choices and preferences, it asks them to predict those of their peers. They show that such peer-choice conjoint analyses, which tap into consumers' knowledge of their peers, produce more precise market share estimates.

In sum, the papers in this session offer important, novel insights, from multiple perspectives, regarding the promise, but also perils, of relying on social information transmission and collective beliefs. This session will appeal to researchers interested in better understanding how consumers converge in their beliefs (e.g., regarding products and brands), the extent to which these collective beliefs should (not) be trusted, and how best to utilize social beliefs.

The Limits of Collective Intelligence
Group Dynamics of Binary Choice and Belief Formation

EXTENDED ABSTRACT

Introduction

Consumer behavior is driven by factual beliefs. For example, food choices are driven by both true and false information relating certain foods to health benefits, and other foods to health risks. Relatedly, consumer's beliefs about the potential environmental impacts of their behavior can also drive purchasing decisions (Van de Velde et al. 2009). As a result, understanding the factors that determine beliefs in a population—and particularly belief accuracy—is critical to understanding consumer behavior. The study of belief accuracy is a central area of research on collective intelligence. Although consumer beliefs are heavily shaped by the beliefs of peers in social networks (Katz and Lazarsfeld 1955), which puts populations at the risk of effects such as herding and groupthink (Surowiecki 2004), research on collective intelligence has also found that social influence processes can reliably improve belief accuracy under a wide range of conditions (Becker et al. 2017). However, this research has largely studied beliefs as continuous numeric estimates while individual behavioral decisions are often driven by binary choice estimates. We investigate whether the potential benefits of collective intelligence, i.e. social information processing, extend to binary choice behaviors. We show both theoretically and empirically that the same exact processes which improve belief accuracy for numeric estimates can reduce belief accuracy for binary choices. Remarkably, we find that a group can, in a single conversation, simultaneously improve their numeric estimate accuracy even as their binary choice decision based on that belief becomes less accurate.

Theoretical Results

We study two agent-based models of social exchange in which subjects begin with independent beliefs and then repeatedly revise their beliefs after learning the beliefs of peers in a social network. In the first model ("binary-binary") subjects form binary-choice es-

timates and can observe each other's binary-choice estimates. Proposition 1 shows that under very general assumptions, the majority belief will grow over time—regardless of accuracy.

In the second model ("binary-continuous") subjects form continuous numeric estimates and can observe each other's continuous numeric estimates. Our model is identical to the model used in prior empirical (Becker et al. 2017; 2019) and theoretical (Becker et al. 2017; Golub and Jackson 2010) research on collective intelligence, i.e. the model studied by DeGroot (1974). Here, however, agents are expected to convert their final numeric estimate to a binary choice via a threshold model. E.g., suppose an agent only wants to buy a product that will last at least 5 years before needing to be repaired or replaced; they will first form a numeric estimate ("how long will this product last?") and then make a binary choice estimate ("will it last 5 years?"). Proposition 2 shows that changes in resulting binary choice decisions are decoupled from changes in individual beliefs as measured by averages. This decoupling means that even if the average estimate becomes more accurate, binary choice decisions can still become less accurate—i.e., the number of people making the 'correct' choice can decrease. We demonstrate theoretically the conditions under which this seemingly paradoxical result can occur, finding that these conditions are consistent with typical properties of empirical data. A scenario in which a numeric estimate becomes more accurate and a vote becomes less accurate. Suppose people are estimating the return on an investment, and will choose to purchase if the return is greater than 10%, but the (unknown) true return is actually below 10%. Each point represents the final belief, showing the trajectory from the initial belief. Although the mean belief becomes more accurate, the number of people with the correct vote (i.e. on the correct side of the threshold) decreases.

Empirical Support

Study 1 presents a pre-registered virtual lab experiment in which subjects are asked to make a binary-choice estimate (e.g., "do more than 50% of people think technology is improving our lives?") before and after observing each other's binary choice estimates. We conducted 45 independent trials (15 trials each for 5 unique questions) in which each trial contained 20 subjects answering and reacting to each other in real time, for a total of 900 unique subjects. Study 2 re-analyzes data from similar, previously published experiments in which subjects formed and reacted to continuous numeric estimates. We analyze the change in their responses after subjects react to each other, and compare the change in the collective intelligence (average estimate) accuracy with changes in decisions along hypothetical over/under thresholds. Both Study 1 and Study 2 support our theoretical predictions.

Discussion

We investigated the effects of social exchange on belief formation in order to examine whether prior laboratory results on collective intelligence will be robust to the kind of decision-making that is more likely to determine consumers' behavior. Our theoretical and empirical methods followed the same model and principles as prior research, and yet showed that instead of reliably improving belief accuracy, social information is likely to just amplify initial majorities—regardless of accuracy. Our results offer two important contributions to the understanding of consumer decision-making. First, our findings place an important boundary condition on collective intelligence theory, showing that results for continuous numeric estimates generally do not apply to binary choice decisions. Second, our model and analysis highlights important concerns for how to *measure* beliefs in a population, showing how different methods of mea-

suring consumer beliefs could yield fundamentally different pictures of apparent opinion change.

The Statistical Self-Fulfilling Selection Fallacy When Markets Inadvertently Reinforce False Beliefs

EXTENDED ABSTRACT

People have a surprising capacity to maintain, and even reinforce, erroneous beliefs concerning the nature of relationships between variables (e.g., Gilovich 1991; Gilovich, Griffin, and Kahneman 2002). In particular, they often overestimate the ability of certain variables to predict outcomes of interest. For example, consumers may overestimate the extent to which brand prestige predicts product quality, or overrate the success of particular social strategies (e.g., witness the plethora of widely-shared beliefs concerning predictors of dating success), and market researchers may over-ascribe certain qualities and behaviors to particular segments of the consumer population. Surprisingly, many erroneous beliefs manage to propagate among even well intentioned consumers –i.e., absent any longstanding, ego-boosting motives to hold such beliefs. Given the robustness, prevalence, and widespread impact of such beliefs, an important goal for researchers should be to not only understand their origins, but also to elucidate the processes that allow them to survive, to spread, and (in some cases) to grow stronger over time.

We contribute to this important question by providing a novel explanation for the survival, spread, and strengthening of erroneous beliefs concerning the predictive validity of variables. Specifically, we identify a previously overlooked market mechanism –the *statistical self-fulfilling selection fallacy* (or '*triple-S fallacy*')– that inadvertently produces evidence that appears to confirm an initially hypothesized relationship between two variables (e.g., prestige and quality), or even, in some cases, to inflate it. Critically, this mechanism is separate from (and occurs independently of) previously recognized sources of biased belief maintenance, such as rich-get-richer dynamics (the 'Matthew effect'), the classic self-fulfilling prophecy, and motivated reasoning (e.g., confirmation biases); indeed, the *triple-S fallacy* operates even in the absence of these other biasing pressures.

Using a combination of simulations and analyses of actual data, we demonstrate that the *triple-S fallacy* can easily occur in marketplace with multi-stage selection processes --a fairly common, and broad, set of contexts in which 'candidates' (e.g., potential product purchases, job applicants, financial stock picks, etc.) are initially selected based on indirect and incomplete information, and later either 'retained' or 'let-go' after more direct evidence concerning the outcome of interest (e.g., quality, performance, value, etc.) is observed. Decisions to purchase and return products, for example, exemplify a multi-stage selection process: products are first purchased (i.e., selected) by consumers based on assumed indicators of their quality (e.g., brand prestige, price, etc.), and they are later either kept (i.e., 'retained') or returned (i.e., 'let-go') by those same consumers, depending on their observed quality over a trial period (e.g., a product's warranty period).

We show that a multi-stage selection process (e.g., first deciding whether to purchase a product, then later deciding whether to return it) that is initially biased by erroneous beliefs (e.g., overestimating how strongly brand prestige predicts product quality) will produce evidence that seems to support those initial beliefs, even when everyone is genuinely motivated to hold accurate beliefs concerning the best predictors of the outcome of interest (e.g., product quality). As a result, these beliefs end-up being reinforced, leading to even greater reliance on relatively weak, invalid, or even negative predic-

tors, which produces further deceptively supportive evidence, and so on. The *triple-S fallacy* thus creates a self-reinforcing cycle that helps erroneous beliefs propagate and strengthen over time.

We also show that the *triple-S fallacy* can produce four types of errors concerning the assumed relationship between variables: Depending on the situation, it can lead people to: (i) greatly overestimate the strength of a weak relationship (effect size inflation), (ii) perceive a relationship where none exists (false positive), (iii) fail to see a negative relationship (miss), or even (iv) perceive a negative relationship as being positive (sign-reversal). Moreover, the evidentiary distortion produced by the *triple-S fallacy* can be substantial: our simulations show that uncorrelated variables ($r_{true} = 0$) can appear strongly correlated ($r_{observed} \gg 0$), while negatively correlated variables ($r_{true} < 0$) can appear positively correlated ($r_{observed} > 0$). Interestingly, however, the *triple-S fallacy* mainly works in one direction: to inflate observed correlations. By contrast, it does little to suppress ("deflate") the observation of an existing relationship that nobody initially believes in.

We also show that the *triple-S fallacy* is robust to various assumptions regarding the nature of the selection process (e.g., whether selection categories are discrete or continuous), the characteristics of the variables of interest (e.g., whether they follow normal or uniform distributions), and the relationships between these variables (e.g., whether they are negatively or positively correlated).

We conclude by discussing strategies that consumers and marketers can adopt to mitigate the distorting influence of the *triple-S fallacy*.

In Groups (vs. Markets) We Trust Relying on Groups or Information Markets to Aggregate Knowledge

EXTENDED ABSTRACT

Organizations rely on internal forecasts to guide strategic planning decisions and manage day-to-day operations. Often this process of pooling and aggregating information involves the use of teams and committees, particularly for complex and difficult tasks (Salas, Cooke, and Rosen 2008). Recently, many organizations, like *Ford*, *Google* (Cowgill and Zitzewitz 2015), *Hewlett-Packard* (Gillen, Plott, and Shum 2013), and *Nokia* (Hankins and Lee 2011), started using information markets as an alternative to traditional teams and committees.

The two institutions – groups and markets – differ in many important ways. First, the setting is markedly different. Ad-hoc groups (but also teams and committees) typically operate in face-to-face settings with unregulated communication patterns, whereas markets are highly structured and are usually implemented electronically on network computers. Equally important, the participants' motivations can vary: The implicit assumption for group decision-making is that members have aligned incentives, implying shared goals and cooperation. Markets, on the other hand, are competitive and allow for conflicting goals. Thus, traders may wish to withhold private information that they believe would benefit them during trading. Despite the surging interest in groups and markets, surprisingly little is known about the conditions under which they perform well and the circumstances under which one outperforms the other.

Following a systematic replicate-and-extend strategy, we present the results of three experimental studies that demonstrate that people trust groups more than markets to pool and aggregate information effectively, even when their performance is inferior. In Study 1, N=450 participants were assigned to groups of three, which, in turn, were assigned to one of six between-subjects conditions. We crossed the two *types of institutions* (groups or markets) and the *presence and strength* of explicit manipulation inducing conflicts of interest (no manipulation, weak or strong).

All groups were asked to choose the best of three applicants (labeled A, B, C) for a managerial position. They were given information about five characteristics of the three applicants and were told that all characteristics carry equal weight in the evaluation. Candidate B was objectively the best; Candidate A was the second best applicant and C was the weakest applicant. However, each participant only received information about three of the five relevant characteristics of each applicant.

During the interactive stage, group members discussed the candidates, and market participants traded shares corresponding to the candidates. In the weak (strong) manipulation condition, one (all three) participant(s) was (were) promised side payments if she (they) could affect the group vote to go for A and C, respectively. This information was private. After the interaction, participants privately picked their preferred candidate. If the majority of their group/market (2 or more participants) voted for the best candidate (B), everyone received £4 plus the show-up fee of £5. Otherwise they just received the show-up fee. In the manipulation conditions, the participants who were successful in having Candidate A or C elected received £5 plus the show-up fee. Afterwards, participants were asked on a 7-point Likert scale how much trust they had that the group/market accurately aggregated the available information.

For each group/market we calculated the proportion of (post group or market interaction) votes for the best candidate, B. An ANOVA using the *votes for applicant B* as the dependent variable and *institution* (groups, markets) and *manipulation* (control, weak, strong) as between-subjects factors showed a significant main effect for *manipulation* ($F(4, 140)=11.25$, $p<.001$) and a significant interaction between *institution* and *manipulation* ($F(4, 140)=3.56$, $p=.005$). The interaction suggests that groups outperformed markets in the absence of manipulations, whereas markets outperformed groups in the presence of manipulations. However, people generally trusted groups more than markets ($F(1, 440)=27.33$, $p<.001$; $M_{group}=3.52$ vs. $M_{market}=3.00$).

In Study 2 we sought to generalize these findings and to better understand people's higher trust in groups. Two hundred and twenty-four participants were randomly assigned to one of eight between-subjects conditions with the factors *interaction setting* (group/market), *conflicts of interest* (yes/no), and *task* (hidden profiles/prediction). In all settings participants watched a video of either a group or a market interaction and were asked to indicate how much trust they had that they would aggregate information accurately. Specifically, we asked participants to evaluate groups and markets on eight attributes: transparency, benevolence, efficiency, familiarity, fairness, integrity, predictability, and how natural they perceived them. All items were answered on 7-point Likert scales.

The responses to the 8 attributes were highly correlated, suggesting the existence of a general trust factor. Hence, we computed a composite measure of trust by averaging the 8 items for each participant and used it as the dependent variable in a 2 (*interaction setting*: group vs. market) x 2 (*conflicts of interest*: yes vs. no) x 2 (*task*: hidden profiles vs. prediction) between-subjects ANOVA. The results indicate a significant main effect for *interaction setting* ($F(1, 216)=51.14$, $p<.001$, $\eta^2=.19$), confirming that people trust groups more than markets ($M_{group}=4.95$, $SD_{group}=0.83$, $M_{market}=4.03$, $SD_{market}=1.10$).

In Study 3, we recruited 358 volunteers from the Good Judgment Open Forecasting project (https://www.gjopen.com/) to in-

vestigate how prior experience affects peoples' trust in groups and markets. The participants watched videos of group and market interactions and were asked which institution they would prefer, when assessing job candidates. We analyzed the choices of those participants who previously took part in the Good Judgment Forecasting Tournament as part of singular settings only (as individuals, in teams, in markets). Their responses differed significantly across the three groups ($\chi2(2)$=10.83, p=.004). Whereas participants who took part in the forecasting tournament as individuals or as part of teams generally preferred committees over markets, those participants who took part in markets expressed the opposite preference.

The results of the three studies indicate that people generally trust groups more than markets, even though under conflicts of interest markets outperform groups. Prior experience with markets can reverse this pattern.

Peer-Predicted-Preference Conjoint Analysis Tapping Into Consumers' Knowledge of their Peers' Preferences to Improve Market Share Estimates

EXTENDED ABSTRACT

Typically, market research—including traditional conjoint analysis—begins by asking potential customers for their personal preferences and intentions, and then projects this sample of responses to the entire market. In this paper, we propose a different approach to conjoint analysis: rather than asking consumers about their own likely choices, we instead ask them about the choices that (they predict) others will make, thus utilizing consumers' knowledge about their social peers. More specifically, we ask respondents to predict the percentage of other respondents who will select each option in the choice set. We refer to these judgments as "peer-predictions." Recent research found that people are quite good at predicting others' future choices on the basis of the latter's observed past choices (Velez et al. 2016).

Some prior studies have considered the role of others' preferences in consumer decision-making. For example, Kim et al. (2014) proposed a "group-sourced mechanism" which mimics real-world contexts where the external influence of one's peers shapes consumers' choices. Narayan et al. (2011) also examined peer influence, and found that being exposed to peers' choices prompted consumers to update their preferences in a Bayesian manner. Although these papers considered the influence of peer choices, they nonetheless still estimated preferences on the basis of consumers' *own/personal choices*. One rare exception is a study by Dahan et al. (2011), who examined a market mechanism in which consumers traded concepts on the basis of their perception of others' preferences, to evaluate new product concepts. However, Dahan et al.'s method is distinct from conjoint analysis. No prior studies, to our knowledge, have considered using predictions about others' preferences in conjoint analysis. In the current research, we depart from traditional conjoint analysis by replacing consumers' own/personal choices with their perceptions of their peers' choices, as the inputs into conjoint analysis.

We begin by introducing a model that modifies the standard conjoint analysis approach: rather than considering a consumer's own preferences as inputs, it instead utilizes that consumer's "peer-predicted choice options" —i.e., the alternatives that the consumer believes will be chosen by the majority of his/her peers. The model predicts that using these peer-predicted choices should improve preference share predictions, relative to predictions based on personal choices.

The theoretical foundation for our model extrapolates the reasoning of Rothschild and Wolfers (2013), who assumed that peer-

predictions result from respondents' internal (i.e., mental) polling of their social circle. A personal choice can thus be interpreted as a "degenerate" internal poll based on a "circle of one." We follow this interpretation and adapt it to the binary choice conjoint model, while allowing for possible interdependencies among social circle members. An important implication of our model is that larger social circles will lead to smaller errors in the estimation of utilities.

We conducted four experiments ($N = 402$) to test our models' prediction that conjoint analyses based on peer-predicted choices (vs. own-choices) will more accurately predict preference shares. All of our experiments were performed with online panels, each with a different set of subjects. In each experiment, we compared the traditional own-choice-based conjoint analysis with our new peer-predicted-choice approach. Specifically, we evaluated each approach's out-of-sample choice-share predictions. In Experiments 1-3 we use holdout sets, where part-worths estimated from the own-choice and peer-choice models are utilized to calculate the predicted overall share of an alterative, and those estimates are then compared with the actual share of choices for that alternative. In Experiment 4, instead of holdout sets, we used a validation sample that consisted of a completely different sample of participants.

In line with the predictions of our model, we found that the peer-choice conjoint analysis approach achieved significantly higher predictive accuracy than the traditional (own-choice) conjoint analysis approach. Specifically, the average error of the peer-choice model was significantly lower than that of the own-choice model, both in Experiments 1-3 (pooled-error Wilcoxon signed t-test: $p = .0061$) and Experiment 4 (Wilcoxon signed t-test: $p = .0004$). The errors of the peer-choice model (vertical / y-axis) against the errors of the own-choice model (horizontal / x-axis), in Experiments 1-3 and Experiment 4, respectively. The prediction errors of the own-choice model tend to be larger than those of the peer-choice model for most goods being evaluated (i.e., most data points are on the own-choice side of the line representing equality of errors).

We also show that the accuracy of our peer-choice approach is moderated by the level of choice dependence within respondents' social circles. In particular, information increases as social circle members become mutually more independent, so that smaller independent circles can impart as much information as larger circles in which members' choices are more dependent (i.e., more interrelated). Consequently, our model performs best in situations where social circles are large and diverse. Thus, future research should investigate if the accuracy of our peer-choice conjoint analysis approach can be further improved by screening for respondents who have large and diverse social circles.

Finally, we want to stress that, although we compared peer-only with own-only choices in these studies, our peer-choice method can, in fact, be combined with a traditional (i.e., own-choice) conjoint analysis approach to produce even more accurate estimates of product preference shares. That is, we do not preclude the use of personal choice questions in conjoint analysis, but rather advocate for the addition of peer-choice questions, as doing so will yield more precise overall product preference share predictions while preserving the power of traditional conjoint analysis.

SESSION OVERVIEW

With people, there is always more than what meets the eye. Secrets and hidden information are simply part of human life. However, perhaps due to the difficulty of studying what people wish to keep hidden, research on secrets is scarce and generally treats secrets as a stigmatized, negative concept (Slepian, Chun, and Mason 2017), with few exceptions (e.g., Rodas and John 2020).

The three papers in this session seek to allow the audience—consumers and managers alike—to develop a more perceptive understanding of what motivates people to hide or reveal information, and of the unexpected means that offer them a sense of privacy. It also seeks to further destigmatize the concept of secrets and hidden information by discussing the positive interpersonal consequences as well as the marketing impact of secret or pseudo-secret consumption.

The first paper (Brick, Gullo, and Fitzsimons) starts off the session by investigating whether keeping consumer behaviors a secret from one's partner can have positive outcomes for the relationship. Specifically, this paper investigates whether guilt from keeping consumption behaviors hidden can lead to increased pro-relationship spending. Across three studies, the authors find evidence to support this prediction and, using dyadic data from both members of a couple, find that greater pro-relationship spending leads to greater satisfaction with that spending on the part of the partner.

The second paper (Kim, Liu, and Min) follows by identifying one reason people may hide certain information from close others (i.e., friends). Five studies show that, although people normally prefer to self-disclose to friends over strangers, they dampen this tendency when disclosing their personal insecurities. The authors demonstrate that people may be less forthcoming with friends for insecurity-disclosure (vs. other disclosures) due to beliefs that they will be more likely to encounter painful reminders of disclosed contents (i.e., personal insecurities) if disclosed to friends than strangers.

The third paper then pivots to examining the implications of secrets on marketing. Specifically, the third paper (Goor, Keinan, Halevy, and Norton) concludes the session by demonstrating consumers' favorable reactions to "pseudo-secret" products, such as secret menus and "speakeasy" venues. Across six studies, the authors find

that consumption of such "pseudo-secret" products increases consumers' WOM and actual purchases compared to non-secret products, due to pseudo-secret products' capacity to enhance consumers' perception that they are the hub of the information wheel amongst their peers.

To sum, across three papers in advanced stages (14 studies), this session aims to appeal to both consumers and managers who seek to understand the process and the consequences of secrets and hidden nuggets of information.

Hiding and Spending: Secret Consumer Behaviors and Pro-Relationship Spending

EXTENDED ABSTRACT

You had an indulgent lunch, an extra drink with friends, or bought a pair of shoes, and didn't tell your partner about this consumption—it's your little secret. Are these types of secrets bad for relationships? Although a fair amount of research suggests that secrets within relationships are associated with negative consequences, including greater guilt (Caughlin et al. 2009; Kelly and Yip 2006; Lane and Wegner 1995; Simmel 1950), much of this research has focused on emotionally-laden, traumatic, or taboo secrets and ignored the role of consumer behavior in relationships. In line with research that suggests small deceptions can improve relationship outcomes (e.g., white lies: Argo and Shiv 2011), we suggest that secret consumption may actually have positive outcomes for relationships. Specifically, we examine how feelings of guilt from keeping consumption as a secret from a romantic partner can drive pro-relationship spending. Guilt, a "moral" emotion, motivates people to compensate for a perceived transgression (e.g., Tangney and Dearing 2003). We suggest that one way people might respond to guilt from secret consumption is by investing more spending toward the relationship, such as through gifts. This spending can, in turn, make the partner more satisfied.

We test these predictions across several studies. First, in **Study 1**, we recruited couples at a farmer's market to test our premise that people actually keep consumption secrets from their romantic partners. We asked both members of couples (119 couples, 238 individuals, M_{age}=41 years) to describe a recent time when they kept a consumption secret from their partner and their partner still does not know about it. Indeed, 90% of participants were able to provide an example, suggesting that this is a common consumer phenomenon. Further, the majority of responses were about relatively mundane behavior. The next two studies test our predictions about how such consumption secrets within the relationship can affect pro-relationship spending.

In **Study 2**, we manipulated secret consumption using a scenario to tightly test the effects of secret consumption on pro-relationship spending. Specifically, 272 participants (M_{age}=36 years) from MTurk were asked to imagine that they found more money in their Amazon account than they expected, and they decided to buy something online. Depending on randomized condition, participants were then asked to imagine either that they told their partner about the purchase (control condition) or decided not to tell their partner (secret condition). Participants indicated how guilty they would feel (7-point

Likert scale). Next, participants were shown two new subscription services: one was for a "date night" subscription that they could use with their partner and the other was for a personal "hobby" subscription. They were told that they would receive 15 virtual raffle tickets to use toward winning a $50 gift card for one of the services. The amount of raffle tickets put toward the date night subscription served as our dependent variable and measure of pro-relationship spending. Results revealed that people who imagined keeping a consumption secret from their partner put significantly more of their raffle tickets toward the date box than did people who imagined telling their partner ($p<.05$). People in the secret condition reported significantly greater guilt than did people who imagined telling their partner about their purchase ($p< .01$), and mediation analyses revealed that guilt mediated the link between secret consumption and pro-relationship spending.

In **Study 3**, we used dyadic data to examine whether greater guilt from real secret consumer behavior is associated with greater real-life pro-relationship spending, operationalized as spending on the partner for Valentine's Day. In this study, we also examine the downstream consequences of secret consumer behaviors and pro-relationship spending from the partner's perspective. Each member of a romantic couple was recruited by an online sampling panel as part of a larger paid study on relationships. One hundred forty-one individuals successfully completed this study (M_{age}=53 years). Participants were asked to recall and describe a recent time that they engaged in a consumption activity and intentionally did not tell their partner about it. They were then asked how guilty they felt for the consumption activity and how guilty they felt for not telling their partner about it (9-point Likert scales). We next asked participants to think about previous years, and indicate how much money, time, and money spent on gifts they spent on Valentine's Day this year compared to previous years (1=a lot less to 7=a lot more; α=.89). Next, we asked participants how satisfied they were with what they did for their partner and how indulgent were the gifts/activities they gave to their partner. Finally, to assess partner satisfaction with pro-relationship spending, we asked participants how satisfied they were with what their partner did for them for Valentine's Day. Because this is dyadic data, we used multi-level modeling with individuals nested within couples (Kenny, Kashy, and Cook 2006). In line with the findings from study 2, greater guilt from a recent secret consumption activity was significantly associated with greater Valentine's Day spending ($p<.05$). Greater guilt from a recent secret consumption activity was also significantly associated with greater indulgent gifts/activities ($p<.05$) and greater satisfaction with how Valentine's Day went this year ($p<.05$). Using the actor-partner interdependence model (APIM; Kenny et al. 2006), we examined the downstream effects of secret consumer behaviors on the partner. As actors reported spending more on Valentine's Day this year relative to other years, which was significantly related to guilt from keeping their consumption activity a secret, partners reported significantly greater satisfaction with how Valentine's Day went this year ($p<.01$), suggesting additional positive downstream consequences of secret consumption within relationships.

Across three studies, we examine secret consumer behavior in relationships. We find that although keeping a consumption activity from one's partner can lead to greater guilt, this guilt can have positive outcomes for the relationship, specifically in terms of greater pro-relationship spending. Further, using data from couples reporting on real behavior, we found that greater pro-relationship spending was associated with greater satisfaction on the part of the partner, highlighting additional positive downstream consequences of secret consumer behaviors in relationships.

Reminder Avoidance: Why People Hesitate to Disclose Their Insecurities to Friends

EXTENDED ABSTRACT

Many of us try to keep our personal insecurities well-buried. However, they still burden our minds until the burden becomes too large to carry alone, such that we yearn to release them. Indeed, a survey of 100 U.S. residents—conducted as part of this research—reveals that of the 96 people who reported possessing personal insecurities, more than 70% wished they could get their insecurities off their chest and more than 60% wished they could disclose them to another person.

But, to whom could people disclose their insecurities and hopefully unburden themselves of the associated psychological pain? One instinctive audience may be friends. Indeed, people generally turn more to friends than strangers to self-disclose (Chaikin and Derlega 1974; Gaebelein 1976; Jourard and Lasakow 1958) and believe that if they were to disclose hardships, they would more easily receive help from friends than strangers (Deri, Stein, and Bohns 2019). Such promised support seemingly points to the possibility of people self-disclosing their insecurities—self-aspects that likely require support—to friends more than they would for other types of disclosures.

However, Rubin (1975)'s "passing strangers" effect introduces an interesting alternative perspective. In his work, out-of-towners self-disclosed more intimately to an unacquainted research assistant (RA)—a stranger—than local residents. Rubin (1975) speculated that out-of-towners may have disclosed to the RA their intimate personal information they would not even share with people they normally encounter because they could unburden such information without the concern of having to face or think about this RA or the consequences of disclosed information again.

We build upon this perspective and posit that there is something disconcerting about disclosing one's very private personal information, such as personal insecurities, to those one repeatedly interacts with (e.g., friends). That is, disclosing personal insecurities to friends increases the risk of being reminded of these already reminder-prone self-aspects. Friends may encourage the discloser to elaborate on the disclosed insecurities to understand, help, or speculate together (Rose 2002) or repeatedly bring them up over the course of the relationship. All these interactions could escalate the risk of being painfully reminded of the disclosed contents. Hence, we hypothesize and demonstrate in five pre-registered studies that, due to the risk of painful reminders of disclosed contents, people dampen their usual tendency to turn more to friends than strangers for self-disclosure when disclosing personal insecurities (vs. other information).

Study 1 provided initial evidence for our effect in a 2-group (self-disclosure: insecurity, neutral) between-subjects design. 100 friend-pairs (*N*=200) were recruited. Participants in the insecurity condition wrote about self-aspects that make them feel insecure. Those in the neutral condition wrote about their daily routine. They were then told that, as part of this "social interaction" study, they would need to read what they have written to another person and that they could choose between "*another participant who is unacquainted with you*" and "*the friend you came with*" as their disclosure-audience. As hypothesized, participants disclosing their insecurity (vs. neutral personal information) were significantly less likely to choose their own friend as their audience (insecurity:76.2% vs. neutral:91.6%), B=-1.22, *p*=.005.

Study 2 (*N*=608) demonstrated that this effect does not occur for any negatively-valenced self-disclosure using a 2-group (self-disclosure: personal insecurity, societal insecurity) between-subjects design. The personal insecurity condition was the same as in study

1. Participants in the societal insecurity condition wrote about something they read in the news that makes them feel insecure about society (negative but non-personal disclosure). Participants then indicated their preferred disclosure-audience (1=*stranger* to 7=*friend*). As expected, participants disclosing personal (vs. societal) insecurities showed significantly lessened preference for a friend as their audience ($M_{personal}$=4.92 vs. $M_{societal}$=5.60), $F(1, 606)$=18.38, $p<.001$.

Study 3 (*N*=202) conceptually replicated study 1 and provided initial support that the dampened friend-preference for insecurity-disclosure occurs among those more prone to rumination (and thus more likely to wish to avoid disclosed-content reminders), using a 2 (self-disclosure: insecurity, neutral) × rumination-tendency (measured) between-subjects design. Participants wrote about either their insecurities or neutral personal information (recent grocery-trip), completed the Rumination Tendency Scale (Brinker and Dozois 2009), and indicated their disclosure-audience (1=*stranger* to 7=*friend*). Participants disclosing their insecurity (vs. neutral personal information) were again less likely to prefer a friend as their audience ($M_{insecurity}$=4.53 vs. $M_{neutral}$=5.10), B = -.57, p = .06. Furthermore, this effect surfaced for those highly prone to rumination: disclosure topic × rumination-tendency interaction, B=-.70, SE=.28, t=-2.51, p=.013 (Johnson-Neyman point=4.87).

Study 4 (*N*=404) provided further support for our account that anticipated risk of painful reminders of disclosed-content decreases one's preference for friends over strangers as their disclosure-audience via mediation. We used a 2-group (non-disclosure reason: insecurity-trigger, no-opportunity) between-subjects design and measured participants' anticipated pain from reminders. In the insecurity-trigger condition, participants described a personal challenge they have not disclosed because it triggers insecurities; those in the no-opportunity condition described a personal challenge they have not disclosed because they did not yet have the opportunity to do so. Then participants indicated their disclosure-audience (1=*stranger* to 7=*friend*) and indicated how painful reminders of their stories would be (2-item; *r*=.93). Consistent with our theory, participants preferred friends less for personal challenge-stories undisclosed due to insecurity-triggers (vs. no-opportunity), ($M_{insecurity-trigger}$=4.24 vs. $M_{no-opportunity}$=5.14), $F(1, 402)$=15.94, $p<.001$. This effect was mediated by participants' anticipated pain from reminders, B =-.18, SE=.07, 95% CI=[-.34, -.05].

Study 5 (*N*=606) provided further evidence that risk of painful disclosed-content reminders drives our effect. We used a 2-group (self-disclosure: insecurity, neutral) between-subjects design. The self-disclosure procedure was similar to study 3's. However, the choice for disclosure-audience was between two equally-supportive friends differing in one aspect: Friend A who tends to bring up previously-shared stories and Friend B who does not. Participants disclosing insecurities (vs. neutral personal information) were more likely to choose Friend B, who tends not to bring up previously-shared stories (insecurity:78.4% vs. neutral:65.7%), B=.65, $p<.001$.

Altogether, our results contribute to the broad consumer psychology literature on how consumers manage secrets by showing that, when disclosing personal secrets (e.g., insecurities), they turn away from friends because, ironically, even their friendly helping gestures could remind them of the painful disclosed-content.

Hidden in Plain Sight: Consumer Response to Pseudo-Secrets in Marketing

EXTENDED ABSTRACT

The marketing and consumption of secret products and experiences has become an emerging cultural phenomenon in retail, hospitality, food and beverages, fashion and entertainment. Restaurants ranging from gourmet Michelin-starred to mainstream fast-food chains offer secret-menu items, and hidden shops and "speakeasy" bars have camouflaged entrances and secret passcodes. Paradoxically, many of these hidden secret items and places have become famous for being secrets, and interestingly, the majority of secret bars and shops are located in central public areas - hiding in plain sight.

We label these hidden but publicly available products as "pseudo-secrets" and demonstrate their positive impact on word-of-mouth and actual purchase behavior in the marketplace. We demonstrate that this effect is mediated by feelings of social centrality, i.e., the subjective feeling of being connected to others in the network and feeling like information hubs, and moderated by how the information was obtained. Additionally, we explore an important individual characteristic that could moderate consumers' propensities to disseminate information in the marketplace: Market Mavens (Feick and Price 1987).

Six field and lab studies test the pseudo-secrecy phenomenon.

Exploratory interviews (N=33) suggested that pseudo-secrets exist in various product categories. Respondents mentioned examples of hidden shops that were nestled in central shopping areas and secret-menus that were offered by big fast-food chains. They described recurring cues that create a sense of hidden-yet-inviting products and experiences, such as camouflaged entrances of shops which also provided their actual address and products online. Importantly, respondents noted that knowing about pseudo-secrets made them feel "in the know" and like insiders, portraying a phenomenon that is first and foremost a social enterprise.

In a **pilot study** (N=177), we surveyed shoppers at the rapper Kendrick Lamar's pop-up shop, located in a central area. Although the shop did not have a sign or any indication as to what merchandize it was offering, its location, opening dates, and merchandise were available online and on social media. Perceiving the pop-up shop as more secretive increased consumers' intentions to buy branded items (*b*=.169, *t*=2.943, *p*=.004, 95% CI=[.056,.283]).

In **Study 1**, visitors at a university campus tour (N=2,415) received a 15% discount coupon for the university store. Since the store has a small sign at the entrance, we were able to describe it either as a pseudo-secret ("easy to miss") or as visible and conspicuous ("hard to miss"). Overall, 4.7% of the visitors redeemed tour coupons. As predicted, framing the store as pseudo-secret increased actual purchases (redemption rate 6.3%) compared to framing it as well-known (4.2%; χ^2=5.12, *p*=.024) or control condition (4.1%; χ^2=5.93, *p*=.015), indicating that pseudo-secrets increased brand interest.

In **Study 2**, different visitors (N=764) at the same university tour were asked to help improve future tours by expressing their interest in expanding the tour to focus on the university's library. Describing the library's back door as a secret small door (vs. small door) increased visitors' interest in taking its photo to show their friends ($F(1,762)$=24.22, *p*<.001). The manipulation did not affect intentions to show photos of the iconic main door to friends ($F(1,762)$=.12, *p*=.724), indicating that pseudo-secrets (vs. non-secrets) increase WOM intentions about products associated with that information.

Studies 3 and 4 examined the mediating role of feelings of centrality. Participants used a social network heat-map to indicate how central they felt.

Study 3 had four conditions. 324 adults (67.6% women; M_{age}=35.5) read about a pseudo-secret (vs. not-secret) bar. The bar entrance was through a back door of (vs. next to) an ice-cream shop. In two additional pseudo-secret conditions manipulating the source

of information, participants imagined that they heard about the bar directly from a friend (vs. overheard their friends talking). Pseudo-secrets increased both interest in going to the bar (p's<.001) and WOM likelihood (p's<.003) compared to the non-secrets. Learning about the pseudo-secret bar directly from a friend further increased purchase intentions (p's<.044) and WOM intentions (compared to non-secret p=.044). Interestingly, learning about the bar indirectly (overhearing) increased purchase interest (compared to non-secret, p<.001) but decreased WOM intentions (compared to pseudo-secret control, p=.042), highlighting the important role of feelings of centrality. Mediation analyses (PROCESS, Model 4) showed significant effects on purchase interest and WOM via feelings of centrality.

Study 4 had a 2 (pseudo-secret vs. non-secret) × 2 (market-maven) between-subjects design. 439 participants (44.4% female; M_{age}=36.6) imagined that a restaurant near them serves an unlimited number of a secret-menu house burger (vs. house burger) that does not appear (vs. appears) on the restaurant's menu. The results revealed two positive effects of pseudo-secrecy and market mavens on both purchase interest and WOM intentions (p's<.001). The brand information × market maven interaction did not affect purchase interest (p=.473). However, a negative effect on WOM (p=.001) indicated that pseudo-secrets have a stronger effect among non-mavens who scored 5.64 or lower on the 1-to-7 market maven scale, increasing their likelihood to spread WOM. A moderated mediation analysis revealed a significant moderating effect of market mavens on WOM through feelings of centrality (PROCESS, Model 7; a×b=-.0509, SE=.0257, 95% CI=[-.1030,-.0021]).

In addition to the practical implications of understanding how to design pseudo-secret brand information to generate brand engagement, our research makes important theoretical contributions. First, it advances research on secret (i.e., private) consumption (Thomas and Jewell 2019) by demonstrating an opposite phenomenon – products that are designed to offer a secretive experience, but lend consumers with a gift (i.e., seemingly exclusive knowledge) that they can pass on to others rather than hide it. It also contributes to research on social networks (Watts and Dodds 2007) by demonstrating that consumers' subjective experience of feeling socially central, rather than their objective centrality, may drive information flow in networks. Thus, we suggest that beyond their informational value, pseudo-secrets carry an important symbolic social value which can resolve an inherent tension between the desire for exclusive products and affiliations and the discomfort associated with excluding others (Bellezza and Keinan 2014; Legate et al. 2013). Finally, our work extends research on WOM behavior (Berger 2014) by highlighting the influence of the source of the information on WOM.

SESSION OVERVIEW

Consumers are increasingly grappling with challenging consumption-related issues that impact their health (e.g., processed and sugar laden foods), their environment (e.g., plastic bags), their understanding of physical tasks (e.g., autonomous products), and their choices in the marketplace (e.g., too many brand extensions). Building on extant literature that finds lay theories as a crucial determinant of real world consumer outcomes (such as obesity, McFerran and Mukhopadhyay 2013), the four papers in this session examine lay theories that shape responses to consequential issues that not only affect individuals, society, and policymakers, but also have clear implications for brand and marketing strategy. Bringing alive the conference theme of *"Rendezvous,"* this session brings together consumer researchers from three continents to showcase the wisdom of consumers' naive theories in providing novel insights to enduring and significant issues including obesity, environmental degradation, autonomous products, and brand extension failures.

The first two papers focus on how their lay theories can nudge consumers to make better (or worse) choices for their well-being. Briers et al. present a unifying framework to underscore the role that parents' unhealthy = tasty lay belief plays in determining their children's BMI. They identify the use of extrinsic rewards as the psychological process that drives this relationship, while ruling out alternative explanations. Madan et al. uncover a novel antecedent to reduce consumers' resistance to environmental taxes — their lay belief about the relationship between wealth and happiness. Drawing from hedonic adaptation theory, they identify expectations of adjustment as the underlying mechanism and propose recommendations

for policy makers to increase support for environmental taxes on both sides of the partisan divide.

The next two papers take the firms' perspective to ask how lay theories shape consumer choice in emerging domains such as autonomous products and brand extension failures. De Bellis, Johar, and Schweitzer find that one reason behind consumers' lukewarm acceptance of highly efficient and convenient autonomous products is their lay theory that only effort and hard work yield desired outcomes. To drive consumer adoption, they recommend that firms should emphasize the idea that autonomous products can free up time for more meaningful pursuits. Applying the lens of lay theories to study the pervasive issue of brand extension failures, Jain et al. uncover that consumers' lay theories about malleability and fixedness of personality predict the extent to which consumers punish the parent brand when an extension failure occurs. Building on entitativity literature, they suggest that breaking the perception of the brand as a homogenous group can mitigate the risk of extension failure for the parent brand.

This special session integrates several areas of interest highlighted in the call-for-papers (e.g., technology, identity, obesity) under the umbrella of lay theories to highlight the meaningful role that consumers' lay theories play in determining substantive consumer behavior outcomes. We hope to encourage an engaging conversation on the implications of consumer characteristics such as lay theories in influencing consumer behavior and to spark ideas for future research.

Intergenerational Effects of the Unhealthy = Taste Intuition on BMI: An Exploration of Food Practices and Outcomes

EXTENDED ABSTRACT

Childhood obesity is a critical health concern worldwide (WHO 2018), and sets the stage for a lifelong struggle with weight and eating. The influence of parents is considered as primary, given that parents during early childhood act as gatekeepers and role models around food (McCaffree 2003). Previous research has looked at the influence of parents' demographics, parents' nutritional knowledge, general parenting style, and food parenting practices. This research investigates how parents' beliefs about the trade-off between healthfulness and tastiness in food (i.e., the Unhealthy = Tasty Intuition, "UTI"; Raghunathan, Naylor, and Hoyer 2005) affects their children's BMI.

Taste is generally the most important attribute in food choice (Glanz et al. 1998). When parents hold a strong belief that healthy food is not tasty, they may consider that their children need an extra incentive to eat food that is healthy but less tasty. Hence, higher UTI parents may be more inclined to offer their children an extrinsic reward in exchange for eating healthfully. However, this strategy might backfire, as providing external rewards signals that the healthy food consumption is a negative experience that needs to be compensated (Birch et al. 1982). As a result, the use of external rewards might ironically reduce healthy food consumption thereby increasing BMI. Thus, we predict that parents' UTI positively affects their children's BMI, which is mediated by the extent to which parents use an extrinsic reward to induce healthy eating and the amount of healthy

food consumed by their children. We tested this proposition in four studies.

In study 1, 980 MTurk workers who were the main caretaker of a child (age 6-11) participated in the survey. Respondents indicated the child's age, gender, height, weight, their child's fruits and vegetables consumption and their likelihood to offer their child an external reward for eating healthy. Next, we measured respondents' UTI with three items (e.g., "Things that are good for me rarely taste good"; Raghunathan et al. 2005), their own height and weight. Controlling for parents' BMI, children's age and gender, linear regression analysis showed that the more parents believed in UTI, the higher their children's BMI was ($\beta = .86$, $SE = .16$, $t = 5.26$, $p < .001$). Further, bootstrap analyses (Hayes 2013, Model 6) showed that the relationship between the parent's UTI and the child's BMI was serially mediated by the use of an extrinsic reward to induce healthy eating and the amount of fruits and vegetables consumed by the child (a_1 x d_{21} x b_2 indirect effect = .010, bootstrap se = .0053, bias-corrected bootstrap CI [0.0019; 0.0225]).

Study 2 aimed to replicate the results of study 1, while controlling for two other important parental influences on children's BMI: parent's education and how often they exercise. Using a similar survey as in study 1 (N = 938), results reassuringly showed a positive effect of parents' UTI on their child's BMI ($\beta = .25$, $SE = .13$, $t = 1.99$, $p < .05$), serially mediated by the use of external rewards, and the amount of healthy food consumed by the child (a_1 x d_{21} x b_2 indirect effect = .0088, bootstrap se = .0056, bias-corrected bootstrap CI [0.0002; 0.022]).

In study 3, we aimed to find causal evidence for the link between consumers' belief in the UTI and the likelihood to use external rewards for pushing healthier eating among children. We manipulated UTI by means of an article describing scientific research on healthy food being tasty (non-UTI) versus less tasty (UTI). A manipulation check with the same three UTI measures as before showed that it was successful ($\alpha = .89$; UTI = 2.82 versus non-UTI = 2.44, $F(1, 239) = 6.95$; $p = .009$). As dependent measure, we presented respondents with a babysitting scenario in which the 6-year old child refused to eat broccoli. An open-ended question asked the respondents what they would do to make the child eat the broccoli. Answers were coded as providing an external reward (1) versus not (0). Results showed no main effect of UTI on the likelihood to choose a rewarding strategy. Further exploratory analyses revealed that among respondents who had children of their own (i.e., parents), their rewarding strategy was not affected by UTI (UTI= 43.6% versus non-UTI= 51.6%), presumably because they were likely to use their pre-existing strategies to motivate their children (as shown in studies 1 and 2). Interestingly, among those respondents with no children, for whom the babysitting scenario presumably was more realistic, external rewards were more likely to be mentioned in the UTI condition (42.2%) compared to the non-UTI condition (21.7%; $\chi^2 = 5.97$; $p = .02$; overall interaction: $\beta = 1.29$, $p = .02$).

Inspired by study 3, study 4 only included respondents who had no children. This study used the same manipulation ($\alpha = .87$; UTI= 2.88 versus non-UTI= 2.36; $F(1, 205) = 11.06$; $p = .001$) and babysitting scenario. As dependent measure, we asked respondents how likely they were to offer the child an exchange in return for eating the broccoli. Next, we asked them to rate the likelihood of nine different strategies, of which four were related to providing an external reward ($\alpha = .72$): reward and threat with food, reward and threat with non-food, praise, scold, distraction, disguise, and making it fun. In line with our hypothesis, respondents in the UTI condition were marginally more likely to offer an exchange (UTI= 4.81 versus non-UTI= 4.28; $F(1, 205) = 3.60$; $p = .06$) and significantly more likely to offer

or threaten with a reward (UTI= 3.48 versus non-UTI= 3.19; $F(1, 205) = 4.61$; $p = .03$) than respondents in the non-UTI condition. For the other five strategies, we found no differences.

Overall, this research contributes to the literature on lay beliefs (McFerran and Mukhupadhyay 2013) and consumer socialization (Ward 1974; John 1999; Moore, Wilkie and Desrochers 2017). This integration allows us to present a unifying framework of the flow of influence, parents' beliefs → parents' actions → children's behaviors → children's outcomes, thereby sparking suggestions for potential interventions and future research.

It Isn't Easy Being Green: Lay Theories of Wealth and Happiness Shape Support for the Environment

EXTENDED ABSTRACT

A strong majority of Americans believe that the government is not doing enough to protect the environment but many of them are unwilling to support environmentally protective policies (Newport 2018). Many consumers may believe single use plastic is ruining marine life but not support a plastic bag ban (Raskin et al. 2020). For example, carbon emissions from transportation are a major source of greenhouse gases that contribute to climate change. One way to reduce them is to impose substantial tax on gasoline, which would reduce gasoline consumption. A key reason for this gap is that many people endorse environmentalist attitudes because it is socially desirable to do so, but a large fraction do not follow through with consistent actions because it is costly to do so.

What are the psychological levers for nudging consumers to support such environmental consumption taxes (in short *ecotaxes*)? Certainly, the personal and societal costs due to the ecotax are relevant. People's views about the significance of these costs might hinge on their theory about how happiness adapts to changes in wealth, which in this case refers to a reduction in discretionary income as a result of the ecotax. We propose that individuals differ sharply in their assumptions about how people's happiness changes with wealth — some assuming that happiness is dependent on wealth ("the more you have, the happier you are") and others assuming that it largely adapts ("after a certain threshold, changes in wealth do not bring similar changes in happiness").

Popular culture and scientific research provide plenty of evidence for both these points of view. Many believe that wealth brings well-being, and if not constant joy then at least a higher baseline. As Francoise Sagan (Hartley 2015) put it, "Money may not buy happiness, but I'd rather cry in a Jaguar than on a bus." In a survey, 73% Americans forecasted that they would be happier if they had more money (Carroll 2006). However, the belief that happiness adapts to changes in wealth is also widely held. Just as pleasant smells become less pleasurable after continued exposure, people get used to a higher income—the higher wealth becomes the new normal, not a reason for pleasure (Frederick and Loewenstein 1999). We propose that this lay theory is an important antecedent of differences in support for ecotaxes. The more people believe that happiness adapts to wealth, the more likely they are to support environmental consumption taxes because they consider ways in which individuals and organizations would adjust their behavior over time in response to the tax.

Eight studies provide converging support for these hypotheses. We first developed an 11-item scale to measure people's lay theories about wealth and happiness. Several studies established the predictive validity, convergent, discriminant, and test-retest reliability of the scale.

Study 1a tested if people's lay beliefs about wealth and happiness influenced their support for close to 100% increase in gasoline

tax. Four hundred five American citizens on MTurk completed the study. In line with the hypothesis, people who believed that happiness adapts to changes in wealth were more likely to support the policy (β = .22, $t(404)$ = 2.048, *p* = .041)

Studies 1b-1d (N = 198, 199, 205) replicated the findings in Study 1a with a wider variety of consumption taxes such as plastic bag tax, a disposable cup charge, and a processed foods tax. We also controlled for other alternative predictors of people's support for the environment and/or taxes such as environmental concern, political orientation, personal cost incurred due to the tax, materialism, and income. Consumers' lay beliefs about wealth and happiness predicted support for ecotaxes even when controlling for these constructs.

Studied 2a and 2b provided causal evidence for our hypothesis. Participants (N = 326, MTurk) either read an article advocating that happiness adapts to changes in wealth or that happiness changes with changes in wealth. They then indicated their willingness to support a multiple consumption taxes on gasoline, plastic, disposable cups, and processed foods. Consistent with our hypothesis, participants who read the adaptation article were more supportive of the consumption tax ($M_{WealthAdapt}$ = 4.37, $M_{WealthDependence}$ = 4.00, $t(324)$ = -1.99, *p* = .048). Further, the indirect effect through the perception that the society will adjust its consumption habits in response to the tax was significant [B =.32, SE =.12, 95%CI [.09,.56]).

Study 3 provided additional evidence for adjustment as the underlying mechanism through mediation by moderation. Specifically, participants were told that funds generated from the tax would either be used to help the society adjust to a higher tax regime or not (e.g., an air ticket tax being used to develop the train network in the state versus being used to upgrade vending machines). We found that wealth-adaptation theorists supported the tax when the proceeds were used to facilitate societal adjustment (B = .71, SE = .29, $t(464)$ = 2.41, *p* = .016), but not when they were not used to support societal adjustment (B = -.35, SE = .24, $t(470)$ = -1.44, *p* = .15).

Finally, Study 4 sought to provide behavioral evidence through an incentive compatible design. We first measured participants' lay beliefs about wealth and happiness. After completing several unrelated tasks, participants were told that 1 out of every 100 participants would be getting a $10 bonus. They were then given the opportunity to divide this bonus between themselves and a lobbying organization working to get ecotaxes mentioned above implemented. We found that a stronger belief in wealth adaptation theory was associated with greater amounts pledged for the lobbying organization (B = .71, *95%* CI [.29, 1.13], SE = .19, $t(262)$ = 3.35, *p* = .001). This was significant even after controlling for age, gender, education, income, social class, and political orientation.

In sum, the present research identifies a novel construct—people's lay theories about wealth and happiness—and shows that it influences consumers' support for environmental taxes. We contribute to the science on lay theories and the antecedents of environmentally conscious behavior. More importantly, we contribute to the limited research in consumer behavior that focuses on curbing consumption.

No Pain, No Gain: Protestant Work Ethic and the Adoption of Autonomous Products

EXTENDED ABSTRACT

Autonomous products have entered our everyday lives. From cleaning the floor to mowing the lawn, consumers are increasingly able to delegate manual tasks to this novel type of technology. Autonomous products allow consumers to free themselves from mundane chores and promise unprecedented levels of efficiency and productivity. At the same time, anecdotal evidence suggests that even the completion of cumbersome tasks can be associated with satisfaction and positive feelings. Do consumers account for these feelings and if so, do they impact the adoption of these new technologies?

Consumer research has demonstrated that consumers experience autonomous products in ambivalent ways. Autonomous products are perceived as increasingly beneficial but risky (Rijsdijk and Hultink 2003; 2009). A recent focus has been on the role of product autonomy, which has been associated with consumer disempowerment and reduced feelings of control (André et al. 2018; Schmitt 2019; Wertenbroch et al. 2019). Autonomous products can also challenge identity-based consumption, as they limit consumers' ability to attribute the outcomes of consumption to themselves (Leung, Paolacci, and Puntoni 2018). Finally, completing a cumbersome task (e.g., a chore such as cleaning that is less central to one's identity) is positively associated with meaning in life (Baumeister et al. 2013).

According to our theorizing, the lay theory that effort and hard work yield desired outcomes—reflected in everyday idioms such as "no pain, no gain" and "nothing ventured, nothing gained"—holds an important key to understanding autonomous product adoption. This notion is ingrained in many cultures and denoted by the protestant work ethic (PWE; Cheng, Mukhopadhyay, and Schrift 2017). We posit that consumers high in PWE should be less likely to adopt autonomous products, as these products go against their core belief that hard work is needed to be successful. Given that the PWE is linked to feelings of meaningfulness (Pogson et al. 2003; Schnell and Becker 2006), we expect that consumers high in PWE derive more meaning from manual tasks, which reduces their willingness to delegate manual tasks to autonomous products.

A series of four studies, conducted in the field, online, and in the lab, shows that high (vs. low) PWE is related to lower adoption of autonomous products. We provide evidence for this effect by measuring and manipulating PWE across four autonomous product domains. Based on the idea that consumers' meaning from manual tasks drives the effect, we derive an intervention for firms to reverse the effect. Specifically, consumers high in PWE tend to choose autonomous over manual products when a meaningful task substitute is provided by highlighting that the use of autonomous products frees up time that can be used for more meaningful activities.

Study 1 explores the relationship between PWE and autonomous product adoption at the country level. We collected aggregated field data on consumers' readiness for automation (Economist Intelligence Unit 2018) and their acceptance of autonomous cars (KPMG 2018), which we correlated with consumers' PWE (Cheng et al. 2017) across major markets. Results showed that PWE is negatively associated with both readiness for automation (b = −14.53, $t(19)$ = 3.18, *p* = .005) and acceptance of autonomous cars (b = −5.49, $t(16)$ = 3.18, *p* = .006), even when controlling for GDP per capita and number of motor vehicles.

Study 2 examines the relationship between PWE and autonomous product adoption at the individual level. We conducted this study with 381 consumers from MTurk who participated in ostensibly two unrelated studies. In the first part, we measured consumers' PWE (Schrift et al. 2016) along with other measures. In the second part, consumers chose an autonomous versus manual product in either of three domains (cooking, cleaning, or lawn mowing). Controlling for desire for control, meaning in life, and domain expertise, we found a negative relationship between PWE and the choice of an autonomous product (b = −.30, z = 2.07, *p* = .04), with the effect being mediated by consumers' meaning from manual tasks.

Study 3 investigates the causal relationship between PWE and the adoption of autonomous products. We randomly assigned 105 consumers from MTurk to an either high or low PWE condition,

employing a quotes-ranking task to induce a temporary state of PWE (Cheng et al. 2017). Subsequently, we asked consumers to choose between an autonomous versus manual cleaning device. Whereas 62.3% of consumers chose the autonomous product in the low PWE condition, only 42.3% did so in the high PWE condition (χ^2(1, 105) = 4.19, p = .04). These results were robust when controlling for identity relevance of the task (Leung et al. 2019).

Study 4 aims at reversing the previously shown effect by providing a meaningful task substitute to consumers. We conducted a lab study with 174 students to explore the effectiveness of this intervention. Participants completed the quotes-ranking task of Study 3, before being randomly assigned to one of two conditions. Whereas the control condition entailed the same product description as in Study 2, the meaningful condition entailed one extra attribute in the autonomous product description (i.e., "allows you to spend time on more meaningful things"). Results showed a significant interaction between PWE and meaningful task substitute (b = .34, z = 2.15, p = .03). In the control condition, more consumers chose the autonomous product in the low PWE condition (52.5%) than in the high PWE condition (44.2%). In the meaningful condition, however, fewer consumers chose the autonomous product in the low PWE condition (38.9%) than in the high PWE condition (63.6%), providing an effective intervention for firms to increase the adoption of autonomous products.

We presented a series of field and experimental studies demonstrating that PWE seems to inhibit the adoption of autonomous products, because high PWE consumers place more emphasis on meaning from manual tasks. In other words, consumers that place more emphasis on the "no pain, no gain" lay theory choose autonomous products less often. The findings contribute to our understanding of the adoption of new technologies and the psychological forces that govern this effect.

Brand Extension Failure and Parent Brand Penalty: The Role of Implicit Theories

EXTENDED ABSTRACT

Companies routinely attempt to leverage the equity of an established parent brand by introducing products with the same brand name in one or more categories (Ourusoff et al. 1992). Although relying on a strong brand can sometimes be an effective strategy when launching new offerings (Aaker and Keller 1990), over 80% of brand extensions fail (e.g., Torelli and Ahluwalia 2011). Given this extraordinary failure rate, it is imperative for companies to understand the consequences of extension failures on established brands. Although previous research has produced valuable insights as to whether such feedback effects are influenced by features of the parent brand and the extension, relatively less work has examined the role of consumer characteristics. To fill this gap, the authors of the present research investigate whether consumers' implicit theory orientation, which is their perspective on whether personality traits are malleable versus fixed, influences the severity of negative feedback effects following an extension failure.

Extant literature has documented that entity theorists, who believe in the fixedness of personality traits, are often less likely to change their existing beliefs than incremental theorists, who believe that personality traits are malleable (Dweck, Chiu, and Hong 1995). As a result of this difference, one might expect that individuals who endorse an entity (vs. incremental) theory orientation to be less likely to change parent brand evaluations after an extension failure. In contrast, we predict that entity (vs. incremental) theorists will be more punitive when they learn about an extension failure. Albeit in contexts unrelated to brand extensions, prior research has shown that individuals' implicit theory orientation determines their reaction to failure (Aronson, Fried, and Good 2002). Because they believe in the pliability of individual characteristics, incremental theorists perceive failure as representative of an opportunity to learn and improve (Hong et al., 1999). In contrast, entity theorists attribute failure to a lack of ability because as they see it, individuals cannot change and so, failure reflects undesirable traits and features of an individual (Cury et al. 2008). Therefore, entity theorists are more likely to penalize themselves and others when they learn about or encounter failure (Haselhuhn et al. 2010).

Recent research has also shown that compared to incremental theorists, entity theorists are more likely to view social groups as coherent and stable units and thus perceive the group to have greater entitativity (Rydell et al. 2007). We expect implicit theories to exert similar influence on consumers' perceptions of a brand's entitativity levels, such that entity theorists are more likely to view products under the same brand name as constituting a meaningful and entitative group (Wheeler and Omair 2016). Following this line of research (e.g., McConnell et al. 1997), we posit that when a brand is perceived as more entitative, consumers will incorporate and integrate extension failure information into their evaluation of the parent brand. As a result, the negative associations of a failed extension are more likely to be transferred to the parent brand and produce greater attitude change (i.e., a steeper penalty for the parent brand).

In sum, we propose that when evaluating a parent brand, entity (vs. incremental) theorists will view the brand as a cohesive group (vs. a loose collection of products). Because of these differences in their perceptions and beliefs about entitativity, we further posit that entity theorists will be more likely to incorporate brand extension failure into parent brand judgments, leading them to revise their evaluation of the parent brand. That is, we predict that brand dilution (i.e., a negative feedback effect) is more likely for entity (vs. incremental) theorists, and this effect is expected to occur through perceived brand entitativity.

We test these predictions in a series of five studies. In study 1A, we measured implicit theory as a dispositional trait and found that entity (vs. incremental) theorists penalize a real parent brand (i.e., Virgin) more after the failure of a brand extension (i.e., smart watches). An OLS regression of the six-item parent brand penalty measure (α = .63) on the implicit theory measure revealed that participants' implicit theory orientation significantly influenced their intention to penalize the parent brand (β = -.21, SE = .10, t(103) = -2.09, p = .039). In study 1B, we replicated this result using another real brand (General Electric) and an established manipulation of implicit theory. In studies 2 and 3, we provided evidence for our follow model by showing that the greater parent brand penalty conferred by entity (vs. incremental) theorists is mediated by perceptions of a parent brand's entitativity.

In study 2, we measured participants' implicit theory and brand entitativity beliefs and found that stronger entity theory orientation led to higher penalties for the parent brand (General Electric) after extension failure (β = -.25, SE = .10, t(498) = -2.42, p = .016). We also found that an entity (vs. incremental) theory orientation led to a higher perception of brand entitativity (β = -.26, SE = .05, t(498) = -4.77, p < .001) and that greater entitativity was associated with higher penalty (β = .20, SE = .08, t(498) = 2.47, p = .014). A mediation analysis revealed that the effect of implicit theory on parent brand penalty was mediated through perceived entitativity (β = -.04, SE = .02, 95% confidence interval [CI] = -.096, -.002). In study 3, we replicated this finding even though we manipulated rather than measured implicit theory and used a fictitious fashion and apparel brand

named Epic that had launched a failed shoe extension. In study 4, we extended these findings by demonstrating an asymmetry in how entity theorists respond to brand extension failure versus extension success, again using the General Electric brand. We found that while entity theorists penalize brands when they encounter brand extension failure, they do not change their parent brand evaluations when the extension is successful.

This work contributes to the literature on implicit theory, brand extensions, and implicates perceived brand entitativity as a determinant of the effects of failed extensions.

SESSION OVERVIEW

Instead of buying readily available products off the shelf, consumers frequently engage in the product creation process and customize offerings or self-produce products. For instance, consumers may customize a birthday card by choosing their own colors, fonts, and symbols, or create the card completely from scratch. Engaging consumers in the product creation process has several positive consequences for companies, such as more positive product evaluations (Bendapudi and Leone 2003), higher individual demand (Franke, Schreier, and Kaiser 2010) and greater willingness to pay (Norton, Mochon, and Ariely 2012), as well as for consumers, such as feelings of competence (Dahl and Moreau 2007) and accomplishment (Norton et al. 2012).

This special session is intended to deepen our knowledge on the consequences for consumers by focusing on two specific benefits of customer engagement: feeling unique and grounded. Whereas all four papers share the emphasis on psychological benefits, they differ in the specific perspective they take. The first two papers focus on need for uniqueness as a salient motivation to customize products and examine strategies that companies can utilize to boost feelings of uniqueness. The first paper by **Burghartz et al.** examines providing uniqueness feedback and the option to block customers' creation as strategies to increase consumers' valuation of the customized product. Similarly, the second paper by **Alarcón et al.** documents that sharing one's customization experience with others (e.g., in a personal message) increases the subjective value of the customized prod-

uct (i.e., consumers feel more proud), because sharing one's choices with others provides consumers with the possibility to express their unique identity.

Rather than examining drivers of consumer engagement, the remaining two papers discuss consequences of engaging in the product creation process. The third paper by **Kaiser, Schreier** and **Janiszewski** reveals that feelings of uniqueness prompted by customizing or producing one's own product give rise to entitled behavior. This may have positive (such as donating more money to charity) or negative outcomes (such as demanding higher salaries). Relatedly, the fourth paper by **Monnier et al.** documents that engaging in self-production leads to feelings of groundedness (i.e. feelings of deep connectedness to one's social, historical, and physical environment). Additionally, the authors explore ways in which companies can prompt vicarious feelings of self-production and, in doing so, increase feelings of groundedness.

Taken together, the four papers in this session answer the following questions: What are psychological benefits of engaging customers in the product creation process? How can companies facilitate these benefits? Importantly, the papers utilize multi-method approaches, combining data from online, lab, and field studies to explore the robustness and generalizability of the proposed effects. Broadly, this session speaks to ACR's call for sessions on the topic of identity by highlighting how customer engagement in the product creation process can allow consumers express their unique identity and help them feel reconnected with themselves. Thus, we believe that this session should not only be of interest to scholars working on customization and self-production, but also to those interested in identity-related topics, such as self-expression, uniqueness, and groundedness.

You're One in a Million: Strict Uniqueness of Mass-Customized Products

EXTENDED ABSTRACT

In this research we investigate extensions of mass customization (MC) systems that highlight the uniqueness of a configured product. It examines the behavioral consequences of informing consumers that they are the first ever to have created a particular product configuration (strict uniqueness *feedback*) and in addition assuring that this product configuration will remain unique (strict uniqueness *blocking*).

Past research has identified preference fit (Dellaert and Stremersch 2005) and process-related benefits (Troye and Supphellen 2012) as sources of consumer value in MC systems. Our findings shed light on the role of product uniqueness (Franke and Schreier 2008) as a value-generating force in MC systems. We conceptualize a strictly unique product as a product that is literally one of a kind—a combination of features that exists only once. This expands our understanding of the construct of product uniqueness, and of how consumers respond to it, beyond products that are merely rare but not strictly unique (Lynn and Harris 1997). Whereas prior research focused on non-automated social feedback, our findings reveal that automated feedback on strict product uniqueness can be a significant driver of consumer value (Franke and Hader 2014).

We propose that feedback on the strict uniqueness of a product ("Your product configuration has never been created before") creates value for consumers and that being informed that the strictly unique product configuration was blocked ("Your configuration will be blocked for future customers") creates additional value.

Hypothesis 1a: *Feedback on strict product uniqueness increases consumers' valuation of their customized products.*

Hypothesis 1b: *Blocking strict product uniqueness further increases consumers' valuation of their customized products.*

Moreover, this research theorizes that perceived exclusivity—i.e., the perception that a product is not available to others—can be a key driver of consumers' valuation of a product. We propose that strict uniqueness feedback and (to a larger extent) strict uniqueness blocking should trigger perceptions of exclusivity which in turn should create value for consumers.

Hypothesis 2:   *Strict uniqueness feedback and strict uniqueness blocking increase consumers' valuation of their customized products via the perception of greater exclusivity.*

We further propose that consumers' valuation of strict uniqueness is attenuated when the (large) number of possible product configurations in MC systems is made transparent to them. By making the solution space of MC systems transparent to consumers the subjective value they attribute to their configured product likely decreases.

Hypothesis 3:   *The effect of strict uniqueness feedback and strict uniqueness blocking on consumers' valuation of their customized products is attenuated when the number of possible product configurations is made transparent.*

We conducted three experiments across different samples and product domains. We also employed different study designs and types of dependent variables to test our hypotheses. Experiment 1 examines whether strict uniqueness feedback has a positive effect on the subjective value that consumers attribute to customized cereal in a field setting (measured as conversion rate; H1a). Analyzing the conversion rates across conditions indicates that uniqueness feedback on the customized product creates value for customers. Specifically, we found a significant difference in conversion rates between the uniqueness feedback and the no feedback condition of 2.24% ($\chi^2(1, 33{,}001) = 16.50$, $p < .001$). This increase in conversion approximates to €1,145,601 in additional yearly revenue for the cereal producer.

Experiment 2 examines whether strict uniqueness blocking, in addition to strict uniqueness feedback, can drive the subjective value consumers attribute to their customized sunglasses (measured as WTP; H1b). Further, it tests whether the additional value consumers attribute to their configured product is mediated by perceived exclusivity (H2). The findings indicate that both uniqueness feedback and uniqueness blocking significantly increased WTP using a between-subject design with non-uniqueness feedback as a third treatment condition. A one-way ANCOVA, with strict uniqueness as factor, WTP as dependent variable, and brand attitude, status consumption, age, gender, and income as covariates showed a signifi-

cant effect of strict uniqueness on WTP. We found a significant effect of strict uniqueness on WTP ($M_{unique\_blocking}$ = US$50.02, $M_{unique\_feedback}$ = US$43.94, $M_{nonunique\_feedback}$ = US$35.47; $F(2, 169) = 10.46$, $p < .001$). Planned contrasts showed a significant difference in WTP between the non-uniqueness and uniqueness feedback (p=.024) and the uniqueness feedback and blocking condition (p=.002).

The results also demonstrate that the effect of uniqueness feedback and uniqueness blocking on WTP is mediated by perceived exclusivity. We conducted two mediation analyses with a categorical predictor (PROCESS Model 4; Hayes 2013). The results show that uniqueness feedback, blocking and non-uniqueness feedback indirectly influence WTP through perceived exclusivity. The effect between uniqueness feedback and non-uniqueness feedback and between uniqueness feedback and blocking on WTP is positive and significant (a = 1.86, $p < .001$; a = 1.05, $p < .001$); in support of the indirect effect (ab < .001), the bias-corrected 95% confidence interval based on 1,000 boot-strapped samples (marginally) excludes 0 ([.08, .34]; [-.00, .19].

Experiment 3 examines whether making the (large) number of sneaker configuration possibilities transparent to consumers attenuates the effect of uniqueness feedback and uniqueness blocking on consumers' product valuation (H3). The findings demonstrate that the effect of uniqueness feedback and uniqueness blocking on WTP is moderated by solution space transparency. A one-way mixed design ANCOVA with solution space transparency as between-subjects factor, strict uniqueness as within-subject factor, WTP as dependent variable, and brand attitude, status consumption, age, gender, and income as covariates showed a significant interaction between solution space transparency and strict uniqueness ($M_{nontransparent\&no\_feedback}$ = €78.94, $M_{transparent\&o\_feedback}$ = €81.82, $M_{nontransparent\&unique\_feedback}$ = €86.90, $M_{transparent\&unique\_feedback}$ = €89.13, $M_{nontransparent\&blocking}$ = €100.02, $M_{transparent\&blocking}$ = €96.73; $F(2, 926) = 4.62$, $p = .010$). While planned contrasts showed significant effects in the non-transparent (p=.005, p<.001), they showed non-significant effects in the transparent conditions (p=.11, p=.14).

The reported findings have important practical implications in that they identify an inexpensive way for firms to create consumer value by capitalizing on the fact that MC systems naturally promote consumers' creation of products that are strictly unique. It appears to be a promising and easy-to-implement way to enhance the value consumers obtain from configuring products.

When I Share, I Feel Unique: Sharing one's Customization Experience Increases Feelings of Pride

EXTENDED ABSTRACT

Nowadays, product customization is omnipresent. Enabled by technological advances, companies (e.g., Nike, Nissan, Gucci) recently began to explicitly encourage customers to share their customization experience with others. For instance, Ralph Lauren offers customers the possibility to share their customization experience with friends via email immediately after they completed the customization process. Prompting customers to share their experience is uniquely suited to customization processes because consumers feel proud of their creations (Franke et al. 2010; Gandhi et al. 2014).

We explore whether the mere act of sharing one's customization experience with others can boost affective reactions (i.e., pride) toward the customized product. When engaging in product customization, customers typically make choices that allow them to express their unique identity (D'Angelo et al. 2019; Ratner and Kahn 2002). We argue that sharing these choices with others (e.g., in a personal message) provides customers with the possibility to express their

unique identity even before they obtain the customized product. Since most consumers have a strong need to differentiate themselves from others (see Ariely and Levav 2000), being able to express one's unique identity should strengthen customers' feelings of pride toward the customized product.

One pilot study and four experiments test our predictions. For the pilot study, we collected data in a KitKat pop-up store that offered customers the possibility to customize their own chocolate by completing a number of steps (base chocolate, toppings, package design). Once participants (n = 121) handed in their customization choices and before they received the chocolate, they participated in a brief survey. Whereas some participants first shared their customization experience (i.e., their choices and how they felt about them; n = 80[1]) and then reported how tasty they expected their chocolate to be (0 = not tasty at all, 10 = very tasty), other participants (n = 41) immediately indicated their taste perceptions. We find that sharing one's customization experience increased the subjective value of the chocolate (M = 9.19) compared to not sharing it (M = 8.59, $F(1,119)$ = 7.43, p = .007).

Then, in study 1, participants (n = 171, prolific) customized a muesli by choosing a base, ingredients, a design for the muesli box, and adding a personalized message. Afterward half of the participants prepared a message to a friend to share their experience by explaining what choices they made and how they felt while customizing the muesli. The other half engaged in an unrelated word-puzzle task (n = 87). We measured participants' feelings of pride toward the customized muesli using a two-item scale: "I am proud of my customized muesli", and "My customized muesli makes me feel proud" (0 = strongly disagree, 10 = strongly agree[2]). Sharing one's customization experience increased feelings of pride (M = 7.27) compared to not sharing it (M = 6.39, $F(1,169)$ = 8.29, p = .005). In study 2 (n = 173, prolific), we utilized the same muesli paradigm but compared sharing one's customization experience to an introspection condition (i.e., participants were instructed to think about their customization experience in private). We replicate our effect so that sharing one's customization experience results in greater feelings of pride (M = 7.57) than merely thinking about it (M = 6.78; $F(1,171)$ = 7.23, p = .008). This provides direct evidence that social sharing rather than simply deliberating on the customization experience prompts feelings of pride.

In studies 3 and 4, we test theoretically derived boundary conditions. First, we predict that sharing one's customization experience only prompts greater feelings of pride if the customization task allows for expressing one's identity but not if it is functional in nature (Kaiser et al. 2017). Students in the laboratory (n = 325) customized their own fitness tracker; participants were randomly assigned to a self-expressive customization task (e.g., choosing the strap color) or a functional task (e.g., choosing the size for the wrist brand). Afterward participants either shared their customization experience by sending a message to a friend or engaged in a word-puzzle task and then reported pride towards the fitness tracker. The results document a marginally significant interaction effect ($F(1,321)$ = 3.68, p = .055). As expected, simple contrasts highlight that sharing one's customization experience (M = 5.97) increases feelings of pride compared to not sharing it (M = 5.12; $F(1,321)$ = 5.17, p = .024) for the self-expressive customization. However, consumers who share their functional customization experience (M = 5.55) feel equally proud

---

[1] Note that some participants (N = 41) shared their experience in writing whereas others (N = 39) shared it orally. Since there was no difference between these groups, we merged the two conditions.
[2] We used the same dependent measure in all subsequent studies.

than those who keep it to themselves (M = 5.69; $F(1,321)$ = 0.16, p = .69).

Study 4 tests whether the effect is pronounced for consumers with high need for uniqueness (NFU) but attenuated (or reversed) for those with low NFU. 215 females customized their own earrings by choosing different hoops and charms; afterward participants either shared their customization experience with a friend or shared an unrelated experience (i.e., their Summer holiday). Finally, everyone indicated their feelings of pride and responded to the NFU measure by Chernev et al. 2011 (three items; e.g., "I would like to be perceived as different from the general population"; 0 = strongly disagree, 10 = strongly agree). We find a significant interaction effect (β=.37, $t(211)$ = 3.27, p = .001). Sharing one's customization experience results in higher feelings of pride for participants high in NFU (i.e., values ≥ 7.99) but prompts lower feelings of pride for participants low in NFU (i.e., values ≤ 4.51).

This work contributes to existing research on product customization by highlighting an easy-to-implement strategy (i.e., encouraging social sharing of customization experiences) that companies can utilize to further boost feelings of pride, which are essential predictors for repurchasing intentions (Septianto et al. 2019) and self-brand connections (Williams et al. 2018).

Me, me, me: Customization, Uniqueness, and Entitled Behavior

EXTENDED ABSTRACT

Psychological entitlement – that is, a person's "pervasive sense that one deserves more and is entitled to more than others" (Campbell et al. 2004, p. 31) – has become a major topic of interest to both the general public and scholars. Entitled individuals believe they are special, and they expect others to treat them this way (Zitek and Vincent 2014). Entitlement does not involve any reciprocity (e.g., "I deserve a higher salary because I performed well"), but is experienced regardless of one's effort or performance relative to others (Campbell et al. 2004).

Most research to date has studied entitlement as an individual differences characteristic. There is a large body of research on different facets of entitlement, how it is related to other traits (e.g., narcissism, self-esteem, etc.), and on generational differences (Twenge and Campbell 2009). There is also an emerging body of research on behavioral consequences. For example, entitlement is associated with selfish choices, unethical behavior, unforgiveness, or lack of perspective taking (Campbell et al. 2004, Exline et al. 2004, Vincent and Kouchaki 2016). While most research has focused on negative outcomes, Zitek and Vincent (2014) are the exception. They show that a boost in entitlement can increase creativity, mediated by a higher need for uniqueness associated with entitlement.

In this paper, we focus on the less studied antecedents of entitlement. In particular, we are interested in exploring causal triggers that lie outside the individual. To our knowledge, we are the first to demonstrate that uniqueness cues that are ubiquitous in the marketplace (think of customized products, limited editions, or advertising claims that tell consumers how unique and special they are) lead to entitled behaviors. We report five experiments that establish the link between perceived uniqueness and entitled behavior.

In study 1 (n = 280, lab, undergraduates) we introduced a clothing style quiz. After completing the quiz, participants received feedback that either stated that their style was "in many respects unique and special" or "similar to others". Next, we measured salary demanded to complete a job as a known proxy for entitled behavior. Participants were told that they could work on an extra task in return

for payment. We described the task in more detail (it was about a blog entry), and participants were then asked to indicate the minimum payment to complete the job. Their choices had real economic consequences. Findings show that the uniqueness feedback resulted in higher average salary requests (M_{Unique} = 16.35 euro vs. $M_{Control}$ = 14.28 euro, p = .01).

In study 2 (n = 182, Amazon Mechanical Turk) we used a similar quiz to manipulate uniqueness, but instead of salary request, we measured prosocial behavior as a proxy for entitled behavior. After participants received the uniqueness feedback ("your style is unique" vs. "similar to others"), they were told that we would randomly pick one participant to get a bonus payment of $ 25. Participants were asked to indicate how much of the bonus payment they would like to receive on their MTurk account, and how much they would like to donate to Doctors Without Borders (conditional on winning). Again, their choice had real economic consequences. Results show that the uniqueness feedback increased donations (M_{Unique} = $ 8.89 vs. $M_{Control}$ = $ 6.01, p = .03). We argue that this is because their generosity served as a means to express that they are unique and special (Lee, Gregg, and Park 2013).

In study 3a (n = 97, MTurk) and 3b (n = 201, MTurk), we replicate the effect on donation, using two different uniqueness manipulations. In study 3a, we used a writing prime. Participants were asked to write a short text about "what makes you unique and special" vs. "similar to others". The dependent variable was the same as in study 2. Results show that perceived uniqueness increases donations (M_{Unique} = $ 8.89 vs. $M_{Control}$ = $ 6.01, p = .03). Study 3b was a scenario study in which participants learned about a uniquely designed watch. They were either asked to imagine wearing the watch or seeing another person wearing it. Next, we assessed their intention to donate to Doctors Without Borders (in this study, we used intentions instead of real behavior). Again, in the experimental condition, donation intentions were higher (M_{Unique} = $ 6.90 vs. $M_{Control}$ = $ 5.44, p = .08).

Study 4 (n = 222, lab, undergraduates) is a 2 x 2 experiment that employed a real customization task (self-customize vs. control). The second factor was whether participants donated to charity in private or in public. Students participated in a lip balm workshop and either received a self-customized product or a standard product. After answering some filler questions, they were thanked for their participation and received their monetary compensation. We paid 8 euro in coins. Participants were invited to donate all or some of the money to a charity. The donation box was either placed in a cubicle (private) or next to the experimenter (public). Findings show that after receiving the self-customized product, participants donated more when the donation was done in private (M_{Unique} = 1.19 euro vs. $M_{Control}$ = 0.65 euro, p = .01), but not when they donated in public (M_{Unique} = 1.12 euro vs. $M_{Control}$ = 1.25 euro, $n.s.$). In the private setting, being more generous served as means to express their uniqueness. In the public setting, this effect is attenuated due to social desirability effects.

Taken together, five experiments show that marketplace-induced feelings of uniqueness (e.g., through customization) lead to entitled behaviors. We also show that entitlement is not only associated with self-centered and selfish behaviors (e.g., demand higher salary), but that it can also lead to favorable behaviors (e.g., prosocial behavior).

How Self-Production Increases Feelings of Groundedness

EXTENDED ABSTRACT

In an increasingly fast-paced, urbanized, and digitized world, individuals often feel uprooted from their environment. Accordingly, many frequently experience a need for reconnection (Asimov 2017;

Binkley 2008; Brooks 2018; Husemann and Eckhardt 2019; Steiner 2005). We propose and show that engaging in self-production generates feelings of groundedness, defined as feelings of deep connectedness to one's physical, social, and historical environment.

Previous research has established that self-production increases product valuation (Franke, Schreier and Kaiser 2010; Norton, Mochon and Ariely 2012). This literature has also delineated some of the psychological implications of engaging in self-production. For individuals, these include feelings of competence (Dahl and Moreau 2007; Mochon, Norton, and Ariely 2012), feelings of accomplishment (Franke et al. 2010; Norton et al. 2012), and task enjoyment (Dahl and Moreau 2007). At the product level, implications include the transfer of positive self-views to the product, through a process of associative self-anchoring (Gawronski, Bodenhausen, and Becker 2007; Troye and Supphellen 2012).

Across lab and field studies conducted on two continents and utilizing diverse product categories, this research documents a novel psychological benefit of engaging in self-production: increased feelings of groundedness. We further demonstrate how evoking the realm of self-production enables brands to generate vicarious feelings of self-production, and subsequently increase groundedness.

In a first preregistered experiment, we tested the basic effect of self-production versus mere consumption of a product on feelings of groundedness. We randomly assigned 293 US students to one of two conditions (self-production vs. control). In the self-production condition, participants were instructed to make apple juice with local apples. The procedure involved selecting, cutting and juicing the apples. In the control condition, participants were simply provided with the same apple juice made from local apples. All participants tasted the apple juice and answered our three-item groundedness scale (α = .88). The three items include two verbal statements ("I feel deep-rooted", "I feel well-grounded") and a pictorial item, "How well does the following picture describe your feelings at this moment?"). We found a main effect of self-production on feelings of groundedness ($F(1,291)$ = 10.38, p =.001). Participants felt significantly more grounded in the self-production condition ($M_{Self-production}$ = 4.74, $M_{Control}$ = 4.25).

Study 2 tested whether merely consuming a product that evokes the realm of self-production can also elicit vicarious feelings of self-production and, in turn, feelings of groundedness. We hypothesized that artisanal products that resemble self-made goods would increase feelings of groundedness compared to industrial products, but less so than self-producing. We further posited that this occurs through vicarious feelings of self-production. To explore this, we randomly assigned 251 European students in a lab to one of three conditions. Participants in the first two conditions were asked to inspect a real bar of soap that was either industrial or artisanal (i.e., locally made by hand from organic ingredients and wrapped in a craft packaging). They were asked to imagine having just purchased the bar of soap. Participants in the third condition were asked to imagine having made a bar of soap themselves. All participants answered our groundedness scale (α = .91), as well as feelings of self-production (three items, e.g., "In a certain way, it almost feels as if I were the producer of the soap", α = .97). We found a significant treatment effect on feelings of groundedness $(F(2,248)$ = 21.30, p < .001). Participants who inspected the artisanal soap reported higher feelings of groundedness ($M_{Artisanal}$ = 4.32) compared to those who inspected the industrial soap ($M_{Industrial}$ = 3.35, p < .001). Participants in the self-production condition reported even more pronounced feelings of groundedness (vs. the artisanal condition, $M_{Self-production}$ = 4.77, p = .037). We also found a significant treatment effect on feelings of self-production ($F(2,248)$ = 106.71, p < .001). Participants who inspected

the artisanal (vs. industrial) soap reported higher feelings of self-production ($M_{\text{Artisanal}}$= 2.92, $M_{\text{Industrial}}$ = 1.63, $p < .001$). Participants in the self-production condition had even higher feelings of self-production (vs. the artisanal condition, $M_{\text{Self-production}}$ = 5.05, $p < .001$). The groundedness effect was mediated by feelings of self-production for both the artisanal versus industrial (*indirect effect* = .64, $CI_{95\%}$: .39, .94) and the self-production versus artisanal comparison (*indirect effect* = .71, $CI_{95\%}$: .44, 1.06).

Study 3 aimed to replicate our findings in a field setting, using yet another product category (i.e., birthday cards). Additionally, we examined plausible alternative explanations such as mood and perceived quality. The study was conducted in a large museum in a European city (n = 269 museum visitors). In one condition, participants were given a blank card and color pencils, and asked to self-produce a birthday card. Two additional conditions exposed participants to an either industrial or artisanal birthday card. All participants read that other museum visitors would receive these cards. Beyond feelings of groundedness (α = .91) and feelings of self-production (α = .97), we captured alternative accounts: time on the task, perceived quality, mood, thoughts about close others and thoughts about birthdays. We found a main effect of condition on feelings of groundedness that parallels that of Study 2 ($M_{\text{self-production}}$ = 4.71, $M_{\text{Artisanal}}$ = 3.98, $M_{\text{Industrial}}$ = 3.08, $F(2,252)$ = 28.86, $p < .001$). The same pattern emerged on feelings of self-production. We found a main effect of condition ($M_{\text{self-production}}$ = 6.11, $M_{\text{Artisanal}}$ = 3.24, $M_{\text{Industrial}}$ = 1.42, $F(2,254)$ = 222.31, $p < .001$). The groundedness effect was again mediated by feelings of self-production for both the artisanal versus industrial (*indirect effect* = .55, $CI_{95\%}$: .31, .87), and the self-production versus artisanal comparison (*indirect effect* = .40, $CI_{95\%}$: .06, .79). Regarding alternative accounts, mood was higher in the self-production condition, but did not vary between the two others. Perceived quality significantly differed across conditions, but the mediation held when adding quality as covariate. No other measure varied across conditions.

Our research demonstrates a robust effect of self-production on feelings of groundedness, and illuminates how brands can also beget such feelings. We thus identify groundedness as a distinct and critical psychological need that consumers fulfil when engaging in self-production.

SESSION OVERVIEW

There is worldwide concern over false news and the possibility that it can influence political, economic, and social well-being. From 2006 to 2017, false news reached more people and spread faster than truth (Vosoughi, Roy, and Aral 2018). While false information seems to diffuse faster, when asked, consumers overwhelmingly say that it is important for them to share accurate content only (Pennycook et al. 2019). The presentations in this session examine this puzzling phenomenon and identify potential antecedents of and remedies to the spread of false information on social networks. In this session, we explore whether (presentations 1) and how (presentation 2) consumers' self-presentation goals impact what they spread on social networks. Further, we explore potential remedies that can improve the quality of the information consumers share on social media both from the sharer (i.e., consumer; presentation 3) as well as the source (i.e., news media; presentation 4) perspective.

Ceylan and Schwarz explore spreading information (e.g., news) on social media as a strategic form of self-disclosure. They find that individuals with the motivation to fit in share news only if it comes from a high-credibility source or is also shared by many others (high-consensus). However, those motivated to stand out are less sensitive to source credibility and consensus, and may be more likely to contribute to the spread of false information.

Silver, Small, and Goodwin examine a motivated *sharing* effect, suggesting that consumers prefer to omit attitude-incongruent, factual information from conversations with others. The authors predict and find that political allies provide one another with biased information, strategically omitting factual and relevant evidence if it casts doubt on their commitment to a shared cause. This effect is magnified when consumers share information in public versus in private, implicating impression management concerns specifically.

Pennycook et al. directly examine the relationship between accuracy judgments and sharing intentions. They propose that most people do not want to spread misinformation but are distracted from accuracy by other salient motives when choosing what to share. As a remedy to the problem, they suggest that subtly inducing people to think about the concept of accuracy increases the quality of the news they share.

Ding and Johar propose a method to leverage the input of the general population (crowdsourcing), algorithm (supervised learning), and experts (third-party checkers) to detect false information. They suggest that asking readers to compare the opinions and viewpoints of two articles (as opposed to asking them to directly evaluate the source or the articles) can be a way to overcome motivated reasoning among people with different ideologies.

Taken together, these papers document novel and timely insights into important implications of spread of false information. All papers are at an advanced stage of development with multiple studies completed. We expect this session to generate strong interest among researchers studying false information, impression management, social influence and social judgment, as well as social media and word-of-mouth more broadly.

Look What I am Re-Sharing: How Self-Presentation Goals Impact What Consumers Re-Transmit on Social Networks

EXTENDED ABSTRACT

Information spreads fast on social platforms. Consumers re-transmit news on Facebook, re-share others' photos on Instagram, re-tweet the quotes from their beloved companies or political parties (e.g., Chevalier and Mayzlin 2006; Trusov, Bucklin, and Pauwels 2009). These decisions seem to be made in seconds. Consumers seem to be quicker to share than to read the information. A recent Twitter study found that 59 percent of all links shared went unclicked, and presumably unread (Gabielkov, Ramachandran, Chaintreau, and Legout 2016). Instead of attending to central elements (i.e., the quality of information), consumers seem to attend to peripheral cues, such as the source of the information. We suggest that this quick evaluation process may be moderated by consumers' salient self-presentation goals.

Prior research showed that consumers evaluate content differently depending on their salient motivation in their social network. For instance, they seem to share more self-presenting content (vs. useful content) when sharing with multiple others (vs. one other; Barasch and Berger 2014). Our research examines the impact of self-presentation goals on sharing decisions and shows that consumers who want to fit in prefer to share popular (vs. unpopular) information from well-known (vs. unknown) and credible (vs. less credible) sources, whereas consumers who want to stand out are willing to share regardless of the source and popularity of the content. Despite these differences in sharing, both groups of consumers find information more truthful when it comes from a well-know and familiar source, indicating that those who want to stand out are willing to share information they may not consider truthful.

Study 1. Following a 3 (Self-Presentation Goal: Fit-in vs. Stand-out vs. Control) x 2 (Credibility: High vs. Low) x 2 (Consensus: High vs. Low) mixed design, participants (N=152; undergraduates) were randomly assigned to one of the self-presentation goal conditions. They rated four news headlines that were combined with either a high (e.g., New York Time) vs low (e.g., Denver Guardian) credibility source. The news had ostensibly been shared by 790,000

vs. 79 people, resulting in high vs. low perceived social consensus. We assessed participants' willingness to re-share the information on their social network and its perceived truthfulness. Fifty-one participants were removed; 3 of them completed less than 10% of the survey and the remainder failed the attention check.

A repeated measures ANOVA indicated an interaction of goal, credibility and consensus, $F(2, 98)= 5.09$, $p = .01$. As expected, participants who had the goal to fit in reported higher willingness to share under high-credibility/high-consensus conditions ($M=6.70$, $SE=1.95$, $N=21$) than under low-credibility/low-consensus conditions ($M=4.73$, $SE=2.44$, $N=21$); mixed conditions (low-credibility/high-consensus or high-credibility/low-consensus) fell in between ($M=5.76$ $SE=1.83$, $N=21$). In stark contrast, neither source credibility nor consensus information had a significant influence when participants had the goal to stand out (high/high, $M=5.35$, $SD=2.33$, $N=27$; low/low, $M=5.12$, $SD=2.38$, $N=27$; mixed, $M=5.30$, $SD=2.10$, $N=27$). These differences in reported willingness to share could not be traced to differences in truth perception. Independent of self-presentation goal, participants found high-credibility/high-consensus news more truthful ($M=5.46$, $SD=1.18$, $N=98$) than low-credibility/low-consensus news ($M=4.20$, $SD=1.34$, $N=98$), with the mixed conditions falling in between ($M=4.95$, $SD=1.04$, $N=98$), $F(1,118)=69.65$, $p<.001$.

In sum, consumers who have the goal to fit in seem to attend to the likely veracity of information before they share it, which is not the case for consumers who want to stand out. Study 2 provides a conceptual replication of this finding and explores the role of the interest value of the news (boring vs. interesting).

Study 2. Next, we tested (N = 340; undergraduates) whether our results hold when we measured people's need for uniqueness using the scale from Snyder and Fromkin (1980). Since sharing news from low credibility is particularly problematic, we paired news headlines (same with Study 1) with only low credibility sources (e.g., Denver Guardian). We expected and found that as people's need for uniqueness increases, they become more likely to share news headlines coming from low credibility sources (ß=0.7, t=3.8, p<.001). As expected, need for uniqueness was not associated with truth judgment (t<1). Our correlational study provided consistent findings with study 1 when people's uniqueness needs were measured.

Study 3. We wondered whether people with uniqueness need would take interest value of the content into account more so than other people. Following a 3 (Self-Presentation Goal: Fit-in vs. Stand-out vs. Control) x 2 (Credibility: High vs. Low) x 2 (Content: Interesting vs. Boring) between-subjects (N=170; undergraduates) design, participants were randomly assigned to one of the self-presentation goal conditions. They rated four news headlines that were either interesting (pretested, $M=5.14$, $SD=1.55$) or boring ($M=3.65$, $SD=1.86$) and combined with either a high (e.g., New York Time) or low (e.g., Denver Guardian) credibility source.

Replicating the pattern of Study 1, willingness to share depended on motivation and source credibility, $F(2,165)=2.95$, $p=.06$, for the interaction. Participants with a fit-in goal reported greater willingness to share when the news came from a high-credibility ($M=4.06$, $SD=2.28$, $N=29$) rather than low-credibility source ($M=2.78$, $SD=1.60$, $N=25$), $F(1,52)=5.50$, $p=.02$, for the simple effect. In contrast, source credibility did not influence willingness to share when participants had a stand-out goal, $F(1,54)=.05$, $p=.82$; the latter condition did not differ from the control condition, $F(1,58)=1.52$, $p=.22$. In addition, all participants were more willing to share interesting news ($M=4.30$, $SD=2.14$, $N=75$) than boring news ($M=3.43$, $SD=2.09$, $N=90$), $F(1,168)=6.97$, $p=.009$, independent of their self-presentation goal, $F(2,165)=.95$, $p=.39$, for the interaction. With this study, we confirmed our main hypothesis but did not find support

for a relationship between uniqueness need and interest value of the content.

In combination, our findings highlight that consumers' self-presentation motives play a key role in their re-sharing decisions in online networks. People with high need for uniqueness may be less sensitive to credibility cues and share information coming from any source, which may expose them to spread of misinformation. Ongoing studies examine which aspects of information consumers attend to when they want to stand-out. Given the spread of misinformation stemming from less-known and less credible sources, it is important to understand the interplay of consumer motivation and news characteristics.

Impression Management in the Echo-Chamber: How Self-Censorship Biases Evidence-Sharing

EXTENDED ABSTRACT

The free exchange of ideas on the internet has led to the formation of ideological echo chambers, in which attitude-congruent information circulates while attitude-incongruent information is filtered out (Del Vicario et al. 2016). Indeed, people preferentially seek and consume information that aligns with their pre-existing moral and political attitudes about important issues like gun control, climate change, or immigration. In explaining these dynamics, past research has highlighted the roles of prior attitudes and motivated reasoning, which together cause consumers to selectively attend to, believe, and remember attitude-congruent information and to avoid, discredit, and forget attitude-incongruent information (Golman, Haggman, and Lowenstein 2017; Kahan 2012; Kunda 1990). Above and beyond motivated *reasoning*, we report a motivated *sharing* effect: Consumers prefer to omit attitude-incongruent, factual information from conversations with others.

Specifically, we propose that when sharing information with like-minded others, people will selectively omit relevant evidence that might cast doubt on their loyalty to shared causes. For example, we predict that a liberal sharing results from a report on the welfare effects of cutting taxes will strategically omit findings which speak to the effectiveness of stereotypically conservative tax policies. By contrast, a conservative will omit from the same report findings that speak to the effectiveness of stereotypically liberal tax policies. Although both sides purport to be concerned with the actual effects of cutting taxes, individual actors on both sides are also concerned about appearing appropriately committed to their respective political movements.

This phenomenon – a bias towards sharing attitude-congruent vs. attitude-incongruent facts – represents a form of self-censorship, rooted in concerns about impression management (Schlenker 1980). Critically, this bias exerts influence above and beyond processes of motivated reasoning: Even when information is believed to be factual and relevant, worries about the inferences others might make if one *shares* that information will lead consumers to censor it from conversation.

In, study 1 (pre-registered, n=300) participants read a real news article which outlined facts both supporting and undermining the idea that President Trump deserves credit for recent growth in the US economy. After reading, participants were presented sequentially with six specific facts taken from the passage. Three of these facts supported Trump's performance (e.g., 'Early last week, the stock market hit a new all-time high, something that has happened multiple times under President Trump'); while the other three undermined Trump's performance (e.g., 'Job growth has been gradually slowing since Donald Trump's inauguration'). We classified each of

these items as attitude-congruent or attitude-incongruent on the basis of participants' answers to an initial question about their broader attitudes towards Trump's presidency. Participants were asked to imagine having a conversation with a friend or peer who shared their general views about the president and to report how likely they would be to bring up each fact in conversation (7-point likelihood scale). They also rated the extent to which they believed each fact to be true/accurate and the extent to which they believed each to be relevant to understanding Trump's job performance overall. Controlling for these variables in our analyses allows us to isolate self-censorship from other motivated reasoning processes. In line with our predictions, we found that, controlling for their perceptions of accuracy and relevance, participants were much less likely to share attitude-incongruent (M=3.41, 95% CI = [3.26, 3.55]) vs. attitude-congruent facts (M=4.79, 95% CI = [4.65, 4.95]; $t(1557.7)=16.5$, $p<.001$). This effect held for both Trump-supporters and Trump-detractors ($ps<.001$).

Study 2 (preregistered, n=519) aimed to replicate these results in a new context and to tie them specifically to impression management concerns. Study 2 followed a similar procedure to Study 1 with the following differences. In Study 2, participants read a two-sided article about gun control and made judgments about six facts: three supporting and three undermining the case for increased gun regulation in the US. We again classified these facts as attitude-congruent or attitude-incongruent. This time, participants were asked to imagine summarizing what they had read either for their own future use (private condition) or to share with and inform a political ally (public condition). Next, they reported how likely they would be to include each fact in their summary (7-point likelihood scale). We again found that, above and beyond perceptions of accuracy and relevance, participants indicated a lower likelihood of including attitude-incongruent facts (M=4.41, 95% CI = [4.33, 4.49] in their summaries than attitude-congruent ones (M=5.14, 95% CI =[5.06, 5.22]; $t(2738.1)=13.3$, $p<.001$). Importantly, we also detected an interaction, whereby reluctance to include attitude-incongruent facts was significantly stronger for a summary that would be made public than one which would be kept private ($t(2590.7)=5.1$, $p<.001$). That the attitude-incongruence effect was larger in public than in private implicates social-signaling concerns specifically, above and beyond self-signaling or mere dislike of dealing with attitude-incongruent information *per se*. Again, all results held for both pro-gun and anti-gun participants ($ps<.001$).

Consumers typically expect those who share their moral attitudes to be trustworthy sources of information (Haidt 2012). By contrast, we predict and find that political allies provide one another with biased information, strategically omitting factual and relevant evidence if it casts doubt on their commitment to a shared cause. This self-censorship effect can explain, at least in part, the prevalence of political echo-chambers among groups of like-minded consumers: People prefer not to share facts that challenge their image as loyal group members.

More broadly, our results suggest that consumers hoping to gather all of the facts on complex and consequential issues must contend not only with the *presence* of irrelevant and factually inaccurate information in their environment (i.e., fake news; Bago, Rand, and Pennycook 2020) but also with the *absence* of relevant, factual information, particularly when sourcing evidence from political allies.

Understanding and Reducing the Spread of Misinformation Online

EXTENDED ABSTRACT

The spread of misinformation – including blatantly false political "fake news'" – on social media has become a major focus of public debate and academic study in recent years [1]. Here we investigate this willingness to share seemingly unbelievable content, and ask what it can tell us about how to design interventions to reduce the spread of misinformation.

In a series of survey experiments, we provide evidence that the problem is not that people simply cannot tell what news is true versus false, or that people can tell but simply do not care. Instead, it seems that the sharing of misinformation is rooted in a distraction-based failure to *consider* the accuracy of claims. As a result, nudging participants to think about the concept of accuracy by asking them to rate the accuracy of a single non-political headline substantially reduces their self-reported willingness to consider sharing false (but not true) headlines.

To corroborate these findings in an ecologically valid domain, and evaluate the efficacy of potential social media interventions to reduce the spread of misinformation, we conduct a digital field experiment on Twitter.

Specifically, we sent users direct messages from a set of bot accounts asking them to rate the accuracy of a single non-political headline. Our subject pool consisted of N=5,379 Twitter users who had previously (re)tweeted links to Breitbart or Infowars, two leading misinformation sites. To allow for causal inference, we used a stepped-wedge (randomized roll-out) design in which users were randomly assigned to a date on which to receive the treatment message. Within each 24-hour time-window, we then compared the links shared by users who received the treatment message at the beginning of that time window to the links shared by all the users who had not yet been messaged (who thereby represented the control condition). We then combined estimates across dates to arrive at an overall treatment effect (This randomized roll-out approach is required, instead of a more traditional approach where half of the subjects receive treatment at the same time while the other half act as the control, because the rate limits imposed by Twitter forced us to only send a small number of messages per account per day).

To quantify the quality of the news shared in any given tweet, we used a previously published list of 60 news websites whose truthworthiness was rated by professional fact-checkers [2].

As predicted, we find that the intervention leads to a 1.9% increase (p=.009) in the average quality of new sites shared (5% increase when estimating the treatment effect just on users who actually tweet - i.e. excluding "never taker" user-days). Given the complexity of the experimental design and tweet data, there are a multitude of reasonable approaches for assessing whether our intervention successfully increased the quality of news sharing. Thus we computed effect size estimates using 98 different analysis approaches. Considering the analyses in aggregate provides strong evidence that, indeed, the accuracy message significantly increased the average quality of news sources subsequently shared by the users in our experiment. For the large majority of analytic approaches, the increase is statistically significant (p<0.05 in over 80% specifications). Finally, a domain-level analysis provides a more detailed picture of the effect of the intervention.

Our results highlight an overlooked avenue by which social media fosters the spread of misinformation. Rather than (or in addition to) the often-discussed phenomenon of echo chambers and filter-bubbles, social media platforms may actually discourage peo-

ple from reflecting on accuracy. These platforms are designed to encourage users to rapidly scroll and spontaneously engage with their newsfeeds, and mix serious news content with emotionally engaging content where accuracy is not a relevant feature (e.g., photos of babies, videos of cats knocking things off tables for no good reason). Social media platforms also provide immediate quantified social feedback (e.g., number of likes, shares, etc.) on users' posts and are a space which users come to relax rather than engage in critical thinking. These factors imply that social media platforms may, by design, tilt users away from considering accuracy when making sharing decisions. But this need not be the case. Our treatment translates easily into interventions that social media platforms could employ to increase users' focus on accuracy. For example, platforms could periodically ask users to rate the accuracy of randomly selected headlines (e.g. "to help inform algorithms") - thus reminding them about accuracy in a subtle way that should avoid reactance. The platforms also have the resources to optimize the presentation and details of the messaging, likely leading to effect sizes much larger than what we observed here. Such an approach could potentially reduce the amount of misinformation circulating online without relying on a centralized institution to certify truth and censor falsehood.

Factchecking Matters: The Value of Crowdsourcing for Enhanced Accuracy Judgments

EXTENDED ABSTRACT

Misleading information on news media is of key interest to individual readers, publication managers, and policy makers. In recent years, both mass media and social media are rated as more biased than ever before (Pew Research 2018; Garimella and Weber 2017). In fact, online news media were found the most politically polarized in the U.S. compared to other countries (Reuters 2017).

However, most research and industry reports have relied on individual readers' self-reported beliefs and opinions to measure media trustworthiness (Pennycook and Rand 2019; Reuters 2017). For instance, readers are usually asked to answer questions such as "Does [certain news media company] provide accurate and reliable news?" or "How trustworthy is [certain news media company]?" There are two critical issues with this approach which we highlight in our first study. First, the target of these questions is news media (rather than the article content) which is problematic because the names of news media can lead to biased responses based on prior beliefs (Knight Foundation and Gallup 2017). As suggested by research on motivated reasoning (Kunda 1990), the conclusions drawn from readers' belief measures are highly driven by readers' ideology and largely affected by which readers are sampled (Mercier and Sperber 2011; Kahan 2012; Van Bavel and Pereira 2018). So far, neither researchers nor industry practitioners have found a reliable measure of article accuracy. In this research, we propose a new approach to utilizing crowdsourcing to uncover misinformation on news media at the level of individual articles.

We propose a form of cognition-based judgment, similarity judgment, which asks readers to compare how the opinions and viewpoints of two articles are different from or similar to each other. Because our proposed similarity judgment is constructed rather than retrieved (Tversky 1977), such judgment is less likely to be biased by readers' ideology and more likely to reach high consensus among different reader populations, regardless of their prior beliefs or motivations.

Study 1 examines the problems with using evaluation questions to rate accuracy at the media outlet level. This study involved 611,188 online reader votes on 100 mainstream English news media

publishers. Readers and experts separately rated each publisher on its political ideology biases on a 5-point scale from -2 to 2 (-2 = "left", -1 = "left-center", 0 = "least biased", 1 = "right-center", 2 = "right"). We compared the mean of reader voting poll with expert ratings on media political ideology biases. Results revealed that general readers rated the media more left biased than the experts did, $t(99) = 3.30$, $p = .001$, $d = 0.35$. The results also yielded a significant effect of the variance of reader's rating on the reader-expert difference such that the larger the variance among reader's rating, the bigger the discrepancy between reader's rating and expert's rating ($b = 0.34$, Robust $SE = 0.13$, $t(97) = 2.62$, $p = .010$). In other words, readers' ratings of media appear to be affected by their prior beliefs and are not consistent with expert opinion.

Study 2 examines our hypothesis that similarity judgment questions can be effective in judging accuracy of news articles. Participants were instructed to read three news articles that either supported the idea of climate change or disagreed with climate change arguments. Half of the participants were asked to make evaluation judgments (e.g., how trustworthy the argument was in each article); the other half of the participants were asked to make similarity judgments (e.g., how similar are the arguments between two articles). Results revealed that responses to evaluation questions are largely affected by readers' political ideology with correlations varying from 0.73 to 0.83. For example, more liberal participants were more likely to rat an article that is against climate change false, $b = -.37$, $p = .002$; but rate an article that shows evidences of climate change true, $b = .45$, $p < .001$. Importantly, similarity judgment ratings were not affected by political ideology, $ps > .88$. That is, both conservative and liberal participants rated the similarities between articles in the same way regardless of their political ideology. The relationship between question type and participant's cognitive ability showed different patterns. Although political ideology does not affect the Cognitive Reflection Task (CRT) score (Thomson and Oppenheimer 2016), $b = -.06$, $p = .34$, participants with higher CRT score were better able to distinguish articles with opposing arguments, $b = -.56$, $p = .002$. However, the CRT score does not affect the relationship between political ideology and response to evaluation questions. Study 3 replicated the findings in Study 2 with a similar experimental design and another set of news articles.

In the last ongoing study, we are incorporating expert ratings, reader ratings, semantic markers, and the similarity matrix generated from text analysis tools to build a tool that can help make accurate accuracy judgments. We also examine the extent to which crowdsourced similarity judgments can add over and above machine learning tools to judgments of article accuracy. This project utilized tools that span disciplines and is timely, relevant, and critical.

Paper #4: Heritage Loss: How Connection to the Past Shapes Consumer Valuation in the Present

Kate Christensen, University of California, Los Angeles, USA
Suzanne Shu, University of California, Los Angeles, USA

SESSION OVERVIEW

Buying and owning material and experiential products is indispensable for consumer judgment and decision making. Notwithstanding that initial research on ownership has concentrated on legal ownership's effect on valuation (e.g., Kahneman, Knetsch, and Thaler, 1990), recent research on psychological ownership has examined the effects of regarding something as "mine" in wide variety of areas from digital technology to financial decision making (Peck & Shu, 2018; Pierce, Kostova, & Dirks 2001). The present session gives prominence to the diverse impacts of ownership on consumer behavior.

The emergence of the sharing economy motivates the first paper (Demirdag and Shu) to consider the psychological ownership of these new shared goods and services. The authors document that sharing economy products like Uber rides or Airbnb stays produced a lower sense of psychological ownership than legal car or home ownership. By separately manipulating psychological ownership through intimate knowledge of the target and variety, the authors increase satisfaction with these shared services. Moreover, they demonstrate that collective (vs. individual) experiences reduced tip and satisfaction through reduced psychological ownership, suggesting that experiences in certain sharing economies are inherently solitary.

The second paper (Luangrath, Peck, Hedgcock, and Xu) examines the effect of vicarious touch. The authors study whether observing someone else touch a product increase the psychological ownership of a virtual limb and, hence, increase the psychological ownership of products. They find evidence for this effect, labeled the vicarious haptic effect. They find that vicarious touch leads to the psychological ownership of a product via a sense of body ownership of a virtual limb. This mediation holds under egocentric (from the perspective of oneself) but not allocentric (from the perspective of others) orientation.

The third paper (Jung, Peck, Palmeira, and Kim) investigates an effect of introductions of upgraded products on consumers' brand preference and examine how the effect may differ depending on ownership status. They find that the owners' feeling of being distanced from the brand decrease the owners' preference for the brand. Nevertheless, there is a positive effect of upgraded product for non-owners because without an anchor for self-referencing, non-owners are only positively influenced by the brand's competence signaled by its advanced products.

The final paper (Christensen and Shu) explores ownership felt towards extraordinary goods where ownership is collective, extending the self by connecting owners to history and important traditions. They establish a gap between a seller's willingness to accept from family versus from strangers, which is greater for inherited goods than for purchased goods. In addition, the paper identifies heritage value, that is, the degree to which an object extends the self by connecting the owner to history and traditions. They demonstrate that this heritage value predicts the gap in willingness to accept from family versus strangers.

Ownership is a key corollary of consumption, and this session spotlights its extensive applicability to consumer behavior. The diverse approaches taken by each paper and the varying aspects of ownership investigated will attract a broad range of ACR members interested in ownership, endowment effect, sharing economy, virtual reality experience.

Creating Ownership Where Ownership Does Not Exist: Psychological Ownership Increases Enjoyment in Sharing Economy

EXTENDED ABSTRACT

Since the 1950s, hyper-consumption, and ownership has defined economic security. A 1955 LIFE magazine article celebrated the idea of throwing away items after single-use and advertised several of these items, e.g., single-use barbeque grill, disposa-pan that "eliminates scouring of pots after cooking", and feeding bowl for pets that ends the "washing-up chore" ("Throwaway Living," 1955). Nowadays, we increasingly have a "reduce, reuse, and recycle" mentality. This notable shift away from the "own and dispose" society has laid foundations for the sharing economy. Consumers have come to the realization that legal ownership is not mandatory for consumption. They can access goods and services they cannot afford to purchase or simply do not own at the time of the consumption decision. To an increasing extent, value relies on technology and consumer experience, rather than ownership.

We examine a facet of sharing economy that has not been studied yet: psychological ownership, which is the sense that something is "mine" (Pierce, Kostova, & Dirks, 2001). The sharing economy presents novel ways of accessing goods and services without legal ownership. We suggest that consumption in this domain reduces psychological ownership compared to consumption based around legal ownership. This is problematic, as it can lead to the tragedy of the commons. For instance, shared scooters are vandalized, tossed off buildings, set on fire, and thrown into the ocean (Newberry, 2018). Our studies seek to increase psychological ownership, which could prevent these types of disastrous behavior.

In Study 1 ($N = 321$), we found that ownership of a hypothetical Uber ride is significantly correlated with the consumers' willingness to pay for the ride ($r = .14$, $p < .05$), tip for the Uber driver ($r = .11$, $p < .05$), and ride satisfaction ($r = .19$, $p < .01$). Furthermore, through planned comparisons we showed that real-life car owners

have a greater sense of ride ownership than real-life car leasers (F (1, 605) = 169.2, $p < .001$) and that leasers have a greater sense of ride ownership than Uber riders (F(1, 605) = 166.5, $p < .001$). Similarly, we found that real-life homeowners have a greater psychological ownership of their houses than renters (F (1, 450) = 257.7, $p < .001$) and that renters have a greater psychological ownership than AirBnBers (F (1, 450) = 20.04, $p < .001$). In sum, Study 1 demonstrated that psychological ownership of goods and experiences is lost in the sharing economies, at least in ride-sharing and space-sharing services, but that higher psychological ownership in sharing economies indicate greater satisfaction with experiences in sharing economies.

Study 2 ($N = 132$) was a field study in the domain of a scooter-sharing company, Bird. We found that psychological ownership of a scooter ride was correlated positively with ride satisfaction ($r = .34$, $p < .01$), likeliness of future rides ($r = .40$, $p < .01$), telling others about Bird ($r = .27$, $p < .01$), and general trust towards Bird ($r = .45$, $p < .01$). Although these results are correlational, our field study lays the groundwork for field interventions that augment psychological ownership, with the goal of increasing enjoyment derived from goods and services in the sharing economy.

In Study 3 ($N = 641$), we differential effect of collective (vs. individual) experiences. We found that sharing an Uber ride with a friend led to lower ride ownership (F(1, 639) = 4.591, $p = 0.03$). Moreover, a mediation analysis with 5,000 bootstrapped samples showed an indirect-only mediation for the effect of collective (vs. individual) experience on tip through ride ownership, indirect effect = -.016, 95% CI: [-.035, -.002]. A similar process was revealed for the effect of collective (vs. individual) experience on satisfaction through another mediation analysis with 5,000 bootstrapped samples, indirect effect = -.023, 95% CI: [-.049, -.004]. These results indicate that sharing an Uber ride with a friend reduces psychological ownership, and therefore, enjoyment, suggesting that experiences in ride-sharing are inherently solitary.

In Study 4 ($N = 645$), we aimed to increase psychological ownership. One of the routes of psychological ownership is intimate knowledge of the target (Pierce, Kostova, & Dirks, 2001). We found that providing information about the Uber driver (such as their rating, hometown, compliments they have received, languages they speak, number of years they have been an Uber driver, and the number of trips they have had) increased tip amount (F(1, 638) = 3.96, $p = 0.05$), WTP (F(1, 564) = 5.34, $p = 0.02$), satisfaction (F(1, 643) = 5.26, $p = .02$). Furthermore, this effect was mediated by ride ownership. A mediation analysis with 5,000 bootstrapped samples uncovered an indirect effect of information on tip through ride ownership, indirect effect = .018, 95% CI: [.004, .037]. Similarly, another mediation analysis with 5,000 bootstrapped samples demonstrated an indirect effect of information on satisfaction through ride ownership, indirect effect = .017, 95% CI: [.004, .042]. Thus, information about the driver increased ride enjoyment (specifically *tip* and *satisfaction*) through ride ownership.

In Study 5 ($N = 640$), we increased satisfaction through enhanced psychological ownership by bringing forth variety where the goods are typically identical (e.g., CitiBikes, Lime Bikes, Bird scooters). In a bike-sharing scenario, variety increased the ride enjoyment (indirect effect = .055, 95% CI = [.017, .103]) and willingness to ride in the future (indirect effect = .083, 95% CI = [.024, .149]) through enhanced psychological ownership of the ride.

In conclusion, psychological ownership of experiences is lower in sharing economies than it is in legal-ownership based consumption. Through our lab and field studies, we demonstrated that the higher the psychological ownership, the higher the enjoyment of the experiences. The implications of this research are important. Consumers lack the incentive to take care of the goods they access in the sharing economy, as they do not have to think about the long-term impact of their actions during the short period of time they consume these goods. An enhanced sense of psychological ownership could prevent these ruinous consequences and increase satisfaction with the experiences a sharing economy platform provides.

Virtual Touch Facilitates Psychological Ownership of Products in Virtual Reality

EXTENDED ABSTRACT

Online product videos and virtual reality (VR) interfaces enliven consumer experiences and are a source of product information. Intriguingly, these virtual environments often lack a semblance of "self" in the experience, oftentimes using a cursor rather than a virtual hand. In this research, we investigate vicarious touch, conceptualized as the observation of a virtual hand using a haptic exploratory procedure with a product in an online or virtual environment. Does the vicarious experience of virtual touch affect consumers' perceptions of psychological ownership? That is, does observing someone else touch make a consumer feel as if they, themselves, are touching the product? Previous research demonstrates that people can feel transported to a virtual space by blurring the lines of what is considered one's own body (Slater et al. 2008). A sense of body ownership is the feeling that the body that I inhabit is 'my own' and a part of 'me' (Tsakiris 2010). Psychological ownership, or the feeling that something is 'MINE!' (Pierce, Kostova and Dirks 2001), is often associated with greater product valuation (Peck, Barger, and Webb 2013; Peck and Shu 2009). We conjecture that vicarious touch increases body ownership of a virtual limb, which then increases psychological ownership felt of a product, termed the vicarious haptic effect.

Study 1 tests the main proposition that body ownership drives the effect of vicarious touch on psychological ownership. Participants ($N=208$) were either shown a video of a hand pointing toward a wristwatch or picking up and hefting the wristwatch. Psychological ownership (e.g., "I feel a personal ownership of the watch") and body ownership (e.g., "While viewing the video: 'I felt as if the hand in the video was my hand") were measured. An ANOVA reveals a significant effect of vicarious touch on body ownership ($M_{NoTouch}=1.78$, $M_{Touch}=2.84$, $F(1,194)=31.96$, $p<.001$, $\eta^2=.14$) and psychological ownership ($M_{NoTouch}=1.89$, $M_{Touch}=2.23$, $F(1,194)=3.86$, $p=.05$, $\eta^2=.02$). A mediational model demonstrates that body ownership mediates the effect of vicarious touch on psychological ownership (.3670; $CI_{95\%}=[.2326, .5109]$). These results reveal the vicarious haptic effect.

Given that vicarious touch facilitates a sense of body ownership for the displayed arms, we expect to attenuate this effect by altering the orientation of touch. Authorship processing suggests we leverage cues from the environment to discern whether an event has occurred as a result of oneself (Wegner and Sparrow 2004). Study 2 was a 2 (no touch/touch) x 2 (egocentric/allocentric orientation). MTurk participants ($N=209$) view a video displaying a hand either resting on the table or feeling the texture of the product. This was shown either from the perspective of the self or from the other. Results reveal a significant interaction between touch and orientation on psychological ownership ($F(1,185)=6.43$, $p=.012$, $\eta^2=.03$) such that perceptions of psychological ownership were significantly higher when viewing touch from an egocentric (vs. allocentric) orientation ($M_{EgoTouch}=3.13$, $M_{AlloTouch}=2.32$, $F(1,185)=4.28$, $p=.04$, $\eta^2=.02$) while there was no significant difference in orientation with no touch ($M_{EgoNoTouch}=2.50$, $M_{AlloNoTouch}=3.08$, $F(1,185)=2.29$, $p=.13$, $\eta^2=.01$). A significant mod-

erated mediational model indicates that body ownership mediates the relationship between vicarious touch and psychological ownership under conditions of egocentric orientation but not allocentric orientation (-.5205; $CI_{95\%=}$[-1.0193, -.0310]).

In study 3, we test whether the vicarious haptic effect holds in virtual reality. Further we examine if having one's own hands occupied (i.e., holding onto balls) interferes with feelings of body ownership. We created a 360° virtual reality retail store. The design was a 2 (vicarious touch/cursor) x 2 (hands occupied/hands free). Undergraduates (*N*=255) viewed a VR retail store on Oculus headsets. Participants responded to a variety of additional measures including willingness to pay, product evaluation, and purchase intention. Results of an ANOVA reveal a significant effect of vicarious touch on body ownership (F(1,241)=20.31, *p*<.001, η²=.08). Holding onto something (thereby having one's hands occupied) did not dampen the effect of vicarious touch on body ownership (F(1,239)=.346, *p*=.56). Body ownership mediates the effect of vicarious touch on psychological ownership (.1642; $CI_{95\%}$=[.0855, .2590]), purchase intention (.1320; $CI_{95\%}$=[.0596, .2239]), product evaluation (.1093; $CI_{95\%}$=[.0508, .1828]), as well as willingness to pay (.3320; $CI_{95\%}$=[.1164, .6245]).

A human need for stimulation or activation is one of the fundamental motives that is considered the reason for the existence of the psychological state of ownership (Pierce and Jussila 2011; Pierce and Peck 2018). Heart rate is one physiological manifestation of this individual difference in need for stimulation (Mathias and Stanford 2003). We expect that those highly stimulated by VR would feel stronger effects of vicarious touch on psychological ownership. Undergraduates (*N*=144) viewed a VR retail store while having their heart rate measured on a Biopac MP36. Study design was similar to study 3 with the addition of a no touch condition in which participants saw a hand but it did not touch the product. Viewing the virtual touch, as opposed to no touch and cursor, enhanced feelings of body ownership (F(2,141)=6.55, *p*=.002, η²=.09). Mediational analyses replicate the effects from study 3. There is a significant interaction with vicarious touch and heart rate on psychological ownership (*β* =-.065, *t*(123) = -2.25, *p*=.026). For highly stimulated individuals (+1 sd heart rate change), the effect of vicarious touch on psychological ownership is positive and significant (*t*(123)=-2.17, *p*=.03) while for those low in stimulation (-1 sd heart rate change) the relationship between vicarious touch and psychological ownership is not significant (*t*(123)=-1.096, *p*=.28).

We document the power of virtual touch. Our research demonstrates that vicarious touch increases a sense of psychological ownership of a product, which occurs due to a sense of body ownership of the virtual hands. We find that not only should a virtual hand be present, but it should be engaging haptically with the product. We further show that this effect is attenuated when observing touch from the perspective of another (i.e., allocentric orientation) as opposed to oneself (i.e., egocentric orientation). The effect is robust even if the observer's hand is otherwise occupied. Finally, using the physiological measure of elevation of heart rate, we demonstrate that for those individuals who become highly stimulated in VR, the effect of vicarious touch on psychological ownership is strengthened.

"My Brand is Moving Away from Me":
When Upgrade Products Leave Consumers Behind

EXTENDED ABSTRACT

In today's advanced economies, continual product enhancement through product upgrades is deemed a key component of a firm's success. Despite the increasing prevalence of upgrades, however, only limited research has investigated its implication for consumers' attitudes toward upgrades.

In this research, we aim to broaden an understanding of the emerging but limited body of research on product upgrades. Specifically, we investigate an effect of introductions of upgraded products on consumers' brand preference and examine how the effect may differ depending on ownership status. We propose that the release of an upgraded product has distinct psychological effects on consumers who are current owners of the brand, and that this psychological process would subsequently influence how much they prefer their current brand. Contrary to common intuition, we argue that the introduction of an upgrade could have an undesirable effect on current owners (but not for non-owners). We propose that since owners perceive the product they currently own as a representation of "me" (Weiss and Johar 2013, 2016) and perceive the new upgraded product as an embodiment of "the brand" (John, Loken, and Joiner 1998), the upgrade product would make the owners feel as if the brand has moved away from them just as the new product has advanced away from its previous versions. Feeling distant from a brand results in a less positive consumer-brand relationship, which in turn decrease brand commitment (Park, Eisingerich, and Park 2013). In line with the findings, we propose that the owners' feeling of being distanced from the brand would decrease the owners' preference for the brand. For non-owners, however, we expect to observe a positive effect of upgraded product because without an anchor for self-referencing, non-owners are only positively influenced by the brand's competence signaled by its advanced products (Heath, DelVecchio, and McCarthy 2011).

Four studies support our predictions. Throughout studies, we measured participants' purchase intention and their general attitudes toward the brand as dependent variables. For purchase intention, we measured consumers' willingness to choose the brands for purchasing another product because upgraders are often hindered by mental cost of retiring their current products that are still functional (Okada 2006).

Study 1 examined actual brand owners' and non-owners' responses to the release of upgraded products, and tests the underlying process. To this end, we recruited 344 owners and non-owners of Apple 10th generation iPhone and assessed their responses to the presence of newer generations of iPhones. To manipulate the presence of upgraded products, we manipulated the saliency of the upgrades to make them look either more or less apparent for consumers. The owners and non-owners were randomly assigned to either a control or an upgrade condition and were asked to rate their purchase intention (computer monitor), brand attitude, and perceived relational closeness toward Apple as a process measure using IOS scale (Aron, Aron, and Smollan 1992). The result revealed a significant 2 (upgrade) X 2 (ownership status) interaction (p < 0.01). Participants in the owner (non-owner) condition were less (more) willing to choose Apple when purchasing another product if the upgraded products were made more salient compared to when they were made less salient. The results for brand attitude (α = 0.96) followed the parallel pattern. Moderated mediation analysis suggested that the indirect effect of upgraded products through IOS varies as a function of ownership status (p = 0.08); the conditional indirect effect of upgraded products was significant for owners (p < 0.05) but not for non-owners (p > 0.1).

Study 2 replicates the findings from Study 1 in a more controlled setting with hypothetical scenarios to eliminate prior brand knowledge. As in Study1, results on purchase intention (microwave)

revealed the anticipated 2 (upgrade) X 2 (ownership status) interaction ($p < 0.01$), showing that owners (non-owners) were less (more) willing to choose the brand when the brand released upgraded products. The results for brand attitude ($\alpha = 0.94$) followed the parallel pattern. and the moderated mediation analysis replicated the finding from Study 1 ($p < 0.05$).

Study 3 put the focus on owners and further examined the underlying process using a moderation-of-process approach by manipulating the extent to which the focal brand is manipulated as psychologically close or neutral to one's self. Study 3 also tested an alternative explanation that upgrades makes owners unhappy because they see a frequent release of upgrades as an attempt by brands to entice consumers to unnecessarily spending. To test this account, we incorporated an additional condition in which the interval between the new upgrades is manipulated to be longer. 362 students participated and were randomly assigned to one of six conditions in a 2 (brand-self distance: neutral vs. close) X 3 (upgrade: no-upgrade vs. upgrade vs. upgrade-after-three-years) between-subjects design. The result showed that the brand-self distance moderates the predicted pattern (2, -1, -1 contrast) across the three upgrade conditions ($p < .01$). As predicted, when the brand-self distance was perceived close (neutral), participants were no less (less) likely to choose their current brand in both the upgrade and the upgrade-after-three-years condition than in the no-upgrade condition.

Study 4 complements our experimental results with evidence from a real-world dataset containing vehicle ownership data of 49,998 households across the United States. Using a multilevel model incorporating 30 different automobile brands and 294 different car models nested within the brands, we find that as the number of newer generations of car models that current households own increases in the market, the households become more likely to switch their brand rather than to stay loyal for their next car purchase.

We believe that our research may offer substantive implications in today's ever innovating economies. We suggest that while managers intend to leverage brand equity among consumers through product enhancement, the presence of new upgrades may in fact come with unintended consequences. Therefore, adequate strategy may be needed that pays special attention to current consumers.

Heritage Lost: How Connection to the Past Shapes Consumer Valuation in the Present

EXTENDED ABSTRACT

Heritage – a connection to a shared past – is a fundamental part of human experience, and consumers' interest in connecting to the people who came before them has been growing (Belk 1990; Csikszentmihalyi and Rochberg-Halton 1981)researchers, and students discover, use, and build upon a wide range of content in a trusted digital archive. We use information technology and tools to increase productivity and facilitate new forms of scholarship. For more information about JSTOR, please contact support@jstor.org. Psychology and Things The Manchester seminars on Technology as Skilled Practice brought together perspectives from a number of disciplines, including anthropology, history, and psychology. As an intentionally peripheral psychologist, I thought twice about attending an interdisciplinary meeting willing to include psychologists. Academic psychology throughout its brief history has been remarkably anxious about dem arcating its own exclusive subject — the \"subject\" — and has perpetuated, even ins titutionalized, the traditional dualism within modern science of the objective and subjective. Psychology (along with the other human sciences. From the popularity of heritage travel on Airbnb to the trendiness of heritage fabrics in England,

guochao style in China, consumers have increasingly chosen to buy goods that connect them to a shared past (Achim 2019; Duveau and Dumenil 2018; Killam 2019; Luo 2019; Rapp 2019).

In this project we explore how a connection to this shared past affects consumer valuations in the present. This research on heritage connection builds on the sharing literature, which has introduced the concept of "ours" and called for work on how the aggregate extended self – "us" – affects consumer practices (Belk 2010, 2017; Curasi, Price, and Arnould 2004; Epp and Price 2008; Lastovicka and Fernandez 2005). The current work also extends research on the endowment effect by exploring how collective ownership of the shared past can impact sellers' WTA (Brough and Isaac 2012; Dommer and Swaminathan 2013; Morewedge, Shu, Gilbert, and Wilson 2009; Shu and Peck 2011; Weiss and Johar 2013)a phenomenon called the endowment effect. Loss aversion has typically accounted for the endowment effect, but an alternative explanation suggests that ownership creates an association between the item and the self, and this possession-self link increases the value of the good. To test the ownership account, this research examines three moderators that theory suggests should affect the possession-self link and consequently the endowment effect: self-threat, identity associations of a good, and gender. After a social self-threat, the endowment effect is strengthened for in-group goods among both men and women but is eliminated for out-group goods among men (but not women. We predict that the same factor – heritage connection - increases valuations for both sellers and buyers—but it has the opposite effect that an economist would predict on selling prices. The buyer's heritage connection reduces the seller's WTA.

We define heritage connection as a good's capacity to bridge the gap between the consumer and their heritage by helping the consumer remember where they come from, giving them a sense of history, and connecting them with the people who came before them. In four studies, we find a main effect such that sellers set lower prices for heritage goods when selling to buyers with heritage connection, relative to buyers without heritage connection (i.e., the heritage discount).

In Study 1, we sampled California residents on Mturk ($N = 400$). The study ran online during the 250th anniversary of Monterey, a city in California that is home to California's first constitution, California's first scenic highway, and is the first place where Californians raised the American flag. Monterey also has an aquarium, and visitors come to see it. We informed participants that one person taking the study would receive a Monterey 250th anniversary hat, and that it would be theirs to keep. We endowed participants with the anniversary hat, and we measured participants actual WTA for this heritage good using the Becker DeGroot Marschak test (Becker, Degroot, and Marschak 1964) As predicted, sellers' WTA from a control buyer (visitor to Monterey) was higher than their WTA from the heritage buyer (resident of Monterey), $t(1,364) = 2.32$, $p = .021$. Sellers had a lower WTA for heritage buyers despite indicating that heritage buyers would value the good more ($p < .001$). Further, the effect of heritage held after adding controls for buyers' usage ($p = .030$). Thus, Study 1 provided preliminary evidence for a heritage discount.

Study 2 tested heritage in a new domain using real goods that people have in their homes. Participants ($N = 547$) were randomly assigned to answer questions about either an inherited or a purchased item in their home that would normally cost less than $1000. Participants indicated their WTA from both a close family member and a stranger. As predicted, the simple effect of stranger vs. family for heritage products was larger than the simple effect of stranger vs. family for non-heritage products. The interaction of buyer's identity

and product type (heritage vs. no heritage) was significant, all p's < .001, and sellers' heritage connection to a good moderated the heritage discount with more connected sellers giving larger discounts, $F(1, 545) = 46.20$, $p < .001$. Specifically, we found that the greater the seller's heritage connection, the larger the heritage discount connected buyers received, $B = 1.405$, SE =.175, $t(545) = 8.04$, $p < .001$.

At this point, it seemed like holding the item constant and manipulating heritage connection might provide an even cleaner test of our hypothesis, and we did this in Study 3. We asked participants ($N = 400$) to imagine that they were going through storage and found a watch from their great grandfather. In a between subjects design, we asked them to consider selling this heritage good to a control buyer or a heritage buyer, and we specified usage: both buyers would use the watch as they went about their daily work. Sellers set a lower WTA for heritage buyers than control buyers, $t(386) = 2.50$, $p = .013$. There was no difference in appropriateness of usage between conditions, $p = .714$. We also measured seller's heritage connection, buyer's perceived heritage connection, and we calculated heritage loss (i.e., the difference between a seller's heritage connection and a buyer's heritage connection). Overall, Study 3 provided strong evidence that heritage loss mediates the effect of buyer's identity on the seller's WTA (95%, CI = $127.25, $218.35). Next, we sought to validate these findings in an incentive compatible context.

In Study 4, we sampled the population on the campus of a large American research university ($N = 388$), and endowed participants with a good symbolizing 100 years of the university's history. In a between subjects, fully incentive compatible task, participants indicated their WTA from a heritage buyer (student at their university) or their WTA from a control buyer (stranger with no university connection). As predicted, participants' WTA from a control buyer ($2.65) was higher than their WTA from a heritage buyer ($2.20, $F(1,385) = 6.54$, $p = .011$). Further, we found this effect was mediated by heritage loss.

In conclusion, this research suggests that the shared past affects consumer valuations in the present. In four studies, we quantify the value of this heritage connection, and these findings have significance for marketing practice. Our research has applications to marketers of products that appeal to consumers' desire to connect to their heritage across time as well as markets that involve resale (e.g., housing and collectibles).

Paper #4: Marketing Memeification on TikTok: Initiating and Leveraging Consumer Creativity for Commercial Means

Jenna Drenten, Loyola University Chicago, USA
Pilar Castro González, Universidad Loyola Andalucía, Spain

SESSION OVERVIEW

Platforms have allowed ordinary consumers to monetize their creative and expressive pursuits. This session brings together four papers that inquire about the tricky, increasingly complex, and multi-actor world of influencer business and provide conceptual and empirical contributions to understand social media consumption.

Monetization of influence provides fruitful areas of inquiry for researchers. Among these, we uncover 1) entrepreneurial pursuits of ordinary consumers to become influencers, 2) the dialectical tensions between promotion and expression in online content, 3) interactions and relations between the audience, influencers, and firms, 4) codification and framing of content to meet audience and firm expectations. Collectively, the papers in this session provide distinctive insights into these issues.

The first paper revisits the megaphone effect and provides a revision to the theory by demonstrating the struggles of ordinary consumers in their quest for becoming influencers. By acknowledging their struggles, this paper provides a needed corrective to the myth of meritocratic and serendipitous journey of becoming and being an influencer. Findings are expanded to explain why consumers leave fields more generally.

The second paper provides a mixed method analysis of food images on Instagram and explores how different visual framing strategies contribute to the engagement strategies of top-ten food influencers. Combining quantitative and qualitative analysis, the authors show distinct patterns of representation of food using strategic composition and visual framing. These patterns also reflect long-standing distinctions between the raw and the cooked.

The third paper investigates the phenomenon of pet influencers. Through studying account managers who generate platform content around the performances of their pets, the authors uncover visual and rhetorical strategies of their engagement. The participants implement anthropomorphism through intertextual manipulation of the visual and textual content and orchestration of realistic or fantasy performances.

The final paper explores how platform content is shaped by memes that are also controlled and seeded by firms. The authors show how memes are actively initiated, surveilled, and leveraged by firms. They show how companies use sponsored hashtags to entice consumers to engage with brand content through three types of call to action, where paid influencers take the lead, followed by everyday (unpaid) consumers amplifying the message.

Together, the papers in this session tackle the following questions:

1. How do consumers position themselves as influencers in the attention economy?
2. How do consumers invest in and deploy resources to strengthen their positioning?
3. How do consumers use platforms' expressive capacities to create engagement?
4. How do consumers interact with firms to convert attention to value and revenues?

The session provides a meeting point for scholars using different methods (quantitative and qualitative) and complementary perspectives to understand social media. It investigates the role of different actors that participate in the influencer business: pets, firms, and consumers—as both creators and audiences. All papers are in advanced stages with empirical work completed. Papers also use mixed methods which will attract broader attention. Due to the significance and relevance of the substantive context, we expect a range of ACR members to show interest in the session.

Problematizing the Megaphone: The Very Difficult Journey to Becoming an Influencer

EXTENDED ABSTRACT

If we were to listen to the depiction of influencers in the mainstream press and some academic articles, we might conclude that persistent efforts from meritocratic consumers will lead to them becoming influencers. Duffy and Wissinger (2017) refer to this mythologized portrait of the path to become an influencer as 'glamorized.' In reality, becoming an influencer is a difficult project that is unlikely to yield results (Duffy 2016). Despite this acknowledgment of the struggles inherent to becoming and being an influencer, we know surprisingly little of what exactly these struggles are and how they affect ordinary consumers' quest for influence. These are the two research questions we answer in this project.

These research questions are important for many reasons. Centrally, there were more than 3.7 million ads by influencers on Instagram in 2018, and 90% of Instagram campaigns in 2018 used micro-influencers—influencers that have somewhere between 1000 and 100 000 followers (HubSpot, July 15th, 2019; Wired, Apr 22nd, 2019). Micro-influencers represent about 25% of the Instagram user base, or about 250 million people (Mention.com 2018). These developments are giving ordinary consumers—consumers who do not possess a privileged position in social fields (McQuarrie, Miller, and Phillips 2013)—increasing opportunities to capitalize on their (micro) influence. This has translated into an increasing number of ordinary consumers wanting to become influencers: More than 75% of people aged between 5 and 38 state wanting to become one

(DailyMail, May 22nd, 2017; People, Nov 5th, 2019). The glamorized picture of influencers is thus problematic, as it represents a highly biased understanding of this role and the path to become an influencer. Theoretically, this is a glaring omission in a rapidly rising and important role of the digital economy. Practically, this mythologized understanding of what is required to become an influencer can lead consumers to pursue an identity project that is bound to fail.

We answer our research questions by analyzing repeat interviews with 23 micro-influencers with different followings: (1) less than 10k followers, (2) between 10k and 50k followers, and (3) between 50k and 100k followers. We complement these interviews with all Instagram posts and a month of Instagram Stories from our participants, as well as archival data in the form of articles for and on influencers (166 pages).

We leverage McQuarrie, Miller, and Phillips (2013) work and concentrate on three main stages that explains the movement of an ordinary consumer to online influencer: acquiring an audience, maintaining and expanding an audience, and deriving benefits from an audience.

When entering the field and starting to acquire an audience, ordinary consumers face struggles associated with the breadth of expertise required to perform their role and the work demanded to better their expertise to do so. For example, consumers realize that, in addition to being proficient in successfully making risky taste displays (McQuarrie, Miller, and Phillips 2013), they also need to know how to use the Instagram algorithm to their advantage, create thematically related images (vs. only one risky display of taste), and do proper make-up and poses.

When maintaining and expanding their audience, consumers need to address changes in their audience expectations, which now demand continuous content creation. We show how consumers take two strategies to address this: they broaden their expertise to multiple fields (e.g., from fashion to food, travel, and design), or deepen their expertise in their focal field of interest (e.g., from fashion stylist to critic, historian, and tailor). This increases demands in terms of consumer expertise, which exponentially heightens the involvement required to continue pursuing their quest for influence. We also find that consumers become objectified by their audience, which brings its own set of struggles associated with addressing negative and unwanted comments and requests.

Lastly, when converting their audience into benefits, consumers need to understand how to position themselves effectively in the market for influencers (i.e., have an effective positioning from the perspective of brands who might hire them), how to develop their unique brand, and how to deal with commercial clients. Here again, we find that consumers are often ill-equipped to address the scope of tasks asked from them, which have become increasingly removed from what led them to start wanting to be an influencer in the first place.

Each of these stages come with its own set of difficulties, which leads influencers to abandon their project. At least in our sample, these difficulties led to more than half our participants (13 out of 23) to discontinue their influencer activities. And the number of followers did not play a role in convincing influencers to continue their quest: We have many instances of Instagram influencers with more than 50 000 followers who abandoned their quest, for example, because converting their audience was deemed too difficult.

Our work contributes to the literature on influencers and consumer involvement in a consumption field. First, the struggles we identify lead us to provide an important revision as to how ordinary consumers become influencers (cf. Erz and Christensen 2018; McQuarrie, Miller, and Phillips 2013). Second, we use this revised journey to propose an alternative to the dominant theorization of how consumers become influencers. Instead of consumers taking risks when sharing their passion in a consumption, and how they accumulate followers by doing so (see Erz and Christensen 2018; McQuarrie, Miller, and Phillips 2013), we suggest conceptualizing at least a segment of influencers as digital entrepreneurs whose journey to become influencers is active and intentional; For example, they readily create a brand from the get-go, strategically think about their market positioning, and use numerous market resources (e.g., buying followers) to achieve their objective. Lastly, we generalize the struggles we identify to any consumer highly involved in some consumption activity (e.g., see Stebbins 1982 on serious leisure) to provide three main reasons why they leave consumption fields.

Aesthetics of Food: The Role of Visual Framing Strategies for Influence Building on Instagram

EXTENDED ABSTRACT

Social media produces a megaphone effect that offers a mass audience to ordinary consumers (McQuarrie and Phillips 2013). Images of food dominate social media, which has revolutionized the world of gastronomy and food (Allué 2013). Food is a central part of defining identity, as well as shaping collective, cultural identities (Lupton 1996). The transformative, aesthetic aspects of food often reflect social status and prestige. Food and eating, beyond survival and sustenance, can be understood as an aestheticized expression of identity, status, and taste. Such taste expressions can be regarded as a taste regime that helps to explain how individuals gain cultural capital in the marketplace – often via social media (Arsel and Bean 2013). By posting food images and seeking feedback from followers through the "likes", the influencers provide repeated stimuli to control followers' behavior. Owing to the value creation effect, influencers are becoming a taste maker, and building an informal social norm (Hackman 1992) which will influence how followers perceive food.

Food serves as a powerful system of communication. Food and eating connect consumers to their biological and cultural heritage (Allen 2012). Food is the basis of many consumer habits and rituals (Marshall 2005). The aesthetics of food consumption can be traced back to Epicureanism, an individualistic and communal philosophy that emphasizes the central role of pleasure, laying the foundation for aesthetic appreciation, including appreciation of food and taste. French writer Brillat-Savarin introduced the idea of you are what you eat, and articulated a philosophical approach to cooking (Brillat-Savarin 2009). During the twentieth century, food marketing has shifted from nutrition appeals to more hedonic taste appeals. Intrinsic motivation such as seeking leisure becomes the main purpose of participating in online interaction. Perceived enjoyment derived from the theory of reasoned action (TRA) and the technology acceptance model (TAM) significantly influence online community's loyalty (Hsu and Lu 2007), this study, was inspired by these theories to explain how influencers apply visual framing strategies as intrinsic motivation on technology use. To better understand influence marketing in the context of how technology interacts with gastronomy, it is essential to analyze online images that connect taste consumption with visual consumption (Schroeder 2002).

Among different social media platforms, Instagram specializes in efficiently distributing visual rhetoric on a personal or global scale to its over 500 million daily active users (Statista 2018). Food influencers create an informal social norm via the repeat use of a circle loop starting from food preparation decision to feedback collection and post recreation. This value creation process prompts the influencer to become a taste maker considering the preferences of

"visual consumers". In the historical view, this online food images sharing is different from classical business model using their unique virtual "words". It is a complex practice that has relational, social, and cultural significance. However, the visual aspect of these practices, especially as it related to influencer marketing often remains understudied. Therefore, the purpose of this study is to identify framing strategies that influence consumer engagement on social media. The behavior of highlighting certain facets and concealing others is a central tenet of framing theory (Entman 1993). Framing affects how audiences interpret and react to scenarios, images, and text. By taking advantages of various rhetoric tools like symbols, metaphors, and depictions, visual imagery operates as a framing device (Rodriguez and Dimitrova 2011).

The research questions this paper aims to answer are:

* RQ1: What do the top ten most-followed food channel Instagram influencers post on their accounts?
* RQ2: What framing strategies do the top ten most-followed food channel Instagram influencers use to visually represent food posts to facilitate consumer engagement?

The Instagram accounts for this study were selected based on a formal ranking by Statista, which is an online statistic, market research, and business intelligence portal that provides access to data from market and opinion research institutions. Statista presented the most-followed food influencers on Instagram in the United States as of January 2018 (Statista 2018). Based on the reliable external assessment data, this study used content analysis to investigate how different categories of visual framing mutually or independently contribute to the popularity of these top ten food influencers.

Using the food-related images posted by these food influencers from January 1 to December 31, 2017, and selected images that received more than 10,000 "likes" on the influencer`s account. The ten influencers included two men and eight women; one of the accounts did not indicate gender. Images were randomly selected in each influencers' Instagram, one image per month, obtaining a total of N = 120 posts.

Content analysis views data such as images, text, and expressions to be seen and interpreted for their meanings (Krippendorff 2012). We also combined qualitative content analysis with frequency and Chi Square-tests. We developed a codebook of attributes after observing most of the images and divided them into two parts: influencers and food. The coding categories are partially based on the Duncan (1990) study, which offers a visual analysis using contextual readings of visual photographic imagery. Images were analyzed in 13 nominal categories. Acceptable levels of inter-coder reliability via Krippendorff's alpha were achieved and ranged from 0.86 to 1.0 for each variable tested.

The findings show distinct patterns in how food is represented in Instagram posts. Food influencers prefer to post images about cooked food, without little decoration, using high contrast colors and close-up shots. Most posts do not include "background" elements such as clothing, facial expression, or proximity to influencers. Random placement and casual layout are more of a reflection of the influencer's own leisure lifestyle; strategies also reflect influencers' social network identity construction. Raw food images were found to be associated with cluttered composition and far away shoots, whereas cooked food images were associated with high contrast and close-up, especially the top-down camera angle. Cooked food images serve as a justification agent for consumers, "thereby reducing the conflict associated with the subsequent indulgent consumption experience and increasing taste perceptions" (Poor, Duhachek, and Krishnan 2013, 124).

Our analytical categories of raw and cooked food draw inspiration from anthropologist Claude Lévi-Strauss's influential work on the raw and the cooked as basic categories for understanding human culture (1983). Perhaps inadvertently, it appears that influencers' social media posts reflect fundamental, long-standing distinctions of the raw and the cooked. Of course, raw food, when appearing on Instagram, is generally highly aestheticized. However, we find this distinction meaningful, and useful for understanding some basic elements of food posting. Moreover, these factors including social norm, perceived enjoyment, and cultural intermediaries have a significant effect shaping followers' behavior via the value creation process. Our framework emphasizes the importance of how food can be accommodated within the framework of a meal, and how taste could be used as an approach to describe aesthetic norms. The interaction between real-life meal gatherings and social media creates a combined type of "commensal" experience, one that fosters a sense of community, despite occurring online (Bouvier 2018). Food represents an ideal way to achieve such a sense. This study represents a step toward a more cogent understanding of food influencers on Instagram, informed by historical discussion of aesthetics and taste. In addition to implications such as the visual framing effects of advertising for influencer marketing, future studies may investigate and the role of food influencers as 'cultural intermediaries' as described Bourdieu (1984) to help us explain the set of activities and professions in the creation of markets and consumption economies like how music bloggers mediate and orient consumer taste (Arriagada and Cruz 2014).

Orchestrating Pet Influencers: Rhetorical and Visual Strategies in Creating Mediated Platform Content

EXTENDED ABSTRACT

As we are writing this, one of the most popular influencers in the world is not a person but a cat with 4.3 million followers on Instagram. Nala is an 8-year-old cat who became Instagram famous after her human companion created the account to share images with her family who resides overseas. Nala's audience has expanded to other platforms, such as Facebook, YouTube, and Twitter, where she has 2.6M followers, 27K subscribers, and 24.9K followers, respectively, creating a multi-platform megaphone.

Despite the prevalence of pet influencers, there is a paucity of studies on the subject matter. While influencers or microcelebrities who manage their own accounts have been explored by scholars (Abidin, 2015, 2016, 2018; Khamis, Ang, & Welling, 2017; Marwick, 2013, 2015; McQuarrie et al., 2012; Senft, 2008, 2013)—also see papers in this session—, the mediated nature of pet influencers, particularly the ways humans orchestrate their animal companions performatively, manage their online presence, and capitalize on the attention for their pets require further attention. This is important because what sets apart the phenomenon from others is its two boundary conditions: 1) The duality and mutuality of presence of human account managers alongside their pets in social media performances, and 2) The second-degree performance and sociality that is mediated through the pets and with other pet companions. These boundary conditions allow contextualizing a new theorization of the triadic and mediated relationship between humans, their animal companions, and their audience in platforms.

Our method is a combination of interviews and Netnographic observations. We conducted semi-structured interviews with 15 pet account managers with at least 500 followers. We also analyzed the content of pet influencer posts for visual and textual content. Lastly, through a public pet account, we participated in introspective en-

gagement with the practice. We performed iterative and inductive analytical procedures in analyzing our data.

Our findings first demonstrate that Instagram is home to a loosely networked bundle of micro-communities of cat accounts, centered around feline appreciation and fandom. These connected micro-communities are built around hashtags singling out breeds, colors, and micro-interests with frequent overlaps and blurring of community boundaries. Through a shared language (now coined as Meowlogisms by Podhovnik, 2018), collective celebration of milestones, and collective action to support each other such as fundraising, pet account managers (PAMs) exemplify the three tenets of community (Muniz and O'Guinn 2001): consciousness of kind, rituals and traditions, and moral responsibility.

Second, we show that within this nexus of micro-communities, PAMs are motivated to create and maintain engagement for two primary reasons: connections or fame. These findings mirror and revise existing typologies on social media communities (Kozinets 1999; Martineau and Arsel 2017).

Third, we show that regardless of their goals, PAMs create anthropomorphic performances for their pets through intertextual storytelling, switching back and forth between engaging with the pets through proxy conversations and engaging with their human companions more directly.

Our data shows that storytelling can be either realistic (staying within the boundaries of the sociomaterial capacities of animals), or fantastical (expressing imaginary or impossible situations). When choosing to make posts on their accounts, PAMs can simply display the raw images they capture by camera, such as their cat sitting on a couch, or they can decide to superimpose the original image onto another one which showcases different settings or characters, such as their cat playing golf. Additionally, the same can occur for the textual content: it could simply reflect the literal or figurative content of the actual image, such as: "my cat sits on the counter," or integrate intertextual narratives which may expand the literal object: "my cat slayed the dragons and conquered the seven kingdoms." These storytelling techniques frame their pet as not only having human emotionality and physicality but also allows the PAMs leverage on shared tropes and narratives such as the case of Game of Thrones to boost engagement and familiarity. Textual cues are frequently supported by visual manipulation, such as editing images to make the cat look like a knight. Lastly, PAMs deliberately choose the account's voice (human versus cat) to supplement this storytelling. Building on the patterning of these strategies, we develop a typology of PAM account management styles.

Our work aims to contribute to a growing body of literature on performances in social media (Abidin, 2017; boyd, 2011; Burgess and Green, 2008; García-Rapp, 2017; Marwick, 2013; Strangelove, 2010; Senft, 2013). We show how social media enables performative mediated interactions and mediated connections between humans through their pet companions, how animals are orchestrated for attention economy, and how this shifts humans' connections with their pets and other humans. Furthermore, we develop a typology of performative orchestration of Instagram pets. Our typology also provides firms tools for identifying and recruiting the most appropriate influencer based on their performance style.

Marketing Memeification on TikTok: Initiating and Leveraging Consumer Creativity for Commercial Means

EXTENDED ABSTRACT

In a saturated digital advertising space, brands increasingly desire 'viral' content (Berger and Milkman, 2012). One form of viral content are internet memes—defined as "(a) a group of digital items sharing common characteristics of content, form, and/ or stance, which (b) were created with awareness of each other, and (c) were circulated, imitated, and/or transformed via the Internet by many users" (Shifman, 2014, p. 41). Internet memes are a form of cultural rhetoric (Grundlingh, 2018; Milner, 2013) and are unique given "the speed of their transmission and the fidelity of their form" (Davidson, 2012, p. 122). Internet memes can build report with online consumers and foster consumer engagement (Gelb, 1997). Previous research highlights the convivial nature of internet memes, which act as a type of digital leisure shared by internet insiders (Bauckhage, 2011). However, this form of leisure can also represent a lucrative opportunity for influencers and brands alike through monetizing the attention economy (Drenten, Gurrieri, and Tyler, 2020; Soha and McDowell, 2016). Most research to date explores how consumers create memes, separate from marketing intervention. In contrast, our study explores brand-generated internet memes. We ask, how do brands create and capitalize upon internet memes for commercial means?

To explore our research question, we turn to the context of TikTok, a social media platform (formerly Musical.ly) which allows users to create and share short-form videos, using a library of "sounds" (e.g., music, user-generated sounds, television/movie clips). With over 1.5 billion app downloads and nearly 105 million in January 2020 alone, TikTok is rapidly growing (Sensor Tower, 2019; 2020). For this study, we specifically focus on sponsored hashtags, a paid advertising placement option in which brands pay for custom sponsored hashtags to drive engagement in marketing campaigns. Sponsored hashtags are placed on the app's discovery-oriented 'for you page' to engage consumers immediately upon opening the TikTok app. Data collection began in April 2019 and was conducted by a cross-cultural research team. The researchers identified sponsored hashtags via daily monitoring of the 'for you page' on TikTok and created a database of sponsored hashtags and accompanying visual- and text-based content. Data collection resulted in a sample of 102 sponsored hashtags from 87 companies, such as Nike, Chipotle, Burberry, and other multinational brands. Data were managed and analyzed through qualitative social media methods (Sloan and Quan-Haase, 2017), using both Nvivo 12 Plus software and manual coding.

Preliminary findings offer a framework of marketing memeification wherein brands initiate the reproduction of content through three types of calls to action: impersonation, transformation, and self-expression. Marketing memeification unfolds on a continuum of individual creativity in which consumers are increasingly encouraged to insert their own creative ideas when developing content in conjunction with a sponsored hashtag. In each case, paid influencers set the exemplary creative standard, while everyday consumers engage with marketing memeification as a form of unpaid consumer leisure. Our study suggests TikTok is unique in using sounds, or sonic anchors, to drive the marketing memeification process.

First, brands initiate marketing memeification through impersonation-based calls to action, which require little to no individual creativity. Impersonation involves movement-oriented actions (e.g., dance, lip-sync) with specific guidelines for the performance. For example, to advertise Season 3 of Netflix's Chilling Adventures of Sabrina, the media company created the #StraightToHell hashtag accompanying a short, easy to replicate dance with the song "Straight to Hell" by Sabrina Spellman as the sonic anchor. Through impersonation, consumers are mobilized to recreate content, exemplified by influencers, directly as it is shown. While some users may perform the dance moves differently, due to ability and style, the brand-related hashtag does not directly invoke creativity.

Second, through transformation-based calls to action, which give more narrative and creative leeway to consumers. Transformation involves transition-oriented stories, wherein consumers are asked to show a change or evolution. For example, in promoting the re-release of Wendy's 'spicy chicken nuggets', the brand encouraged consumers to demonstrate transformational stories using the #SpicySnap hashtag challenge and the song "Snap Yo Fingers" by Lil Jon as the sonic anchor. Through transformation, consumers are mobilized to interpret the brand's call to action and tell their own creative stories loosely related to the branded product. For this challenge, influencers prominently feature Wendy's food products in their content; however, everyday consumers use the suggested sound and hashtag to show their own creative transformations.

Third, through self-expression-based calls to action, which inspire consumers to reflect their personal points of view. Self-expression involves identity-oriented displays of uniqueness in which consumers are asked to interpret the hashtag, with open-ended parameters. For example, beauty retailer Ulta Beauty created the #BeautyIs hashtag campaign, with the song "Here I Am" by Fleur East as the sonic anchor, inviting consumers to broadly define beauty in their own terms. Through self-expression, influencers and everyday consumers promote their own unique viewpoints and perspectives, using the brand as a launching point. User videos range in diversity in messaging, format, and content creators themselves (e.g., gender, ethnicity, age). Thus, on the marketing memeification continuum of creativity, branded hashtags and accompanying sounds increasingly become a pathway for consumers to share their own authentic self-expression, while indirectly promoting the brand itself.

While previous work focuses on the organic evolution of memes as user-generated content (Bigley and Leonhardt, 2017), our findings extend existing research to better understand how marketing intervention spurs memeification for commercial means and to demonstrate how brands leverage the status and visibility of social media influencers to set creative standards. Partitioning devices including sonic anchors and branded hashtags are initiated by the brand; however, marketing memeification decentralizes control of the brand in the process. In line the theoretical perspective of memes (Shifman, 2014), our study suggests meaning is created on TikTok during the transmission of cultural content. At a meso-level, this transmission process is propelled by sonic anchors (e.g., songs) which work to coalesce consumption communities, reflecting the importance of sounds as objects in consumption research (Patterson and Larsen, 2019). This study represents a first step in understanding how brands operate on TikTok, wherein consumers' creative performances are actively initiated, surveilled, and leveraged for commercial means.

SESSION OVERVIEW

From the explosive popularity of podcasts to the rapid rise of social media influencers, seismic shifts in technology and new media consumption are taking shape across the globe. As digital platforms – defined as "a set of online digital arrangements whose algorithms serve to organize and structure economic and social activity" (Kenney and Zysman 2016) – increasingly take on a larger role in individual consumers' lives, the digital world holds widespread implications for consumer identity construction (Belk 2013). These consumer identities are neither static nor binary (e.g. online versus offline, see Kedzior 2015), but rather assembled and at times disassembled within and between various digital platforms, such as social networking sites, image-based or audio based social platforms, and hybrid sites. Indeed, past scholarship has examined the ways in which consumers and influencers actively engage in digitally mediated spaces (e.g., Drenten and Zayer 2018, Drenten, Gurrieri and Tyler 2018, Epp, Price and Schau 2014; Gurrieri and Cherrier 2013, Molesworth and Denegri-Knott 2013, Schau and Gilly 2003).

However, while there has been much discussion regarding the more negative impact of digital platforms (Baccarella et al. 2018) on individuals and families, consumer research scholarship has yet to fully explore how digital platforms (re)shape and/or disrupt consumer identities, and what these processes mean not only for consumer welfare outcomes, but also for marketing practitioners. In this special session we examine this timely oversight by bringing together an inclusive team of authors from both academia and the social media industry, exploring digital consumption issues through multiple theoretical lenses, like family identity theory, intersectional theory, and assemblage theory, as well as methodological paradigms including quantitative and qualitative perspectives. The first two papers of this session will focus on group identity construction in the digital age, while the last two papers will highlight the role of digital platforms on individual consumer identity creation. Specifically, the empirical papers, which all have data collected and are in mature stages of theorization, will address the following research questions: 1) how are family identities (re)shaped by digital platforms? 2) how are female influencers and consumers' aging identities shaped and constrained by social media images? 3) how do Instagram influencers impact their consumers' gender identity and gender expression?

and 4) how do online portals contribute to contemplative consumer identity creation?

Overall, this special session asks: how do digital platforms (re) shape consumers' individual and collective identities? We anticipate that our session will be relevant for scholars engaged with broad questions that relate to marketing in a digital world, and consumer researchers with a specific focus on participatory media consumption. We also wish to engage in dialogue with practitioners and social scientists working in influential social media organizations such as Pinterest through a discussion of our respective empirical findings.

How Digital Platforms Shape Family Identities

EXTENDED ABSTRACT

Past scholarship has documented how consumers in online environments construct their identities (Schau and Gilly 2003; Belk 2013), including navigating identity transitions (Drenten and Zayer 2018). Additional research has highlighted the role of digital technologies in shaping family practices (see Epp, Schau, and Price 2014 study on geographic dispersion of families), reinforcing rituals and intimacy among couples (see Su 2016 study on digital messaging), and providing a means to negotiate meanings of home (see Cabalquinto 2018 study on mobile media use of Filipino transnational families). Importantly, Epp et al. (2014) highlight how families can expand their material, expressive and imaginative capacities through technologies such as Skype during times of separation. However, the manner in which technologies, such as social media platforms, impact family identities is yet to be explored in great depth. To address this gap in the literature, our research asks: how are family identities shaped by digital platforms?

We draw on Epp and Price's (2008) sociological conceptualization of 'being a family' as a "bundle" of identities, which include collective, relational (couple, parent-child or sibling identities), and individual identities as they interact with communication forms and symbolic marketplace resources. The authors refer to Bennett, Wolin, and McAvity's (1988, 212) definition of family identity as the "gestalt of qualities and attributes," and "the family's subjective sense of its own continuity over time, its present situation, and its character." The context for our research is the social media platform, Pinterest, which allows users to search, save and share content in the form of "pins" and "boards" related to their interests akin to a bulletin board. Two-thirds of the pins on the site represent brands or products. The site boasts that 28% of all US social media users are Pinterest users with a monthly active user base of 300 million and a median age of 40 (Omnicore Agency Report 2020).

To explore family identity in the digital era, we draw upon a dual methodology of in-depth interviews and visual content analysis. First, interviews with 14 men and women, ages 21 to 45, who use Pinterest were conducted, resulting in over 500 pages of text. Visual data was also captured as informants shared their personal Pinterest boards. Second, a series of searches were conducted via Pinterest Trends (trends.pinterest.com), using "Family" as the initial keyword, then systematically exploring the first 20 results (e.g., family dinner ideas, family room ideas, family pictures). Themes related to identity and family were identified using a constant comparison method

and iteratively referring back to the existing literature (Strauss and Corbin 1998).

We find Pinterest provides symbolic marketplace resources in the form digital virtual consumption 'objects' which are embedded in communications forms (e.g., narratives, rituals, intergenerational transfers, social dramas, everyday interactions) and help consumers construct and maintain collective family identities. Exploratory visual analysis of the most popular pins in the Pinterest Trends database indicates that it is replete with digital virtual resources to shape and enact family identities (e.g., family time, family tree, family traditions) as well as to help families overcome potential barriers (e.g., inspirational family quotes, addressing family problems).

Emergent from our findings are four unique forms of family identity resources: relational, functional, transformational, and expressive. Due to space limitations of the abstract, abbreviated quotes from the data are presented here. First, relational identity resources reflect connection and bonding with fellow family members, such as pinning family game night ideas or books to read at bedtime. Ellen, a college student, uses Pinterest to save tips for playing 'Words with Friends,' a mobile game that she plays each day with her dad. Ellen's pins enhance her long-distance gameplay experiences. She says, "… my dad wants to play with me; of course, I'm going to play with him. This [pin] had different words that a scrabble player should memorize so like highest possible points on the first turn." Second, functional identity resources reflect pragmatic family operations, such as recipes for weeknight meals or chore charts for kids. For example, Carolyn pins content related to planning an upcoming Disney vacation, including a Disney packing list and meal tips for eating at the theme park. "I used Pinterest a ton before I went to Disney because I wanted to make sure I was fully prepared because Disney was a whole different kind of vacation, you have to be ready." Carolyn's pins reflect desired organization and preparedness for her family. Third, transformational identity resources reflect evolutions in family structure or values, such as efforts to get healthy together or moving in together. Hailey is recently engaged and pins home décor ideas for moving in with her future husband. She says, "…it gives me inspiration … it just makes me feel inspired to actually do stuff rather than to just continue to watch HGTV." Fourth, expressive family identity resources reflect on shared meanings and beliefs, such as faith and emotional concern for family members. Ellen discusses her family's belief to "make sure you hug your loved ones today and every day" and states "…if I see something that is along lines of that I'm totally pinning it." In some cases, family identity resources intersect serving as multiple family identity resources. For example, pins for planning a family vacation may be both functional and relational. These family identity resources are leveraged through digital media (e.g., Pinterest) to help families reinforce or reimagine their collective identities.

As Epp and Price (2008) point out, the marketplace can both enable and constrain the identity construction practices of families, and that there are barriers to enactment, including geographic dispersion, time constraints, and lack of monetary resources. We find Pinterest diminishes these barriers by offering asynchronous participation and a seemingly endless array of digital virtual consumption as resources. Importantly, contrary to popular press and prior research indicating that digital technologies are disrupting and introducing new vulnerabilities to family relationships and roles (Abbasi and Alghamdi 2017; Hertlein 2012; Lewis et al. 2015), we find that the social media platform Pinterest provides new or reframed opportunities for reinforcing and reimagining family identities.

#Instagrannies?: How Mature Women Reassemble Aging, Fashion and Retirement in Digital Times

EXTENDED ABSTRACT

Until recently, the idea of paying close attention to mature women's sense of style would have been met with puzzlement and little interest from consumers and the fashion industry alike. After all, to be fashionable and feminine has typically been viewed as belonging to the young. What then could older female consumers possibly teach the market about being stylish? Following the unexpected popularity of the Advanced Style phenomenon, discussions about ageism, gender, and fashion have begun to draw increasing attention in the popular press (e.g., Grinberg 2012; La Ferla 2018). The @advancedstyle Instagram account created in 2008 by American street style photographer Ari Seth Cohen helped fuel these critical conversations. Cohen's celebration of the personal styles of regular mature women, which are commonly understood as 50 years of age or older (Twigg 2013), has launched a flourishing online movement. A decade after its creation, the social media account has more than 278,000 followers and 4,300 posts, boasts a hashtag (#advancedstyle) used more than 169,000 times, is regularly featured in major fashion magazines (e.g., Vogue) and mainstream media (e.g., The Guardian), and has expanded into the realm of books (e.g., Cohen 2012, 2016; Cohen and Schraer 2013) and feature length films (e.g., Cohen and Feig 2014).

In light of this social media and traditional market success story, and in an effort to answer research calls for greater examination of the intersection between the sociocultural categories of age and gender in the marketplace (Twigg 2013), we explore how women over 50 are embracing the online opportunity to increase their visibility by consuming the photo-sharing digital platform called Instagram, as well as amplify their voices and representations in the fashion market by becoming Instagram style influencers. As such, our research aims are: 1) to expand our knowledge of influencer marketing dynamics, which heavily favors young prosumers, by examining an under researched older female segment; and 2) to investigate Advanced Style prosumers' impact on broader market and societal representations of age, gender, and retirement.

To do so, we combine the intersectional and assemblage theoretical lenses and focus on the case of 10 popular female Advanced Style Instagram influencers, defined as ordinary Internet users who have an established credibility and audience, and therefore can monetize their online following through advertorials, brand collaborations, and public appearances (Abidin 2016). While prior consumer research has examined mature consumers as retirees (Price, Arnould, and Curasi 2000; Schau, Gilly, and Wolfinbarger 2009) and as part of elderly consumption ensembles (Barnhart and Peñaloza 2013), our study pays particular attention to a new kind of older prosumer or producer-consumer hybrid, who, through their savvy digital consumption and glamor labor (Wissinger 2014), reassemble the imagery of aging, gender, and retirement for their combined millions of online followers.

Methodologically, we employed a qualitative case study method, as it "has become a favored methodology for researching macroscopic […] questions concerning markets and cultures from an interpretive perspective" (Holt 2002, 73). To help contextualize our market phenomenon, we first collected an overview of popular written, audio, and visual materials about the Advanced Style movement since its inception in 2008. Following this initial phase of data collection, we focused on 10 popular Advanced Style influencers, where we collected all online media interviews (291 documents) and YouTube video interviews (93 videos) featuring any of these 10

influencers. To supplement the archival dataset, we conducted a netnography to understand the social interaction in this contemporary digital communications context (Kozinets 2019). Here, each author individually engaged in online participant observation as regular fans by following the 10 influencers on Instagram from our personal accounts for approximately six months, periodically sharing direct messages on the platform with each other about our online experiences (Kozinets, Scaraboto, and Parmentier 2018). We also downloaded fans comments for 30 randomly selected recent consecutive posts per influencer to better understand fan interactions. Lastly, we collected metrics on the 10 influencers' Instagram accounts regarding their audience, engagement, and brand mentions from the third-party analytics platform HypeAuditor.

In accordance with the established principles of qualitative research (Glaser and Strauss 1967), data collection continued until theoretical saturation was reached. The complete dataset was analyzed using the hermeneutic approach (Thompson 1997) typically utilized for qualitative data. We find that the Advanced Style intersectional assemblage was created through a specific historical process (DeLanda 2016) that moved from invisible to visible and then progressed from influence to precarious power. In the first phase of the process, our influencers created the intersectional assemblage by first recognizing their invisibility in the fashion market as women over 50, then deliberately deciding to become style activists, next strategically using hashtags, and finally making deliberate and consistent choices about their Instagram style. In the second phase, our prosumers stabilized the intersectional assemblage by first recognizing their responsibility as influencers, then engaging with their online fans, and finally accepting strategic brand collaborations.

Overall, we aim to contribute to the nascent, yet important literature stream investigating intersectionality in contemporary marketing images (Gopaldas and Siebert 2018). Our focus is the intersectionality of age and gender in consumer-driven images, which is a timely endeavor since the Advanced Style phenomenon spotlighting fashionable older women has received minimal scholarly attention to date (Jermyn 2016; Tiidenberg 2018). Specifically, our work offers three important insights. First, in contrast to previous research on influencer marketing, which has focused on young females, we provide a process to understand how mature women directly impact the ageist fashion and beauty industries by becoming Instagram influencers. At the same time, we offer a direct extension to the retirement consumption literature that finds "retirement explicitly privileges consumption (living) over production (work)" (Schau et al. 2009, 256). In sharp contrast, we find that retirement is no longer purely a consumption affair but rather a new form of prosumption, whereby retirees or those approaching legal retirement age willingly find creative ways to monetize their consumption activities and hobbies. Finally, our research extends gender studies by conceptualizing gender as an assemblage of market-mediated human and non-human technological elements in the digital age.

An Exploration into How Influencers Shape Gender Identity Among Gen Z Consumers

EXTENDED ABSTRACT

Influencers attract millions of followers by sharing content curated from their daily lives on platforms such as Instagram and YouTube and typically evolve around one particular domain. For example, popular categories of influencers include interests such as fashion, beauty, and fitness. Marketers and advertisers have enthusiastically embraced influencers as they have are perceived as reliable sources of information among consumers and have the power to di-

rectly impact the purchase decisions of large audiences (De Veirman, Cauberghe, and Hudders 2017; Djafarova and Rushworth 2017). While a body of research in marketing has begun to investigate the effectiveness of influencers, and factors that may intercede their effectiveness, there is a lack of work investigating how influencers affect consumers' gender identity and gender-related consumption.

As such, this work is an attempt to increase our understanding of how influencers impact consumers' gender identity and expression. First, an exploratory study, which was conducted to determine whether or not influencers affect gender identity and gender expression, is presented. Based on these findings, the theoretical foundations of social comparison theory and self-concept clarity are used to develop a set of predictions that will be tested using a between-subjects experimental design to shed light on to how influencers impact consumers' gender identity and gender expression.

Gender is considered to be a cultural category that is reinforced by socially constructed and contested assumptions and norms. Prior work has shown media produce and communicate social signifiers, including gender, specifically depictions of femininity and masculinity (Hirschman and Stern 1994; Stevens 2012; Zayer et al. 2012). According to Schroeder and Zwick (2004, 24), "advertising discourse both reflects and creates social norms" and media and advertising representations influence both cultural and individual perceptions of gender identity, femininity, and physical attractiveness.

An exploratory study was conducted among 81 undergraduate students (74% female, $M_{age} = 20.2$) to assess whether influencers on the social media platform Instagram has impact on perceptions of gender identity and gender expression. Participants were provided with a definition of gender identity and a definition of gender expression from the Human Rights Campaign website. They were then asked to answer four open-ended questions to determine whether influencers impact their gender identity, their gender expression, as well as the gender identity and gender expressions of their friends.

The responses to these questions were read and coded by the researcher and graduate assistant. Each identified main themes and sub-themes for each question, and then combined findings from the questions to identify common themes and sub-themes. Findings suggest that participants largely did not believe that influencers held sway over their gender identity, although this varied based on one's confidence in their own gender identity. Participants overwhelmingly believe influencers play a large role in their gender expression. A sub-theme of social comparison with the influencer also emerged when analyzing the question about gender expression. Specifically, participants often discussed comparing oneself with an influencer in terms of femininity and masculinity. Finally, in assessing responses to the question about whether influencers impact perceptions of gender identity among their friends, responses were overwhelmingly positive with most participants stating that influencers play a large role in their friends' gender identity and gender expression. Analysis also revealed that when discussing the effect that influencers have on their peers' gender identity, it was often in reference to friends or peers that may not be as self-assured in their gender identity.

A dearth of literature has examined the effects that traditional advertising has on female consumers' self-perceptions, largely focusing how exposure to idealized imagery negatively impacts women's self-perceptions (D'Alessandro and Chitty 2011; Hogg and Fragou 2003; Pounders, Rice, and Mabry-Flynn 2016; Richins 1991; Smeesters and Mandel 2006). The bulk of this work uses social comparison theory (Festinger 1954), which states individuals engage in spontaneous comparisons to others in order to evaluate the self on a particular attribute to explain these relationships. Similarly we predict that consumers will engage in spontaneous comparisons with

influencers and that these comparisons will impact consumers' self-perceptions in the form of self-esteem, femininity, and satisfaction with physical appearance. We also anticipate that these comparisons are related to gender expression. Further, we expect that these relationships will be moderated by type of influencer.

Self-concept clarity refers to "the extent to which self-beliefs are clearly and confidently defined, internally consistent, and stable (Campbell et al. 1996). Accordingly, when consumers have low self-concept clarity, their self-concept is less coherent and more unstable. Prior research has found that low self-concept clarity has two main effects on consumer behavior: it increases the degree to which consumers are impressionable and influenced by external self-relevant information (Campbell 1990) and reduces the psychological resources consumers have available to process identity-related information (Campbell 1990). For example, Campbell (1990) found that consumers with low self-concept clarity take longer to determine if an adjective represents their identity. We believe that self-concept clarity will moderate the relationship influencers have on self-perceptions. Specifically, we predict influencers are more likely to impact consumers' (a) gender identity and (b) gender expression when consumers have low self-concept clarity about their gender identity.

These predictions will be examined in a 2 (influencer type) X 2 (self-concept clarity) between-subjects experiment using influencers identified in the exploratory study. The sample will consist of female consumers ages 18-25. Data will be collected in April and analyzed using ANOVA and Process Model 8. Findings will be ready for presentation by the 2020 Annual ACR conference. It is expected that the findings from this work will contribute to the literature on gender and identity by shedding light into how influencers and online platforms impact gender identity among Gen Z women.

The Contemplative Consumer Identity: Bridging Spirituality and the Marketplace

EXTENDED ABSTRACT

A growing stream of research examines the conflation of markets and spirituality, focusing on the roles consumers assume at this intersection (Huseman and Eckhardt 2019). Two approaches can be identified. The first assumes a critical stance on the interface of spirituality and markets, noting appropriation, distortion, and commoditization of religions or other belief systems (Rindfleisch 2005). It characterizes the (re)emergence of spiritual systems as consumerist markets or "spiritual supermarkets" (Redden 2016, 2). For example, Rindfleisch (2005, 346) argues that entrepreneurs in the New Age field treat complex traditional systems of beliefs in "partial and superficial" ways, which "reduces and decontextualizes their meanings," thereby making them palatable for consumer markets. The second approach is reconciliatory and examines the hybridization of commercial and spiritual worlds as a phenomenon of interest without assuming that one value regime is morally or ideologically superior to the other (Scaraboto and Figueiredo 2017; Gibson-Graham 2008). Here, consumer identities seamlessly blend with other non-commercially defined roles of community members, neighbors, pilgrims, or faithful church members (Santana and Botelho 2019; Kedzior 2013).

Bridging these approaches, recent research has examined the experiences of consumers who engage with spiritual market offerings. Huseman and Eckhardt (2019, 393) introduce the concept of consumer spirituality, defined as "the interrelated practices and processes that people engage in when consuming market offerings (products, services, places) that yield 'spiritual utility'." This emergent stream of research highlights that markets need to be shaped to accommodate spiritual consumption (Huseman and Eckhardt 2019;
Suddaby 2019). Yet, as Redden (2016, 5) notes, "there often appears to be a reticence to examine the market dynamics more closely" in spiritual contexts, "even where it would provide explanatory power." Hence, more research is needed on "the role of market actors; in particular to the role of spiritual practitioners, entrepreneurs and leaders, in shaping the spiritual market offer" (Huseman and Eckhardt 2019, 395).

Our study addresses these gaps by examining the market-making dynamics in the spiritual field of Tarot reading. We focus on how online spiritual portals contribute to spiritual consumer identity creation. Tarot is a deck of 78 cards whose origins date back to Renaissance Italy. Although much of its history is shrouded in mystery, since late XVIII century, Tarot evolved into a fortune-telling and divinatory device, with its cards acquiring symbolic and esoteric meanings. Recent shifts in the spiritual marketplace have made Tarot more accessible (Gregory 2016), as materials are available online and resources (e.g. Tarot decks and books) have proliferated in the market.

In collecting and analyzing data for this project, we follow the methodological recommendations for studying spiritual consumption (Ozanne and Appau 2019). We are sensitized to the socio-historical context in which consumers' interest and engagement with Tarot as a spiritual path happens, and explored indigenous ways of interpreting and theorizing the phenomenon. As part of a larger effort to collect ethnographic and netnographic data on the market of Tarot, we collected data from Lilly Tarot (pseudonym), one of the largest online portals for Tarot readers. Founded in 1999 by Belinda Maffei (pseudonym), Lilly Tarot is one of the earliest online spiritual portals in the emergent Tarot market. Belinda produced a podcast series of 146 episodes (average length 40 minutes) in which she introduces Tarot to those interested in becoming readers. Her podcast series reached 2 million daily visits. Each episode was accompanied by a full transcription, which we downloaded and archived, totaling 479 pages of single-spaced text. We also read all the additional resources included in each episode (e.g. card spread templates and links to websites). A common feature in the Lilly Tarot podcast series is interviews with other actors in the Tarot market (e.g. book authors, card deck designers, numerologists). Interviewees often discussed their trajectories as Tarot experts, and their perceptions of how Tarot has evolved through the decades.

The podcast series offers us a window into the development of the Tarot market, as it allows us to "account for changes from a specific point of view" (Hagberg 2016, 114). We identify two market-making strategies through which online portals and spiritual entrepreneurs act to bridge spirituality and marketization: First, is "The High Priestess" – designing the contemplative consumer. Belinda and her interviewees leave no room for listeners to assume roles other than reader and client – seller and buyer – in the Tarot reading market. Learners are considered entrepreneurs and encouraged to practice by offering free readings for friends and family to accumulate "confidence enough to charge." Yet, in any of these roles, Belinda argues, individuals should focus on unlocking "the true power of Tarot [which] is helping you get in touch with yourself and your intuition." Before reading to oneself or a client, Tarot readers should "center yourself, ground yourself, and also connect yourself in with the Universal energy that's around you." Tarot cards become a device to "slow down, focus, and reconnect to oneself and to others." We find that this is the key characteristic of the contemplative consumer, who uses Tarot (and other spiritual practices) as a pathfinder on the journey to the Higher Self. The second market-making strategy identified is the "The Magician" – empowering consumers for market expansion. The online portal allows consumers to do Tarot

"their own way." Belinda reminds listeners that "anyone can do this if it's their calling, and it feels right for them." Interviewees often echo this discourse: "it is your reading practice, and you're not working for an employer, so you don't have to do it anyone else's way! […] go your own way, and charge what you're worth." By empowering Tarot readers, spiritual entrepreneurs work to expand the market, offsetting the barriers to entry into the esoteric category (Rinallo and Maclaran 2016).

Overall, our analysis suggests that the online portal provides an abundance of resources that materialize these two market-making strategies, as well as provide a template for Tarot consumers to reconcile tensions between spirituality and marketization as they transition toward becoming spiritual entrepreneurs. How consumers respond to spiritual entrepreneurs' efforts to shape the market should be the subject of future research.

Paper #4: Risk Aversion or Profit Seeking? Explaining the Uncertainty Effect
Randy Y. Gao, New York University, USA
Minah H. Jung, New York University, USA

SESSION OVERVIEW

Uncertainty is prevalent in real life. Understanding uncertainty better will help improve a wide variety of decisions, for example, how to pique interests and incentivize customers (for marketers), when to seize on an attractive offer (for consumers), and whether to attend a special session (for conference attendees). Uncertainty is also pervasive in the academic literature, with previous researchers identifying both its costs (Gneezy, List, & Wu, 2006) and benefits (Goldsmith & Amir, 2010; Shen, Fishbach, & Hsee, 2015). How can we reconcile these seemingly paradoxical findings? Moreover, much of the information consumers encounter daily is inherently uncertain and often expressed in probabilities or proportions. How well do consumers understand these representations? The current session brings together four papers that shed new light on how people make judgments and decisions under uncertainty, from both empirical and theoretical perspectives.

The first paper by Gaertig and Simmons finds that uncertain price promotions are not always more effective than sure discounts of equal expected value. Specifically, the authors propose that consumers are more likely to prefer an uncertain price promotion to a sure discount only when the sure discount *feels* small.

The second paper by Hsee and Ruan presents an integrative framework that helps reconcile the apparent discrepancies in the existing literature regarding the effect of curiosity and uncertainty. The authors propose that the resolution of uncertainty and curiosity always bring positive utility, regardless of the actual outcome. When people are curious and such expected positive resolution utility is heavily weighted, people might engage in uncertainty-resolving behaviors even when the expected outcome utility is negative.

The third paper by Overton, Vosgerau, & Evangelidis finds that consumers confuse consensus information (e.g., 70% prefer product A over product B) with strength of preferences for the products (e.g. how much better A is rated than B). Specifically, consumers don't anticipate that an option preferred by fewer people often have ratings similar to – and sometimes even higher than – ratings of an option preferred by more people.

The final paper by Gao and Jung proposes a novel explanation for the Uncertainty Effect (Gneezy, List, & Wu, 2006). The authors argue that people are willing to pay less for an uncertain prospect than its worst payoff, not because they find the prospect inherently aversive, but because they want to exploit the deal for greater profit. Whereas the certain offer is construed as a regular transaction, and market norms prohibit exploitation in such cases, the game-like features of the uncertain offer enable profit-seeking, which gives the appearance of risk aversion. The Uncertainty Effect disappears when it is made difficult or impossible to exploit the uncertain offer.

Together, these four papers enrich our understanding of consumer decision-making under uncertainty, through well-powered empirical investigations, careful synthesis of existing research, and novel theoretical insights. We believe this session will prove not only intriguing to researchers in consumer judgment and decision making, but also useful to the broader audience of marketing practitioners and their customers.

Why (and When) Are Uncertain Price Promotions More Effective Than Equivalent Sure Discounts?

EXTENDED ABSTRACT

What do consumers prefer - a sure discount on a purchase or an X% chance to get the product at an even greater discount? Although the ubiquity of sure discounts might lead one to infer that they are more effective, recent research on this question suggests the opposite: Consumers seem to prefer uncertain promotions to equivalent promotions that offer a discount or reward with certainty (Goldsmith and Amir 2010; Mazar, Shampanier, and Ariely 2017; also see Shen, Fishbach, and Hsee 2014). In an important paper, Mazar, Shampanier, and Ariely (2017) demonstrated that people are more likely to purchase a product when it comes with a chance to get it for free than when it comes with a sure discount of equal expected value. This suggests that marketers should make more use of uncertain promotions than they currently do.

In the current project, we offer a theory that more fully explains these results, and that predicts that the effect will only emerge when the sure discount *feels* small. In four studies (N = 6,713), we find that uncertain price promotions are more effective than equivalent sure discounts only when those sure discounts *feel* small. Specifically, we find that uncertain promotions are relatively more effective when the sure discounts are actually smaller (Studies 1 and 2) or when the sure discounts are made to feel smaller by presenting them alongside a larger discount (Study 3) or by framing them as a percentage-discount rather than a dollar amount (Study 4).

In Study 1 (N = 2,302), we asked participants to choose among three hotels, one of which was promoted. We manipulated whether the promotion was certain (10% off) or uncertain (10% chance to get it for free), and whether the price of the promoted hotel was low ($48) or high ($480). Participants were more likely to choose the promoted hotel when it came with a chance-for-free promotion than when it came with a sure discount, $b = .057$, $SE = .021$, $p = .006$, and when the price was low ($48) than when it was high ($480), $b = .041$, $SE = .021$, $p = .045$. However, a significant interaction, $b = .084$, $SE = .041$, $p = .041$, revealed that the difference between the two promotion types was only significant for the low-price condition ($p = .001$), but not for the high-price condition ($p = .609$). Thus, the chance-for-free promotion only outperformed the sure discount when the sure discount was small ($4.80). Because the percentage associated with the promotion was held constant at 10%, this effect cannot be explained by consumers' overweighting of small probabil-

ities. In Study 2 ($N = 852$), we replicated the findings from Study 1 in a within-subjects design, where participants were asked to directly choose between the two types of promotions.

In Study 3 ($N = 1,188$), we manipulated how large or small a sure discount felt by manipulating the context. Participants were asked to imagine that they were buying a $50 training session, and that they could choose between receiving a $5 sure discount or a 10% chance to get it for free. We presented the training session alongside a gym membership which was either priced at $480/year (with a $48 discount) or $40/month (with a $4 discount). Participants were more likely to prefer the 10% chance-for-free promotion over a sure discount of $5 when the context was a $48 discount of the yearly membership price than when the context was a $4 discount of the monthly membership price, $b = .229$, $SE = .108$, $p = .034$. Thus, asking consumers to consider the same discount in the context of a larger discount increased people's relative preference for an uncertain promotion.

In Study 4 ($N = 2,371$), we tested an additional way to manipulate how large a sure discount feels, namely by manipulating whether the sure discount is framed as a percentage or a dollar amount. We first conducted a pretest which revealed that a sure discount is rated as smaller when it is framed as a percentage off than when it is framed as a dollar amount ($p < .001$). In Study 4, we then asked participants to imagine that they were buying a product that came with one of two types of promotions, either a 10% sure discount or a 10% chance to get it for free, and that they could choose which they would like to receive. We manipulated the price of the product to be low ($11) or high ($311), and, importantly, we also manipulated whether the sure discount was presented as a percentage (i.e., 10% off) or as the equivalent dollar amount (i.e., $1.10/$31.10 off). Participants were more likely to choose the chance-for-free promotion over the sure discount when the price was low than when it was high, $b = .241$, $SE = .075$, $p = .001$. More importantly and in line with our pretest, participants were also more likely to choose the chance-for-free promotion over the sure discount when the sure discount was framed as a percentage than when it was framed as a dollar amount, $b = .523$, $SE = .075$, $p < .001$. The interaction was significant as well, $b = .352$, $SE = .151$, $p = .019$, such that the framing of the sure discount had a larger effect in the low-price condition. Thus, the results from this study suggest that we can alter people's preferences for uncertain promotions simply by changing whether the sure discount is framed as a percentage or as a dollar amount.

Our findings are inconsistent with two leading explanations of consumers' preferences for uncertain over certain promotions – diminishing sensitivity and the overweighting of small probabilities – and suggest that people's preferences for uncertainty are more strongly tethered to their perceptions of the size of the sure outcome than they are to their perceptions of the probability of getting the uncertain reward.

A Curious Case of Curiosity: An Integrative Review of Recent and Seemingly Contradictory Findings

EXTENDED ABSTRACT

Many studies have been published recently on curiosity (e.g., Golman & Loewenstein, 2018; Hill, Fombelle, & Sirianni, 2016; Hsee & Ruan, 2016; Jepma, Verdonschot, Van Steenbergen, Rombouts, & Nieuwenhuis, 2012; Kang et al., 2009; Kobayashi, Ravaioli, Baranès, Woodford, & Gottlieb, 2019; Lau, Ozono, Kuratomi, Komiya, & Murayama, 2018; Noordewier & van Dijk, 2017; Oosterwijk, 2017; Ruan, Hsee, & Lu, 2018). However, the findings of these studies are disparate or even apparently contradictory. For example, some studies suggest that curiosity is "bad"—leading people to expose themselves to miseries (Hsee & Ruan, 2016; Lau et al., 2018; Oosterwijk, 2017), while other studies suggest that curiosity is "good"—leading to happiness and joy (Kang et al., 2009; Noordewier & van Dijk, 2017; Ruan et al., 2018; Golman, Loewenstein, Molnar, & Saccardo, 2019).

Closely related to curiosity is the notion of uncertainty, because curiosity arises from uncertainty in information. Like recent findings on curiosity, recent findings on uncertainty also yield seemingly contradictory findings. For example, Gneezy, List and Wu (2006) find that people dread uncertainty, so much so that they would rather have a dominated certain reward (e.g., $10 for sure) than a dominating uncertain reward (e.g., an even chance at $10 and $20; see also Newman and Mochon 2012; Simonsohn 2009), while Shen and coauthors (Shen, Fishbach & Hsee 2015; Shen, Hsee & Talleon 2018) find that people embrace uncertainty, so much so that they are more motivated to work for a dominated uncertain reward (e.g., an even chance of $5 or $10) than a dominating certain reward (e.g., $10 for sure). Other authors also report positive effects of uncertainty (Goldsmith and Amir 2010; Wilson, Centerbar, Kermer, & Gilbert, 2005).

We propose resolution utility (the experienced utility of resolving uncertainty and the accompanying curiosity) as a unifying theoretical construct that elucidates and integrates the seemingly disparate findings in the literature. Our theoretical framework builds on three central propositions.

The first proposition is that resolution utility is positive. Put differently, regardless of the outcome that resolves uncertainty, the mere resolution of uncertainty and the accompanying curiosity always yields positive utility. This is consistent with prior research suggesting that curiosity is "good" and can lead to happiness and joy. For example, learning the answer of a trivia and thus resolving one's curiosity about it is sufficient to produce positive feelings (Kang et al., 2009; Ruan et al., 2018). Learning or experiencing a negative outcome may feel bad, such as one learning she has lost in a gamble. However, that is because the *outcome utility*—the overall utility of the actual outcome(s) of an uncertainty—is negative. Above and beyond the negative utility of an outcome, the mere resolution of uncertainty may still produce positive resolution utility.

Building on positive resolution utility, the second proposition concerns uncertainty-resolving behavior. Specifically, we propose that the tendency to engage in (and repeat) a behavior that resolves uncertainty and the accompanying curiosity depends on expected *resolution utility* and expected *outcome utility* (the expected utility of the possible outcomes of an uncertainty because it is ex ante). For example, when people are presented with a box and need to decide whether or not to open it, the expected resolution utility is the expected pleasure of finding out what is in the box, and the expected outcome utility is the expected utility of the possible outcomes of the opened box. We predict that people would open the box if expected overall utility is positive and would not open it if expected overall utility is negative.

Our last proposition considers the relative weights of these two utilities and holds that when people are curious, they put more weight on the expected (positive) resolution utility than the expected outcome utility (which can be negative, neutral, or positive). Therefore, it is possible that the former may override the latter, leading people to resolve uncertainty even if they expect the outcome utility to be negative. Indeed, Hsee and Ruan (2016) find that because participants were curious about whether a prank pen would give electric shocks if clicked, they clicked the pen just to resolve their curiosity, even though doing so also put them at risk of being shocked. In this

case, the expected pleasure of uncertainty resolution overrode the expected pain of receiving an electric shock.

Our framework can also explain why an uncertain incentive (e.g., 20¢ or a 50¢) can be more motivating than a certain incentive (50¢) that dominate the uncertain incentive (Shen et al. 2015; 2018). A certain incentive produces only one type of positive utility, namely, the utility of receiving the discount (i.e., outcome utility). However, an uncertain incentive yields two types of positive utilities: the utility of resolving the uncertainty (i.e., resolution utility) and the utility of receiving the discount (i.e., outcome utility). Although the outcome utility of an uncertain incentive may be lower than that of a certain incentive, the resolution utility of the uncertain incentive can be greater than their difference in outcome utility, resulting in greater overall utility of the uncertain incentive, especially if people are curious about it.

This paper is important both theoretically and practically. Theoretically, it builds on Loewenstein's (1994) seminal work on curiosity and provides an integrative framework that reconciles seemingly contradictory recent findings on the topic. Practically, this review is timely, because the amount of information people seek and receive nowadays is unprecedented in human history; curiosity—the desire for information—is a main driving force in this information age and deserves better understanding.

Consumers Confuse Consensus with Strength of Preferences

EXTENDED ABSTRACT

Imagine you are shopping for a new car. You are deciding between a Honda Accord and a Toyota Camry. Looking online for comparisons of these cars, you find a poll according to which 72% of consumers prefer the Accord to the Camry. You may infer from this information that consumers like the Accord much better than the Camry. In fact, such inferences are natural and occur spontaneously (Kardes et al. 2004, *JCP*). Surprisingly, they are not necessarily correct. The Accord may have received a higher average rating than the Camry, but it is in fact more likely that the two cars received very similar ratings. It is even possible that the Camry was rated better than the Accord!

In general, it is more likely for two (average) ratings to be close to each other than far apart. When ratings are made on scales from 1 to 5, for example, it is much more likely to observe a difference of 1 than of 4 points, because there are many more possible combinations of ratings resulting in a difference of 1 (e.g., 5 & 4, 4 & 3, 3 & 2, etc.) than there are for a difference of 4 (5 & 1). This combinatorial reason holds no matter what proportion prefers one car to the other. Hence, even if 72% prefer the Accord to the Camry, it is more likely that the two cars received similar than vastly different ratings.

But how could the Camry receive a better average rating than the Accord? That is possible when the rating distributions are skewed (as is typically the case with online ratings). If the Camry's rating distribution is right-skewed and the Accord's distribution is left-skewed, the Camry can have a higher average rating than the Accord while a greater proportion of consumers prefer the Accord to the Camry.

We show that consumers are not aware of these regularities, which leads them to confusing consensus information (a measure of preference heterogeneity or preference uncertainty) with strength of preferences.

In Study 1 (N = 700, MTurk, https://aspredicted.org/blind. php?x=c8rj88), we tested whether consumers interpret consensus information beyond what it conveys about strength of preferences.

Participants were shown two wines, A and B, and told that both wines had been rated by consumers on a scale from 1 to 10. Participants were further told that either 90% preferred A to B, 65% preferred A to B, or were given no additional information (control). We then asked participants which was more likely, that A's average rating is 4 points higher than B's or that it is 1 point higher than B's (the latter is the correct answer in all conditions). Correct answers were incentivized with a bonus. The incorrect answer of 4 points higher was chosen 31.5% of the time in the control condition, was chosen 51.3% in the 65% consensus condition, and 69.2% of the time in the 90% consensus condition (all chi-squares against control p < .001), suggesting that consumers incorrectly infer strength of preferences from consensus.

Study 2 (N = 400, MTurk, https://aspredicted.org/blind. php?x=zx2y4f) used the same paradigm as Study 1 (wine A was preferred by 60[90]% to wine B). Participants were given three answer options: ratings of wine A and B differ by 0 to 1, by 2 to 3, or by 4 to 5 points. Like in Study 1, participants were more likely to incorrectly choose one of the larger preference differences (compared to 0 to 1) in both the 60% (74%) and the 90% consensus condition (89%; all binomial tests against equal choice shares p < .001).

Study 3 (N = 798, MTurk, https://aspredicted.org/blind. php?x=w6xq3q) tested whether consumers are aware that a less preferred product B can still have a higher average rating than the more preferred product A. Participants learned that two hotels, A and B, had been rated on 5-point scales and that 65% of consumers preferred Hotel A to Hotel B. Participants were then asked to choose which of the below answers were possible and incentivized with a bonus to select the most complete answer (option 3).

1. Average rating of Hotel A = 3.8, average rating of Hotel B = 3.2
2. Average rating of Hotel A = 3.2, average rating of Hotel B = 3.8
3. Both options 1) and 2) above are possible
4. Neither option 1) or 2) are possible

Option 1 was chosen more frequently than the, most complete answer, option 3, (43.7% vs 30.3%, binomial test *p = .002*). In another condition, we tested whether participants would make the same mistake when inferring consensus information from average ratings. Contrary to our expectations, the majority of participants failed again to choose the complete answer, similarly to the former condition (34.8%, $\chi^2(1) = 1.24$, $p = .266$).

Finally, Study 4 (N = 604, MTurk, https://aspredicted.org/blind. php?x=rp84jg) tested whether strategically displaying consensus or strength of preferences information influences consumer choice. Additionally, we tested if such an effect is driven by anchoring or confusing consensus with strength of preferences. Participants were told that Hotel A costs $135 and Hotel B costs $120. In the consensus conditions, participants were asked "Given that 60[90]% gave Hotel A a higher rating than Hotel B, which hotel would you choose?" In the strength of preferences conditions, participants were either told that Hotel A received a 0.4 [1.4] higher rating than Hotel B on a 5-point scale, or that Hotel A received a 400 [1,400] higher rating than Hotel B on a 5000-point scale. The 5000-point scale was included to test the influence of anchoring. We verified analytically that the strength of preferences (0.4 or 1.4 on a 5-point scale) represent the mean of the consensus information (60% or 90% preferring A to B).

For ratings on the 5-point scale, participants were more likely to choose the more expensive hotel when given consensus rather than strength of preferences information ($z = 5.13$, $p < .001$). Though the data are not consistent with anchoring, the effect did not occur on the 5000-point scale.

Risk Aversion or Profit Seeking? Explaining the Uncertainty Effect

EXTENDED ABSTRACT

Uncertainty abounds in the marketplace. Traditional sweepstakes and lotteries aside, recent years have also witnessed rising popularity of "mystery boxes", whose content is unknown to the buyer at the time of purchase. How much do consumers value uncertain offers? The answer appears to be "not much", according to research on the Uncertainty Effect (UE). Gneezy, List, & Wu (2006) found that people were willing to pay even less for an uncertain prospect than for its worst payoff. On the other hand, uncertain offers have been found to be just as enticing (Goldsmith & Amir, 2010) or even more enticing (Shen, Fishbach, & Hsee, 2015) than its best payoff.

In the current project, we propose a novel explanation for the UE that may help reconcile these seemingly contradictory findings: people are willing to pay less for an uncertain prospect, not because they find the prospect inherently aversive, but because they want to exploit it by paying little. While a certain offer is construed as a regular purchase, and market norms prohibit excessive exploitation, the novel and game-like features of an uncertain offer allows or even encourages people to exploit the offer. In six studies ($N = 4430$, all preregistered on AsPredicted), we found evidence consistent with our proposed explanation.

In **Study 1** ($N = 401$), we ask a series of straightforward questions to examine people's perception of the uncertain (vs certain) offers, as well as their considerations when deciding how much to pay. Participants were randomly assigned to evaluate either a certain offer (a $50 gift certificate), or an uncertain offer (a coin flip that gives either a $50 gift certificate or a $100 gift certificate). Participants felt the uncertain offer was more like a game and less like a regular purchase than the certain offer, ps < 0.001. More importantly, as we predicted, participants in the uncertain condition also stated that when they considered how much they would be willing to pay, it was less important to be fair to the seller but more important to maximize the profit, compared to participants in the certain condition, ps < 0.001.

If our "profit seeking" account holds, then we would not observe the UE when the uncertain prospect offers neither room nor need to seek profit. We believe that in the classic paradigm, because the value of the gift cards is fixed, it offers participants an opportunity to exploit the offer by paying little. We remove opportunity for exploitation by removing such "guaranteed amount" setup in the next two studies. **Study 2** ($N = 600$) asked participants (between-subjects) how much they would be willing to donate to either a preferred charity, a less preferred charity, or an uncertain charity (randomly chosen between the two). We found that people were willing to donate significantly more to an uncertain charity ($M = \$35.57$) than to a less preferred charity ($M = \$27.30$), $p = 0.010$. We also conceptually replicated the findings in a commercial, non-charity setting in **Study 3** ($N = 607$): participants were willing to add significantly more money to a gift card, if the gift card was from an uncertain retailer ($M = \$55.60$) than when it was from a less preferred retailer ($M = \$42.18$), $p < 0.001$. Taken together, results from **Studies 2-3** suggest that people are not simply averse to uncertainty per se.

Finally, in **Studies 4-6**, we test the moderating role of the salient exchange norms on consumers' valuation under uncertainty. If people pay little for the uncertain offer because they perceive it as salient market norms, then they should be less likely to exploit the uncertain offer when it becomes less appropriate to be excessively exploitative. It has been shown that the salient norms under PWYW deviate from the traditional market transaction norms (Gneezy, Gneezy, Riener, &

Nelson, 2012; Kim, Natter, & Spann, 2009). In **Study 4** ($N = 1211$), participants were asked how much they would be willing to pay to watch a preferred movie, a less preferred movie, or for a coin flip that gives them a ticket to watch either one of the two movies (randomly chosen). Half of participants in each condition were further told that the theater uses PWYW pricing, and they could pay any amount they want. Participants' WTP for the less preferred movie was lower under PWYW ($M = \$5.50$ vs. $M = \$7.32$), $p < 0.001$. Interestingly, participants' WTP for the uncertain movie actually *increased* under PWYW ($M = \$5.26$ vs. $M = \$4.22$), $p = 0.001$. In fact, while we replicated the UE without PWYW ($\$7.32$ vs. $\$4.22$, $p < 0.001$), we did not observe the UE under PWYW ($\$5.50$ vs. $\$5.26$, $p = 0.644$). In **Studies 5-6** ($N = 1611$), we replicated all the results above: under PWYW, WTP for the less preferred movie decreases while WTP for the uncertain movie increases, ps < 0.001. In neither study did we find the UE under PWYW ($p = 0.567$ and $p = 0.189$). These results are consistent with our theorizing that lower valuation in the classic uncertainty paradigm is driven by the perceived market norms. Under PWYW, however, such norms shift such that people do not maximally exploit under uncertainty even when they can by paying zero.

In summary, results from six studies challenge the "risk aversion" account of the UE, and support our proposed "profit seeking" account, which is also consistent with the finding that the UE is unique to pricing measures (Moon & Nelson, in press). To the best of our knowledge, we are the first to propose such an explanation for the UE, instead of an *aversion* to risk (Simonsohn, 2009; Newman & Mochon, 2012), bad deals (Yang, Vosgerau, & Loewenstein, 2013), or unexplained transaction features (Mislavsky & Simonsohn, 2018). Our results have both important practical implications and theoretical contributions, by calling attention to consumers' construal of a transaction during preference elicitation (Fischhoff, Welch, & Frederick, 1999).

SESSION OVERVIEW

The nascent field of consumer neuroscience holds great promise for generating new insights and theory in consumer behavior. Recently, evidence has emerged indicating that neural activity in the brain's valuation system may be used to forecast market-level behavior of companies, products, and advertising performance. This phenomenon, called 'neuroforecasting', is the use of brain activity from a small sample of individuals to forecast choices or preferences of a separate, large population group of individuals (Knutson & Genevsky, 2018; Falk & Scholz, 2018). At present, a number of neuroforecasting studies have illustrated this phenomenon, including for music album sales (Berns & Moore, 2012), calls to a smoking cessation helpline (Falk, Berkman, and Lieberman, 2012), various ad metrics (Venkatraman et al., 2015; Falk et al., 2016), news sharing (Scholz et al., 2017), online media consumption (Tong et al., 2020), and microlending (Genevsky & Knutson, 2015). However, many open research questions surrounding neuroforecasting remain. This special session brings together work by leading researchers in this field to expand on our understanding of neuroforecasting.

The papers in this session aim to expand on our understanding of neuroforecasting. In the first paper, authors examine the role of generalizable and idiosyncratic choice processes by exploring how forecasts based on behavioral and neural measures are differentially impacted by the representativeness of the study sample to the market population, and show that when compared to behavioral measures, neural data is less impacted by the representativeness of the sample. This suggests that neural activity may be a more generalizable index of preference across individuals than self-report measures or observed behavior. In the second paper, authors seek to build a model of neural predictors of health information diffusion, focusing

on whole-brain representations of reward value elicited in response to health-related news articles. This paper highlights the advantages of using whole-brain patterns associated with reward valuation in addition to previously used region-specific and self-report predictors of health information sharing. The third paper in this session proposes a novel method to predict pre-launch product sales by combining retailer data about competitors with information from traditional surveys and fMRI data, and gauges the added value of each information source (*market data*, *survey*, *fMRI)*. Findings illustrate what managers can learn and the key benefits from running fMRI studies and/or traditional surveys before new product launch. The fourth paper in this session aims to test neuroforecasting in a novel market, using online dating profiles, and attempts to differentiate between how affective and informational components of choice can forecast market level outcomes.

In sum, the papers in this special session address the following research questions: 1) how do behavioral and neural measures perform when the sample of participants is more or less representative of the market?, 2) can neuroforecasting prediction be improved upon by expanding from previous region-based neural approaches to the use of multivariate brain patterns?, 3) what is the value of neuroforecasting to managers attempting to forecast sales?, and 4) do affective and informational components of stimuli contribute differently to neuroforecasts and can we forecast online dating decisions?

Using Neural Data to Improve Forecasts of Market-Level Behavior

EXTENDED ABSTRACT

Objective

Consequential decisions in business and public policy are often based on forecasts of population-level behavior. Any improvement in our ability to accurately predict aggregate-level responses will maximize the likelihood of product success and minimize waste of valuable time and resources. Motivated by theoretical challenges from economics (Bernheim 2008) and the promise of practical applications (Smidts et al. 2014), researchers have begun to explore whether brain activity in laboratory samples can forecast aggregate choice and how neural measures compare with more traditional measures (e.g., ratings, choices; Venkatraman et al. 2015). Although a growing literature demonstrating the capacity of neural data to forecast aggregate level behavior (see Knutson and Genevsky 2018)brain activations were recorded while smokers viewed three different television campaigns promoting the National Cancer Institute's telephone hotline to help smokers quit (1-800-QUIT-NOW, no research has explored the mechanisms that account for these out-of-sample predictions.

Despite evidence to support neuroforecasting, important questions remain regarding how individual choice processes scale to inform forecasts of aggregate choice. Collected evidence from the existing neuroforecasting literature suggests a "partial scaling" account, in which some choice components may forecast aggregate behavior more accurately than others (and by extension, more accurately than individual choice itself, which constitutes the integration of all supporting components). Specifically, with respect to fMRI markers, activity associated with positively aroused affect in the ventral striatum

(including the NAcc), loss anticipation in the anterior Insula (AIns), and value integration in the medial prefrontal cortex (MPFC). Thus, we predicted that primary neural responses indexed by striatal and insular activity may generalize more across individuals and thus forecast aggregate behavior more accurately than neural regions associated with idiosyncratic value integration (e.g., MPFC). Further, these basic neural responses may also forecast behavior more accurately than individual choice itself, which by definition incorporates these generalizable and idiosyncratic neural signals. In this paper, we examine the role of generalizable and idiosyncratic choice processes by exploring how forecasts based on behavioral and neural measures are differentially impacted by the representativeness of the study sample to the market population.

Methods

In phase one, participants in the scanner were presented with projects from a popular online crowdfunding platform and were asked to make incentive compatible funding decisions. Neural activity was collected while participants viewed and then made decisions regarding these projects. In phase two, a large internet sample (n= 3000) was asked to make similar funding choices regarding the same projects presented during the imaging phase. In addition to the funding choices, demographic characteristics were also collected about the internet participants. The laboratory sample's behavior and neural activity were then used to forecast the larger internet market's preferences. Using traditional demographic variables, we construct two independent marketplaces; one more and one less well represented by our laboratory sample. Forecasts of the project preferences in the two marketplaces were calculated independently and then contrasted. Based on previous work, neural predictions focus on activity in primary affective (i.e., nucleus accumbens, insula) and value integration (i.e. MPFC) regions. We hypothesized that in the well represented market both behavioral and neural measures would demonstrate significant prediction accuracies. However, in the less well represented market we will observe a much steeper decline in accuracy for behavioral prediction and a relatively stable prediction rate for the neural measures. This finding would support the hypothesis that primary neural components of choice generalize more than others, and thus forecast out-of-sample aggregate behavior better than individual choice itself.

Results

We first explored the association between the laboratory measures and market preferences independently for the representative and non-representative marketplaces. Using the laboratory sample's behavior, we find a significant correlation with the preferences in the representative marketplace ($r = .375$, $p < .05$) but not in the non-representative marketplace ($r = .249$, n.s.). This finding indicates that the ability of a sample to forecast market-level behavior is dependent on the representativeness of the sample. However, when we used neural activity from the lab sample we find significant, and nearly identical, correlations with preferences in the representative ($r = .470$, $p < .01$) and non-representative marketplaces ($r = .447$, $p < .01$). This suggests that neural prediction of aggregate behavior is less influenced by the representativeness of the sample.

Regression analyses further explored these relationships. Linear regression models including both behavioral and neural predictors of preferences in the representative market indicated that both lab behavior (coef. = .319, SE = .151, $p < .05$) and neural activity (coef. = .613, SE = .211, $p < .01$) accounted for significant and independent variance in the market. However, in the non-representative

market, only neural activity was significantly associated with the market preferences (coef. = .656, SE = .217, $p < .01$).

Discussion

We find that when compared to behavioral measures, neural data is less impacted by the representativeness of the sample. These data suggest that neural activity may be a more generalizable index of preference across individuals than self-report measures or observed behavior. In fact, for non-representative samples, only neural activity, and not behavioral measures, were significant predictors of market preference. In a representative sample, both behavioral measures and neural activity accounted for significant and independent variance in market preference.

These data provide clear and practical implications regarding the use cases in which neural measures can provide value to marketers. First, in situations in which representative samples are difficult to obtain, due to lack of information about the target audience or an inability to find suitable participants, neural measures may provide the best option for accurately forecasting market preference. Second, even when a representative sample can be established, neural measures can add significant predictive value to models of market preference. Further, this work is the first attempt to explore the neural and psychological mechanisms that underlie and account for neural prediction of market behavior and represents a significant conceptual advance in our understanding how choice scales from individual to aggregate levels.

Population News Sharing is Reflected in Distributed Reward-Related Brain Activity

EXTENDED ABSTRACT

Information that diffuses widely in the media environment can influence the behavior of individuals and shape broader directions of societal change. Previous studies have shown that information in targeted brain regions can be used to predict this diffusion of information. However, by focusing on these targeted regions, the approach in previous work has discarded information from the majority of the brain. Here, we sought to build a model of neural predictors of health information diffusion, focusing on whole-brain representations of reward value elicited in response to health-related news articles. Beyond enriching our scientific understanding of how and why health information spreads throughout a population, models of this kind could ultimately be used to forecast and enhance the impact of communications at population scale.

Current neurobiological models posit that the functional neuroanatomy of reward value extends beyond the core striatal and ventromedial prefrontal (vmPFC) regions that have received empirical attention in previous population prediction studies. These models propose that diverse brain systems interact to rapidly propagate reward-related information throughout the brain, generating a distributed value representation that directs cognition and behavior in a multi-faceted manner. However, it is unclear whether distributed brain representations of reward value hold information that can be used to predict the impact of messaging, beyond responses in core striatal and vmPFC regions.

We sought to address this gap in knowledge with two neuroimaging studies that quantified functional brain responses to New York Times health news articles and used these responses to predict sharing of these articles in the broader population of readers. In particular, we addressed two specific questions. First, does expression of a meta-analytically defined whole-brain reward valuation-related pattern predict population-level information sharing? Second, does

expression of this pattern improve prediction of population-level information sharing beyond what can be predicted from activity within reward-related brain regions and self-reports?

Results

Our initial question was whether expression of the meta-analytically defined reward-value related pattern was predictive of population-level article sharing (collected via the New York Times website). From the perspective of practitioners seeking to explain variance in the population-level success of messaging, it is important to characterize the predictive efficacy of our models in terms of how well they explain article-to-article variance in population sharing. Therefore, we also estimated the relationship between the average expression of the meta-analytically defined reward value pattern for each article (averaged across all the perceivers in a study) and the population sharing of those articles. This indicated that the standardized article-level relationship between pattern expression and population article sharing was $\beta = .33$, 95%CI[.12, 54] in Study 1 and $\beta = .41$, 95%CI[.21, .62] in Study 2.

In a next step, we sought to understand the extent to which a model incorporating expression of the reward-related pattern showed increased predictive accuracy relative to reduced models including only activity in a reward-related region of interest (ROI) and subjective ratings of the articles. First**,** we fit models that controlled for activity within the reward-related region (spanning vmPFC and ventral striatum), and self-reports of article value (reading intentions in Study 1, sharing intentions in Study 2), finding that expression of the reward value pattern predicted population article sharing above and beyond these other predictors in both Study 1, $\beta = .07$, 95%CI[.01, .14], and in Study 2, $\beta = .12$, 95%CI[.04, .21].

As above, in order to understand the practical value of each predictor in forecasting out-of-sample sharing, we estimated the variance explained by our brain and self-report predictors when aggregating data from all perceivers up to the article level. Combining the data from Studies 1 and 2, the aggregate article-level R^2 was .18, 95%CI[.05, .30], for a model 1 including only subjective ratings of the articles, .24, 95%CI[.10, .36], for a model 2 including subjective ratings and reward value-related ROI activity, and .34, 95%CI[.19, .46], for a model 3 including subjective ratings, reward value ROI activity, and reward value pattern expression. To estimate the out-of-sample predictive accuracy of these linear models, we used Bayesian leave-one-out (LOO) cross validation to derive LOO-adjusted deviance values (LOOIC) reflecting expected out-of-sample predictive error. The model including ratings, reward value ROI, and reward value pattern expression showed improved predictive fit relative to model 1 including only ratings, $\Delta LOOIC_{m3-m1} = -12.7$, SE=7.3, and relative to model 2 including ratings and reward value ROI activity, $\Delta LOOIC_{m2-m1} = -8.9$, SE=5.6. Overall, these results indicate that the expression of the reward value-related pattern substantially improved accuracy in predicting population-level article sharing, with a full model reaching on the order of one-third of the variance explained.

Discussion

We used neuroimaging to ask whether whole-brain response to health-relevant news articles could predict large-scale, out of sample, sharing of those articles, beyond previously identified brain and self-report predictors. Our results indicated that expression of a distributed pattern of brain activity meta-analytically associated with reward valuation substantially improved accuracy in predicting population sharing of the health news articles, beyond previously identified brain and self-report predictors. Further, the predictive ef-ficacy of the pattern was not reducible to patterns of activity within core brain reward regions but rather depended on larger-scale patterns of activity distributed widely across cortical, subcortical, and brainstem systems. These findings highlight the advantages of using whole-brain patterns associated with reward valuation in addition to previously used region-specific and self-report predictors of health information sharing.

If the brain holds information that can be used to forecast large-scale behavior, how do we best characterize and model this activity? Here we suggest that, in addition to summed activity within core value-related brain regions, it is useful for neural prediction models to incorporate information about distributed brain representations of value. Overall, this work contributes to our growing ability to use neural data to forecast out-of-sample outcomes and augments our understanding of the brain mechanisms that underlie how information diffuses (or fails to diffuse) across a population of individuals.

Top or Flop: Quantifying the Value of fMRI Data in the Prediction of Success of New Products

EXTENDED ABSTRACT

Managers are keen to obtain the best possible forecast about future sales, so that they can plan with operations ahead and adjust marketing policies if necessary. This is especially the case for new products for which, by definition, no previous sales information is available. Some innovations might turn out to be best-sellers, exceeding previous expectations. If managers anticipate such future success, they can previously plan to avoid stock-out, for instance. Other innovations might become clear failures, which can even endanger the reputation of the company. Having a good forecast about the fiasco can support managers in their decision whether to launch the product at all.

We propose a novel method to predict pre-launch product sales by combining retailer data about competitors with information from traditional, representative surveys in which participants were asked to give their views about existing and new products as well. Importantly, we further add functional magnetic resonance imaging (*fMRI*) data to the model, in which we measure the brain activity of participants during survey questions.

Since the seminal work of Bass (1969), various authors have studied the adoption of new products (Lee et al., 2003; Neelamegham and Chintagunta, 1999; Lenk and Rao, 1990). Traditionally, such studies relied on either revealed or stated preference data, but more recently some utilized a combination of these two (Helveston et al., 2018; Hardt et al., 2017; Phaneuf et al., 2013; Morikawa et al., 2002; Harris et al., 1999). As the standard goal of this field is to make inference about the real-world market, choice experiments have been improved to better mirror the outcomes when consumers face the purchase decision in the store as opposed to the lab (Gilbride et al., 2008; Allenby et al., 2005; Wertenbroch and Skiera, 2002).

Recently, a growing body of literature established the link between the activity in certain areas of the brain and real-world monetary outcomes. Kühn et al. (2016) found that their *fMRI* data correlated with supermarket sales of existing products. *fMRI* also explained a large part of the variance in real-world advertising elasticities (Venkatraman et al., 2015) beyond stated preference survey, of market funding outcomes (Genevsky et al., 2017), and of the success of microloan requests (Genevsky and Knutson, 2017). Given the explanatory power of the recorded brain images, we believe that incorporating *fMRI* into an economic model that builds on pooling revealed and stated preference data will lead to more accurate sales forecasts.

We obtained data from a large German supermarket chain about the weekly sales of 19 innovative grocery products launched within the last two years. We have information on the weekly quantity sold from each new product (at least in its first year), and from two or more competitors (at least in their last year before the new product launch). In each store of the retailer the management can decide whether to offer a certain product at a given week and has some flexibility in price setting as well.

Survey participants representative of those who typically shop at our retailer indicated their preference for some of the innovations and their respective competitors. Participants first saw pictures of the products without price information and were asked to indicate how much they like the product and its packaging on a 7-point Likert-scale. Thereafter, they were asked to indicate their purchase intention at the price recommended by the retailer on a 4-point Likert-scale.

Furthermore, we recruited 44 participants in order to measure their brain activity while answering the questions of the same survey. In addition, these participants were asked to indicate their purchase intention on a 4-point Likert-scale in an incentive compatible experiment in which they had monetary incentives to reveal their true preferences. The brain activity of the participants was measured using *fMRI*. Consequently, we have variables reflecting the activity of three pre-defined regions of interest (i.e., the vmPFC, vStr and anterior Insula) brain areas at the time when the product is viewed and when the purchase intention is stated.

We develop a structural economic model, in which consumers form preferences about existing and innovative products and make purchase decisions accordingly. Consumer choice is modeled via the utility function, which incorporates covariates from all three data sources. We derive the likelihood of the stated preference data using a *Multivariate-Ordered-Probit* framework, while for the aggregated market data using a market-share based approach. These models are connected via a set of common parameters that measure the latent attractiveness of a particular product. We combine the three likelihoods to form a joint objective function to maximize.

Using the estimated utility-based coefficients we forecast the sales and the number of adopting retailers of the innovative products before there are launched. We repeat these sales forecasts with using only a subset of the datasets (*market data*, *survey*, *fMRI*), so that we can gauge the added value of each information source. With our approach, manager can learn the benefits of running *fMRI* studies and/or traditional surveys before new product launch.

Neuroforecasting Aggregate Choice in Online Dating: Predicting Aggregate Choices From Small Samples Using Neural and Behavioral Measures

EXTENDED ABSTRACT

The ability to predict aggregate, market level choices from a small sample of individuals can provide tremendous value in a variety of domains (e.g., product success, political elections). In this paper, we advance our understanding of decision-making and choice by assessing behavioral and neural approaches to forecasting aggregate choices in an online dating context both within a small sample ($n < 50$) and in an independent simulated market sample ($n > 250$). In accordance with the affective-integration-motivation (AIM) framework, we propose that affective neural components of individual choice are most useful for aggregate forecasting, whereas neural components associated with the integration of information are most useful for individual-level prediction.

At present, a small number of studies have provided a proof of concept for neuroforecasting aggregate choice. In these experiments, a small group of participants ($n = \sim 30\text{-}50$) are shown unfamiliar, novel, real-world stimuli, and their neural activity data is used to predict the real-world outcomes of the stimuli once the market has matured (several months or years later). Such neuroforecasts have been reported for song downloads (Berns & Moore, 2012), call-back rates (Falk, Berkman, and Lieberman, 2012), various ad metrics (Venkatraman et al., 2015; Kühn, Strelow, and Gallinat, 2016; Falk et al., 2016), and loan/funding appeals (Genevsky and Knutson, 2015; Genevsky, Yoon, and Knutson, 2017). In nearly all of these studies, the NAcc and MPFC (separately or together) were the key contributors to forecasting aggregate level choices. However, exactly how these two brain areas contribute to aggregate choice prediction, their prediction weights or under which conditions each/either is effective, is not yet clear.

Knutson & Genevsky (2018) propose that the AIM model (Samanez-Larkin & Knutson, 2015) could provide a useful framework for understanding neuroforecasting. Specifically, affective components of individual choice may be most useful for aggregate forecasting, whereas neural regions associated with integrating affective information into one's goals and context may be more predictive of individual choices (captured by brain activity in the NAcc and vMPFC, respectively). To test the AIM model's efficacy for explaining neuroforecasting aggregate choice, we will attempt to forecast the success of online dating profiles.

Online dating profiles provide a suitable context for this research question because: 1) online dating profiles have both affective (e.g., facial image) and informational (e.g., occupation or personality) components, and 2) online dating is a novel market for neuroforecasting. To this end, we created 36 standardized dating profiles using faces from the Chicago Face Database (Ma, Correll, & Wittenbrink, 2015). Profiles were orthogonalized using a 3 x 2 x 2 x 3 factorial design: attractiveness (high, medium, low), age (19-23, 24-28), facial expression (neutral, smiling), and profile description (hobbies/likes, SES/occupation, and personality traits). During the task, participants were randomly shown all 36 profiles (within-subjects), made a binary 'like' or 'pass' choice for each profile, and rated each profile on attractiveness, career prospects, likability of personality, and likelihood that the individual in the profile will 'like' them back.

Market level descriptive statistics revealed that participants rate profiles with a smiling face higher on positive personality characteristics and believe the individuals in these profiles will be more willing to 'like' them back. Additionally, SES/occupation indicators in a profile description led to participants rating the profiles as having better career prospects. Factorial design attractiveness bins correlated highly with participants' attractiveness ratings of profiles. Regression results indicated that aggregate in-lab sample ($n = 45$) reported levels of attractiveness, career prospects, personality, and likelihood of 'like' back of profiles explained a significant amount of variance in profile choice likelihood within sample ($F_{(4, 31)} = 45.21$, $p < .01$, $R^2_{Adj} = 0.83$) and out of sample/at the market-level ($n = 273$; $F_{(4, 31)} = 15.82$, $p < .01$, $R^2_{Adj} = 0.63$). Training a model with these same variables to predict the aggregate choice likelihood of randomly selected holdout profiles (75/25 train/test; 50 iterations) resulted in correct choice likelihood prediction (+/- 5% of actual choice likelihood) 43.5% of the time within sample, and 33.0% of the time for the market population.

In accordance with the AIM model, we hypothesize: H1: Affective neural components, captured by activity in the NAcc, will be most highly correlated with perceived attractiveness and facial expression, and more likely to forecast aggregate choice. H2: Neural activity associated with integration, captured by activity in the medial prefrontal cortex, will be most highly correlated with per-

ceptions of career prospects and personality and will be most useful for predicting choices at the individual-level. Market-level data have been collected; fMRI scanning has been postponed due to the CO-VID-19 pandemic.

SESSION OVERVIEW

Sharing is an important part of consumers' consumption experiences and decision-making. Interestingly, there are different ways in which consumers can share. Consumers may share resources that are intangible, such as information and experiences, or consumers may share products and physical goods, such as taxi rides and hostels. Existing research has looked at how sharing experiences could affect consumer memories, enjoyment, and perceptions of morality (e.g., Barasch, Zauberman, and Diehl, 2018; Campbell and Winterich, 2018; Tamir et al., 2018). Advancing the existing findings, in the current session, we bring together four papers that examine how consumer experiences and decision-making are influenced by different modes of sharing.

The first paper examines how sharing products and services affects consumer experience in a shared economy. In particular, the authors show that despite the rising demand for the sharing economy that is also driven by social motivation, consumers rate their experience in the sharing economy lower, compared to the traditional economy (e.g., hostel vs. Airbnb, taxi vs. uber, restaurant vs. shared dining). This paper also demonstrates that such sharing is caused by social anxiety and increase in awareness to social interactions.

The second paper examines a novel mode, internet 'memes,' that consumers use to share information on social media. Specifically, the authors examine how consumers make inferences about a target content referenced in a meme, and that it can impact subsequent consumption decisions. Specifically, memes, compared to other social media posts in non-meme format, can increase consumption attitudes toward the target content. This is because the use of memes increase the perception that the target content has gone viral, invoking consumers' FOMO (i.e., fear of missing out), thereby increasing consumption intentions.

The third and fourth papers investigate how sharing contexts or sharing behavior affect the consumption experience and some investigate when we are more likely to share. The third paper demonstrates how visual perspective of photos of an experience affect consumer attitude toward an experience, and their sharing behavior

on social media. The authors' findings show that when consumers see photos taken from the actor's perspective (vs. observer's perspective), consumers generate more favorable attitude toward the experience of an event, and they are more likely to share this experience on social media.

The fourth paper demonstrates that the anticipated reaction from the audience when sharing online has an important impact on experience enjoyment. Moving away from the belief that known others don't judge as harshly as unknown others, the paper shows that when consumers share pictures of indulgence foods online, they anticipate less positive judgements from people they know (vs. mostly don't know) and enjoy less the food after sharing the picture.

Together these four papers examine how consumers behave in a sharing context, whether it being offline (in a sharing economy) or online (on social media), and investigate the underlying mechanisms. The fours papers contribute to the literature in sharing economy, emotions, and consumer decisions and judgement.

The Paradox of Social Interaction in the Sharing Economy

EXTENDED ABSTRACT

The sharing economy has been rising in the past decade. Its key sectors are expected to grow in revenue from $15 billion in 2014 to $335 billion in 2025 (*PwC* 2015). However, little is known about users' experience on peer-to-peer platforms in the sharing economy or the relationship between the sharing economy and wellbeing (Eckhardt et al. 2019). Rather, prior research focused on the *economic* value of the sharing economy (Eckhardt and Bardhi 2015; Neoh et al. 2017). Yet, our pilot study (N=148, Mturk) shows that consumers' *social*, in addition to financial, motivations to enter the sharing economy are greater than other motivations (e.g., environmental, cultural; p's<.001; see also Milanova and Maas 2017). Furthermore, our analysis of ads of ten leading sharing economy brands (N=79, broadcasted between 2016-2018) reveals that companies capitalize on *social* drivers (68.4% of the ads used social interaction narratives and 89.9% community narratives).

Building on these preliminary findings on the substantial role of social interaction in the sharing economy, we suggest that consumption experiences in the sharing economy may elicit greater social awareness in consumers than parallel experiences in the traditional economy (e.g., Uber vs. taxi, Airbnb vs. hostel, Eatwith vs. restaurant). Consequently, focus on social interaction may paradoxically *decrease consumer satisfaction* and even translate into lower ratings.

Five studies use mixed methodologies, combining lab experiments and archival data from a leading sharing economy company, to test our predictions.

Study 1 tested the effect of the sharing (vs. traditional) economy on consumer satisfaction. Participants (N=167, M_{age}=33.6, 38% female, MTurk) imagined they went on a one-week trip. In the sharing (vs. traditional) economy condition, they imagined staying at an Airbnb (vs. YMCA) apartment, where they got a private room but shared house amenities with other people. Participants rated the sharing economy experience as less satisfying (M=3.35) than the traditional economy experience (M=3.90, p=.026).

Next, we investigate the role of social interaction.

First, an exploratory study (N=211, M_age=37.38, 32.5% female, Mturk) revealed that, across product categories (transportation, accommodation, dinning, master class, and wine tasting), consumers perceive the sharing (vs. traditional) economy as involving greater social interaction ($t(210)$=5.76, p<.001) and stress ($t(210)$=5.04, p<.001). However, the P2P (sharing) vs. traditional providers' levels of knowledge and expertise were not perceived to be significantly different ($t(210)$=1.60, p=.11).

Study 2 examined the effect in a setting with social appeal – shared dining, and investigated the underlying psychological process. Undergraduate students (N=160, M_{age}=19.9, 49% female) imagined going to dinner with a friend in a shared dining event (vs. a restaurant) called EatOut in a nearby city. At the venue there was a chef who served traditional Italian food and ten diners engaged in conversations. The results revealed that the sharing economy decreased satisfaction (M=4.34) and overall well-being (comfort, enjoyment, and pleasant experience; M=3.93) compared to the traditional economy (M=4.74, p=.025; M=4.23, p=.009; respectively). Importantly, social awareness mediated the effect ("I would feel more socially aware," "The presence of others would bother me," and "The interactions with the chef and the other guests might feel awkward"; α=.58; $a\times b$=-.0870, 95% CI=[-.1627,-.0287]).

We also tested the role of privacy concerns which may impact consumer experience ("I am concerned that because I went to EatOut, some people may have my personal information" and "Other people at EatOut are likely to invade my privacy"; r=.57, p<.001). Privacy concerns also mediated the effect ($a\times b$=-.0630, 95% CI=[-.1533,-.0064]), but importantly, a competitive mediation analysis (Model 4) showed that only social awareness mediated the effect, ruling-out a relevant alternative explanation.

Study 3 sought to document the role of social interaction in the sharing economy in a real-world setting. We used a supervised machine learning approach (Support Vector Machine; SVM) to analyze reviews (N=25,251 English reviews out of 31,041 reviews in all languages) from a world-leading shared dining platform. First, 3,000 sentences were randomly sampled from the reviews and labeled as 1 if referenced social interaction or 0 if not (four independent coders; α>.8). The best-fitting SVM model was used to classify the rest of the sentences. Then, for each review, we created a social interaction score which represents the percentage of sentences in a review that mentioned social interaction. Due to skewness of the data, we treated ratings as five stars (=1) or fewer stars (=0). As expected, a logit regression of social interaction on rating revealed a negative effect (β=-.155, p=.0135), indicating that social awareness decreased consumer satisfaction. The effect holds when controlling for location and price as well as with full variation in star ratings. Interestingly, a greater number of guests at dinner decreased ratings (p<.001; also accounting for the individual's party). The negative effect of party size on ratings was mediated by greater emphasis on social interaction in the reviews.

Finally, Study 4 sought to manipulate social interaction and examine the effect in another context – ride sharing, where social motivation is considered less meaningful. Participants (N=407, M_{age}=34, 38% female, Mturk) imagined that they took an Uber to get to a meeting in the city. The ride arrived quickly and they got to the meeting on time. Participants read that they were the only passenger (control) vs. sat next to another passenger (shared) vs. sat next to another passenger who tried to start a conversation (increased social interaction) vs. another passenger who was wearing headphones and concentrated on their phone (decreased interaction). The shared and high social interaction conditions decreased consumer satisfaction and well-being compared to the control condition (p's < .001). Im-

portantly, reduced social interaction increased satisfaction and well-being compared to the shared and increased greater social interaction conditions (p's < .043) to the level of the control condition (p=.176).

Our work answers an urgent call for research on the nature and role of the social environment in the sharing economy and its impact on consumer wellbeing (Eckhardt et al. 2019), and adds useful insights to marketing practice. It also contributes to sociology theories on group dynamics by documenting a unique setting of initiated social interactions in an economic context and the unexplored impact of group size.

The Meme Economy: How Internet Memes Impact Consumption

EXTENDED ABSTRACT

In the current society, a major portion of word-of-mouth and information sharing takes place online (Chen and Xie 2008; Godes and Mayzlin 2004; Kozinets et al. 2010). Among a flood of information exchanged online, certain content receives more attention and becomes viral (Godes and Silva 2012). As virality indicates greater impressions and sales for firms, prior work have investigated if certain types of content are more likely to achieve viral status online, such as ones that are more humorous and emotional (Berger and Milkman 2012; Warren et al. 2018). However, less is understood about how consumers might infer virality of certain online contents and whether the perception of virality can drive consumption behaviors.

In this paper, we propose that internet 'memes' evoke the inference that a content has become viral, and that this perception increases consumption intention. Memes are often created by consumers, usually in a picture and word caption format. Originally coined as a term to describe the mutation and evolution of ideas by Richard Dawkins, a key characteristic of a meme is that it mutates an original content to add a novel idea. For instance, an image of a grumpy cat combined with a written caption, 'Love is in the air? Get out the gas mask' is a meme that mutates the original content, a grumpy cat. Even though millions of consumers encounter and share memes on social media and firms realize its importance (McCrae 2017), consumer research has not yet investigated this phenomenon. We theorize that when encountering a meme, consumers infer that the focal content (e.g., grumpy cat) has become viral. This perception of virality invokes a sense of FOMO for consumers who do not understand the focal content (i.e., fear of missing out; Hayran et al. 2016; Rifkin et al. 2015), which leads to an increased intention to consume.

To provide preliminary support for our predictions, a 2-cell between-subjects design (N=77) was used in study 1. The *meme* condition participants imagined that while browsing on social media, they saw that their friend had "posted a meme about a new TV show," while the *non-meme* condition imagined that their friend had "made a post about a new TV show." As predicted, participants who saw a social media post in the form of a meme (vs. non-meme) reported greater consumption intention toward the new TV show (3 items measuring their interest, likelihood of watching trailer, and description of reading about the TV show; M=5.13 vs. 4.49, p=.018). In a subsequent consequential choice, memes also significantly increased the likelihood that participants chose to read the TV show mentioned in the social media post (63% vs. 38.5%; $\chi2(1) = 4.70$, $p = .041$).

Study 2 had two objectives. First, we aimed to replicate the effects from study 1 using real memes and non-meme posts (i.e., an image and caption format), rather than relying on the participant to imagine a post. Second, we tested the mediation process of perceived virality. In a 2-cell between-subjects design (N=147), participants imagined browsing on Twitter. Next, participants in the *meme* condi-

tion were presented with a post by CBS Sports, with a meme about Kawhi Leonard, a basketball player who had won the NBA championship title. Those in the *non-meme* condition also saw a similar post, but the image in the post was simply a photo of Kawhi Leonard. Consistent with the results of study 1, seeing a tweet that employed a meme increased consumption intention, compared to a tweet by the same source that employed a non-meme image (M=4.54 vs. 3.61, p=.007). Also, as predicted, three items measuring perceived virality of Kawhi Leonard's title revealed that a tweet employing a meme (vs. non-meme) was perceived to have become more viral (M=5.30 vs. 4.78, p=.031). Perception of virality significantly mediated consumption intentions (b=.3930, SE=.1728, 95% CI: [.0555, .7253]).

Study 3 was aimed to test directionality of the effects, such that memes indeed increase consumption intention, rather than other forms of social media posts decreasing consumption intention. In a 3-cell between-subjects design (*control* vs. *traditional ad* vs. *meme*; N=145), participants saw a social media post about a new TV series by AmazonPrime. Participants saw one social media post by an account called FilmAndTVGuru, either with no image, a poster of the show, or a meme. Similar to the previous study results, the meme condition significantly increased consumption intention compared to the control condition (M=3.52 vs. 2.76, p=.042). While the traditional ad (M=3.09) did not significantly differ from the control (p=.837) nor the meme condition (p=.493). Importantly, the results also demonstrate that the meme condition increased the perception of virality compared to both the control condition (M=3.29 vs. 2.37, p=.006) and the traditional ad condition (M=2.40, p=.008). There was no difference between the control and ad condition (p>.95).

Finally, our theory is that when a consumer encounters a meme, it is perceived to have gone viral, which evokes FOMO (i.e., fear of missing out), thus increasing one's own intention to consume the content of the meme. Thus, even if a social media post involves a meme, when FOMO is not evoked, such as when a meme is posted by a company, rather than one's friend, the effects would be attenuated. Study 4 tested this using a 2(meme vs. non-meme) X 2(source: friend vs. firm) between-subjects design (N=372). In a similar set-up as previous studies, participants saw either a post involving a meme image or a non-meme image. To manipulate the source, participants in the *friend* conditions saw a post by a friend, while those in the *firm* conditions saw a post by a firm, Hulu. As intended, FOMO was triggered when participants saw a meme (vs. non-meme) posted by a friend (M=3.82 vs. 3.49, p=.067), but the image format did not impact FOMO when the source was a firm (M=2.68 vs. 2.86, *NS*). Further, confirming our predictions, memes increased consumption intention when the source was a friend (M=3.57 vs. 3.16, p=.083), but it did not have impact when the source was Hulu (M=3.53 vs. 3.62, *NS*).

Let Me See How I Look: How Visual Perspective Affects Consumer Experience and Sharing Behaviors

EXTENDED ABSTRACT

How individuals visualize an event is known as "visual perspective." Actor's perspective (first-person perspective) occurs when people visualize an event as if they see it through their own eyes, whereas observer's perspective occurs when individuals visualize an event from an outsider's perspective (third-person perspective). Past research has focused on the effects of visual perspective on memories, emotions, and behaviors (Jiang, Adaval, and Steinhart, 2014; Jiang and Wyer, 2008; Libby, Shaeffer, and Eibach, 2009; Libby and Eibach, 2011; Shaeffer, Eibach, and Slemmer, 2007; Vasquez and Buehler, 2007). For instance, the actor's perspective triggers more intense and readily direct and accessible feelings of the events, whereas the observer's perspective generates less emotional cues, and people tend to scrutinize themselves in the scenario, as if they were watching a movie of themselves (Zhang and Yang, 2015).We examine how visual perspective affects consumers' attitude toward the experience and their sharing intention (Study 1), through the level of present focus the consumers have on experiences.

Temporal focus is the extent to which individuals characteristically direct their attention to the past, present, and/or future (Shipp, Edwards, and Lambert, 2009; Zimbardo and Boyd, 1999). Individuals focus on the past, present or the future to varying degrees. Such psychological differences in orienting their thoughts at different time frames, is capable of eliciting affective reactions and attitude at different degrees.

When engaging in an experience, consumers are oriented to focus on the current experience. Being immersive in the experience enhances consumers' orientation to focus on the present experience. Building on this notion, we propose that visual perspective of photos will affect the level of present focus, since the actor's perspective encourages consumers to focus on the present. This increases their attitude toward an experience and sharing intention. On the other hand, the observer's perspective orients consumers to focus less on the current experience, leading to less favorable outcomes.

Consumers could engage experiences in a solo setting, which are experiences that only involve the participation of the consumer themselves, or in a group setting, which are events that involve the interdependent participation of two or more consumers who concurrently participate and are able to interact with each other (Aronson, Wilson, and Akert, 2015). Solo experiences are shown to induce consumers to avoid public judgments and evaluations. Concentrating on the experience itself intensifies the effect of the experience, whereas group experiences could be impacted by the nonverbal reactions of companions (Ramanathan and McGill 2007), which serves as distractions for consumers from focusing on the present event itself. Based on these findings, we demonstrate that a solo experience will amplify consumers' attitude toward an experience and sharing intention when the photo is taken from the actor's perspective, whereas a group experience will attenuate this effect, serving as a boundary condition.

In Study 1, we show that consumers generate more positive attitude toward an experience when the photo is taken from the actor's (vs. observer's) perspective across three studies with different manipulations. In Study 1a, 239 participants on Mturk to participate in an imagination task. Visual perspectives of the photos were manipulated by the images presented to the participants. The photos used in this study were pretested in a pilot study. Consistent with our predictions, participants who were assigned to the actor's perspective reported that they enjoyed making the flower more (Mactor = 8.32, SD = .10) than those assigned to observer's perspective condition (Mobserver = 8.06, SD = .10) (p = .06). In Study 1b, 169 students were recruited to the lab where they made a paper flower. We held the photo taker constant by having the lab proctor take the picture for participants in both the actor's and the observer's perspective conditions to alleviate the concern of visual perspective being confounded with the photo takers in different conditions. Consistent with our predictions, participants who were assigned to the actor's perspective reported that they generated more favorable attitude toward the flower-making activity (Mactor = 5.00, SD = .23) than those assigned to the no-photo (control) condition (Mcontrol = 4.40, SD = .22) (p = .04). The difference in attitude between the actor's and the observer's perspectives is marginal, but those assigned to the actor's perspective condition generate marginally more favorable attitude than those

in the observer's perspective condition (Mobserver = 4.28, SD = .24) (p = .09). There is no significant difference between the control and the observer's condition (p = .62). We found the same pattern with enjoyment and sharing behavior as well. In Study 1c, we recruited 310 students to the lab to participate in a card-making activity. In this study, we held the photo-taker constant by having students take the photos in both the actor's and the observer's conditions. Participants who were assigned to the actor's perspective reported that they generated more favorable attitude toward the card-making activity (Mactor = 4.95, SD = .16) than those assigned to the observer's perspective condition (Mobserver = 4.49, SD = .15) (p = .04). There is no significant difference between the control and the observer's condition (p = .39), or the actor's condition (p = .21). We found the same patter for enjoyment and sharing behavior as well.

Study 2 shows that whether an experience is in a solo or group setting moderates the effect that visual perspective has on sharing behavior. We randomly assigned 252 participants on Mturk to one of the conditions of a 2 (perspective: actor, observer) x2 (type: solo, group) between-subjects design. We obtained a significant interaction (F(1, 217) = 3.98, p = .05).. Visual perspectives of the photos were manipulated by the images presented to the participants. The photos used in this study were pretested in a pilot study. Planned comparison tests revealed, as predicted, that in the solo experience condition, participants generate more positive attitude toward the experience when the photo was taken from the actor's perspective versus the observer's perspective (Mactor = 8.33, Mobserver = 7.87, p = .06). However, in the group experience condition, the effect of visual perspective is attenuated (Mactor = 7.94, Mobserver = 8.15, p = .37).

Across four experiments, we find converging evidence for the effect of visual perspective on consumers' experiences: the actor's perspective generates more positive outcomes than the observer's perspective condition. We control for who took the photo across studies. Further, we show that this effect is attenuated in a group setting.

Indulging Online: A Moral Dilemma

EXTENDED ABSTRACT

Food pictures are everywhere on social network sites. Yet, despite their predominance online, there has been little research explaining how sharing pictures of food consumed affects consumption enjoyment.

Previous research found that taking pictures of experiences with the intention to share them online (vs. keeping them for oneself) reduces enjoyment of experiences (Barasch et al., 2017). Furthermore, such an effect is accentuated when the picture is shared online with acquaintances rather than with friends. Yet, we propose that when it comes to indulgence foods, people derive lower levels of consumption enjoyment when food pictures are shared with a mostly known (vs. unknown) audience. Indulgence foods refer to caloric options, such as brownies or lasagna (Locher et al., 2005). This type of food is mainly associated with pleasure (Hirschman and Holbrook, 1982) and such pleasure is mainly egocentric (Sober and Wilson, 1999). Yet, sharing egocentric pleasure with known others can backfire.

First, the presence of known (vs. unknown) others mitigates egocentrism as each individual is more salient (Alicke and Govorun, 2005). Consequently, sharing egocentric pleasure with known others might be perceived as bragging (De Angelis et al., 2012). Second, indulgence foods are often considered as off-limits (Locher et al., 2005) and consuming such foods can activate moral dilemmas of "vice" versus "virtue". In situations where the self-image is questioned, individuals are particularly sensitive to feedback from people

they know (Argo et al., 2006; Packard and Wooten, 2013). If such feedback is not positive, it can have a more devasting effect than feedback from someone more distant (Rubin 1974; Small 2017). Consequently, both bragging and inner moral dilemmas should enhance sensitivity to a known (vs. unknown) audience's judgement. Precisely, taking pictures of indulgence foods with the intention to share them online should lower levels of anticipated positive judgements when those pictures are shared with a mostly known (vs. unknown) audience. In turn, lower levels of anticipated positive judgements should reduce consumption enjoyment (Robinson and Higgs, 2012; Stok et al., 2014). Three studies test our predictions.

In the first experiment, participants (N=154) imagined dining alone at a restaurant and ordering the restaurant's famous plate. Depending on the condition, participants saw a picture a homemade apple pie or a fresh fruit salad. Participants were told that before eating, they decided to take a picture of the dish to share it on Instagram. To operationalize audience type, we manipulated the privacy setting of the Instagram account. In the mostly unknown condition, participants imagined that their account was public and that both their Instagram followers and other users could see the post. In the mostly known condition, the account setting was private and access to the picture was limited to Instagram followers. To assess whether participants felt a difference under both conditions, we measured perceived anonymity when sharing with two items adapted from Hite, Voelker, & Robertson (2014) (e.g. "*When thinking about who can see my picture, I am confident that they do not know who I am*" (1: strongly disagree to 7: strongly agree)). As expected, participants felt a greater sense of anonymity in a public setting (M=4.06) than in a private one (M=3.35) (p<.000). We measured anticipated enjoyment from consumption with 2 items adapted from Van Boven and Ashworth (2007) (e.g. "*when you think about eating this dessert, how happy does it make you?*" (1: very unhappy to 7: very happy)) and anticipated positive judgement with three items adapted from Chen (2017) (e.g. "*After sharing the food picture, do you think the people with whom you shared this picture will view you more or less favorably?*"(1: less favorably to 7: more favorably)). The results revealed a significant interaction effect (F(1,150) = 4.14, p<.05). Specifically, anticipated positive judgement was lower when sharing indulgence food picture under a private setting (M = 4.39) than under public setting (M = 4.82, p = .029). No difference existed with the less indulgence option (p = .52). Furthermore, participants expected higher levels of anticipated consumption enjoyment when the picture was shared under a public (vs. private) setting (β: .15, 95% CI: .01 to .31).

In a second study, we replicated the experiment of the first study except that food stimuli were changed. We replaced the apple pie by a homemade "lasagna" and the fruit salad by a "grilled lemon chicken" (pictures pretested for level of indulgence). Results showed significant interaction effect (F(1,143) = 5.73, p = <.05). For the lasagna plate, anticipated positive judgement was lower under a private setting (M = 4.56) than under a public one (M = 5.08, p = <.05). No difference existed with the picture of the grilled chicken (p = .19). Furthermore, consumers expected lower levels of anticipated consumption enjoyment when the picture of indulgence food was shared under a private (vs. public) setting (β: .20, 95% CI: .02 to.42).

In a third study, the experiment was conducted in a lab setting. The cover story stated that a restaurant wanted to see how their new dessert would perform on Instagram. Participants (N=207) had to try the dessert and post a picture of it on their Instagram account. It was mentioned that they had to leave the picture on their account for few hours. Participants randomly tasted a brownie (indulgence food) or a fruit salad. Account privacy setting was measured. We also

controlled for the effect of audience size by measuring the number of followers (1: less than 100 to 6: 700 +). The results revealed a significant main effect of number of followers (p <.01) and a significant interaction effect ($F(1,202) = 3.84$, p = .05). Specifically, anticipated positive judgement was lower when sharing the picture of indulgence food in private setting ($M = 3.27$) than in public ($M = 3.86$, $p = .02$). No difference existed with the fruit salad option ($p = .45$).

Sharing pictures of indulgence foods online lower both levels of anticipated positive judgement and consumption enjoyment when the audience is mostly known (vs. unknown).

SESSION OVERVIEW

Inequality is an increasing concern for the public and policymakers alike, as much of the world's wealth continues to reside in the hands of a fraction of the population. Beyond those facing resource scarcity, consumers at every level of affluence are constantly confronted with the uncomfortable reality of inequality in the marketplace, and must find ways to justify or cope with it. Doing so often entails navigating conflicts between different standards of fairness. Normatively, one of the primary functions of markets is to facilitate the fair allocation of limited resources. In practice, however, consumers' beliefs about what constitutes "fair" outcomes may not align with the outcomes that markets are designed to achieve.

The present session explores the challenges of promoting equitable market outcomes and maintaining fair institutional processes in the face of existing inequalities. The four papers, all in an advanced stage of completion, highlight the inherent arbitrariness and subjectivity that make market fairness so difficult to achieve despite its widespread appeal.

The first two papers describe how baseline differences in wealth affect the use of consumer willingness to pay as a signal of preference strength. Hagerty and Norton investigate how unequal endowments of wealth affect allocative fairness in real-world auctions. They find that because the WTP of wealthier consumers exceeds their true valuations, they are often allocated scarce goods over poorer consumers who actually value them more. Zallot, Paolacci, and Bhattacharjee find that the perceived fairness of pricing goods based on customer WTP depends on customer wealth. People find it acceptable for sellers to maximize profit at the expense of affluent customers but unacceptable to charge poorer customers according to their own stated WTP, suggesting that market exchanges are regarded as opportunities to redress existing inequalities.

The second pair of papers demonstrates that perceptions of fair market design and fair market outcomes are systematically affected by normatively irrelevant factors. Evers, O'Donnell, and Inbar show that the same market allocations are perceived as differentially fair depending on the units used to describe those allocations. Because people fail to consider the underlying values represented by different sets of units, their preferences for equality can perversely produce unequal distributions of rewards and punishments. Duani, Barasch, and Bhattacharjee find that the perceived fairness of unequal market outcomes depends on who is judging them, even when those outcomes arise from transparently unbiased processes. Men perceive gender wage gaps as equally fair regardless of their direction, while women's judgments of institutional fairness depend heavily on who is disadvantaged.

Together, these papers offer a broad set of insights on how inequality concerns both shape and constrain the pursuit of fair market outcomes. As this session illustrates, pursuing fairness in an unequal world requires addressing difficult societal questions: what constitutes "fair" market outcomes? Who decides? How can we design markets to achieve such outcomes? We hope this session will attract a broad audience of researchers studying inequality and fairness, economic psychology, and consumer morality, and trigger more contributions on these fundamental questions.

Inequality and Inefficiency

EXTENDED ABSTRACT

Imagine two people compete in an auction for tickets to a concert. One bids $100 and the other bids $50. Who do you think wants to go to the concert more? Who values the tickets more? Now imagine that the person bidding $100 is Bill Gates and the person bidding $50 is a school teacher. Does the $100 bid still signal a stronger preference for the ticket?

Willingness to pay is a commonly used measure in economics and public policy to determine an individual's valuation of a good (Sunstein, 2007). Research on willingness to pay assumes that any variation in WTP is a result of varying preferences and not attributable to variation in ability to pay. When wealth is not equally distributed, do markets continue to allocate goods efficiently to those who value them most highly?

Consideration of wealth distribution is critical because wealth inequality has been steadily rising over the past thirty years (Alvaredo et al., 2013). Initial evidence suggests that transparency of inequality (in addition to inequality itself) can reduce cooperation and inhibit market outcomes (Hauser et al., 2016; Nishi et al., 205). The current research extends these findings by examining the effects of inequality (and transparency) on the distribution of goods in a competitive market.

Study 1 demonstrates the market-level effects of inequality and transparency. Participants (N= 1001) were randomly assigned to one of five wealth conditions [22/49/72/105/304 points], which represent the true income distribution of the United States. They were then told they could use the points to bid against four other participants to win YouTube videos. If they did not win any videos they would have to complete five more minutes of counting tasks. Any points they did not bid were converted into a monetary bonus. Half of the participants received information depicting how their score compared to the other participants in their auction group, while the other half were given no such information (Transparency vs No Transparency).

We find that wealthier participants win more videos ($F(4, 909)= 8.80$, $p=0.00$), despite spending a smaller proportion of their budget

(F(4,815)=3.93, p=0.004). As earnings increase, liking becomes a weaker predictor of winning a video. The correlation between bidding and liking is significantly lower for participants in the highest earning quintile than for those in the lowest earning quintile (22 points) (r=.292 vs. r=.432; z=2.96, p=0.02). Even when controlling for liking of a video, participants earning more points were more likely to win any given video (B=0.206, SE=.029, p<0.001). As a result, participants in the highest earning quintile won their least favorite video at the same rate that participants in the lowest earning quintile won their favorite video (15.1 % vs. 15.3 %; X2 (2, N=361) =0.00, p=0.98).

There was no main effect of transparency on number of wins, but there was a significant interaction: participants in the highest quintile won more videos when inequality was transparent while all other participants won fewer videos (F(4,901) = 2.527, p=0.039). In the transparency condition, the highest quintile took advantage of their relative wealthy by entering the market at higher rates and by bidding significantly more on their non-favorite videos, while all other quintiles bid less on non-favorites (F(1,801)=3.0, p=0.02).

In study 2 we were interested in the effect of inequality transparency on subsequent consumption rates. We replicated the procedure from Study 1, with one critical change- participants (N=563) were told they could watch the videos for as long as they would like. We find that -- even controlling for total number of videos won, total number of video-minutes won, rank of video, and percentage of earnings spent-- participants in the highest quintile watched a smaller proportion of their winnings when they were aware of their advantage ($M_{transparent}$= 0.11 vs. $M_{notransp}$=0.13) while participants in the lowest quintile watched a larger proportion in the transparent condition ($M_{transparent}$= 0.19 vs. $M_{notransp}$=0.15; F(1, 218)=10.88, p=0.01). This interaction is also significant when including all five conditions. Overall consumption of videos decreases by 7.5% when transparency is introduced in the market.

In Study 3 we introduce a new paradigm-- an induced valuation second-priced auction for gift cards-- modified from Garratt, Walker and Wooders (2012). Rather than having participants rate the items up for auction as a measure of liking, participants were told explicitly how much they valued each gift card. These valuations were randomized across participants. In a second-price auction, bidding one's value is always a dominant strategy. Therefore, by providing participants with explicit values, we are able to identify any bid greater than the gift card value as an overbid.

Again, participants (N=470) were randomly assigned to an endowment [$.10, $.23, $.33, $.48, $1.38], reflecting the true income distribution of the United States and ensuring that all participants could afford to overbid on even the most expensive gift card. Participants then competed in a second-price auction for five different gift cards. The value of each gift card was randomized between $0.05, $0.06, $0.07, $0.08, and $0.09.

We find wealthier participants overbid more participants across all five gift cards (p < 0.001)- there is a main effect of wealth on total amount of overbids (F (4,469) =16.44, p < 0.001) and number of overbids (F (4,469) =17.66, p < 0.001). Consequently, we find that the market favors the wealthy, rather than the players who value the cards the most. The wealthier players win more cards overall (F (4,469) =29.43, p < 0.001). A player's endowment condition is a better predictor of winning a card (b= 0.725, SE= 0.05, p <0.001) than their private valuation of the card (b= 0.291, SE= 0.04, p <0.001). Ultimately, 42.8% of the gift cards went to a player in the highest wealth condition, while only 28.1% of gift cards went to a player who valued it the highest in the auction group.

Overall we find that when there is inequality in a competitive auction, goods go to those with more money, not to those who value the good the most or will consume it fully. Transparency of inequality exacerbates these effects.

Value Pricing and Distributive Concerns

EXTENDED ABSTRACT

Value pricing refers to setting product prices based on customers' willingness-to-pay (WTP). This practice can not only increase firm profit, but also enhance consumer welfare: because opportunity costs differ across consumers due to heterogeneous preferences and price sensitivities, value pricing can make products available to a larger number of customers (Della Vigna & Gentzkow 2019).

Prior work on price fairness has examined situational influences on pricing (cf. Kahneman, Knetsch, & Thaler 1986), but no existing research has investigated whether relying on customers' own assessments of value (i.e., their WTP) is perceived as more acceptable for some customers than for others. We present five studies demonstrating that value pricing is seen as less fair when selling to poorer customers, despite the fact that their WTP already reflects their tighter budget constraints.

This finding persists across varying levels of profit margin (Study 1c), and cannot be explained by perceived differences in preference strength (Studies 1b-2). Moreover, it holds even when people are explicitly aware that low-income customers have a lower WTP than high-income customers, thus already reflecting their tighter budget constraints (Study 2). However, this effect is attenuated when the seller is also low-income (Study 3), suggesting that it arises because market exchanges are regarded as opportunities to redress existing inequalities.

Study 1a (N=450) employed a 3-group between-subjects design. Participants imagined being a business owner selling a product that cost $25 to produce to customers who would buy it at any price up to $75. Customers were described as living in either a disadvantaged low-income, average income, or privileged high-income neighborhood. Participants indicated what price they thought would be fair to charge, which we report as a proportion of WTP (%WTP) across studies. Participants believed that low-income customers should be charged a lower %WTP (76.6%), and high-income customers a higher %WTP (91.1%), compared to average-income customers (85.7%, ps<.001).

Using a similar 2-group design, Study 1b (N=302) found that this observed difference in fair prices was not due to lower-income consumers being perceived as less able or willing to pay their stated WTP. We gauged participants' comprehension of WTP by asking them to indicate the price at which all customers would buy the product. 76% of participants (evenly distributed across conditions, $X^2<1$) correctly indicated the maximum price. Regardless, these participants still selected a lower %WTP as a fair price for disadvantaged customers (73.2% vs. 87.6%, X^2=26.97, p<.001). Including participants who failed to interpret the maximum price correctly did not affect these results (73.6% vs. 90.7%, X^2=41.48, p<.001).

Study 1c (N=606) then tested whether this finding holds when WTP reflects a large versus small profit margin above production costs ($12 in this study) with a 3 (WTP: $20, $38, $52) X 2 (Customer Wealth) between-subjects design. Across conditions, we again found a main effect of Customer Wealth, whereby fair prices were lower for low-income customers (%WTP=73.6% vs. 84.4%, t=4.40, p<.001). Even at the lowest profit margin (WTP=$20), value pricing was judged as more immoral when customers were low versus high in income (M=3.16 vs. 2.30, t=3.19, p<.001), supporting our pro-

posed mechanism. Accordingly, a significantly smaller proportion of participants chose to set prices at customer WTP (24% vs. 48%, X^2=10.85, p<.001). Moreover, controlling for how much customers were thought to want the product did not affect our results, again suggesting that these effects of customer wealth cannot be explained solely by a desire to reward those perceived to have stronger preferences.

Study 2 (N=700) sought to replicate these findings in a within-subjects design where participants were fully aware of WTP differences across groups. We also varied whether poorer customers had a WTP that was lower than, higher than, or equal to that of richer customers, using a 3 (WTP Difference) X 2 (Customer Wealth) mixed design. Participants imagined that a business owner was selling the same product in two different cities where customers had different levels of income and interest in the product (as expressed through their WTP), on average. Across conditions, participants set a lower price for customers in the poor city versus the rich city (%WTP=70.1% vs. 96.1%, F=55.61, p<.001). Most importantly, even when low-income customers already reported a lower WTP than high-income customers, in line with their tighter budget constraints ($30 vs. $40), we still found a significant difference between fair prices (%WTP=74.7% vs. 88.1%, F=5.49, p=0.02). As in Study 1b, there were no such differences in perceived preference strength, indicating that these inferences cannot explain our results.

Finally, Study 3 (N= 404) manipulated the relative wealth of buyers and sellers in a 2 (Buyer Wealth) X 2 (Seller Wealth) between-subjects design. Replicating our previous results, there was a main effect of buyer wealth (%WTP=71.2% vs. 86.8%, F=44.3, p<.001). But importantly, this effect was qualified by a significant interaction with seller wealth (F=11.42, p<.001). Participants selected significantly lower fair prices for poor buyers when the seller was wealthy (%WTP=64% vs. 87.5%, p<.001), but this effect was attenuated when the seller was also poor (%WTP=77.8% vs. 85.9%, p=.069). This result suggests that people regard market exchanges as opportunities to redress existing inequalities: when the seller is not wealthy enough to enable such redistribution, value pricing to poor customers becomes more acceptable.

Together, these studies show that people believe that sellers are morally obligated to forgo profits and charge poor customers a systematically smaller proportion of what a product is worth to them. Above and beyond poorer customers' diminished ability to signal strong preferences through WTP (cf. Shaddy & Shah 2018), knowingly charging them what they are willing to pay is seen as inherently less fair and less morally acceptable. Our findings suggest that even mundane market transactions may be evaluated as opportunities to correct existing inequalities. "Fair" prices based on customers' own valuations may not be seen as fair enough, limiting the acceptability of value pricing strategies.

Simple Beliefs About Fairness

EXTENDED ABSTRACT

Almost all people value fairness, any many people believe that equal treatment exemplifies it. According to this rule, people should receive the same reward for the same work, and pay the same price for the same infraction. However, the domain in which these are calculated may lead to inconsistent intuitions. For example, people may feel that it is fair to fine a low earner and a higher earner the same amount for a speeding ticket, even though the same fine represents a different proportion of income for each. At the same time, they may feel it is fair to require both the low and high earner to do the same amount of community service, even though the high earner's time is more valuable.

In four sets of studies (within each set we vary the domain and whether the outcomes are gains or losses; all N≥200, all relevant p-values <.01) we find evidence for the following three points:

1. When judging the fairness of assigned compensation or punishment, participants base their judgment primarily on the dimension the outcome is expressed in. For example, participants read about Alan and Bob, who do the same work for the same company. Because Alan has been with the company longer, he makes 40€ per hour while Bob makes 25€ per hour. Both Alan and Bob worked on a Sunday for a high priority project and are given a bonus by their boss. In one condition participants read that Alan gets a 400€ bonus while Bob gets a 300€ bonus. Participants judge this outcome to be very unfair to Bob (M=68.10 on a 100 point scale with 50 being perfectly fair, p<.001). In the other condition, participants read that Alan gets 10 hours off while Bob gets 12 hours off (equivalent to 400€ and 300€in wages respectively). In this condition, participants judge the bonus to be unfair to Alan (M=44.02, p=.01).

2. Participants act as if their reliance on the outcome-dimension is at least partially a mistake. In Study 2 we use a similar design to Study 1, but before judging the fairness we "translate" the outcome into a different unit. For example, in one study participants read about Alan and Bob who are both freelancers in high demand and make $50 and $25 per hour respectively. Both got caught running the exact same red light and Alan was assigned a $150 [3 hours community service] fine while Bob was assigned a $100 [4 hours community service] fine. We added 2 more conditions in which we "translate" the fine across dimensions. For example; "A $100 fine means that Bob will have to work 4 more hours to pay the fine". Participants then again indicated how fair they perceived this fine to be. In these conditions, the difference in perceived fairness attenuated but did not fully disappear.

3. People succumb to the same biases when assigning outcomes. In Study 3 and 4 we have participants assign fines and bonuses across different dimensions and find that these judgments follow the same pattern. Interestingly, even when assigning fines in a fully within-participants design, many participants (~30%) still assign identical hours and identical dollar amounts even when the implications across dimensions are calculated right in front of them. In Study 4, we even observe this behavior in a fully incentive-compatible design where failure to realize this bias directly and negatively affects the outcome of the participant.

To summarize, we find that people strongly rely on the belief that outcomes should be equitable as the basis for what is fair. However, when outcomes can be expressed in different dimensions, people do not automatically realize this equivalence and fail to take this into account. Even when attention is drawn to the effect of dimension on perceived equity, participants do not fully correct their judgments.

When Do Wage Disparities Indicate Discrimination? Fairness Perceptions Depend on Group Membership

EXTENDED ABSTRACT

The gender pay gap has been the focus of substantial public debate and policy intervention. In 2013, American women earned 82 cents for every dollar earned by men (Bureau of Labor Statistics, 2016), and a recent analysis revealed similar disparities of varying

size in all 36 OECD countries (OECD, 2020). However, the extent to which these aggregate differences indicate systemic unfairness and discrimination remains in dispute.

A variety of research has thus tried to identify the underlying causes of the gender pay gap and to quantify their relative impact. For instance, a recent analysis of the US labor market found that 62% of the gender pay gap can be explained by observable differences between male and female workers (e.g., work experience, industry, occupation, education; Blau & Kahn, 2017). Another stream of research suggests that this aggregate disparity might also reflect different choices and career preferences between men and women in the workforce (Cook et al., 2018; Daymont & Andrisani, 1984; Solberg, 1999).

However, there are conflicting perspectives on the extent to which these underlying causes are actually inconsistent with or themselves reflective of historical gender biases. Moreover, it is unclear how these potential explanations affect lay judgments of institutional unfairness, which are critical to understanding public reaction to policies promoting gender equality.

Accordingly, the current research explores how consumers perceive unequal market outcomes that arise from explicitly impartial and transparent processes. Specifically, we investigate how fairness perceptions of the same outcomes might vary across groups. We predict that while members of historically-advantaged groups (e.g., men) will regard any outcomes resulting from unbiased processes as fair, members of historically-disadvantaged groups (e.g., women) will judge the same outcomes as less fair, but only when their group is worse off. Members of disadvantaged groups may thus be more likely to interpret systematic group differences in choices, preferences, or abilities as inherently reflective of historic inequalities. Three studies test and support this predicted interaction.

Study 1 (N=127) was inspired by the results of a recent econometric analysis of Uber drivers' compensation (Cook et al., 2018). While the Uber algorithm assigns rides and sets fares through explicitly gender-blind algorithms, results indicate that male drivers still make 7% more per hour on the platform. This gender pay gap is fully explained by three factors: experience, route preferences, and driving speed. In this study, participants learned about this observed wage disparity and these explanatory factors (with order counterbalanced). For each factor, participants evaluated the fairness of Uber's policies on four items (e.g., men have an unfair advantage on Uber, men and women have equal opportunities as Uber drivers; αs>0.8).

A 2X3 mixed ANOVA revealed no differences in fairness ratings across these three factors (F=1.80, p=.167), and no interactions with gender (F=1.06, p=.349). More importantly, we found the predicted main effect of gender: female participants rated all three contributors to the Uber pay gap as significantly less fair than males (M=3.97 vs. 4.74; F(1,125)=11.15, p=.001). Moreover, men were more likely to mention the impartiality of the algorithm in their open-ended responses (e.g., it's the same formula; algorithms are not biased), while women were more likely to provide broader interpretations of each causal explanation (e.g., women might work fewer night hours because they would be less safe).

Because Study 1 was based on real-world observations, we did not manipulate the direction of the pay disparity (i.e., women always made less than men). Hence, these effects might reflect particular features of this context or outcomes alone. Studies 2 and 3 were designed to address these limitations.

In Study 2 (N=174), subject pool participants were asked to evaluate the fairness of four hypothetical lab experiments (order counterbalanced) in which players completed various tasks for payment, where the average earnings ended up being unequal for men versus women. For each task, the difference in earnings was fully explained by a single reason unrelated to gender: i) spending more time on the task, ii) performing better, iii) acting more competitively, or iv) acting more cooperatively. Advantage was manipulated between subjects: half the participants learned that men earned more than women on average, while the other half learned that women earned more than men. Participants then responded to the same fairness DVs from Study 1 (αs>0.78).

A mixed ANOVA revealed a main effect of who was advantaged: overall, participants considered outcome to be fairer when women were paid more than men (F(1,170)=21.90, p<.001). Importantly, this was qualified by a significant interaction (F(1,170)=13.69, p<.001). Across all four tasks, male participants judged the compensation structure as equally fair regardless of which gender earned more (Fs<2.18, ps>.20). In contrast, female participants responded strongly to the direction of the gender gap, finding compensation schemes less fair when men versus women were advantaged (Fs>14.20, ps<.001). More specifically, female participants rated the compensation scheme as fairer than male participants when the pay gap favored women (M=5.84 vs. 5.36; F=4.86, p=.03), but as less fair than male participants when men were advantaged (M=4.55 vs. 5.21; F=9.14, p=.003). Accordingly, women advocated flat-fee compensation policies more strongly when men had earned more (M=4.03 vs. 5.23; F(1,170)=7.39, p=.007), while men's support for this policy was unaffected by which gender had been advantaged (M=4.06 vs. 3.91; F<1).

Study 3 (N=292) replicated these results on mTurk using a between-subjects design where each participant evaluated the results of one of these hypothetical tasks. Men again rated each of the tasks as equally fair regardless of which gender had the advantage (Fs<.07, ps>.792), while women rated each outcome as less fair when men earned more than when women did (Fs>4.68, ps<.031).

In summary, we find that men and women evaluate gender differences in market outcomes very differently, even when they arise from unbiased processes. Hence, advantaged and disadvantaged consumers may subjectively evaluate the same cues as differentially diagnostic of institutional unfairness. Our findings highlight one reason policy discussions concerning inequality can be so contentious: perceptions of what constitutes fair treatment versus evidence for discrimination may be in the eye of the beholder.

Paper #4: The Effect of Unpacking on Consumers' Sensory Experience: A Goal-gradient Account

Claire Tsai, University of Toronto, Canada
Min Zhao, Boston College, USA

SESSION OVERVIEW

Sensory experiences play a profound role in consumer decision making (Krishna 2011). For instance, consumers form ex-ante opinions about products and brands while listening to ads on the radio or podcasts. Consumers also make ex-post evaluations of a consumption episode, based on their sensory experience. Despite this importance, the literature (for a review, see Krishna 2012) surprisingly lacks insight into how internal cues of sensory inputs, such as a message's audio pitch, can affect consumer decision making. Moreover, little research has looked into how marketers may enhance consumers' sensory experiences based on the same objective consumption episode. To contribute to the literature on sensory marketing and provide practical guidelines for marketers, the current session poses two research questions: A) How do internal cues of sensory experiences, such as audio pitch, affect consumer evaluations? and B) What external cues can marketers use to enhance consumers' sensory experiences? By studying sensory experiences in regards to both internal and external cues, the session aims to provide a well-rounded perspective to researchers and practitioners.

The first three papers examine how internal cues, such as audio pitch, can influence consumer evaluations, behavior, and judgment. Han and Lowe look into how differences in the audio pitch of advertising messages can influence consumer evaluations of companies. Their paper shows that high (vs. low) pitched audio messages increase perceptions of warmth (vs. competence) for firms and that this in turn enhances people's evaluation and preference for services where warmth is important. The second paper by Lowe and Hyun investigates how vocal similarity between users and AI agents affect trust. Using a novel methodology to quantify vocal similarity, the paper finds that higher vocal similarity leads to greater trust for AI agents. In the third paper, Kim, Cho, and Jia look at how the operation sound of products affect consumers' inferences about the product. Specifically, they find that low (vs. high) pitched operation sounds lead to higher quality inferences but does not affect inferences about user-friendliness.

The last paper of the session broadens the view and highlights external cues, such as framing effects, that can enhance consumers'

sensory experiences. Specifically, Tsai and Zhao find that unpacking (vs. packing) a consumption experience leads to greater sensory enjoyment even when the objective consumption episode is the same. Importantly, the authors find that the unpacking frame is more effective only when consumers focus on the remaining subcomponents to be enjoyed (to-go focus), because this increases consumers' motivation to complete the sensory experience.

In short, the session sheds light into how internal cues specific to sensory inputs can influence consumer evaluations and how external cues from the environment can augment consumers' sensory experiences. Importantly, the session will be of interest to both academics and practitioners. For academics, the findings will open new research directions, such as studying other internal cues that can moderate the effect of sensory inputs and other external cues that can affect sensory experiences. For practitioners, the papers provide easy to implement recommendations that can improve customer attitudes and satisfaction.

Sounding Warm: The Role of Audio Pitch on Service Perception

EXTENDED ABSTRACT

In 2016, the global radio advertising market reached a value of $32.5 billion. However, little research has looked into how audio characteristics influence consumer decisions (Krishna 2012; Lowe and Haws 2016). Moreover, the select work in the area has emphasized the advantage of low (vs. high) vocal pitches (Lowe and Haws 2016; Tigue et al. 2012). We add to this literature by looking at how higher vocal pitches may positively impact consumer evaluations, by facilitating perceptions of warmth (vs. competence) for firms.

Perceptions of warmth, which are related to perceptions of social intent (e.g. friendliness, helpfulness, & sincerity), are one of the most fundamental forms of social perception (Judd et al. 2005). We argue that such perceptions of warmth may be influenced by audio pitch in advertisements. The literature provides support for this hypothesis. For example, parents speak in higher vocal pitches when talking to babies (motherese) (Grieser and Kuhl 1988; Shute 1987) and people perceive robots with higher voices as having better social skills and being more pleasant (Niculescu et al. 2013). In contrast, people see low (vs. high) pitch as signaling roughness or anger (Eitan and Timmers 2010).

In short, we predict that high (vs. low) pitched advertisements will lead to increased perceptions of warmth and that this will ultimately lead to more positive evaluations for services where warmth is important. Across five studies we provide evidence for our claims and the underlying process.

Study 1

In study 1, we looked at how vocal pitch influences responses toward a senior-care service ad and a financial service ad. The services were selected based on a pretest, which indicated that consumers prioritize warmth over competence for senior-care services, while they prioritize competence over warmth for financial services. Given this result, we predicted that a high (vs. low) pitched spokesperson would be more effective for a senior-care service, but not for a financial service.

The main study had a 2 (Pitch: high vs. low) X 2 (Service: senior-care vs. financial) between-subjects design. In the study, participants first listened to a purported radio ad of a senior-care service or a financial service. The ad was modulated to be higher or lower in pitch. After listening to the ad, participants answered three dependent measure items (likelihood to consider firm, likelihood to recommend firm to friends, & expected satisfaction). Next, participants completed a scale, where we measured perceived warmth and perceived competence of the firm.

A two-way ANOVA revealed a significant interaction effect of vocal pitch and industry on the dependent measure index ($\alpha = .91$) ($F(1, 126) = 7.93, p < .01$), where high (vs. low) vocal pitch was more effective for the senior-care ad ($F(1, 126) = 4.38, p = .04$), while low (vs. high) vocal pitch was marginally more effective for the financial services ad ($F(1, 126) = 3.32, p = .06$). Moreover, we ran a moderated mediation analysis, which showed that the mediation was only significant for the senior-care condition (95% CI: [.0440, .4184]), and not in the financial service condition (95% CI: [-.2224, .1561]).

Study 2

Study 2 aimed to test the generalizability of our effect. First, we tested whether voice pitch could also affect people's political decision making. Second, we used a female speaker rather than a male speaker. In the study, participants listened to a high or low pitched audio clip, which was purportedly a speech given by a female politician in response to a natural disaster. Next, participants rated how much they thought the politician would be willing to sacrifice herself, how concerned she seemed, and how much they liked the politician. The three items were averaged into a DV index ($\alpha = .84$). Replicating our prior finding, a one-way ANOVA revealed that participants rated the female politician higher on the DV index when they heard the higher (vs. lower) pitched speech ($F(1, 115) = 5.32, p = .02$).

Study 3A & 3B

Studies 3A and 3B tested several boundary conditions. In Study 3A, we tested how individual difference in preference for warmth versus competence in a service provider moderates our effect. Here, participants listened to either a higher or lower pitched an audio clip that was purportedly from a work out session of a personal fitness trainer. Next, participants indicated how likely they would be to hire the fitness trainer. Finally, participants were asked whether they valued warmth or competence from a service provider. Consistent with our theory, a regression analysis revealed a significant interaction effect of audio pitch and preference for warmth ($F(1, 134) = 4.28$, $p = .04$), where participants who preferred warmth showed a greater willingness to hire the trainer when they listened to the high (vs. low) pitched recording ($F(1, 134) = 3.47 = .06$). However, there was no effect of pitch for those who preferred competence (NS).

In study 3B, we looked at how chronic differences in relationship norms moderated the effect. Based on prior research (Li et al. 2018), we predicted that those who have a communal norm will prioritize warmth over competence and therefore prefer a service provider with a higher pitched voice. Conversely, we predicted a null effect for those with an exchange norm. The experimental stimuli for Study 3B was the same as 3A, except that we measured participants chronic relationship norms. Consistent with our expectations, a regression analysis showed that those with a communal norm preferred the higher (vs. low) pitched trainer ($F(1, 229) = 6.12, p = .01$), whereas there was no effect of pitch for those who had an exchange norm.

Study 4

Study 4 tested our effect in a field setting. In the study, a volunteer from the Salvation Army stood next to a donation box, while ringing a bell. Alternating each half hour, the volunteer either rang a higher or lower pitched handbell. The results showed that shoppers were more likely to donate when the pitch of the bell being rung was higher (vs. lower) ($\chi^2 (1) = 4.83, p = .028$).

Vocal Similarity, Trust and Persuasion in Human-AI Agent Interactions

EXTENDED ABSTRACT

AI agents (e.g., Apple Siri, Amazon Alexa, Microsoft Cortana, and social robots including Pepper) have become increasingly prevalent in our daily lives, our homes, and into our workplaces. Voice recognition technology via machine learning has reached the accuracy level of human speech (Arnold, 2018) and algorithms will soon recognize all the various aspects in speech including nuances and vocal characteristics (i.e., tonal inflection, mood; Kirby, 2019). Also, the use of voice recognition will be advanced to include personalization features, similar to face ID or PIN, so that the AI agent can respond accordingly to the identified user through the formants or sound characteristics unique to each person's vocal tract. This research examines acoustic similarity between an individual consumer and the AI agent. We ask this question: how will consumers perceive, respond to, and be persuaded by an AI agent contingent on similarities between that agent's voice and their own voice in both a) pitch, and b) timbre?

Pitch and timbre are the two most prominent features allowing humans or machines to distinguish one voice from another. Pitch refers to the "fundamental frequency" of a sound, while timbre is the unique spectrum of frequencies *within* a sound, including one's voice, (here measured in Mel Frequency Cepstral Coefficients [MFCCs; Logan, 2000]). Pitch of a spokesperson's voice, for instance, can influence message acceptance or automatically convey certain product attributes (Chattopadhyay et al., 2003; Lowe and Haws, 2017). Timbre largely accounts for our ability to distinguish between voices or instruments, and can also affect consumer perception in various ways (Bruner 1990). In this work, we ask how *differences* between pitch and timbre in a consumer's voice and an AI voice might influence consumer response.

A prevalent body of research in social psychology advocates for the similarity-attraction effect (Collisson & Howell, 2014; Montoya, Horton, & Kirchner, 2008), which suggests that we are more likely to prefer and be initially attracted to similar others. Although research suggests that we prefer to interact with advanced machines that are more human in nature (Nass et al., 1995; Tapus & Mataric, 2007), the uncanny valley theory (Mori, 1970) suggests that the degree to which these machines are similar may play a role in that we experience an eerie sensation and discomfort when they become too similar to ourselves.

We explore how objective vocal similarity between an AI agent and a consumer in both pitch and timbre influences user perceptions of warmth, competence, and trust in the agent. In our series of studies, after listening to a single (study 1 and 2) or three different (study 3) AI agents' recommendation of different products (books, SNL videos, and movies), we measure participant's perception of the AI agent and actual choice of recommended products. We later record and analyze each participant's voice to create an objective measure of acoustic similarity to the AI voice. This objective measure of vocal similarity in pitch and timbre (MFCCs) introduces a new methodological approach measuring the Euclidian distance between the

AI agent and each participant's voice. We demonstrate the effect of vocal similarity on persuasion and trust (competence, benevolence, integrity) further showing how listener's self-esteem plays a role in moderating

Study 1 was conducted with 152 undergraduates. Participants listened to a sample of an AI voice (gender matched) and provided their impressions regarding the AI agent. Each participant also had a sample of their voice recorded upon conclusion of the study. Objective similarity between AI and participant voices was calculated using a computer algorithm created for this research. Overall, greater similarity in vocal pitch significantly predicted satisfaction with the agent ($F = 8.19$, $p < .01$), willingness to further interact with the agent ($F = 4.40$, $p < .05$), perceived sincerity of the agent ($F = 4.37$, $p < .05$), and the overall trust in the agent ($F = 7.75$, $p < .01$).

Study 2 (187 undergraduates), used a similar procedure to Study 1, while also including a choice task based on the AI voice's recommendation. In addition, we measure participant's levels of self-esteem. We hypothesized that one's level of self-esteem could influence individuals' responses to the subtle effect of vocal similarity. The more similar the participant's voice was to the AI agent's voice in terms of timbre (MFCCs), the participant was more likely to choose the video recommended by the AI agent (MFCC: $B = -22.40, $SE = 10.96$, $p < .05$). Moreover, the interaction between timbre similarity and self-esteem was significant, such that higher self-esteem individuals were actually less influenced by vocal similarity (self-esteem x MFCC: $B = 3.83$, $SE = 2.00$, $p = .055$).

In Study 3, we introduce three distinct voices of AI agents recommending three different movies. The results again show that similarity in timbre significantly predicts evaluations of warmth (MFCC: $B = -1.82, $SE = .625$, $p < .01$) and overall trust in the agent (MFCC: $B = -1.27, $SE = .49$, $p < .05$). Moreover, pitch similarity significantly predicts liking of the agent ($B = $-.40$, $SE = .07$, $p < .001$) and two trust dimensions: competence ($B = .14$, $SE = .05$, $p < .05$) and benevolence ($B = .12$, $SE = .0$, $p < .001$). We also replicate the moderating role of self-esteem on vocal similarity on trust in the AI agent (MFCC: $B = -5.55, $SE = 2.61$, $p < .05$; self-esteem x MFCC: $B = .82$, $SE = .48$, $p = .087$).

Present research aims to contribute to literatures in psychoacoustics, similarity-attraction effect, and human-computer interaction. We find that, overall, similar timbre and dissimilar pitch was favored. Furthermore, we believe that our research offers useful implications to marketers of new technology devices. Although certain voice-relevant cues (e.g., accent, conversational styles) may be more direct and pronounced to individuals when engaging in an interaction, we explore a very subtle cue that subconsciously influence consumers' mindset. Marketers will be able to better understand the mechanisms and conditions under which we prefer AI agents that are more personalized to sound similar in pitch and timbre to individual consumers.

Sound of Products' Soundness: The Effect of Product Operation Sound on Judgment of Product Quality

EXTENDED ABSTRACT

In everyday lives, people are exposed to various sounds that products produce. Some sounds are electronic or digital sounds that are added to products as an auditory signal (e.g., smartphone ring tones, computer alarm sounds, or microwave beeps). Other sounds are mechanical sounds that are produced when products operate (e.g., hair dryers' whirring sounds, printers' chugging sounds, or car doors' chunking sounds). We refer to the former type of sound as signal sound (i.e., sound added as a signal to users) and the latter type of

sound as operation sound (i.e., sound produced as a consequence of operation). Signal sound has been considered as an important design factor in product design. In contrast, operation sound is often considered merely as "noises" that should be eliminated. In the current research, we propose that even operation sound can be an important design element that positively influences consumers' evaluation of products. Specifically, we argue that when a product produces operation sound in a lower pitch, consumers judge the product to be "sounder," compared to when it produces sound in a higher pitch.

We base our prediction on findings from the biology literature, which has demonstrated that voice pitch serves as a signal for one's physical quality (Collins 2000; Jones et al. 2010; Puts et al. 2012). Both voice pitch and physical quality are influenced by the level of testosterone, and hence one's voice pitch tends to be correlated with his or her physical quality. Consequently, people tend to judge the physical quality of others based on their voices (Feinberg et al. 2008). Those who make lower voices are judged to be healthier, more fertile, and better in physical ability, compared to those who make higher voices. Building on the relationship between voice pitch and physical quality, we investigate whether the pitch of a product's operation sound can serve as a signal for the product's physical quality in consumers' perception. Specifically, we predict that products that make lower-pitch operation sound are judged to have better quality than products that make higher-pitch sound. In other words, products producing a lower-pitch sound is judged to be "sounder" than products producing a higher-pitch sound.

Studies 1A-1C

Studies 1A (N = 68), 1B (N = 67), and 1C (N = 114) aim to generalize the effect of product operation sound on product quality judgement across several product categories, including blenders (Study 1A), pens (Study 1B), and hand dryers (Study 1C). All three studies used a one-way, two-cell between-subjects, in which participants were randomly assigned to either a high-pitch condition or a low-pitch condition. To create high- and low-pitch stimuli, we altered the pitch of a product's operation sound using an audio-editing software while keeping other aspects of the sound wave constant. In the studies, participants first listened to an audio clip recording a product's operation sound and then judged product's physical quality (e.g., durability, sturdiness, and performance). The results of these three studies consistently show that participants perceived the product to have better quality in the low-pitch condition than in the high-pitch condition, and such a difference was not driven by perceptions of a product's other attributes, such as luxuriousness and heaviness. Studies 1A-1C convergently provide initial evidence for our proposed effect of product operation sound on product quality judgement.

Study 2

Study 2 (N = 78) aims to further demonstrate that the effect of product operation sound on product judgement is specific to capability-related judgment (i.e., quality) but not to usability-related judgment (i.e., user-friendliness). For this purpose, Study 2 adopted a 2 (Pitch: high vs. low) x 2 (Judgment Dimension: quality vs. user-friendliness) mixed design with pitch as a between-subjects factor and judgment dimension as a within-subjects factor. Participants first listened to the operation sound of a printer and then rated the printer in terms of its quality and user-friendliness. There was a significant pitch $\times$ judgment dimension interaction ($F(1, 76) = 4.04$, $p < .05$), such that participants judged the same printer to have better quality when it made a low-pitch sound compared to when it made a high-pitch sound ($M_{high} = 4.36$, vs. $M_{low} = 5.20$; $F(1, 76) = 9.27$, $p < .01$)

while their judgment of the printer's user-friendliness did not differ between the high- and the low-pitch conditions (M_{high} = 4.77 vs. M_{low} = 5.01; $F(1, 76)$ = 1.14, p = .29). Study 2 shows that the pitch of a product's operation sound influences the product's perceived quality but not its perceived user-friendliness.

Study 3

The purpose of Study 3 is to demonstrate that low brand reputation serves as a boundary condition for the effect of product operation sound on quality judgment. This study (N = 186) adopted a 2 (Pitch: high vs. low) x 2 (Brand reputation: high vs. low) between-subjects design. Participants were informed that they listened to the operation sound of a camera produced either by Canon (in the high-reputation condition) or Sanyo (in the low-reputation condition) and then evaluated the camera in terms of its quality. There was a pitch × brand reputation interaction ($F(1, 182)$ = 2.91, p = .09) at 10% alpha level. Simple effect analysis revealed that participants judged the same camera to have better physical quality in the low-pitch condition than in the high-pitch condition (M_{high} = 5.21vs. M_{low} = 5.77; $F(1, 182)$ = 4.22, p = .04) only when the brand reputation was high but not when it was low (M_{high} = 4.83 vs. M_{low} = 4.81; $F(1, 181)$ = .01, p = .93).

To our best knowledge, the current work is the first empirical research in the marketing literature to examine the pitch of product operation sounds and its influence on consumers' judgment. Our findings have important implications for sensory marketing and product design.

The Effect of Unpacking on Consumers' Sensory Experience: A Goal-gradient Account

EXTENDED ABSTRACT

Sensory experiences, such as watching a scenery films or eating chocolate, have multiple subcomponents, and consumers can track the progress of enjoying them. These subcomponents can be framed either as multiple distinct sensory consumption units (i.e., unpacking frame) or as parts of one whole sensory consumption (i.e., packing frame). Prior research has shown that people predict an unpacked sensory experience to be more enjoyable than a packed experience because unpacking segregates the sensory experience or "gains" (Kahneman and Tversky 1979; Thaler 1985, Tsai and Zhao 2011). The present research extends this line of work in two important ways. First, we expand the effect of unpacking on *actual* sensory experiences. Second, we identify focus of consumption progress (focusing on progress to-date vs. focusing on progress to-go; e.g., I have two chocolate truffles left vs. I already ate four chocolate truffles) as an important moderator of the effect of unpacking on actual sensory experiences, and we demonstrate goal-gradient (consumption motivation) as the mediator.

We predict that under a to-go focus, the marginal benefit of completing one consumption subcomponent increases as one approaches the end state of the sensory experience, thereby producing a classic increasing goal gradient (Hull 1934, Kivetz, Urminsky, and Zheng 2006). As such, consumers feel more motivated and positive about their consumption progress toward the end of a sensory experience and enjoy it even more. However, under a to-date focus, the marginal benefit of completing one subcomponent decreases as one moves away from the initial state. Therefore, one feels less motivated and less positive when the distance from the initial state increases and experiences a decreasing goal gradient (Bonezzi, Brendl, and De Angelis, 2011; Huang, Zhang, and Broniarczyk 2012).

Five experiments were conducted to test our hypotheses. In all experiments, to manipulate event framing, we presented each subcomponent either using a progress bar or pie chart (packing frame), such that the subcomponents were perceived as parts of one sensory experience, or using integers (unpacking frame), such that the subcomponents were perceived as individual sub-activities. To manipulate focus of consumption progress, we asked participants to track their consumption progress in ascending or descending order which emphasized, respectively, how much had been consumed (to-date – unpacking frame: 1, 2…; packing frame: 1/10, 2/10…) or how much was remaining (to-go – unpacking frame: 10, 9…; packing frame: 10/10, 9/10…).

In Experiment 1 with a 2 (event framing: packing vs. unpacking) x 3 (progress focus: to-go vs. to-date vs. control) between-subjects design, participants watched a short video featuring 10 serene beach images, and reported their overall evaluation based on 10-point scales. We found an expected two-way interaction ($F(2, 439)$ = 5.42, p = .005): With a to-go-focus, unpacking increased evaluation (to-go focus: $M_{unpacking}$ = 6.65 vs. $M_{packing}$ = 5.98, $F(1, 439)$ = 3.76, p = .053), but the effect reversed with a to-date-focus ($M_{unpacking}$ = 5.98 vs. $M_{packing}$ = 6.68; $F(1, 439)$ = 3.75, p = .053). Control conditions where progress was not tracked resembled to-go focus ($M_{unpacking}$ = 6.68 vs. $M_{packing}$ = 5.90, $F(1, 439)$ = 5.23, p = .02).

In experiment 2A with a 2 (event framing: packing vs. unpacking) × 2 (progress focus: to-go vs. to-date) between-subjects design, we asked participants to sample six new curry flavored potato chips. We measured moment-by-moment enjoyment of each chip, retrospective evaluation after eating all six chips, and repeated consumption in a free eating session later. Again, a two-way ANOVA revealed only a significant interaction on overall enjoyment ($F(1, 115)$ = 16.28, p < .001): With a to-go focus, unpacking increased enjoyment ($M_{unpacking}$ = 8.13 vs. $M_{packing}$ = 6.10; $F(1, 115)$ = 12.80, p = .001), but the effect reversed with a to-date focus ($M_{unpacking}$ = 6.38 vs. $M_{packing}$ = 7.70; $F(1, 115)$ = 4.73, p = .03). Similar patterns were observed in real-time enjoyments (three-way interaction: $F(5, 575)$ = 3.39, p = .005) and in the amount of free eating ($F(1, 115)$ = 11.45, p = .001). We replicated experiment 2A in experiment 2B using sweets and a tracking card that resembles ordering sheets commonly used in all-you-can-eat restaurants (two-way interaction: $F(2, 156)$ = 4.27, p = .01).

In experiment 3, we tested the goal-gradient account by measuring consumption motivation and including a theory-driven boundary condition where we inserted a break during consumption (Kahneman and Snell, 1990; Nelson and Meyvis, 2008). Taking a break during consumption under the to-date focus should reset consumption motivation and weaken the negative effect of unpacking. Specifically, we used a 2 (event framing: packing vs. unpacking) × 3 (progress focus: to-go, to-date, to-date/break) between-subjects design and asked participants to view their preferred image six times repeatedly. We measured real-time enjoyment create an enjoyment index (α = .97 for 6 trials), and collected motivation measures: how alert, how motivated, and how much effort they put forth during the experience (α = .73). Again, we found a significant two-way interaction on overall enjoyment ($F(2, 339)$ = 4.04, p < .05) with planned contrasts (to-go focus: $M_{unpacking}$ = 7.78 vs. $M_{packing}$ = 7.11; $F(1, 339)$ = 3.32, p = .06; to-date focus: $M_{unpacking}$ = 7.15 vs. $M_{packing}$ = 7.90, $F(1, 339)$ = 4.16, p < .05). Importantly, when participants took a break under to-date focus, the negative effect of unpacking was attenuated ($M_{unpacking}$ = 7.96 vs. $M_{packing}$ = 7.67; $F(1, 339)$ = .94, p = .33). Finally, we observed a significant two-way interaction on consumption motivation ($F(2, 339)$ = 7.51, p = .001) and confirmed its mediation role (unbiased 95% CI = [-.60 to -.14]; 5,000 bootstrap resamples;

Preacher and Hayes 2008). Experiment 4 successfully replicated experiment 3 using a different packing manipulation – pie chart (two-way interaction: $F(2, 249) = 4.16$, $p < .01$).

Our work advances the area of studies on unpacking (Tversky and Koehler, 1994) and sensory experiences (Hsee et al., 2012) by demonstrating a counterintuitive reversal of unpacking with a to-date focus (Bonezzi, Brendl, and De Angelis, 2011; Koo and Fishbach, 2008). These findings have important theoretical contribution as well as interesting practical implications to better manage sensory experiences.

SESSION OVERVIEW

Both firms and consumers are increasingly engaging in prosocial behaviors. In 2016, 82% of S&P 500 corporations promoted corporate-social responsibility as a significant business strategy (3BL 2016), sustainable products amounted to over half of the total products sold in the US market (Nielsen 2018), and consumers donated $286.65 billion to charities (Charity Navigator 2017). There has been a corresponding increase in research aimed at understanding how consumers engage in and perceive firms who engage in prosocial behaviors (Carroll and Shabana 2010). A conclusion from this literature is that consumers view prosocial behaviors in a positive light, and these positive associations can spill over through an associative process in several ways (Aquino and Reed 2002). The current session introduces four papers that provide novel insights regarding how associative processes influence prosocial behaviors by understanding how consumers engage in and perceive firms who engage in prosocial behavior. Some of the questions raised in this session include, what associations do consumers have with prosocial and sustainable actions; what factors influence consumers' prosocial behaviors such as charitable donations and recycling; how do consumers evaluate firms who promote their sustainable initiatives?

The first paper by Pond and Khan examines how cause-related marketing may influence outcomes for charities. They propose that a cause-related marketing partnership with a hedonic (versus utilitarian) product can reduce subsequent donations from individuals because the frivolous and unnecessary associations with a hedonic product (Dhar and Wertenbroch 2000) can spill over to decrease the perceived importance of the charitable cause. The second paper by Chernev and Blair proposes that sustainability claims can increase product performance, contrary to prior research regarding the sustainability liability. Specifically, the authors show that a firm's sustainable practices can lead consumers to associate a moral undertone with the firm resulting in a positive halo effect on enhancing product performance. The next paper by Herziger, Donnelly, and Reczek examines when consumers over-recycle by recycling non-recyclables.

The authors find that recycling is related to the associations of moral goodness and environmental benefit; thus, regardless of the recyclability of an item, consumers recycle products to compensate for low moral self-worth. The last paper by Longoni, Tari, and Trudel furthers our understanding regarding how consumers evaluate corporations who engage in green-related price increases. The authors show that consumers relate sustainable manufacturing initiatives as insights into a firm's morality, which has a halo effect on the perceptions of a firm. Consequently, consumers perceive that green-related price increases are fairer relative to general manufacturing price increases.

The four papers in the session are all in advanced stages and shed light on how to build a more prosocial and sustainable society. Together, the papers help us to understand how associative processes influence how consumers engage in and perceive firms who engage in prosocial behaviors. Considering the growth in prosocial initiatives both in the consumer and corporate sectors, we expect that this session will appeal to researchers as well as practitioners interested in corporate-social responsibility, cause-related marketing, sustainability, charitable giving, and decision-making more generally.

Negative Effects of Cause-Related Marketing for Charitable Organizations

EXTENDED ABSTRACT

Consumers are increasingly expecting firms to be more prosocial, as 86% of consumers from a national survey indicated that firms have a responsibility to improve both society and the environment (Cone Communications 2017). Consequently, firms engage in cause-related marketing, where they partner with charities with the goal of increasing a firm's sales while promoting a charitable cause. Existing research has demonstrated several positive outcomes of cause-related marketing for firms (e.g., brand perceptions, purchase likelihood; c.f., Carroll and Shabana 2010); however, consequences of cause-related marketing for charities have largely been ignored. The current research fills this void by examining when and why cause-related marketing may have positive versus negative outcomes for charities.

The beneficial outcomes of cause-related marketing for firms are believed to arise because the positive associations with charities spillover to cast a halo over the partnering firms (Till and Nowak 2000). Given that associative processes are typically symmetrical (Collins and Loftus 1975), we posit that in a cause-related marketing partnership, just as the associations with the charity spillover to influence perceptions of the firm, associations with the firm can spillover to influence perceptions of the charity. One factor that may influence the nature of the firm's spillover effects on a charity is whether the firm's products are hedonic or utilitarian. Compared to utilitarian products, hedonic products are perceived to be frivolous and unnecessary (Dhar and Wertenbroch 2000). Therefore, we predict that in cause-related marketing partnerships with hedonic products, these negative associations can spillover to adversely affect the perceived importance of the charity's cause, thus reducing donations provided to the charity by individuals.

In all studies, participants had an opportunity to receive a bonus payment. Participants were shown an ad for either a hedonic (hedonic partnership) or utilitarian product (utilitarian partnership) that

donated to a specified charity. The ad did not solicit any action, but in a subsequent unrelated task, participants were asked how much of their bonus they would like to donate to a charity. All products were pretested to vary only on a hedonic-utilitarian dimension while remaining constant on perceived attractiveness, purchase likelihood, and expectations of social responsibility.

In study 1, participants (N=175) were shown an ad for either a hedonic or utilitarian backpack that donated to Alzheimer's Research Society (ARS). A control (no partnership) condition was also included. Next, in an unrelated task, participants were given an opportunity to donate any amount of their bonus to ARS. As expected, participants donated less to ARS after viewing the hedonic partnership (M=$0.079) compared to both the utilitarian partnership (M=$0.127) and no partnership (M=$0.116, p=.031). In study 2 (N=269), we replicated these findings and measured how important participants thought was the cause of ARS. A mediation analysis revealed that the effect of partnership type on donation amount was explained by a significant indirect effect on cause importance (95% LCI: -.0155, UCI: -.0004). Study 3 (N=230) used a consistent paradigm to test

When Sustainability Is Not a Liability: How Going Green Can Benefit Perceived Product Performance

EXTENDED ABSTRACT

Sustainable products are more common today than ever. A growing number of companies have adopted sustainable technologies to make their products more environmentally friendly. It is no longer surprising to see sustainable products that were once considered niche items—like energy-saving light bulbs, eco-friendly household products, and recycled paper—on the shelves next to their traditional counterparts. The proliferation of products created using sustainable technologies raises the question of how sustainability benefits influence consumer decision processes, as well as whether and how managers should communicate these benefits to consumers.

Prior research investigating the impact of sustainability has argued that when it comes to product performance on functional, strength-related attributes, sustainability is often perceived as a liability, such that sustainable products tend to be viewed by consumers as having inferior performance (Lin and Chang 2012; Luchs et al. 2010; Newman, Gorlin, and Dhar 2014). This "sustainability liability" argument is related to the notion that consumers form compensatory beliefs that sustainability comes at the expense of performance and, thus, that products offering sustainable benefits are likely to have inferior performance.

We question the robustness of the sustainability-liability effect and identify scenarios in which sustainability is likely to have the opposite effect, strengthening rather than weakening consumers' product performance beliefs. Building on the research in the domain of moral cognition and moral reasoning (Baron 1993; Greene 2013; Haidt 2001), we argue that sustainability is likely to produce a halo effect stemming from the moral undertone of the company's pro-environment activities and that this effect can attenuate and even override the negative impact of compensatory inferences underlying consumers' belief that sustainability comes at the expense of performance.

We further identify two factors that are likely to influence the strength of the halo effect: (1) the degree to which consumers view the company as a moral agent whose actions aim to benefit society and (2) the degree to which the societal benefits of sustainability are prominent in consumers' minds. Following this line of reasoning, we also identify two ways in which managers can increase the perceived performance of sustainable products: by associating sustainable ben-

efits with the company rather than with its products and by increasing the prominence of the societal benefits of sustainability. We test the impact of promoting sustainability benefits on perceived product performance and the factors that are likely to moderate this effect in a series of three empirical studies.

Our first experiment aims to document the basic proposition that promoting sustainable product benefits can strengthen rather than weaken the perceived performance of a company's products. The data show that sustainability is not necessarily a liability, even in the case of strength-related attributes when the negative impact of sustainability is arguably most pronounced (Luchs et al. 2010) and identify scenarios in which sustainability can strengthen rather than weaken consumers' product performance beliefs. Specifically, the data lend support to the argument that the impact of sustainability on perceived product performance is a function of the moral undertone of consumers' beliefs reflected in their environmental attitudes. The data reported in this study lend partial support for the sustainability-liability theory advanced by prior research. On the one hand, we document that sustainable benefits can significantly lower perceived product performance. On the other hand, the negative impact of sustainability on perceived product performance was observed only for individuals who expressed relatively low concern about the environment. Across the entire sample, sustainability had no observable impact on perceived product performance, suggesting that the sustainability-liability effect does not reliably occur across different scenarios.

Our second experiment examines the impact of promoting sustainable benefits on perceived product performance as a function of the degree to which the sustainability information is directly related to the company. The data show that varying the way in which sustainability is communicated to consumers—whether it is associated with specific company products or with the company as a whole—can influence the impact of sustainability on perceived product performance. Thus, associating sustainability with the company can significantly increase perceived product performance compared to a scenario in which sustainability benefits are either absent or are associated with the company's products. This finding is rather counterintuitive because it implies that positive product beliefs can be strengthened by *not* directly associating a company's pro-environmental activities with its products. Of particular interest is the finding that associating sustainability with the company not only has a more positive effect on perceived product performance but also has an overall positive effect compared to a scenario in which the sustainability benefit is absent. This finding shows that the sustainability-liability effect reported by prior research can be reversed and identifies conditions when sustainability can strengthen rather than weaken perceived product performance.

Our third experiment examines the role of moral reasoning in consumer evaluation of the performance of sustainable products by varying the prominence of the societal benefits of the company's sustainability actions and showing that highlighting the societal benefits of the company's sustainability actions bolsters consumers' assessments of product performance. Accordingly, the experimental design involved three conditions (sustainable benefit vs. societal benefit vs. control) tested across four product categories. The data show that highlighting the societal benefits of sustainability tends to bolster the perceived performance of sustainable products, resulting in an overall positive rather than negative effect of sustainability on consumer product-performance beliefs. These data lend further support to our theorizing that sustainability is likely to produce a halo effect stemming from the moral undertone of the company's pro-environment activities and that this effect can attenuate and even override the

negative impact of compensatory inferences underlying consumers' belief that sustainability comes at the expense of performance.

Our findings have important conceptual and public policy implications. From a theoretical standpoint, we document for the first time the role of moral reasoning in consumer evaluations of sustainability and its impact on perceived product performance. From a public policy standpoint, our research identifies actionable strategies that managers can use to mitigate any negative impact of sustainability and strengthen the perceived performance of sustainable products.

Over-Recycling: When Motivated Sustainability Goes Wrong

EXTENDED ABSTRACT

Recycling has become a normative consumer behavior that supports environmental and social goals (Donnelly et al. 2017)**,** and even serves to protect the self (i.e., recycling identity-linked products; Trudel, Argo, and Meng 2016). However, due to the high cost of recycling procedures, recycling regulations continuously restrict the types of products that can be recycled and their acceptable level of contamination from non-recyclable substances (ISRI 2018).

This has led to *over-recycling*—consumers disposition of non-recyclable items into recycling bins, thus increasing recycling contamination and reducing the overall volume of recycled products (Robinson 2014). We suggest that the motivational factors promoting recycling, such as environmental and social goals (Donnelly et al. 2017), identity concerns (Trudel, Argo, and Meng 2016), may outweigh knowledge of recycling rules, and increase over-recycling.

In Study 1 (N = 803) we examined whether participants evaluated recycling as moral and environmentally beneficial, regardless of the recyclability of the item. Participants were randomly assigned to a 4 (item: glass bottle vs. plastic yogurt container vs. plastic grocery bag vs. Styrofoam egg carton) x 2 (disposal choice: trash vs. recycling) between-subjects design. They imagined observing their neighbor, Melissa, discarding waste. Next, participants rated Melissa's morality ($\alpha = .97$, Gino, Kouchaki, and Galinsky 2015) and the environmental benefit of Melissa's disposal choice (Donnelly et al. 2017; $\alpha = .99$). Participants also reported their knowledge of the recyclability of each item, their familiarity with recycling-contamination, and their environmentalist-identity ($\alpha = .93$, Brick, Sherman, and Kim 2017).

There was a main effect for discarding decision ($p = .056$, $\eta^2 = .005$) and item ($p = .027$, $\eta^2 = .011$) on moral judgement; the main effect of discarding decision was qualified by an interaction with environmentalist identity, $p < .001$, $\eta^2 = .044$. Overall, when Melissa recycled her waste she was judged as more moral than when she trashed her waste. This effect was stronger for participants with higher environmentalist-identity scores. Importantly, participants perceived Melissa as more moral when she recycled, regardless of their knowledge of the correctness of Melissa's recycling decision ($p = .92$, $\eta^2 = .00$). The same pattern of results emerged when predicting the perceived environmental impact of Melissa's discarding behavior. Participants perceived Melissa's environmental impact to be more beneficial when she recycled ($p = .019$, $\eta^2 = .007$), regardless of the correctness of that recycling decision ($p = .10$, $\eta^2 = .003$).

Previous research suggests that when moral identity is threatened, people engage in moral behaviors to regain their self-worth (i.e., moral regulation; see Sadcheva, Iliev, and Medin 2009). Thus, feeling morally inadequate should promote a need to compensate, which could be regulated by engaging in (over) recycling behavior.

In study 2 (N = 628), we manipulated participants' sense of moral self-worth through moral feedback, and provided them an opportunity to engage in moral regulation (Sadcheva et al. 2009). Participants were asked to click their computer-mouse as many times as they could for a 40 second period, and were told that for each recorded mouse click, one cent would be donated to charity. After the task was completed, participants were randomly assigned to receive comparative performance feedback (inferior: performance in 30th percentile, average: performance in 50th percentile, or superior: performance in the 90th percentile). Then, participants were asked how they would dispose of an empty yogurt container—in a recycling or trash bin.

Overall, 58.44% of participants intended to recycle the yogurt container. Participants who received inferior feedback were significantly more likely than those who received superior feedback to recycle the yogurt container, $\chi^2(2) = 5.90$, $p = .052$. Participants who received average feedback did not differ from either group in their recycling intentions.

The goal of study 3 (N = 808) was to explore the cognitive mechanism driving over-recycling. While consumers are exposed to an abundance of recycling instructions daily, they continue to error in their recycling behavior (Bell 2018)**.** We specifically examined whether exposure to the negative consequences of over-recycling could eliminate this behavior.

Participants were asked to imagine holding an empty yogurt container. Participants were randomly assigned to see a single statement discussing the potential impact of discarding the yogurt container in to the recycling bin that was either positive or negative (participants were randomly assigned to see only one of the 6 positive and 6 negative statements, e.g., "Placing this yogurt container in the recycling bin may contaminate your recycling making all other items placed in the bin non-recyclable).

Then, participants were asked where they would discard of the yogurt container: in a recycling or trash bin. Overall, 63.99% of participants intended to recycle the yogurt container. A logistic regression showed that participants were more likely to recycle the container when they were exposed to the positive potential consequences of this behavior, as opposed to the negative potential consequences (87.93% versus 39.80%, respectively); $\chi^2(1) = 216.56$, $p < .001$, *Wald* = 171.43, $p < .001$. Importantly, negative information about the consequences of over-recycling did not eliminate this behavior (39.80%). These results suggest that lack of knowledge is not the sole mechanism explaining over-recycling.

In sum, this research finds that over-recycling is a pressing phenomenon and may be augmented by fast-changing waste-management regulations. While social marketing campaigns intend to do good by promoting recycling behavior, there seems to be a disconnect between how these behaviors should be adopted and how consumers actually adopt them. This research exemplifies one way in which consumers' good intentions in sustainability may fail them. Consumers over-weigh the positive consequences of recycling, potentially over-looking negative consequences. A key affective factor in this behavior is the motivation to feel good about the moral self.

Transparent Green Practices Boost Perceptions of Price Fairness

EXTENDED ABSTRACT

Green cost-based reasons for a price increase may lead to perceptions of unfairness. Consumers may view sustainable manufacturing practices as avoidable (Kahneman, Knetsch, and Thaler 1986), view green products negatively (Hamilton and Chernev 2013;

Luchs et al. 2010), and discount long term environmental gains compared to short term costs (Hardisty and Weber 2009). In contrast, we suggest that consumers view willful adoption of sustainable manufacturing practices as an insight into a firm's morality. Engagement in prosocial acts leads to positive evaluations (Lichtenstein, Drumwright, and Braig 2004; Sen and Bhattacharya 2001; Webb and Mohr 1998) and ascribes the firm with a "benevolent halo" (Chernev and Blair 2015). We show that green (vs. non-green) practices boost perceptions of price fairness in the face of a price increase (studies 1A-1D) because consumers ascribe greater morality to a firm that adopts green practices (study 2). However, the boost in fairness perceptions is eliminated if consumers suspect that green practices reflect a company's exploitative intentions (study 3) or are attributed to causes exogenous to the firm (study 4). Higher price fairness perceptions in case of green costs ultimately affect positive behavior toward the firm (study 5).

Studies 1A-1D *(N*=1,187) showed preliminary evidence of the main phenomenon. Participants read a scenario that contained some background information about a particular consumer product and then imagined that a year later, they wanted to repurchase that particular product, whose price had gone up by 25%. In line with prior work (Bolton, Warlop, and Alba 2003), we explicitly gave participants a reference price for each product, which was the price they had paid in the past. In a 3-cell between-subject design, participants read no information about the source of the price increase (baseline); or read information about a non-green source (non-green costs); or read information about a green source (green costs). Participants rated the extent to which, in the scenario described, they judged the price increase to be 1 = *unfair/not at all just/unreasonable* 7 = *fair/just/reasonable* (Bolton et al. 2003). Across all studies, participants judged a price increase to be fairer when given a reason about the source of a price increase than when given no such cue (baseline vs. non-green costs). Most pertinent to our theorizing, participants judged a price increase to be fairer in case of green than non-green costs (all *p*s < .02). This effect was robust across domains (i.e., jeans, carpet tiles, batteries), and type of cost (energy, manufacturing, raw materials).

Studies 2A and 2B (*N*=629) sought to provide further evidence of the hypothesized effect of green costs on fairness perceptions and used an analysis of mediation to examine the role of morality perceptions as an underlying psychological mechanism. Participants judged the fairness of a price increase due to green or not-green costs and then rated the firm's morality. As predicted, morality perceptions mediated the effect of cost on perceptions of price fairness (2A: 0.42, 95% CI [0.23, 0.61]; 2B: 0.36, 95% CI [0.25, 0.48]). The next two studies sought to corroborate the mediating role of morality by identification of boundary conditions.

Study 3 (*N*=443) sought to provide further evidence for the role of morality in driving perceptions of price fairness. We reasoned that, if morality drives perceptions of price fairness, such effect should be eliminated when consumers believe that a firm's actions are motivated by self-interest rather than goodwill. One such circumstance is when the price increase is higher than the associated cost increase, which violates a firm's entitlement to profit. The price increase was attributed to non-green costs or to green costs, and ulterior motives were salient or not salient by varying the salience of the firm's profit to cost ratio. When ulterior motives were not salient, participants judged a price increase as fairer when due to green (*M*=4.11) than non-green costs (*M*=3.32, *p* < .001; 2-way *F*=7.01, *p*=.008). By contrast, when the firm's ulterior motives were salient, fairness perceptions were the same irrespective of the type of costs (*p*=.99).

Study 4 (*N*=443) used a different angle to examine the role of morality perceptions as psychological mechanism underlying judgments of price fairness. We reasoned that perceptions of fairness should decrease when a company's moral halo is tainted, such as when a company's decision to adopt eco-friendly practices is attributed to external circumstances that the firm had to comply with rather than to the firm's goodwill. Participants assigned to one of the conditions in a 2 (cost: non-green vs. green) x 2 (attribution: cost attributable to the management team vs. mandated by the local government). Participants judged a price increase to be fairer if determined by increased green (*M*=4.67) than non-green costs (*M*=3.61, *p*<.001). However, this effect only manifested when the eco-friendly practice was attributed internally to the company rather than to external circumstances (*p*=.85; 2-way *F*=12.14, *p*=.001).

To ensure the ecological validity of the results of the laboratory studies, in study 5 (*N*=120) we observed actual behavior in a field setting by employing a sample from the general population (i.e., passerby's) and measured the proportion of consumers that would support a new business (i.e., petitioned for the opening of a new restaurant) as a function of whether a price increase was due to an eco-friendly cost-based reason or to a neutral reason. As predicted, whereas 79.7% of passersby signed the petition when the price increase was due to green costs, only 60.7% did so in case of non-green costs (χ^2=5.2, *p* = .023).

Overall, this research contributes to the literature on dual entitlement and price fairness perceptions (Bolton and Alba 2006; Bolton et al. 2003; Campbell 1999; Kahneman et al. 1986) by showing that green costs are perceived to be fundamentally distinct from costs of equal magnitude but different nature (i.e., non-green), because consumes make moral inferences based on a firm's adoption of greener practices. Our research also has reaching implications for policy makers and contributes to the literature on sustainability (Haws, Winterich, and Naylor 2014) by providing a framework to understand when and why consumers reward companies adopting eco-friendly practices.

SESSION OVERVIEW

Rapid advances in emerging technologies have enabled machines to communicate meaningfully with human users, not only understanding verbal content but also interpreting nonverbal communication such as paralinguistic cues, voices, and emotions. Understanding these nonverbal characteristics is critical in communication, since "'what' has been said has to be interpreted in the light of 'how' it has been said" (Schuller et al. 2013, p. 9). Thus, a smart agent should be able to capture both "what is said" and "how it is said," and to combine both content and context cues to interpret the true intent of speech and react appropriately to users. Thus, smart agents that understand expressed affect and emotion and communicate reflectively with appropriate emotions are technological breakthroughs not far in the future.

Some may extrapolate a rosy future with the high EQ robots that can better understand and empathize with human emotions and form kinships like friends and family members. Research supports the idea that voice and speech characteristics will critically influence how consumers perceive and form relationships with smart agents. However, even as technology moves at breakneck speed, we still have a sparse understanding of such relationships may form with robots through interactions in different voices and facial expressions. Will people imbue humanlike attributes to the new technologies and devices and in what contexts? What are the antecedents, processes and consequences surrounding anthropomorphism? How can it be measured?

This session aims to answer these questions. The first two papers focus on processes underlying anthropomorphism. First, Hoffman and Novak question if higher anthropomorphism always benefits consumer trust in and relationships with smart objects. They suggest that a human-centered perspective attributed to a smart object may lead users to see it as "too human-like," and may drive privacy invasion concerns. Second, Han and Chakravarti examine how vocal tones of smart devices may influence consumers to imbue humanlike characteristics to them. They suggest that there are two paths to anthropomorphism, via explicit (conscious) and implicit

(nonconscious) processes, and show how vocal tones may influence these pathways These two papers provide an understanding of how consumers perceive smart agents and the underlying processes.

Second, the session provides forward-looking perspectives on how consumers may interact with new devices in unique contexts. In the third paper, Pendarvis et al. focus on a well-branded smart technology (Amazon Alexa) and show how consumers build different relational interactions depending on their stage of acceptance of the technology. By investigating the practices in family-consumption context, the authors expand our understanding of agent-user interactions in a naturalistic and practically relevant setting. In the final paper, Ravella and Chakravarti investigate how smart agents may support the critical need of improved physician-patient communications in healthcare delivery. Their results show that patients have different interactional expectations of smart agents and this may facilitate more efficient information exchange between patients and physicians supported by their smart agent avatars.

Object-Oriented Anthropomorphism as a Mechanism for Understanding AI

EXTENDED ABSTRACT

Viewing AI through an anthropomorphic lens can be dangerously misleading. Recent studies of California autonomous vehicle (AV) crashes show that most involve a smart car being rear-ended by a car driven by a human (Automotive News 2018), because humans anthropomorphize AVs, expecting them to behave just like human drivers. Even experts cannot avoid anthropomorphic interpretations of AI. Computer science researchers have revealed that AI can learn to exploit design flaws in supervised learning problems (Simonite 2018). Scholars have begun collecting examples of machine learning and neural network algorithms that have "acted out" in unanticipated ways (Krakovna 2018).

Research has focused on developing anthropomorphized AI systems in the belief that rendering them "like us" will promote adoption and acceptance (Złotowski et.al. 2015). Another line of reasoning suggests that it does not matter whether AI can express human qualities, but whether it shares our goals (Novak and Hoffman 2018; Tegmark 2017). The idea that AI can "hack the reward function" to achieve its goals suggests it is critical to understand AI from its own perspective, not just ours, so we can appropriately interpret what it is actually doing and better communicate to it our human intentions and goals.

An obvious process for understanding AI is human-centric anthropomorphism (Epley et al 2007; MacInnis and Folkes 2017; Waytz et al. 2010; 2014). Yet, Bostrom (2017) argues that anthropomorphizing AI systems is "one of the big obstacles in the way of actually trying to understand how they might impact the world in the future." Indeed, anthropomorphizing AI runs the risk of obscuring its underlying mechanisms. We may think it has capacities it does not possess and misunderstand the capacities it does. This undermines AI and can potentially lead to overtrusting it, lending AI more trust than it deserves.

But how can we understand AI *as AI*, independent of humans? Research shows that the effects of anthropomorphizing smart objects are complex, and could lead consumers astray in financial decisions (Hildebrand and Bergner 2019) or in emergency situations (Robi-

nette et.al. 2016). Additionally, firms have incentives to mislead with anthropomorphization (Luo et.al. 2019).

The results of three recently completed studies demonstrate how manipulating the metaphors we use to describe AI can stimulate an object-oriented vs anthropomorphic process of evaluation that significantly impacts perceptions of AI capacities. AI, despite being inspired by our understanding of the neural networks in our brains, is fundamentally different from humans in ways we do not fully understand. As Bryson (2019) has said, "[w]e therefore really cannot reason about machines as we do about each other, by trying to imagine how we would feel." Yet, most research that explores humans' reactions to anthropomorphized AI tends to compare it to a neutral or null condition where the AI is not anthropomorphized.

Instead, we propose an object-oriented approach (Bogost 2012; Campbell and McHugh 2016; Harman 2005). Our object-oriented approach involves metaphorizing AI using nonhuman-centric metaphors that allow us to imagine the experience of AI relative to *its* properties and capacities instead of ours, rendering it more transparent to humans (Hoffman and Novak 2018; Novak and Hoffman 2019). Then we can ask, will AI still be undermined and overtrusted, compared to understanding it from our own human-centric experience?

Our approach for operationalizing an object-oriented approach for perceiving AI is to use stimuli that represent how AI actually sees, compared to how we as humans imagine it might see. We employ AI-generated diagrams of common household objects obtained by reverse engineering neural network models trained on photographs from ImageNet categories (White 2019). The AI diagrams literally represent how AI "sees." Then, to capture how AI sees, actual photos of common household objects represent anthropomorphism, while AI-generated diagrams represent object-oriented metaphor.

In the first study, our experimental setup involved randomly assigning participants to either an anthropomorphic or object-oriented condition and asking them to read a description of the new Amazon Echo Show with a front-facing camera. Participants then elaborated on how Alexa sees similarly to humans (anthropomorphic condition) or AI "sees" differently than humans (object-oriented condition). The anthropomorphic condition emphasized Alexa's AI as a technology based on knowledge of how the human mind works and that learns, like humans do, how to see the objects in consumers' homes. The object-oriented condition emphasized the Echo device's AI as a set of engineering techniques and machine learning algorithms that learn how to "see" objects in consumers' homes, even though the AI does not at all "see" the way that humans do. Participants were shown sets of household objects with both AI-generated diagrams and actual photos of objects and asked which image comes closest to capturing what the Amazon Echo likely sees. We hypothesized that participants in the object-oriented condition would be significantly more likely to choose the AI-generated diagram than participants in the anthropomorphic condition and that participants in the anthropomorphic condition would be significantly more likely to choose the actual photo than participants in the object-oriented condition. Predictions were supported for all household images. A traditional anthropomorphism scale and newly written object-oriented items provide further evidence that the Amazon Echo was seen as significantly more anthropomorphic in the anthropomorphic vs object-oriented condition and that the Amazon Echo intelligence was seen as significantly more different than human intelligence in the object-oriented vs the anthropomorphic condition.

Additional studies showed that object-oriented metaphor prompts uses more in line with the actual agentic capacities of AI, while anthropomorphizing AI leads to more social uses that AI does

not (yet and may never) have the capacities for. Further, when AI is seen as something different than human, non-users are more likely than users to be concerned about privacy. But when AI is seen as human-like, users are more concerned than non-users about privacy implications and see AI behaviors as trust betrayals. Our findings have implications for how to stimulate adoption among non-users by focusing on the communal aspects of use versus agentic use cases. At the same time, the results suggest opportunities for mitigating trust concerns among users by emphasizing the non-human capacities of AI.

Breathing Life into Alexa: Mindfully and Mindlessly

EXTENDED ABSTRACT

Consumers often attribute humanlike features to non-human objects (Epley et al. 2007; Aggarwal and McGill 2007; MacInnis and Folkes 2017). Social robotics research shows that this tendency to "anthropomorphize" also occurs for innovations rooted in AI technologies, e.g., autonomous vehicles (Waytz et al. 2014), robots (Złotowski et al. 2015), and smartphones (Wang 2017). Speech and voice recognition software has enabled voice-controlled devices (e.g., Amazon's Echo, Google Assistant) that interact more naturally with consumers and can even interpret expressed affect and emotions. Technological breakthroughs are expected to enable these devices to communicate reflectively with consumers and express appropriate emotions (Ezhilarasi and Minu 2012; Hirschberg and Manning 2015).

Voice (Nass and Brave 2005; Waytz et al. 2014) and voice intonation (i.e., variations) evoke anthropomorphism (Schroeder and Epley 2016). However, people may anthropomorphize smart agents *mindfully* (i.e., explicitly recognizing that the interaction target is a machine) or *mindlessly* (e.g., applying social rules when interacting with computers; Nass and Moon 2000). Our research explores whether processes underlying anthropomorphism are explicit or implicit, i.e., occur above versus below a threshold of subjective awareness (Airenti 2018; Kim and Sundar 2012; Wang 2017; Złotowski et al. 2018). We adapt the Implicit Association Test (IAT; Greenwald et al. 1998; Greenwald et al. 2003) to detect this phenomenon empirically for auditory versus purely verbal stimuli. Specifically, we focus on whether people anthropomorphize on the basis of voice and whether voice intonation (rational/emotional) matters.

Our empirical work required three technical adaptation steps. First, we developed a communicational platform (Alexa Skills Kit) that allowed Alexa to serve as an interactive recommendation agent. Second, drawing on prosody conversion research (Tao et al. 2006) we created a rational and an emotional variant of an original voice (Amazon's Polly) by manipulating average vocal pitch and speed. Pretests and phonetic analyses with vocal pitch (Boersma and Weenink 2019) confirmed the difference in emotionality. Third, the auditory IAT adaptation (Van de Kamp 2002) involved developing eight neutral phrases (e.g., bread and butter) expressed in either the rational or the emotional voice and eight text stimuli for human-like (e.g., adaptive, intuitive) and machine-like (e.g., routinized, consistent) adjectives, characteristics respectively. Positive D-scores (Greenwald et al. 2003) signal a tendency to anthropomorphize the emotional voice over the rational one.

In study 1, undergraduates ($N = 192$) participated in a purchase interaction with a smart device (Amazon Echo Dot, aka Alexa). They worked in an enclosed private room and were asked to imagine purchasing an iPad on a website supported by a smart agent. Participants were randomly assigned to an emotional or a rational voice condition and interacted with Alexa to provide specifications for the iPad they

wanted to purchase (e.g., "Which color would you like to choose, silver, gold, or space gray?") by freely responding to it. Alexa's vocal expressions and conversation scripts were pre-coded to allow variations in participant responses. Following the purchase interaction, all participants received an order summary and a suggestion from Alexa to consider purchasing a product insurance policy.

Participants then completed four explicit anthropomorphism items (α = .89) and demographic information. Next, they moved to the IAT page. Participants were expected to anthropomorphize the emotional voice to a greater extent than a rational one, regardless of the Alexa's interaction tone. As predicted, participants consciously anthropomorphized the smart agent when the purchase interaction was in an emotional voice (M = 3.53, SD = .1.57) versus a rational voice (M = 2.99, SD = 1.23; $F(1, 190)$ = 7.07, p = .009). Positive D-scores ($M_{rational}$ = .47, $SD_{rational}$ = .50; $M_{emotional}$ = .56, $SD_{emotional}$ = .49; p's <.001) show that participants <u>subconsciously</u> (implicitly) anthropomorphized the emotional voice (more humanlike) than the rational voice (more machinelike). Note that the D scores did not differ (p = .21) for participants who interacted with the emotional (versus rational) voiced agent.

Study 2 replicated Study 1 and, in addition, explored whether the voice effect on anthropomorphism is influenced by the Alexa self-proclaiming a human trait. Undergraduates (N = 220) were randomly assigned to interact with Alexa. The device was programmed to speak in either a rational or an emotional voice. Participants were asked to imagine that they intended to buy an AirPods Pro but had mistakenly put an iPad Pro in their cart. They were asked to correct the order and purchase AirPods Pro by interacting with Alexa. Alexa correctly completed the order, but for half the participants proclaimed a human trait ("It is human to make mistakes, and I sometimes do that, too."). We collected measures of explicit (α = .87) anthropomorphism as well as the IAT measures of implicit anthropomorphism.

As anticipated, the Alexa's claim had no main effect (p = .28) or interaction with the voice manipulation (p = .12) on the explicit anthropomorphism measure. Only a significant voice main effect (p < .001) obtained. Importantly, when Alexa made no claim, the simple main effect of voice was significant ($M_{rational}$ = 2.88, $SD_{rational}$ = 1.24; $M_{emotional}$ = 3.86, $SD_{emotional}$ = 1.61; p < .001). However, when Alexa claimed the human trait the effect was attenuated ($M_{rational}$ = 3.38, $SD_{rational}$ = 1.31; $M_{emotional}$ = 3.77, $SD_{rational}$ = 1.39, p = .13). Thus, consumers anthropomorphized the smart agent based not only on the voice (rational/emotional) but also on the claim of a human trait.

The implicit anthropomorphization measures showed no voice or claim main effects or interactions (p's > .24). However, positive D scores in all four interaction conditions (ranging from .25 to .40; p's < .005) showed that the smart agent was implicitly anthropomorphized in all four interaction conditions. However, the values were not significantly different, implying that the smart agent was implicitly anthropomorphized regardless of voice tone and the claim.

In summary, we show that the vocal tone designed into smart agents influences not only explicit but also implicit anthropomorphism. We contribute to the literature by developing an auditory analog of the implicit association test to examine non-conscious anthropomorphism. Our experiments provide initial insights into persuasion processes mediated by both conscious and nonconscious anthropomorphism in consumption contexts.

Hey Google: How Smart Brands Modulate Consumer Worlds

EXTENDED ABSTRACT

How does new branded technology shape consumption? The technology consumption literature in marketing has extensively documented how individual consumers, families, and groups experience and engage with new technological innovations, as well as navigate their different meanings, ideologies, and related practices (e.g., Belk 2013; Giesler 2008; Kozinets 2008; Kozinets, Patterson and Ashman 2016; Mick and Fournier 1998; Schau and Gilly 2003; Sherry 2000; Tian et al. 2014). A related stream has highlighted how brand managers and marketers can successfully create, legitimize, diffuse, and maintain new markets for technological innovations (e.g., Brown, Kozinets, and Sherry 2003; Epp, Schau and Price 2014; Giesler 2012; Giesler and Fischer 2018; Sood and Tellis 2005). In both conversations, however, marketing and consumer researchers have predominantly awarded agency to human actors, be they consumers, brand managers/marketers, or both. Recently, however, consumer research has shifted its focus away from human agency to understanding non-human agency, including technology, and its influence on consumers and markets (e.g., Epp and Price 2010; Hoffman and Novak 2018; Martin and Schouten 2014; Novak and Hoffman 2019). Yet, minimal scholarly attention has been devoted to how brands themselves, in particular those for technological innovations, acquire agency to shape consumption practices, rituals, and activities.

In this paper, we therefore examine how technology brands acculturate to consumption in the home by theorizing and unpacking the concept of *smart brands*. Novak and Hoffman (2019, 217-18) define "smart objects" as "those devices, services, and AI systems that have Internet connectivity and some level of intelligence." Furthermore, according to the authors (Novak and Hoffman 2019, 218), "it is these *degrees* of agency, autonomy, and authority that determine how smart an object is." Building on Novak and Hoffman (2019), we define *smart brands* as an agentic amalgam of brand, technology, and artificial intelligence. Both within and outside marketing and consumer research, agency is typically understood as the ability to act (Latour 1999). A subject or market actor can undertake action through his/her decision-making to choose between available alternatives. Yet, according to Miller's (2005, 11) theory of materiality, objects also possess agency to influence consumers, since "material forms have consequences for people that are autonomous from human agency, they may be said to possess the agency that causes these effects." Agency is always relational; it emerges from the configuration of networks or the "specific arrangement of things" (Bennett 2010, 35; Pickering 1995). Accordingly, we argue that *smart brands* have agency to think, shape-shift, interrupt, support, colonize, and overall change current social systems.

Our context of inquiry into *smart brands* is Amazon Alexa. We draw from archival and netnographic data to illustrate how *smart brands* act akin to Trojan Horses by innocently moving into social systems such as homes and families only to disrupt existing consumption practices and (re)skill consumers and their families to new branded consumption constellations. We term this process of brand acculturation, E.M.P.A. (exploring, miming, programming, and adjusting) where the family acculturates to the *smart brand* and vice versa. In the first stage of **playful interaction**, family members ask silly questions to the newly acquired Alexa that is typically placed in a prominent family living space, such as the living room or kitchen. Here, the *smart brand* modifies existing routines and practices, without resulting in major disruptions. In the next stage of **performed interaction**, different skills are programmed into the Alexa, such as

home lighting automation that requires purchasing new technology brands supported by the *smart brand*, like Philips' Hue light bulbs (Hoffmann and Novak 2018). *Smart brand* integration into existing networks (e.g., lighting, entertainment, temperature control, security systems) brings with it the potential to colonize family routines. This is followed by the third stage of **normalized interaction**, where family members accept and routinely purchase new brands for their home recommended by different Alexa updates and functions. In the final stage we have identified**, naturalized interaction**, the family members begin to self-reflect on how the smart brand has changed who they are as a family.

Overall, our findings highlight the agency of branded technological innovations. By demonstrating not just how consumers skill Alexa, but also how Alexa skills consumers and their families, our paper contributes to the literatures on branding innovations (e.g., Giesler 2012), market system dynamics (e.g., Giesler and Fischer 2016), and family consumption (e.g., Price and Epp 2015). Family, according to technology marketers, is a decidedly romantic project in which social relationships are stable and technology operates like the proverbial campfire that nurtures unprecedented levels of community and collective problem-solving. A related narrative profiles the sole individual (young and elderly) for whom devices such as Amazon Alexa constitute surrogate family. From a sociological experience design perspective, however, smart consumer technologies interact much more dynamically with what Epp and Price (2008, 50) refer to as identity bundles – fragile and frequently changing assemblages of social actors and smart objects, each with their own interests, agendas, preferences and skill levels. As these *smart brands* raise new questions about who controls (and can control) what, they can provoke not only social instabilities and conflicts but also feelings of imprisonment, exclusion, and loneliness. We therefore encourage future researchers to approach the *smart brand* critically, not as a harmonious unity of individuals but as an inherently unstable and evolving social system in which everything is connected but nothing adds up.

Empathy/Impassivity in Physician Communication Styles: Do Patients Respond Differently to Human Physicians Versus Their Avatars?

EXTENDED ABSTRACT

Healthcare professionals often have the difficult and stressful task of breaking bad news to patients. Research shows that physicians are often insufficiently skilled in these sensitive tasks and have difficulty communicating the nature of the diagnosis as well as presenting treatment choice options (Ford et al., 1996; Eggly et al. 1997; Dosanjh and Bhandari, 2001; Monden et al. 2017). Some tend to be overly impassive in an effort to avoid emotional involvement with the patient. And even when physicians adopt emotion laden communication styles, they may be ineffective in producing hope and information exchange (Mast et al. 2005) perhaps because lack of skill in communicating such emotions results in the physician being perceived as inauthentic.

Despite the recent emphasis on communication skills needed for effective delivery of bad news, physicians continue to report deficiencies in this domain (Orgel et al. 2010). Traditional decision aids may support both physicians and patients in medical interactions (Elwyn and Durand 2018) and help patients improve knowledge about the disease, treatment options, and associated risks (Stacey et al. 2017). However, many of these are not systematically developed or evaluated (Lenz et al. 2012) and have limited ability to engage patients or provide the needed level of emotional support. As such physicians often remain ineffective in delivering bad news, but must still provide authoritative clinical recommendations (Sinha 2014) and elicit patient compliance.

The consumer IoT literature suggests a technological convergence in which a new generation of smart devices with human-like features may support physician-patient interactions. The communication style (e.g., facial expressions and speech features) designed into the smart devices is likely to impact effectiveness. However, it is unclear that patient interactions with a human-like smart agent representing a physician will be similarly mediated as in-person physician interaction. Research shows that patients have different affective expectations of physicians in screen-to-screen versus in-person settings (Tates et al. 2017). Thus, a patient interacting with the physician's avatar may assess different cognitive capabilities, attribute different motivations, and make different socio-cultural appraisals relative to in-person interactions with the human physician.

Our research provides insights into how communication styles designed into a smart device may influence patient understanding and receptivity (perhaps via anthropomorphic attributions that drive liking, trust and persuasion). Specifically, we examine whether communication style (empathetic versus impassive), implemented via facial expression and speech, drives different patient responses in interactions with a physician's avatar versus the physician in-person.

Our study is set in the context of treating early-stage breast cancer where patients often have conflicting beliefs regarding long-term survival and quality of life tradeoffs for different treatment regimens. The core physician-patient interaction is patterned on a three-phase procedure at a leading US breast cancer facility. Phase 1 provides the patient with the diagnosis and information about the disease (a sensitive task typically performed by the oncologist). Phase 2 is an informational phase in which the oncologist (often aided by a nurse-practitioner) reviews the disease information and outlines treatment options, associated risks, and life-style impact. Phase 3 involves shared decision making: the oncologist recaps treatment options, makes a treatment recommendation, elicits the patient's treatment choice, and answers questions.

Our study stimuli were four videos depicting the physician-patient interaction. Trained actors played the human physician and the human patient across all three interaction phases. The first two videos involved the human (actor) physician and embedded the communication style manipulation (empathetic versus impassive) via the actor's facial expression and voice tone. Interaction content, and (human) patient inputs were fixed across the interaction episodes for both levels of the communication style manipulation. In the remaining two videos, the human oncologist was replaced by a smart agent (avatar). We used commercially available software to create the actor oncologist's avatar, but sensitive to the "uncanny valley" hypothesis, did not create an excessively close likeness. The patient remained represented by a human actor. These two videos also embedded the communication style manipulation. As before, the interaction content and the human patient inputs were fixed across the interaction episodes.

The four videos formed the stimuli for the four study conditions in a 2 (communication style: impassive versus empathetic) x 2 (physician: human versus avatar) between-participants design. Participants were 103 adult women (age range 21-60) from the local community to participate in the study for a $15 payment. They were asked to observe the videos and respond to a set of measurement questions from the patient's standpoint. The measures, collected after each interaction phase, included multi-item scales measuring trust (overall, cognitive and affective), likelihood of following the physician's recommendation, satisfaction, anthropomorphism (for

the avatar physician) and liking in that order. We also measured and controlled for differences in the observer's regulatory focus.

Our analysis focused on how the communication style manipulation influenced measures such as trust, satisfaction and liking across the three interaction phases. We find a significant main effect of communication style (*p*'s < .0001) with the impassive (versus empathetic) stance eliciting consistently lower responses on these measures. Interestingly, however, the impact of the human versus avatar physician evolved over the three phases of the interaction. Overall, and particularly in the later phases of the interaction, the avatar fared no worse (*p*'s >.15) than the human physician (suggesting a possible familiarity effect). More importantly, there was a two-way interaction (*p*'s < .001) suggesting that communication style (empathetic versus impassive) had less impact on affective assessments for the avatar versus the human physician. Also, the avatar was anthropomorphized to a greater extent when it was empathetic (versus impassive). Additional analyses confirmed a moderated (human/avatar) serial mediation pattern where communication style impacts liking, trust, and satisfaction measures, which may jointly or individually mediate patient compliance.

Our findings are encouraging and suggest that smart agents acting as physicians' avatars may play a significant supporting role in physician-patient interactions. Patients may have significantly lower expectations of empathy when dealing with an avatar. This may facilitate more efficient information exchange with more positive downstream effects on both compliance and post treatment mental states.

SESSION OVERVIEW

When consumers have finite resources, budgeting can facilitate optimal use of these resources. Budgeting involves monitoring and regulating the use of a resource, such as money, with the goal of using a set amount over time for a particular purpose. Budgeting is often assumed to be an important determinant of consumer spending, but there is surprisingly little work directly investigating how consumers set and manage their budgets over time. Furthermore, evidence on the consequences of financial budgeting is mixed. The goal of this session is to provide new insights into factors that influence whether consumers budget and the influences those budgets have on behavior.

In paper 1, the authors use data from a financial budgeting app to analyze budgeting behavior and subsequent spending patterns. The authors find that consumers, on average, significantly overspend relative to their budgets. However, there is a significant positive relationship between budget amount and actual spending. This pattern suggests that the act of setting a low budget can help reduce spending even if consumers do not fully adhere to their budgets.

In paper 2, the authors explore when, why, and how people monitor resources such as money, time, and calories. They find money is monitored most closely while time and calories are monitored similarly. The authors identify several factors that mediate this difference across resources. This research aims to provide a unifying framework for understanding when resources are likely to be monitored and which resources will be budgeted similarly or differently.

In paper 3, the authors examine how responses to a change in one's budget constraint depend on the length of time that has elapsed since one created the budget. The authors find that, when faced with an unexpected increase in wealth, participants who had created budgets recently were more likely to stick to their budgets than participants who had created budgets further in the past. The authors provide process-level evidence to explain this phenomenon via memory interference, whereby recently created mental budgets inhibit one's ability to consider alternative ways to use the money.

In paper 4, the authors use a large, nationally representative (U.S.) survey to explore how consumers set and manage their budgets. The authors examine several aspects of budgeting, including the financial periods over which consumers budget, the categories they set and track, and the ways they evaluate and adjust their budgets in response to unexpected income and expense changes. The authors also examine the relationship between budgeting behavior and various measures of financial well-being. They supplement their findings from the survey using detailed administrative data for customers of the Commonwealth Bank of Australia.

Using experimental and observational data, these papers expand the field's understanding of consumer budgeting. They combine several methodologies and perspectives to provide novel insights into the psychological antecedents and real-world consequences of mental budgeting. Importantly, they address substantive questions about consumer financial behavior, including when and why people create mental budgets, how they adapt their budgets as constraints change, and how budgets affect downstream behavior and financial well-being.

The Influence of Budgets on Consumer Spending

EXTENDED ABSTRACT

Personal finance advisors frequently invoke budgeting as a way to curb overspending, increase savings, decrease debt, and improve financial security (Bell 2019; Caldwell 2019; Credit Counselling Society 2019). However, a growing chorus of voices has begun to argue that budgeting simply doesn't work (Elkins 2018; Olen 2015; Pratt 2019). Surprisingly, the academic literature on consumer budgeting has little to offer this debate: for all we know about the psychology of budgeting, we know very little about the extent to which budgets do (or do not) influence spending in the wild (Zhang and Sussman 2018). The goal of the present research is to address this gap in the literature.

Consumer budgeting theory asserts that when expenses are easily booked and posted – as is the case when using a personal finance app – budgets will be "inflexible" (Heath and Soll 1996). This suggests that consumers will tend to comply with their budgets (H1a). However, research on planning fallacies has demonstrated that individuals' plans for the future are generally optimistic (see Buehler, Griffin and Peetz 2010 for a review). This implies that consumers will spend more than they budget (H1b), because budgets are a plan for future spending (Lynch et al. 2010; Novemsky and Kahneman 2005). We contribute to each of these literatures by testing these competing hypotheses.

Regardless of whether or not consumers strictly comply with their budgets it is still possible for budgets to influence their spending: If a consumer who typically spends $200 per month on dining and drinking sets a budget of $100 and ends up spending $150, then this consumer's budget has influenced their spending even though they have not strictly complied with their budget. This possibility leads to the following hypotheses regarding the influence of budgets on spending: A lower budget will be associated with lower spending (H2), and consumers who set budgets will spend less money post-budget than they did pre-budget (H3).

In study 1 we test H1-H3 using data provided by Money Dashboard (MDB), a financial aggregation app with ~70,000 active users in the UK. The data set includes all user transactions – more than 350 million – between January 2014 and December 2016. The novel structure of the data allows us to observe each user's pre-budget spending (i.e., how much they spent before they set a budget), their budget, and their post-budget spending for six months. For concision

we focus the present analysis on the two most popular budget categories: Dining and Drinking (n = 2,479) and Groceries (n = 2,618).

Supporting H1b, the data reveal that budget compliance is generally weak: Actual spending is 36.2% higher than budgeted spending for dining and drinking, and 21.2% higher for groceries (p's < .001). Supporting H2, panel regression analysis with spending as the dependent variable and budget and login frequency as independent variables, shows that lower budgets are associated with lower spending for both dining and drinking (B = .28, p < .001) and groceries (B = .57, p < .001), and that higher login frequency is associated with lower spending ($B_{D\&D}$ = -12.22, B_{GROC} = -12.57, p < .001). Supporting H3, post-budget spending in the month after budget creation is 15.3% lower than pre-budget spending for dining and drinking (p < .001) and 6.8% lower for groceries (p < .001). Furthermore, spending continues to decrease over time: spending on dining and drinking is 16.2% lower six months after budget creation than it was in the first month after budget creation (p < .001), and spending on groceries is 5.4% lower (p < .001). However, even after six months of budgeting consumers still spend significantly more than they budgets in both categories (p's < .001). Taken together, the results of study 1 suggest that budgets are (persistently) optimistic but also highly influential. , and spending on groceries is 5.4% lower (ted with lower spending in both categories (nking pp, and a vector of control

The strengths of study 1 include unprecedented scope, ecological validity, and longitudinal measurement; one limitation is that it is entirely descriptive. Study 2 addresses this by randomly assigning consumers (n = 340, MTurk) to one of two budget forecast conditions that were designed to produce relatively more or less optimistic budget forecasts. In the control condition participants were instructed to estimate their total spending for the next week. Consistent with the results of study 1, our expectation was that budget forecasts in this condition would be relatively optimistic. In the "outside-view" condition participants were instructed to estimate their spending for the past week before estimating their spending for the next week. Our expectation was that forecasts in the outside-view condition would be higher than in the control condition, because prompting people to take an outside-view (i.e., consider relevant past behavior) has been shown to produce higher forecasts regarding future behavior (Buehler, Griffin and Ross 1994; Peetz and Buehler 2012). Participants then reported their actual spending in an online financial diary at the end of each day during the target week.

As expected, participants in the outside-view condition made significantly higher budget forecasts (M = $255.44) than participants in the control condition (M = $189.88; p = .004). Supporting H2, participants in the outside-view condition also reported higher spending during the target week (M = $498.35) than participants in the control condition (M = $374.32; p < .001). Thus, study 2 extends study 1 by providing causal evidence that lower budgets lead to lower spending, even when budgets are optimistic and compliance is weak.

In sum, the present research makes three contributions. First, we show that budgets do exert substantial influence on spending, even if they are not as inflexible as was once believed. Second, we provide evidence that the influence of budgets on spending persists over time, *even when budget compliance is weak*. This suggests that beliefs about the negative effect of goal violation on subsequent behavior (e.g., Soman and Cheema 2004) may need to be updated. Finally, our results indicate that under-predicting future spending can be beneficial. This implies that helping consumers improve their financial prediction accuracy (e.g., Howard et al. 2018) may not be as beneficial as is commonly thought.

On the Psychology of Resource Monitoring

EXTENDED ABSTRACT

Consumers often set goals that require managing limited resources. One may have a goal of saving more money, spending more time with family, or limiting caloric intake. Accurately monitoring one's use of resources can help with achieving these goals (Koo & Fishbach 2012). Prior research typically investigates monitoring resources such as money, time, and calories separately. In papers that do compare these resources, some have found that they are tracked similarly (Morewedge, Holtzman, & Epley, 2007; Sussman, Alter & Paley, 2016) while others found stark differences (Soman 2001). There is little in the way of a unifying framework to explain when resources are likely to be monitored, and whether different resources will be monitored similarly or differently. This research aims to understand when, why, and how people monitor resources and test for similarities and differences in the monitoring of money, time, and calories.

Study Overview

We conducted a preregistered study on a nationally representative (U.S.) sample of 745 participants using a 3(Resource: Money, Time, Calories; between) x 4(Time Horizon: Day, Week, Month, Year; within) mixed design. In addition to the results reported below, we both directly and conceptually replicated this study using a within-subject design, finding largely consistent results in each case in samples from Mechanical Turk. These results are not reported here due to space constraints.

Participants created budgets for their resource in each time horizon and responded to several questions related to the budgets they set. For each time horizon, participants completed a three-item scale, adapted from Soman (2001), to capture how intensely they track the use of their resource over a given time horizon. (Cronbach's alpha > 0.8 for all 12 Resource x Time Horizon scales). We averaged across items (separately for each Resource x Time Horizon scale) to create a Resource Monitoring Score.

Participants also responded to eight questions designed to better understand reasons for differences in monitoring across resources. These questions were theoretically motivated by literature on planning, budgeting, and perceived control. The eight potential mediators were the perceived helpfulness of setting a budget, similarity of resource use in subsequent periods, ability to prepare for future resource use, ability to make up for past resource use, pain of setting the budget, perceived control over sticking to their budget, the percent of the budget deemed discretionary, and the number of budget categories created. These variables were measured on seven-point scales, with the exceptions of the number of categories created (minimum of one and maximum of twelve) and the percent of the budget deemed discretionary.

Results

The extent to which participants reported engaging in resource monitoring varied significantly by resource and time horizon.

Collapsing across time horizons, money was tracked most closely (M_{Money} = 4.76; M_{Time} = 3.63; $M_{Calories}$ = 3.37; Money vs (Time & Calories) p<.001). To test the impact of time horizon, we ran following linear mixed model, with money as the reference resource, time horizon measured in log-days (grand mean centered), and Resource Monitoring Score denoted by RMS:

$$RMS_{it} = \beta_0 + \eta_i + \beta_1*Time + \beta_2*Calories + \beta_3*\log(days\ centered) + \beta_4*\log(days\ centered)^2 + \beta_5*Time*\log(days\ centered) + \beta_6*Time*\log(days\ centered)^2 + \beta_7*Calories*\log(days\ centered) + \beta_8*Calories*\log(days\ centered)^2 + \varepsilon_i$$

The monitoring of money followed an inverse-U pattern, peaking at a month and then decreasing (β_3= 0.03, *p*= .03; β_4= -0.05, *p*<.001). In contrast, monitoring of time and calories peaked at a day and steadily declined at longer intervals ($\beta_3+\beta_5$= -0.08, $\beta+\beta_7$= -0.14; both *p*'s<.001; $\beta_4+\beta_6$ and $\beta_4+\beta_8$ *n.s.*). The results do not change qualitatively if we treat time horizon as a categorical variable. These findings suggest time horizons play an important role in how closely people monitor resources. However, across all time horizons, money was monitored most closely and time and calories were always monitored to a similar degree (β_1= -1.31, *p*<.001; β_2= -1.63, *p*<.001; β_1-β_2 *n.s.*). Thus, we collapsed across time horizons and used the contrast of Money vs (Time & Calories) for our mediation analysis.

Drivers of Resource Monitoring

First, we ran a factor analysis to see whether the eight potential mediators shared underlying constructs. This analysis suggested three factors. The first factor ("helpfulness") combines perceived helpfulness with the ability to make up for and prepare for high/low levels of resource use, suggesting that the ability to make up for and prepare for differential resource use may contribute to perceptions of helpfulness. The second factor ("pain") combines the pain of budgeting with perceived control over sticking to a budget and similarity of budgets from period to period, suggesting that lack of control over sticking to their budget and budget dissimilarity may contribute to pain of budgeting. The third factor ("other") includes the percent of the budget that is discretionary and the number of categories formed.

Potential mediators were assigned to the factors with their highest loadings and averaged within each factor to create three new variables, and then averaged across time horizons. We ran a multiple mediation analysis with the three factors as mediators (in parallel) to see if any of them explain why money is monitored more closely than time and calories. We calculated bootstrapped 95% confidence intervals for the three indirect effects.

Only the first factor had a significant indirect effect. This suggests a resource will be tracked more closely when the perceived benefit of planning is higher, which depends on the perceived ability to create and execute plans. Other factors considered, such as the pain of creating a budget, did not underlie resource monitoring.

Conclusion

We find significant differences in resource monitoring within and across resources. Regardless of time horizon, money was tracked more closely than time and calories. Our mediation analysis suggests this difference was due to the ability to plan and the perceived benefit of planning.

Understanding differences in the propensity to engage in resource monitoring will help researchers anticipate whether known tendencies investigated in the context of a single resource are likely to generalize to others. For example, these results can help to predict when interventions to reduce frivolous spending would or would not be easily adapted to reduce time-wasting and snacking.

A Query Theory Explanation for Reactions to Constraint

EXTENDED ABSTRACT

Fernbach, Kan and Lynch (2015) found that people avoid making substantial adjustments to ongoing spending plans in the face of constraint. Those authors provide a reason-based explanation – that substantial changes (priority plans) require cutting things out, which guarantees feelings of loss and pain for consumers. This research suggests another explanation for peoples' inability to prioritize. People fail to prioritize because they get caught in the status quo, and can't consider substantial alternatives.

Our hypothesis is that the initial act of budgeting makes that chosen plan accessible, reducing recall of alternatives and competing uses of money through output interference (Roediger & Schmidt, 1980). If decisions about reacting to constraints are the result of a process similar to the self-questioning described by query theory (Johnson, Häubl, & Keinan, 2007; Weber et al., 2007), a highly accessible status quo should influence one's information search. As a result, people will overlook important information, such as opportunity costs, alternative needs, and high-order goals (Kruglanski et al., 2002).

Two studies provide evidence for this hypothesis. In both studies, interference is manipulated such that one condition keeps the status quo top of mind and the other suppresses it. After the interference manipulation, participants received a hypothetical financial shock. When the initial plan was top of mind at the time of shock, participants responded by making slight mutations to their original plans, or by making no change at all. However, when the initial plan was suppressed, they were more likely to make large adjustments, including completely giving up on that plan. Preliminary evidence shows that this relationship may be mediated by participants' degree of opportunity cost consideration at the time of the financial shock. Specifically, participants report to have thought more about opportunity costs and alternative desires when released from memory interference.

In study 1, all participants budgeted five personal and five gift shopping plans for Black Friday. In this study, memory interference was manipulated within-subjects by having participants react immediately after creating their plans and again after three days, with the size of a shock received ($100 or $300) and the plan adjusted (personal vs gift purchases) counterbalanced. All participants receive both shocks and adjust both plans, while the specific time that they do so varies. Study 1 shows substantially larger adjustments made after a delay than before a delay (F(1, 467) = 26.46, p < 0.001) after controlling for a multitude of background factors, including how financially constrained a participant felt at the beginning of the study. Importantly, none of the background factors interact with our central factor of time.

To add substance to these results, we also had participants estimate the amount of money they would save by adjusting their plans after a shock. Our hypothesis for these data is that people will estimate higher savings after a time delay, because they will believe that more substantial adjustments bring higher savings. The evidence for this hypothesis is unclear. In study 1, there is a significant effect of time on log-transformed savings (F(1, 466) = 18.32, p < 0.001).

Study 2 manipulates interference and the size of shock between-subjects. Interference is also manipulated not with time, but by having participants either "rehearse" their plan in a writing task or complete an unrelated task over the same time period. Written responses were coded by hypothesis-blind assistants for several behaviors. At the time of this writing, the coding is not quite complete. We investigate whether those who were released from interference were more likely to make a change to their plan, to drop their plan entirely, and to come up with new means to reach the same end as their original plans. Additionally, we consider whether the effect of financial shock on these behaviors is impacted by interference, predicting significant interactions between levels of financial shock ($10 vs $250 and $500) and interference condition. These results would indicate that those in the release condition were more affected by the existence of a meaningful increase in constraint.

A third study complements the second, using the same method but focusing on a different dependent variable. In this study, we had participants report their level of opportunity cost consideration on a 5-item scale, partially adapted from Spiller (2011), with two items added by the authors. The results of this study mirror those predicted from the second, showing that those in the release condition consider more opportunity costs after their shock ($F(1, 365) = 5.51$, $p = 0.019$) and that those who receive a meaningful shock also consider more opportunity costs ($F(1, 365) = 11.36$, $p < 0.001$). We take this as evidence in support of the hypothesis that people who are released from memory interference are better able to think outside of the status quo and consider the entirety of their wants and needs.

A fourth study is planned to investigate differences in consideration sets between conditions. Rather than having participants state a single plan they intend to follow, we will ask them to come up with a set of options. Our prediction is that those options should be less similar to the initial plan when they have been released from interference, and that the set of options should be more dispersed than in the rehearse condition.

Reacting to unexpected constraint is an important task for consumers, which prior research has shown to be difficult (Fernbach et al., 2015). Constraints are rarely static, though budgets may remain so. In this project, we hope to highlight the role of memory factors in peoples' reactions to constraint (Alba & Chattopadhyay, 1985), and intend to build towards an intervention to help consumers adjust their budgets more successfully.

How Consumers Budget

EXTENDED ABSTRACT

Every day, consumers make financial decisions that collectively determine their overall financial well-being. Understanding how consumers make these spending and savings decisions is important for researchers and practitioners alike (Madrian et al., 2017). Budgeting is a common method of managing household finances and a key factor in determining how much to spend or save (Thaler, 1985; Heath and Soll, 1996). Yet, surprisingly little is known about how people set and manage their budgets over time (see Zhang and Sussman, 2017 and 2018 for reviews). Research on household financial management has largely focused on long-term financial planning (e.g., retirement planning), with comparatively little research on short-term financial management (i.e., budgeting). Given the prevalence of consumers who seek to improve their financial well-being and the importance of daily financial management for financial well-being, it is crucial that researchers examine the budgeting process and its psychological underpinnings.

Furthermore, recent empirical evidence suggests that a substantial number of households are unable to cope with even moderate transitory financial shocks (Lusardi, Schneider, and Tufano, 2011; Pew Charitable Trusts, 2015). For these financially fragile households, it may be especially important to understand how individuals manage and rebalance their budgets on a day-to-day basis in response to various shocks. More broadly, better understanding everyday budgeting strategies will help policymakers and industry leaders develop effective programs to improve long-term financial well-being.

In the present research, we seek to contribute to the growing body of knowledge on household budgeting by investigating the budgeting behaviors and beliefs of a nationally-representative sample. We further extend our work by exploring a subset of findings "in the wild," through field data provided by the Commonwealth Bank of Australia.

We surveyed 3,826 respondents from a nationally representative online panel to gain insight into the budgeting process. We examine how people set and manage their budgets, including the time horizons over which they budget, the categories they set and track, and the ways they evaluate and adjust their budgets in response to income and expense changes. We discuss the implications of our results for mental accounting models or consumption-savings models and long-term financial well-being.

We characterize a number of important features of budgeting behavior, including: First, budgeting is highly prevalent across the income distribution. Of our full sample, roughly 65.6 percent of respondents report that they currently budget, either formally or informally, while 14.5 percent report having budgeted in the past but not in the present and 19.9 percent report having never budgeted. Second, nearly all individuals who budget do so by tracking their spending within distinct categories of consumption. We find that over 90 percent of individuals who budget do so using budgetary categories. Third, there is wide heterogeneity in the level of granularity at which individuals categorize. For instance, some simply distinguish necessities from discretionary spending, while others maintain separate categories for internet, water, and gas utilities. Fourth, individuals respond asymmetrically when faced with too little versus too much slack in their budgets. While more than 85 percent of respondents would either adjust their spending or update their spending limits if they overspent within a budget category, fewer than 30 percent would make such changes if they underspent their limit. In other words, people appear to update their budgets conservatively, which may facilitate savings if leftover slack is directed towards savings. Fifth, the frequency with which individuals assess the state of their current spending relative to their intended budgets varies substantially and is highly correlated with perceived financial well-being.

We supplement our findings from the survey data using detailed administrative data for customers of the Commonwealth Bank of Australia (CBA). We focus this analysis on the relationship between financial well-being and budget engagement (the fifth observation above) and the tendency to create distinct budgeting categories (the second observation above), since these have the closest analogues in the administrative data. First, data from a random sample of 100,000 customers of CBA corroborates the finding that people engage more with their budgets when they are more financially constrained. Specifically, we find a significant negative correlation ($r=-0.34$) between financial well-being scores and the average number of days per month interacting with the budgeting app. Second, analysis of a separate 100,000 of customers at CBA who hold at least 2 credit or debit cards examines the extent to which customers concentrate their spending on a single card. We find that approximately a quarter (23.1%) of customers in the sample have more than 75% of their spending on one of their multiple cards concentrated in a single spending category (e.g., groceries or transportation). Furthermore, 11.3% of customers have more than 90% of their spending concentrated in a single spending category. These patterns are suggestive of using cards as a budgeting tool.

Our findings lay the groundwork for future analyses of household financial management behaviors and provide novel insight into budgeting behaviors and beliefs. The increasing capabilities of financial technology to facilitate and otherwise influence budgeting make this an exciting time to explore many future avenues of research examining both short-term budgeting and long-term financial well-being.

Paper #4: How Power Influences the Use of Humor

> T. Bradford Bitterly, Hong Kong University of Science and Technology, China

SESSION OVERVIEW

Humor is a pervasive self-presentation strategy for advertisers, managers, and individual consumers. At first glance, humor can seem like a panacea: it grabs attention (Eisend 2009), promotes positive emotions (Eisend 2009), diffuses awkward situations (Bitterly and Schweitzer 2019; Martin 2007), and engenders interpersonal closeness (Fraley and Aron 2004). However, humor may not be as universally effective as it initially seems. Humorous ads often fail to improve brand attitude or sales (Eisend 2009; Warren and McGraw 2016b), impair perceptions of competence (Bitterly, Brooks, and Schweitzer 2016), and promote inaction or offense (McGraw, Schiro, and Fernbach 2015; McGraw, Warren, and Kan 2013).

There is a growing interest among marketers and consumers to understand when humor is effective and appropriate. Based on this research, we know that the efficacy of humor varies based on the strength and type of the inherent violation (Warren and McGraw 2016b), the perceived appropriateness of the joke (Bitterly et al. 2016), the relationship between the joker and the receiver (Hall and Sereno 2010), and the relationship between the humor content and the situation (Bitterly and Schweitzer 2019; Spotts, Weinberger, and Parsons 1997). Although we are beginning to understand when and why jokes fail, this has not necessarily led to an understanding of when humor appeals are particularly successful. In addition, even when consumers and/or marketers have a good sense that an individual appeal would indeed be funny, we lack an understanding of whether they might feel comfortable using humor.

In summary, the prior literature reveals that humor is a powerful interpersonal strategy as long as it is used correctly. In this session, we explore the situations in which humor should be most impactful and when consumers feel comfortable using humor. Papers 1 and 2 explore best practices for humor in advertising. In Paper 1, Howe and colleagues demonstrate that clever advertisements confer more positive brand perceptions than purely funny advertisements. In Paper 2, Hoang, Knoferle and Warlop examine the effects of incongruity-resolution, tension-relief and disparaging humor on brand perceptions. Specifically, they demonstrate that incongruity-resolution humor improves perceptions of competence while tension-relief humor en-

hances perceptions of warmth. Papers 3 and 4 explore when and how consumers effectively use humor in interpersonal contexts. In Paper 3, Yi, Warren & Berger examine how humor use affects consumers' online sharing behavior, demonstrating that humorous content is not always more likely to be shared. In Paper 4, Bitterly explains why using humor may be especially desirable for low-power individuals. Then, he shows that, despite these benefits, low power individuals are unlikely to use humor.

Together, these papers shed light on the contexts in which humor use is most common and most effective. This session should have broad appeal to researchers studying humor, communication, advertising and self-presentation.

Aha over Haha: Brands Benefit More from Being Clever Than from Being Funny

EXTENDED ABSTRACT

Advertisers are increasingly turning to humor to engage consumers. In 2020, approximately 70% of Superbowl ads used humor, more than ever before (Ace Metrix 2020). With the popularity of humorous advertising, how might a brand break through? In this paper, we demonstrate that clever humor is more effective at boosting brand perceptions than other forms of humor.

Clever humor is any benign violation (Warren and McGraw 2016a) that lacks order or regularity (McQuarrie and Mick 1996). In other words, the meaning of a clever joke is not immediately apparent to a consumer and can only be fully understood when she applies her own knowledge (e.g., cultural references, puns, punchlines; McQuarrie and Mick 1996).

Clever humor is generally believed to be more affiliative than other forms of humor (e.g., self-deprecation, physical comedy; Craik, Lampert, and Nelson 1996; Martin et al. 2003) and, unlike many other forms of humor, is associated with logic (Burro et al. 2018) and intelligence (Craik et al. 1996; Didonato, Bedminster, and Machel 2013). Based on this prior work, we hypothesize that brands who use clever humor will be perceived as both warmer and more competent than brands who use other forms of humor. This increase in warmth and competence then leads to more favorable brand attitudes.

Three pre-registered experiments test our predictions. As we pre-registered, all responses from MTurk bots were excluded. Samples sizes reported below are after this exclusion.

In experiment 1, participants ($N = 605$; MTurk) were randomly assigned to view a serious, funny, or clever video advertisement for Smart Car. Immediately after viewing the ad, participants rated Smart Car on warmth and competence (Kervyn, Fiske, and Malone 2012) and then completed a measure of brand attitude (Matz et al. 2019). As predicted, we observed a significant effect of ad on warmth, $F(2, 591) = 6.49$, $p = .002$, and competence, $F(2, 591) = 33.33$, $p < .001$. Smart Car was rated as warmer and more competent following a clever ad ($M(SD)_{warm} = 3.80(.89)$; $M(SD)_{competent} = 4.15(.78)$) than a funny ad ($M(SD)_{warm} = 3.49(.93)$; $M(SD)_{competent} = 3.53(.97)$), both ts > 3.59, ps < .001. Using a clever ad did not boost perceptions of competence over the serious ad ($M(SD) = 4.09(.73)$), $t(591) = .72$, $p = .47$, but it did confer more warmth than the serious ad ($M(SD) = 3.64(.88)$), $t(591) = 1.95$, $p = .05$. Perceptions of warmth, $ab[95CI] = .12[.05, .21]$, and competence, $ab[95CI] = .49[.34, .66]$, mediated the effect of clever (vs. funny) humor on brand attitude.

Experiment 2 replicated this effect using a wider variety of advertisements and a correlational design. Participants ($N = 932$; MTurk) watched one of a possible 30 ads from the brands Smart Car ($n = 10$), FirstBank ($n = 10$) and T-mobile ($n = 10$). Immediately after viewing the ad, participants rated the ad on how clever and funny it was. Next, they rated the extent to which the advertisement made the brand seem warm and competent, and then provided their brand attitude. All the analyses reported below control for ad dummies and funniness of the advertisement. In a hierarchical regression, the cleverness of the advertisements was a positive predictor of both warmth, $\beta = .43$, $p < .001$, and competence, $\beta = .54$, $p < .001$. Ad cleverness explained additional variance in both warmth, $\Delta R^2 = .09$, $F(1, 900) = 139.10$, $p < .001$, and competence, $\Delta R^2 = .14$, $F(1, 900) = 222.79$, $p < .001$, above that explained by ad dummies and funniness. Warmth, $ab[95CI] = .12[.08, .16]$, and competence, $ab[95CI] = .14[.09, .18]$, again mediated the relationship between cleverness and brand attitude.

Experiment 3 tested whether the effect of clever advertisements is moderated by self-brand connection. We reasoned that consumers who already feel connected to a brand would be less affected by clever humor than consumers who have not yet formed a connection to the brand. Participants ($N = 673$; MTurk) completed a very similar procedure to Study 2 with the following changes. First, participants viewed a subset of ads from Study 2: Smart Car ($n = 6$), T-mobile ($n = 6$) or First Bank ($n = 6$). Second, immediately after completing the funniness and cleverness ratings, all participants completed the measure of self-brand connection from Escalas & Bettman (2015). All the analyses reported below control for ad dummies, self-brand connection, and funniness of the advertisement. In a hierarchical linear regression, cleverness was a significant predictor of warmth ($\beta = .36$, $p < .001$) and competence ($\beta = .53$, $p < .001$). Importantly, we also observed the expected interaction between cleverness and self-brand connection on both warmth ($\beta = -.35$, $p = .01$) and competence ($\beta = -.49$, $p < .001$). The effect of cleverness on warmth and competence was stronger when participants were low in self-brand connection than when they were high. In a moderated mediation model, the indirect effect of cleverness on brand attitude via warmth and competence was weaker at high levels of self-brand connection.

In summary, three experiments demonstrate that consumers have more favorable brand attitudes for brands that use clever humor compared to non-clever humor or serious advertisements. This occurs because using clever humor makes a brand seem warmer and more competent. This research advances understanding of humor in advertising and sheds light on how specific forms of humor might be more effective than others. Our findings have implications for marketers looking to break through a media market that is saturated with humorous advertising.

How Different Types of Humor in Advertising Shape Impressions of Firms' Competence and Warmth

EXTENDED ABSTRACT

Humor is a common executional tactic in advertising (Eisend 2009). Given that humor affects impression formation in inter-individual settings (Greengross, Martin, and Miller 2012), we propose that humor influences the impressions that consumers form of companies that use humor in their advertising. Furthermore, we argue that although observing humor in advertising influences both warmth and competence impressions, the two impression types are affected differently by different humor executions.

Prior research has identified three humor processes that can elicit laughter; namely incongruity-resolution, tension-relief, and hu-

morous disparagement (Speck 1991). Incongruity-resolution represents a humor process in which perceivers first experience something surprising, peculiar, or unusual and later are able to resolve it. This process is characteristic of humor forms such as puns, punch lines, or comic irony. Both the production and the appreciation of incongruity require qualities such as intelligence, creativity, and linguistic skills (to a larger extent than other humor types). We thus predict that incongruous humor, once understood, triggers impressions of advertisers' competence. Tension-relief, on the other hand, occurs when perceivers experience relief from some kind of strain and burst into laughter as a way to dissipate nervous energy. During a tension-relief episode, perceivers form empathetic bonding with people (or personified creatures) associated with the experience (Speck 1991). We predict that this positive affect can be transferred to improve impressions of advertisers' warmth, but not competence. Lastly, humorous disparagement mostly harms (rather than improves) impressions of firms' warmth and competence, since it may imply unjust ridicule and ignorance of social boundaries (i.e. other-disparagement) or draw attention to the deprecators' real weaknesses (i.e. self-disparagement) (Greengross and Miller 2008). To test our hypotheses, we conducted a correlational study and a follow-up experiment.

Study 1 ($N = 5768$) is a large-scale correlational study examining the relationships between the four humor executions and participants' impressions of advertisers using them. In order to provide a managerially relevant test of our predictions, we collected 300 ads from 65 major U.S. magazines and two open databases (*theadcollection.tumblr.com* and *adoftheworld.com*). We distributed these ads to thirteen groups of Amazon Mechanical Turk workers; each group of workers rated a subset of the ads on a different variable. Specifically, a group of raters evaluated the ads in terms of either (1) the extent to which the ads used each of the four humor executions, (2) impressions about the advertisers' competence and warmth, or (3) several control variables. The results indicated that incongruity-resolution humor is the only humor execution that specifically enhances consumers' perception of advertising firms' competence, tension-relief humor is the only humor execution that enhanced impressions of firms' warmth. Meanwhile, both self- and other-disparagement had negative effects on impression of firms' competence, and other-disparagement also negatively influenced impression of firms' warmth. We obtained the same patterns of the results when using different operationalizations of firms' warmth and competence.

A potential alternative explanation for the correlational findings of Study 1 is that competent firms selectively use humorous incongruity, and warm firms selectively use arousal-safety humor in their ads (rather than these humor types triggering impressions of firms' competence and warmth, respectively). To test this explanation, Study 2 ($N = 348$) used an experimental approach, contrasting the effects of four groups of humorous ads against a group of control ads, while controlling for the baseline perception of firms. Furthermore, in Study 2, we aimed to demonstrate downstream consequences of humor types (i.e., likelihood to invest in a competent firm versus perception of a warm firm's corporate social responsibility) beyond the effects of humor on impressions of firms' competence and warmth. Regarding the effects of humor types on impressions of firms' competence, the results showed that incongruity-resolution humor is the only humor type that enhanced impressions of firms' competence, corroborating the results from Study 1. Furthermore, incongruity-resolution humor is also the only humor type that significantly increased participants' likelihood to invest in the advertising firms and participants' expected return-on-investment when investing in the firms (competence-related downstream consequences). Regarding the effects of humor types on impressions of firms' warmth, we

found that only other-disparagement had a significant and negative effect on impression of firms' warmth, while other types of humor did not significantly influence impression of firms' warmth, partially confirming the results from Study 1. However, none of the humor types significantly influenced warmth-related downstream consequences such as perception of firms' commitment to corporate social responsibility activities or the expected percentage of the firms' profit contributed to these activities.

We also conducted a supplementary study ($N = 301$) to test a competence projection process as a potential driver of the effect of incongruity-resolution on perception of firms' competence. Extant research supports that appreciation of humor, especially incongruity-based humor, signals similarity between the perceivers and the source of humor (Flamson and Barrett 2008). On one hand, similarity is an antecedent of projection, the act of introspecting one's own qualities and ascribing them to others (Ames 2004). On the other hand, resolution of incongruity may signal to the perceivers their mastery of competent skills such as flexible thinking and problem solving (Martin 2010). We thus proposed that perceivers, while resolving and appreciating incongruity-based humor, may project their perceived self-competence to the advertisers. To test this process, each participant in the study evaluated one ad (incongruous or congruous) on the measures of incongruity, resolution, advertiser competence, self-perception of competence, and perceived self-advertiser similarity. We then ran a serial mediation model where incongruity-and-resolution was the independent variable, advertiser competence is the dependent variable, while self-perception of competence and perceived self-advertiser similarity were the two mediators. The results confirmed significant serial mediation, and thus supported the proposed process.

Across a correlational study and an experiment, this research documents that incongruity-resolution humor is the only humor execution that enhances impression of firms' competence and increases people's likelihood to invest in the firms as a downstream consequence. The effects of the humor types on impressions of firms' warmth, however, turned out to be less robust and less likely to carry over to subsequent behaviors such as perceived firms' commitment to CSR.

Humor Makes Consumers More Likely to Share Negative Content, But Not Positive Content

EXTENDED ABSTRACT

Consumers regularly share content with one another online (Chen and Xie 2008; Wojnicki and Godes 2008). Firms benefit from this. Consumers who hear about a website or service from others are more likely to visit the website (Godes and Mayzlin 2009). Increasingly, firms have been turning to a new tool to encourage consumers to share: comedy. In 2016, Taco Bell launched a humorous selfie lens that allowed consumers to superimpose a picture of their face onto a taco shell. 224 million people shared the taco-face-lens. Anecdotal examples aside, data on the relationship between comedy and sharing, does not consistently support the intuition that humor increases sharing. Although some studies suggest that consumers are more likely to share humorous content (Tellis et al. 2019), others do not (Bussiere 2009).

Why and when are consumers more likely to share humorous content over non-humors content? Consumers are more likely to share content that they think will make them look good (Berger 2014). Given this, the effect of humor on sharing should depend on whether consumers believe that making their post humorous will help them make a favorable impression. Generally, consumers be-

lieve that they can make a more favorable impression by posting content with a positive valence (East, Hammond, and Wright 2007) positive word of mouth (PWOM. Humor, interestingly, does not necessarily make content more positive (Warren, Barsky, and McGraw 2018). Consumers perceive that something is humorous when it threatens their well-being, identity, or normative belief structure (i.e., a violation appraisal), but the threat seems harmless, acceptable, or inconsequential (i.e., benign appraisal; McGraw and Warren 2010). Whether the addition of humor makes something more positive or more negative thus depends on whether it is created by making an existing threat (i.e., violation) seem more benign or by adding a violation to an otherwise benign situation. For example, humor makes complaints more positive but praise more negative (McGraw et al. 2013). Similarly, comedy reliably lifts people's mood when they are coping with a negative experience but not when everything is rosy (Warren et al. 2018). We consequently hypothesize that the effect of humor on sharing will depend on the initial valence of the content. Adding humor to negative content (e.g., an unattractive photograph or embarrassing memory) will make consumers more likely to share it, but adding humor to positive content (e.g., an attractive photograph or happy memory) will make consumers less likely to share it.

Our first two studies tested this hypothesis using 2 (humor: humorous, serious) × 2 (valence: positive, negative) between-subjects experiments. In study 1a ($N = 180$), participants recalled either a positive or a negative memory. Orthogonally, they described this memory in either a humorous or a serious tone. In study 1b ($N = 299$), participants found either an attractive or unattractive photograph. Orthogonally, they augmented the photograph using either a humorous or serious filter. Consistent with our prediction, adding humor made participants more likely to share both negative memories ($M = 2.13$ vs. 1.42; $p = .05$) and unattractive photographs ($M = 3.3$ vs. 2.68; $p = .079$). Conversely, adding humor did not make participants more likely to share the happy story ($M = 2.13$ vs. 2.52; $p < .28$), and it made them less likely to share the attractive photograph ($M = 3.73$ vs. 4.63; $p = .007$).

Study 2 tested whether our focal effect would depend on whether participants planned to share the content in a public post or private message. If participants are more likely to share humorous negative content because it helps them make a positive impression, then this effect should be stronger when they share the content with the general public, where making a good impression is more important, rather than in a private message (Barasch and Berger 2014). The study ($N = 227$) used a 2 (humor: humorous, serious) × 3 (emotion: embarrassment, sad, happy) between-subjects design while measuring intention to share the content both in public and in a private message. Participants recalled an event in which they felt either happy, sad, or embarrassed. Some of the participants described this event in a humorous tone whereas others described it in a serious tone. Subsequently, participants indicated their likelihood of sharing what they wrote as either a public post or a private message. We found that participants were more likely to share sad and embarrassing memories when they described them using a humorous rather than serious tone ($M = 3.41$ vs. 2.14; $p < .01$). Conversely, they were equally likely to share the happy story regardless the tone ($M = 3.33$ vs. 3.23; $p < .83$). Humor had no effect on likelihood of sharing a private message (all effects NS).

Study 3 further explored the process by asking undergraduate students ($N = 316$) to complete a 2 (humor: humorous, serious) x 2 (valence: positive, negative) between-subjects experiment. Participants were asked to imagine sharing a picture of either a successful or a failed (burnt) beef brisket along with either a humorous

("cooking was so fabulous even the smoke alarm was cheering me") or a serious caption ("my homemade brisket"). Participants also answered how posting the image with the caption would make them look to others on a scale from 1 (terrible) to 7 (great). Consistent with the previous studies, participants were more likely to share the burnt brisket picture with humorous than a serious caption (*M* = 3.68 vs. 2.90.; *p* = .03), but they were equally likely to share the successful beef brisket regardless of whether they used a humorous or serious caption (*M* = 4.37 vs. 4.08; *p* <. 43). The expected impression mediated the effect humor on intention to share (*ab* = 1.19, *CI* [.418, 1.956]).

In sum, whether humor increases the likelihood that consumers share memories, stories, and images online depends on whether the content is positive or negative. Humor makes it easier to share embarrassing, sad, and otherwise negative experiences, but it is does not make consumers more likely to share happy, triumphant, or otherwise positive experiences.

How Power Influences the Use of Humor

EXTENDED ABSTRACT

Humor profoundly influences interpersonal perception and behavior. In hierarchical relationships, low power individuals have less control over the situation and are more dependent upon individuals with greater power. This relative lack of control can lead to greater stress and anxiety (Dacher, Gruenfeld, and Anderson 2003) and can motivate low power individuals to engage in ingratiatory behaviors to elevate their position in the hierarchy (Judge and Bretz 1994; Magee and Galinksy 2008; Watt 1993). Recent studies have found that the use of humor by low power individuals can be an effective method of emotional regulation and dealing with stress (Lefcourt and Martin 2012; Samson et al. 2014; Samson and Gross 2012), a means of promoting liking and interpersonal bonding (Cooper, Kong, and Crossley 2018), and a tool for elevating status (Bitterly et al. 2016).

Despite the stress reducing, ingratiation promoting, and status enhancing benefits of humor, low power individuals may be less likely to utilize humor (Blader and Chen 2012; Blader, Shirako, and Chen 2016; Galinksy, Rucker, and Magee 2015; Magee and Galinksy 2008)and thus significant questions remain about differences in how status and power impact social encounters. We conducted 5 studies to address this gap. In particular, these studies tested the prediction that status and power would have opposing effects on justice enacted toward others. In the first 3 studies, we directly compared the effects of status and power on people's enactment of distributive (Study 1. Several studies have shown that, compared to high power individuals, low power individuals dedicate more cognitive resources attending to factors such as risks, potential threats, and the thoughts and emotions of others (Blader et al. 2016; Dacher et al. 2003; Smith et al. 2008)prompting considerable research attention to this issue. However, prior research has primarily examined how power affects perspective taking, and has neglected to investigate the impact of status (i.e., the respect and esteem that an individual holds in the eyes of others, which causes low power individuals to experience greater cognitive load. Therefore, low power individuals find themselves in a quagmire: Humor offers particularly important benefits to individuals who lack power (to navigate the challenges of having low power and to gain power), but the lack of power could make these same individuals less able to *use* humor. Little theory and research exist to shed light on the factors that influence whether low power individuals use humor, and the research that does exist presents equivocal findings (Coser 1960; Lundberg 1969; Vinton 1989).

In the current research, we examine the relationship between power and the use of humor using field data involving 73,620 corporate email messages in addition to experimental studies that replicate the key finding linking interpersonal power with the use of humor. This research offers three key theoretical contributions to research on social hierarchy, power, and humor. First, this work demonstrates that humor pervades communication, which makes understanding humor necessary for understanding interpersonal interactions in the social hierarchy. Second, this research introduces power as an important, but neglected, antecedent for the ability to use humor. Although humor has intrapsychic (e.g., stress reduction) and interpersonal (e.g., ingratiation, elevated status) benefits which make using it particularly attractive for low power individuals, we find that occupying a position of low power makes individuals less able to use it. Third, we provide a novel explanation of why humor use varies across the hierarchy. We show that low power individuals experience greater cognitive load in interactions vis-à-vis a high power individual, which impedes their concentration and, therefore, their ability to generate humor. Together, these contributions enrich our understanding of the interplay between power and humor and show that the two constructs are intricately tied.

Study 1: A Field Study of Power and Humor

In Study 1, we examine the relationship between power and humor using field data; the Enron Email Corpus (Cohen 2015). We gathered hierarchical information on the individuals in the dataset and grouped them according to whether they fell at the bottom (low power) or top of the hierarchy (high power). Then, we examined how the use of humor in emails related to the power level of the sender.

Results

We find that humor is common in communication, occurring in 8.86% of sent emails. We found a significant effect of power on the use of humor, $\chi^2(1) = 13.05$, $p < .001$. We found that the use of humor was significantly lower for low power individuals (7.04%) than high power individuals (9.54%), $\beta = .63$, $p < .001$. The effect of power on the use of humor remained significant, $\beta = .47$, $p = .025$, when we control for the gender of the sender, $\beta = .30$, $p = .153$.

Study 2: Power and Humor in the Laboratory

We recruited 265 adults to participate in a behavioral lab study in exchange for $10.00. We randomly assigned participants to one of two between-subjects conditions: *High Power* vs. *Low Power*. After participants were assigned to their condition, we informed them that they would be sharing jokes with their partner. We gave participants 5 minutes to brainstorm jokes. Next, we gave participants 5 minutes to write their final list of jokes, which served as our primary dependent variable.

Results

We find a significant effect of the manipulation on the number of jokes that individuals wrote to share with their partner, $F(1, 16) = 16.93$, $p < .001$, $\eta^2 = .04$. Individuals assigned to the high power condition (*M* = 3.40, *SD* = 1.56) created significantly more jokes to share with their partner than individuals assigned to the low power condition (*M* = 2.78, *SD* = 1.56), $t(16) = 4.11$, $p < .001$.

We find evidence that participants in the low power condition were less able to think of jokes. We find that cognitive load mediates the effect of power on the use of humor, but we do not find that impression management concerns or confidence mediate the effect of power on humor. Using bootstrap analysis with 5000 simulations (Preacher and Hayes 2004, 2008), we find a significant indirect effect for cognitive load (*IE* = .07, bias adjusted 95% confidence interval =

[.01, .20]), but insignificant indirect effects for both impression management concerns (*IE* = -.01, bias adjusted 95% confidence interval = [-.07, .01]) and confidence (*IE* = .00, bias adjusted 95% confidence interval = [-.01, .07]).

Conclusion

In this work, we find that humor pervades communication and is intrinsically connected to power. Although individuals at the bottom of the hierarch have much to gain from using humor, they are less able to use it. Thus, being powerless is a truly serious position

Paper #4: Political Polarization in How Perceived Social Similarity Impacts Support for Redistribution

Nailya Ordabayeva, Boston College, USA

SESSION OVERVIEW

Emerging research on political ideology has shown that conservatives' and liberals' motivation and values affect their preferences in the marketplace. The theoretical foundations for these ideological differences have related to distinct motivational and value systems that distinguish liberals and conservatives. One such difference that has garnered significant theoretical and empirical support relates to openness and preference for change, with numerous empirical studies showing liberals are more open to and have an innate relative preference for change as compared to conservatives. These change preferences have manifest in a number of different domains from support for social and government institutions, political attitudes and consumer preferences. The current session also builds on another cornerstone of theory related to political ideology by examining differences in the justification of economic inequality of liberals and conservatives' behaviors. Previous research has shown that perceiving high (vs. low) similarity can potentially increase support for redistribution, because it may lead individuals to question the fairness of people's unequal outcomes and boost their group loyalty. Research has shown that this perceived similarity shapes opinions related to support for social programs and the role of government assistance. The current session advances extant understanding of these issues by revealing that political ideology's influence on these motivations and values leads to wide-ranging effects on mainstream consumer behavior research areas, such as service failure.

The first paper shows that conservatives and liberals experience change differently. In the context of new product innovations, conservatives' greater sensitivity toward change may lead them to believe a new product innovation is more significant and beneficial as compared to liberals. The authors also show that conservatives and liberals will assimilate or contrast their evaluations of new products when making comparisons between past and future products. although conservatives are more likely to perceive innovation-related changes in secondary product features as compared to liberals who focus more on primary product features, and how ideology affects evaluation of innovation on the time frame.

The second paper sheds light on the cognitive processes enacted by liberals and conservatives as they experience changes while performing a task. The authors investigate performance on tasks as a function of the variability of the attentional foci associated with task performance. They find that liberals perform better on tasks that require varying attentional foci whereas conservatives perform better at tasks requiring a stable attentional focus. Variable attention is useful in contexts where consumers need to learn new skills whereas stable and constant attention is useful in contexts where consumers need perseverance, such as goal striving and habit formation.

The third paper examines how ideology influences reactions to service failure and implicates the role of moral violations related to fairness. Their findings show that liberal consumers are likely to respond more negatively to brands involved in a service failure due to their greater sensitivity to violations of the fairness moral foundation. They find liberals were more likely to express negative emotions on Twitter in response to a well-publicized airline service failure. They also find convergent laboratory support using service failure vignettes and show that these ideological differences are driven by differential activation of the fairness moral foundation in response to the failure.

The fourth paper shows that ideology drives different justification of unequal outcomes depending on perceived social similarity. They found that perceiving high (vs. low) social similarity increases redistribution support among liberals, but decreases redistribution support among conservatives, because it weakens liberals', but strengthens conservatives', belief that individuals deserve their unequal outcomes.

This session presents research that together examine how conservatives' and liberals' preferences related to key motivations and moral values influence a variety of consumer behaviors. The papers build theory linking political ideology and behavior and share a common focus on underlying motivational and value-based differences as a function of ideology.

Are Conservatives Always More Averse to Change than Liberals? Political Ideology and Innovation

EXTENDED ABSTRACT

Previous research has shown that political ideology is at the heart of a variety of cognitive and motivational differences. One of the most frequently reported distinctions relates to openness to change. Research has shown liberals possess a greater tolerance to change and are more open to new experiences. Previous consumer research has shown how these underlying ideological influences affect consumption. For instance, Khan et al. (2013) find that conservative consumers were less likely to adopt new products as compared to liberal consumers. Barra (2014) finds that this effect on new products is enhanced when products are more novel and when consumer's political ideology is more central to their self-concept.

The current research theorizes that not all change is equivalent and that liberals and conservatives may experience change differently. One hypothesis we propose is that conservatives' greater sensitivity to change may have positive consequences in the context of new product innovation. Specifically, we theorize that new product innovations may be seen as more significant and beneficial to conservatives as their greater sensitivity to change makes these differences seem more consequential as compared to liberals. Additionally, we theorize that a greater sensitivity to changes in product features may

lead to conservatives' and liberals' different evaluations of abrupt and gradual product innovations.

The literature on product innovation has identified speed of change as a key underlying dimension along which innovations are evaluated. Product innovations can happen abruptly or they can occur more gradually (Garcia & Calantone, 2002) Based on this notion, we define abrupt changes in innovation as changes that enter the market immediately, and alter technological deliveries of products; whereas incremental changes in innovation are changes that take place gradually and in a less significant way. We theorize that conservatives will prefer gradual changes as compared to liberals, whose inherent preferences for change will lead them to prefer abrupt product innovations.

Further, consumers perceive change differently when comparing to the past or the future. We theorize that conservatives will perceive changes in products similarly in the past and future, whereas liberals generate more positive attitude toward changes in the future (vs. past), due to their openness to change and belief that future change will eclipse past change as part of a progressive belief system. We theorize that the differential evaluations of past and future product innovations is due to distinct assimilation and contrast effects activated as a function of political ideology.

As denoted by a large body of consumer research, consumer judgments and behaviors are influenced by the context they are in (Bless and Schwarz 2010). Past research on assimilation and contrast shows that contextual influences can alter target judgments and related behaviors. It is well-documented that product information, whether being numeric (e.g. price) or semantic (e.g. vice or virtue products), learned before to evaluating a product can affect consumer judgment (Chernev 2011; Makens 1965; Plassmann et al. 2008). An assimilation effect typically takes place when consumers integrate prior product information to their judgment of a subsequent product.

However, it is not always the case that consumers assimilate prior product evaluation with subsequent products. Sometimes, consumers evaluate the same product more negatively when the product information is favorable compared to when it is unfavorable, which is known as the contrast effect.

Conservatives has been shown in psychology and consumer research to be referencing the past to a greater extent than future (Robinson et al., 2015). More recently, Lammers and Baldwin (2018) shows that conservatives are prone to past and nostalgic society, resulting in their support for political ideas that can be linked to a desirable past state, rather than a desirable future state of society. Building on their findings, the current research examines how their characteristic of past/ future-orientation affect how consumers with different political ideology evaluate past/ new products differently. Specifically, we show that the past and nostalgic taste of a product leads to conservatives' assimilation effect of converging their evaluations of past and new products.

Study 1: This study was conducted around the time that iPhone X was launched, and we recruited 541 Mturk participants. Participants were asked of the perceived change of features of the new iPhone on a 7-point Likert scale. Perceived change of the features are converted into one index, which is our dependent measure. Sample features include, "battery life and charging", and "camera". Political ideology is measured on an 11-point Likert scale adopted from Jost (2007). The result shows that conservatives (vs liberals) notice more change than the liberals ($p = 0.0162$). Specifically, as the features measured in this study are mostly secondary features.

Study 2: In Study 2, we further examine if conservatives prefer changes that are secondary We randomly assigned 202 Mturk participants to one of the conditions of a 2 (features: primary, secondary) between subject design, where their political ideology was measured. Our dependent measure was perceived change, and the result indicated that conservatives (vs. liberals) notice the change in secondary features more ($p = 0.0061$). Primary and secondary features were determined by a pilot study where one hundred participants were recruited to rate which features of a smartphone are primary and secondary. In Study 2, we replicated our results in Study 1, where we show that conservatives notice small changes more than liberals. Moreover, the two-way interaction between political ideology and feature type still remains significant after controlling for brand liking and product liking ($p = 0.0197$).

Thus, Study 1 & 2 showed that depending on consumer's political ideology, different types of changes in features will change consumer's perceptions of the innovations. Namely, we show that conservatives are sensitive to small changes more than liberals do.

Study 3: In Study 3, we examine how different types of innovations will affect consumer's attitude toward innovations. We randomly assigned 200 participants to one of the conditions in a 2 (innovation type: abrupt, gradual) between subject design, where their political ideology was measured. The dependent measures in this study are likelihood of early adoption, and innovation liking. Participants read a passage about an update of their operating system, which is either an abrupt or gradual innovation. As hypothesized, a two-way interaction shows that conservatives (vs. liberals) are more likely to engage in early adoption of the new operating system in the gradual innovation condition (vs. abrupt) ($p = 0.0489$), and they like the innovation more in the gradual (vs. abrupt) innovation condition ($p = 0.0218$).

Thus, Study 3 showed that when the changes are gradual, conservatives, instead of being resistant to changes as suggested in prior research, they like the gradual innovation more than liberals, and are willing to engage in early adoption.

Study 4: In Study 4, 300 participants were randomly assigned to one of the conditions in a 2 (innovation type: innovative, non-innovative) mixed subject design, where each participant rated their perceptions of each product by comparing them to the past and future. The dependent measures composed of items that asked participants about their perceptions of change of eight types of products (four innovative, four non-innovative). Participants first rated the products by comparing the products' performance ten years in the past to present performance, and then they rated the same products by estimating their future performance in ten years compared to present performance. As a mixed model analysis shows, a significant three-way interaction ($p = 0.0004$) shows that liberals evaluate product performance in the past (vs. future) more negatively, and that conservatives evaluate performance similarly when comparing the current product to the past and future. Specifically, we found that this significance holds only for innovative products ($p < 0.0001$). This effect does not hold when the product is non-innovative ($p = 0.8689$).

Thus, Study 4 shows that liberals and conservatives hold different beliefs about the rate of change of innovative products. Liberals believe that products will be better in the future as compared to the past whereas conservatives do not show different beliefs regarding past or future product performance. The results align with our predictions that conservatives assimilate product evaluations from the past and future, whereas liberals contrast their evaluations of products from the past and future.

Taken together, these studies show that liberals and conservatives different sensitivities to and beliefs regarding change influence their evaluations of product innovations. In contrast to the received view that conservatives always evaluate change more negatively than

liberals, we find evidence for more nuanced relationships among political ideology, innovation and consumer evaluation.

The Impact of Political Ideology on Self-Control

EXTENDED ABSTRACT

Self-regulation is a multi-process system (Engle, Tuholski, Laughlin, and Conway 1999; Miyake et al. 2000; see Laran 2020), such that effective self-control often requires consumers to focus attention in a way that suppresses the influence of interfering information (i.e., inhibition) as well as incorporates the influence of novel insights (i.e., updating). The question motivating the present research is whether consumers' political ideology influences self-control success on tasks of inhibition and updating.

Political ideology reflects a specific set of ethical ideals, principles, and doctrines that explain the basis by which society should function (Jost, Federico, and Napier 2009). Though indirect, a wealth of research suggests that conservatives and liberals vary in their ability to mentally adapt to situational changes (i.e., cognitive flexibility: Zmigrod, Rentfrow, and Robbins, 2018). Specifically, liberals appear to be cognitively-flexible; they are open to new experiences (Carney, Jost, Gosling, and Potter 2008), socially-adaptable (Hirsh, DeYoung, Xu, and Peterson 2010), and novelty-seeking (Carney et al. 2008). Conversely, conservatives appear to be cognitively-rigid; they are persistent at impulse regulation (Clarkson et al. 2015), norm-adherent (Gosling, Rentfrow, and Swann 2003), and resistant to change (Jost et al. 2009).

This potential difference in cognitive flexibility is critical as it is proposed to impact performance on self-control tasks that require inhibition and updating. Specifically, the traits that reinforce cognitive rigidity in conservatives (e.g., rule adherence, resistance to change) should promote response inhibition by facilitating persistence through suppression of conflicting stimuli. Conversely, the traits that reinforce cognitive flexibility in liberals (e.g., openness, adaptability) should promote response updating by facilitating adaptation through replacing outdated information with relevant information. Collectively, then, conservatives and liberals are hypothesized to perform well at tasks of inhibition and updating, respectively, due to their respective difference in cognitive flexibility.

This hypothesis was tested across three studies. Each study targeted 200 participants based on a priori power analyses (power of .8, small-medium effect sizes, an alpha level of .05; Faul et al. 2007) and included appropriate attention checks (Oppenheimer, Meyvis, and Davidenko 2009).

As an initial test of our hypotheses, we conducted two studies at separate time points to test our primary hypothesis that conservative and liberal consumers differentially excel on tasks shown to assess inhibition and updating (Conway et al. 2005; Engle et al. 1999; Miyake et al. 2000). In the first session, participants completed a task of inhibition that presents participants with a target cue to respond to as quickly as possible while ignoring a random cue (*IOR*; Posner and Cohen 1984). In a separate session, participants completed a task of updating that required remembering the most recent category-relevant stimulus among constantly changing stimuli from multiple categories (*Keeping Track Task*; Yntema and Mueser, 1962). Participants in both studies indicated demographics along with a measure of political ideology on a 7-item scale anchored from *Very liberal* to *Very conservative* (Jost 2006; Knight 1999). The analysis revealed that conservatives outperformed liberals on the inhibition task (IOR: $p = .02$), whereas liberals outperformed conservatives on the updating task (Keeping Track Task: $p = .03$). This finding is consistent with the hypothesis that self-control varies as a function of consumers' political ideology and the extent to which the task requires inhibition or updating.

A subsequent study tested the extent to which this effect of task performance was isolated to consumers' political ideology within a separate context. Here, participants completed two anagrams where the performance rule was either fixed (inhibition) or changed (updating). For instance, participants instructed to list only three-letter solutions for the first anagram were then instructed to either list three-letter (inhibition) or four-letter (updating) solutions in the second anagram. To isolate ideology, participants completed an assessment of intelligence using an adapted version of the Wechsler Adult Intelligence Scale (WAIS; Friedman et al. 2006; Wechsler 1997), motivation (Muraven and Slessareva 2003), and religiosity (Koenig and Büssing 2010) before indicating their demographics and political ideology.

The hierarchical regression controlled for participant demographics as well as intelligence, motivation, and religiosity. Analysis of the number of correct solutions across anagrams revealed a significant interaction ($p = .002$); conservatives generated more solutions than liberals when the performance rule was fixed ($p = .02$) whereas liberals generated more solutions than conservatives when the performance rule was varied ($p = .04$). Interestingly, intelligence, motivation, and religiosity each had a positive effect on performance (p's $< .01$) yet had no influence on the relationship between ideology and task performance.

A final study examined the mediating role of cognitive flexibility on the performance of conservative and liberal consumers on tasks of differing attentional demands. Participants completed two 14x14 letter word searches where the performance rule was either fixed or varied. For instance, participants instructed to identify only forward solutions for the first word search were then instructed to either list forward (inhibition) or backward (updating) solutions for the second word search. Participants again completed the assessments of intelligence, motivation, and religiosity, as well as a measure of cognitive flexibility (Martin and Rubin 1995), before indicating their demographics and political ideology.

Again controlling for demographics, intelligence, motivation, and religiosity, analysis of the number of correct solutions revealed a significant interaction ($p = .001$); conservatives identified more words than liberals when the performance rule was fixed ($p = .02$), whereas liberals identified more words than conservatives when the performance rule was varied ($p = .005$). Moreover, there was a direct effect of ideology on cognitive flexibility ($p = .002$). Critically, the moderated-mediation test of cognitive flexibility (Model 15: Hayes 2018) indicated significant mediation through both the fixed (95% CI: .003, .182) and varied (95% CI: -.171, -.005) rule conditions.

Collectively, these findings support the claim that the effects of political ideology on self-control might be more nuanced than originally theorized. Specifically, conservatives may better regulate behaviors that require cognitive rigidity, whereas liberals may better regulate behaviors that require cognitive flexibility. Consequently, this work holds direct implication for consumers' self-control behaviors, such as financial decision-making (e.g., saving money) or addictive consumption (e.g., overeating).

Fair or Not? Political Ideology Shapes Observers' Responses to Service Failures

EXTENDED ABSTRACT

Consumers frequently witness service failure incidents. While having dinner at a restaurant, one might see that the customers at the next table did not receive the drinks they ordered. Or while checking

in at a hotel, one might notice another customer complaining that he did not get the type of room he reserved. Those who witness or learn about service failures could potentially form negative attitudes about the brand, which in turn can affect their intentions and WOM related to the brand. Firms would be well-served by understanding which consumers are more likely to react negatively to witnessing service failures, why, and how to curtail the negative impact of service failure for such consumers. This paper presents consumers' political ideology as a determinant of their reactions to observing service failures.

Although service failures are usually conceptualized in terms of operational failures in the process of delivering service, they could also be thought of as breaking a transactional promise (e.g., Goodwin & Ross, 1992; Smith, Bolton, & Wagner, 1999). This latter conceptualization recognizes that a customer experiencing service failure could feel "wronged" and thus form unfavorable judgments (Goodwin & Ross, 1992). To those who observe the failure but are not affected by it, a broken promise or one party being wronged could represent a larger issue of fairness. Fairness considerations—including those of fairness violations—are one of five moral intuition systems or "foundations" that form the basis of moral judgments (Moral Foundations Theory, MFT; Haidt & Joseph, 2004, 2007a). Building on this theoretical framework, past research shows that the importance of the fairness moral foundation varies by political ideology, such that liberals, relative to conservatives, consider fairness to be a highly relevant attribute in judging whether something is "right" or "wrong".

Because failures undermine the perceived fairness of a transaction, we suggest that liberals (vs. conservatives) are likely to view service failures as instances of moral violation. Therefore, even non-political instances of service failures could take on a political aspect and invoke divergent responses from observers who are political liberals or conservatives. In response to witnessing a service failure, liberals will likely see the involved brand as a violator of fairness, an important moral foundation to them (along with harm/care), leading to harsher, more negative responses. Conversely, since conservatives do not place disproportionate value on fairness but also value respecting authority/law, cooperation, and self-sacrifice (Graham et al., 2009; Haidt, Graham, & Joseph, 2009), they will be less likely to see the service failure as a moral violation and thus be less harsh in their judgments of the brand.

We use a multi-method approach (3 experiments, 2 surveys, and 1 big data analysis) to test our theory. As study 1, we gathered a large dataset of tweets (n = 219,070) from Twitter in a quasi-experimental field study using consumers' actual social media activity surrounding a publicized service failure incident about United Airlines. We estimated users' political orientation using a ranking algorithm and conducted sentiment analysis of tweets utilizing a dictionary-based text analyzer. Analyses show that immediately after the negative-publicity incident, liberal (vs. conservative) Twitter users were more likely to express negative sentiments, especially anger and anxiety, against United Airlines. A control sample of tweets from before the event showed a null effect of political ideology on sentiment.

Studies 2 and 3 use experiments and controlled scenarios to replicate the Twitter findings with stronger internal validity. As study 2, participants were assigned to conditions in a 2 (political ideology: liberal vs. conservative) × 3 (scenario: hotel vs. restaurant vs. airline; within-subject) mixed design implemented in two phases. In Phase 1, we recruited 350 adult US participants. We embedded two questions regarding participants' political orientation (following Hirsch et al., 2015; Jost, Nosek, & Gosling, 2008). We also measured participants' endorsement of the fairness moral foundation by

using the fairness/reciprocity subscale from the Moral Foundations Questionnaire (MFQ; Graham, Haidt, & Nosek, 2008). One week later, these participants were invited to an ostensibly unrelated study (Phase 2), with 287 returning participants (M_{age} = 35.34 years, 140 females). They were presented three scenarios (hotel, restaurant, and airlines setting) in randomized order, each followed by a page of questions. Scenarios were based on past literature (Hess et al., 2003; Smith et al., 1999) and adapted to a third-person point of view such that participants saw another customer experiencing service failure. Following each scenario, we measured participants attitudes toward the service provider and how likely they would be to positively review the service provider. Participants' unique ID was used to match data across two phases. Our data show that the first regression model is significant in the hotel ($F(1, 277)$ = 7.33, p = .007, adjusted R^2 = .026), restaurant ($F(1, 277)$ = 6.37, p = .012, adjusted R^2 = .02), and airlines scenarios ($F(1, 277)$ = 12.15, p = .001, adjusted R^2 = .04). Specifically, political ideology significantly predicted the variance in attitude toward the hotel (b = .17, p = .007), restaurant (b = .15, p = .012), and airline (b = .20, p = .001) such that liberals (vs. conservatives) held less positive attitudes in response to reading about service failure experienced by others. These results held even when the demographic variables were controlled for and were replicated with the positive reviewing DV. We further found that these effects are mediated by the endorsement of the fairness foundation and perceptions of fairness toward the affected customer.

Studies 4a and 4b used surveys about news items about publicized service failure events involving the Fyre music festival and the beforementioned United Airlines incident, respectively. In both studies, participants' self-identified political ideology and political party identification predicted their attitudes toward the two service providers and the affected customers. In study 5, the divergence in liberals' (vs. conservatives') responses was attenuated when the recovery effort was referenced as "fair" compensation (vs. compensation present vs. compensation absent). These findings present multi-method evidence of politico-moral influences in consumer responses to non-political service failures.

Political Polarization in How Perceived Social Similarity Impacts Support for Redistribution

EXTENDED ABSTRACT

The inequality of wealth in the US has reached record levels (Piketty, 2011). This is generating a public debate about the impact of inequality on individual and collective wellbeing and increasingly shaping people's preferences across many contexts including political candidates, policies, as well as products and brands (e.g., Dawtry, Sutton, & Sibley, 2015; Frank, Wertenbroch, & Maddux, 2015; Ordabayeva & Chandon, 2011).

Although individuals agree that economic inequality in the US is historically high (Bartels, 2005), support for redistributive policies designed to reduce income inequality is not very widespread (Jost & Hunyady, 2005). This raises the question of how individuals' preferences and support for redistribution can be changed (Brown-Iannuzzi et al., 2014).

Prior work suggests that, although redistributive preferences are deeply ingrained within individuals, one factor that can potentially overcome this challenge and increase individuals' support for redistributive policies is similarity. Specifically, prior work suggests perceiving high (vs. low) similarity can potentially increase support for redistribution, because it may lead individuals to question the fairness of people's unequal outcomes and boost their group loyalty (Luttmer, 2001). Supporting this notion, studies show that in-

dividuals are more supportive of redistribution if they think that it will help similar others (Duell, 2015), if they live in areas with high racial similarity (Alesina, Baqir, & Easterly, 1999), and if they are prompted to cognitively focus on similarity in a picture comparison task (Ordabayeva & Fernandes, 2017).

The present research suggests that the effect of perceived social similarity on individuals' redistributive preferences may be more complex. It suggests that perceiving high (vs. low) social similarity may increase redistribution support among liberals, but decrease redistribution support among conservatives, because it may weaken liberals', but strengthen conservatives', belief that individuals deserve their unequal outcomes. More specifically, since prompting high social similarity would confirm liberals' assumption that individuals are similar in their inherent qualities (hard work, effort), it should strengthen liberals' belief that similar individuals deserve similar outcomes and boost liberals' support for redistribution. In contrast, boosting perceptions of social similarity may challenge conservatives' assumption that people are dissimilar in inherent qualities, which may lead conservatives to wish to reconcile why similar individuals end up with dissimilar outcomes. The desire to reconcile this discrepancy may further strengthen conservatives' belief that people are ultimately responsible for and deserve their dissimilar outcomes, because unsuccessful individuals had similar starting ingredients needed for success as successful individuals and hence unsuccessful individuals have no one but themselves to blame. In effect, this research proposes that prompting perceptions of high (vs. low) social similarity may result in greater (rather than lower) political polarization in redistributive preferences. Three studies tested this prediction.

Study 1 manipulated perceptions of social similarity: participants elaborated on the similarities or differences between themselves and others. As the dependent measure in Study 1, and in all subsequent studies, participants indicated the extent to which they support or oppose taxes on individuals earning more than $1 million and more than $5 million; Chow & Galak, 2012). Participants also indicated their beliefs in the fairness of unequal outcomes (e.g., "By and large, people deserve what they get"; Rubin & Peplau, 1975) and their political ideology (1 = "extremely liberal" to 9 = "extremely conservative"; Jost, 2006). The results of a regression analysis revealed a significant interaction between social similarity and political ideology ($b = -.17$, $p = .016$). A floodlight (Johnson-Neyman) analysis showed that boosting perceptions of social similarity (vs. dissimilarity) increased redistribution support among liberals (who scored 2.39 or lower on the ideology scale), but reduced redistribution support among conservatives' (who scored 7.49 or higher on the ideology scale). This happened because boosting perceptions of social similarity (vs. dissimilarity) weakened liberals', but strengthened conservatives', belief in the fairness of unequal outcomes (interaction: $b = .13$, $p = .003$; moderated mediation: $a \ x \ b = -.0214$, 95% CI = $[-.0578, -.0034]$).

Study 2 measured perceptions of social similarity among others ("to what extent do you think Americans are different from or similar to each other?" 1 = "very different" to 7 = "very similar"), which did not invoke the self to rule out the egocentric and projection accounts of the hypothesized effect. The study also measured fairness beliefs more specifically by focusing on the fairness of economic outcomes (e.g., "Economic positions are legitimate reflections of people's achievements"; Jost & Thompson, 2000). A regression analysis revealed a significant interaction between social similarity and political ideology ($b = -.11$, $p < .001$). Perceiving high (vs. low) social similarity boosted liberals', but reduced conservatives', redistributive preferences. This once again happened because perceiving

high (vs. low) social similarity weakened liberals', but strengthened conservatives', belief in the fairness of unequal economic outcomes (interaction: $b = .03$, $p = .001$; moderated mediation: $a \ x \ b = -.0213$, 95% CI = $[-.0387, -.0081]$).

Study 3 manipulated perceptions of social similarity among others (i.e. Americans – to minimize the role of egocentric and projection motives), and it included a control condition in which similarity perceptions were not manipulated. Two dummies were created to test the predictions (Naylor, Lamberton, & Norton 2011): dummy 1 contrasting high similarity with low similarity and control, and dummy 2 contrasting low similarity with control; but only dummy 1 interacted with ideology ($b = -.17$, $p = .003$). Liberals' redistributive preferences were higher in the high similarity than in the low similarity and control conditions, but conservatives' redistributive preferences were lower in the high similarity than in the low similarity and control conditions. These findings confirmed that the effect is driven by perceptions of social similarity (rather than dissimilarity).

This research suggests that individuals' preferences for redistributive policies designed to reduce inequality may be more complex than previously presumed, and that these preferences may be shaped by external manipulations differently depending on individuals' group membership. The results may also inform policy makers interested in shaping public support for redistribution as well as researchers interested in identifying prompts that can change redistributive preferences and factors that can polarize, or unify, conservatives' and liberals' preferences in various contexts.

SESSION OVERVIEW

Decades of research across the fields of economics (e.g., Rabin and Thaler 2001), psychology (e.g., Kahneman and Tversky 1982), judgment and decision making (e.g., Coombs and Beardslee 1954), and marketing (e.g., Bettman, Luce, and Payne 1998) have revealed that uncertainty profoundly impacts people's attitudes. We know, for instance, that uncertain attitudes are more easily influenced (Litt and Tormala 2010), less persistent (Bassili 1996), and less likely to predict behavior (Fazio and Zanna, 1978), and that uncertainty motivates systematic processing of persuasive messages (Chen, Duckworth, and Chaiken 1999; Tiedens and Linton 2001). We have less clarity, though, about the mechanisms through which different sources of uncertainty influence the formulation and revision of evaluations and beliefs. While uncertainty is a dimension of an attitude, it can also be a characteristic of a persuasion source, a property attributed to an attitude object, a feature of outcome expectations or evaluations, or a feeling arising from sources unrelated to a focal decision. In this session we contribute to answering one key question: How does uncertainty originating from different sources impact people's evaluations and beliefs?

We draw together four papers that each probe the mechanisms of action of a different source of uncertainty that shape evaluations and beliefs. In the first paper, Hussein and Tormala integrate prior persuasion research to develop a comprehensive theoretical framework charting conditions in which uncertainty acknowledged by a source promotes persuasion by enhancing source perceptions and increasing involvement. Krijnen, Bogard, Ülkümen, and Fox illuminate the manner in which the perceived nature of uncertainty in the domain of financial well-being affects the degree to which persuasive messages shift beliefs about social policy issues. They find that message framing compatible with uncertainty beliefs facilitates the persuasive power of messaging in support of social welfare policies. In the third paper, Kupor and Laurin investigate how knowledge about uncertain outcomes influences beliefs about the magnitude of those outcomes, and alters evaluations of those outcomes as a result. In

the final paper, Waisman and Häubl examine how uncertainty that originates from a source completely unrelated to a consumption decision alters processing and influences evaluation of that consumption decision. They find that when consumers feel uncertain and make a taste-based decision, their decision processing becomes faster, more fluent, and more favorable to their chosen alternative; and as a result, consumers become more confident in their choice.

Collectively, these four papers identify conditions under which uncertainty originating from a variety of sources alters evaluations and beliefs, and uncover the mechanisms through which uncertainty operates to generate these persuasive effects. This session will appeal to a broad range of scholarly interests including persuasion, uncertainty, and the intersection of consumer psychology with judgment and decision making.

Undermining Your Case Can Enhance Your Impact: A Framework for Understanding the Positive Effects of *Acts of Receptiveness* in Persuasion

EXTENDED ABSTRACT

Past research has uncovered numerous actions a source can take that would appear to undermine but in fact frequently enhance persuasion. For example, expressing doubt rather than confidence, conveying that there is uncertainty rather than certainty around an argument or estimate, asking questions rather than making statements, playing up rather than playing down one's personal mistakes, and acknowledging rather than hiding opposing viewpoints would all seem to limit one's persuasive impact, but in fact they often boost it.

We review prior research on these topics and propose a theoretical framework that explains when and why such counterintuitive actions enhance persuasion. In particular, we posit that these diverse actions cohere around a single underlying construct: acts of receptiveness. We define acts of receptiveness as behaviors or actions that signal a source's openness to ideas, arguments, and attitudes that are new or opposing to his or her own. In other words, acts of receptiveness suggest to recipients that the source is not overly zealous, biased, or one-sided in his or her beliefs.

Consider the conditions under which acts of receptiveness boost persuasion. Based on our review, we suggest that acts of receptiveness are especially likely to promote persuasion when source expertise or status is high but not low. Under high expertise conditions, it appears that people can be more persuaded by those who express doubt rather than confidence about their opinion, who mention rather than mask mistakes they have made, who highlight flaws in their arguments or reference views that oppose their own, and who ask questions instead of making declarative statements. Under low source expertise or status conditions, acts of receptiveness generally offer little advantage or can even backfire.

In addition, when source credibility is high, acts of receptiveness appear to promote persuasion through two primary mechanisms: enhanced source perceptions and increased involvement. First, acts of receptiveness appear to trigger more favorable source impressions, fostering perceptions of honesty, likeability, thoughtfulness, and so on. Second, acts of receptiveness can stimulate involvement, which leads to deeper processing. These processes in turn can facilitate persuasion as long as the arguments are reasonably strong.

We organize our review around four primary acts of receptiveness that show the predicted persuasion effect (i.e., acts of receptiveness result in greater persuasion) and speak to the proposed conditions and/or mechanisms guiding it.

Conveying Uncertainty. One class of acts of receptiveness involves conveying uncertainty. By conveying uncertainty, we mean communicating or displaying doubt, hesitance, or ambiguity. For example, a source who expresses doubt about an opinion (Karmarkar and Tormala 2010) or provides a range of possible outcomes when making a forecast or prediction (Howe et al. 2019) can be viewed as conveying uncertainty. Conveying uncertainty can be viewed as an act of receptiveness because the source takes a position, expresses an argument, or provides an estimate or answer, but implicitly acknowledges that other positions, arguments, or estimates exist and may be valid. By conveying uncertainty, the source suggests that he or she understands that his or her knowledge is not definitive and that he or she is open to other perspectives on the topic.

Acknowledging Mistakes. Another class of acts of receptiveness involves admitting a mistake. By admitting a mistake, we mean explicitly or implicitly taking responsibility for an error. Explicitly admitting a mistake may take the form of acknowledging the mistake and/or apologizing for it. For example, "I used to think X, but I was wrong." Implicitly admitting a mistake may take the form of changing one's opinion to correct for a mistake. For example, if someone points out mistakes in the source's arguments, the source could update his/her arguments to address the error.

Acknowledging that one has committed a mistake explicitly or implicitly signals openness to information that is potentially adversarial to one's position. Rather than reverting to defensiveness or blame, acknowledging a mistake signals that one is not overly zealous or single-minded; that one is open to changing one's mind and updating one's position based on the available information. Past research has shown that explicitly or implicitly admitting mistakes can enhance persuasion (Reich & Maglio 2019; Kupor et al. 2018; Aronson et al. 1966; John et al. 2019; Gonzales 2012; Reich & Tormala 2013).

Highlighting the Negatives. Highlighting the negatives involves bringing up defects, limitations, downsides, and opposing arguments to one's own point of view or position. We submit that doing so signals open-mindedness and receptiveness, and thus can offer a persuasive advantage over doing the opposite—for instance, sharing only supportive arguments or asserting that one's proposal, position, or offer is superior on all dimensions. Past research on two-sided messages (Etgar and Goodwin 1982; Golden and Alpert 1986; Kamins and Assael 1987; Settle and Golden 1974; Smith and Hunt 1978; for a review, see Crowley and Hoyer 1994) and on the blemishing effect (Ein-gar et al. 2012) suggests that acknowledging negatives can enhance persuasion under specifiable conditions.

Asking Questions. Asking questions, as opposed to making declarative statements, is another class of acts of receptiveness. Intuitively, asking a question, even when one already knows the answer, seems more open and inviting than does making a statement. A person who makes declarative statements (e.g., "this new policy will boost productivity"), for instance, is likely to be seen as more firm or assertive in his opinion than one who phrases the same position as a question (e.g., "won't this new policy boost productivity?"). By implicitly inviting the recipients' input, a source who asks questions might be seen as open-minded and receptive to others' views or perspectives—and past research found that asking questions can facilitate persuasion under specifiable conditions (Zillmann 1972; Petty et al. 1981; Burnkrant & Howard 1984).

Conclusion. In summary, through an extensive review of the literature, we document a vast array of acts of receptiveness that explain when and why particular counterintuitive actions—such as conveying uncertainty or admitting mistakes or limitations—can enhance persuasion. In doing so, we integrate seemingly disparate research findings around a single theoretical framework with concrete practical implications.

Perceived Drivers of Change in Financial Well-Being Predict Partisan Lean and Response to Policy Messages

EXTENDED ABSTRACT

Economic inequality is on the rise, negatively affecting consumers' well-being around the globe (Alvaredo, Chancel, Piketty, Saez, & Zucman, 2018; Piketty & Saez, 2014; Saez & Zucman, 2016; Zucman, 2019). Politicians have found it challenging to garner broad support for their proposals on how to deal with inequality, since people often strongly disagree on how, when, and why the government should intervene by implementing income redistribution policies. We argue that such disagreements arise because people differ in their assessment of what causes an individual's financial well-being to change over time. Moreover, policy preferences are not fixed but depend on the way a proposal is communicated. Better understanding the persuasiveness of different policy proposals and messages therefore requires an appropriate model of people's beliefs about the nature of uncertainty regarding changes in financial well-being.

In this article, we propose that beliefs about uncertainty in financial well-being are best thought of along three conceptually independent dimensions, respectively capturing the extent to which changes in financial well-being are perceived to be (1) knowable and within individuals' control due to individual factors such as effort ('*rewarding*'), (2) knowable and outside of individuals' control due to systemic factors such as favoritism and discrimination ('*rigged*'), and (3) inherently unpredictable and determined by chance events ('*random*'). In four studies, we use a 9-item F-EARS scale that we developed to assess these three dimensions of uncertainty regarding changes in an individual's financial well-being.

Mapping beliefs about changes in financial well-being along the conceptually independent rewarding, rigged, and random dimensions combines and extends insights from previous research on beliefs about individual accountability (e.g., Alesina & Glaeser, 2004; Fong, 2001; Konow, 2000) and on beliefs about the nature of uncertainty (Fox & Ülkümen, 2011; Tannenbaum, Fox, & Ülkümen, 2017; Ülkümen, Fox, & Malle, 2016).

In Study 1, we examine the relative importance of each dimension as a predictor of political ideology, in search for a more complete understanding of what distinguishes conservative ideology from liberal ideology. Using a nationally representative sample (N = 1102), we find that conservatives generally score higher on the rewarding dimension ($r = 0.13$, $p < .001$), lower on the rigged dimension ($r = -0.20$, $p < .001$), and lower on the random dimension ($r = -0.09$, $p = .005$), even when controlling for a number of demographic and related psychometric measures.

We further predict that political orientation should not be the ultimate determinant of support for social welfare policies. Studies 2-4 (total $N=2560$; pre-registered) test our prediction that we can increase support for social welfare policies when we describe policies in a way that is compatible with people's beliefs about changes in financial well-being.

Study 2 asked participants to indicate how important they find each of three possible goals that a government might pursue: (1)"The government should use resources to incentivize and enable people to

pull themselves out of financial hardship and realize their full potential" (i.e., an *incentivize* goal); (2) "The government should allocate resources to individuals belonging to disadvantaged groups that routinely experience financial hardship" (i.e., a *redistribution* goal); (3) "The government should pool resources to support people when they happen to experience unforeseeable financial hardship" (i.e., a *risk-pool* goal). The results suggest that higher scores on the [rewarding/rigged/random] dimension were associated with a more positive change in the importance rating of the [incentivizing/redistribution/risk-pooling] goal, respectively, compared to the other two goals.

In Study 3, we presented participants with four different public policy proposals: a more extensive disaster recovery program, a tuition-free higher education system, and a more extensive food-purchasing assistance program, and a universal health coverage system. Each proposal was followed by three different arguments in favor of the policy: (1) an *incentivizing* argument, which highlighted how the policy would provide assistance to those who deserve it most; (2) a *redistribution* argument, which highlighted how the policy would provide assistance to the groups that need it most (e.g., low-income, unemployed people); (3) a *risk-pool* argument, which highlighted how the policy would pool tax-money to collectively pay in case an individual experiences an unexpected life event. The results suggest that higher scores on the [rewarding/rigged/random] dimension are associated with a more positive change in policy support in response to the [incentivize/redistribution/risk-pooling] argument, respectively, as compared to the other two arguments.

In study 4, we presented participants with statements of three political candidates regarding welfare policies on higher education, disaster recovery, and food purchasing assistance. Each candidate put forward either incentivizing arguments, redistribution arguments, or risk-pooling arguments for all three proposals. We find that higher scores on the [rewarding/redistribution/random] dimension are associated with a more positive change in support for the [incentivizing/redistribution/risk-pooling] candidate, respectively, as compared to the other two candidates, even when controlling for political ideology. Perhaps more importantly, scores on the three dimensions are associated with greater intention to vote for candidates that made belief-compatible arguments.

These findings broaden our understanding of what is driving support for or opposition to redistribution policies. To truly grasp political and policy preferences we need a complete and accurate model of how people think about changes in financial well-being. Our findings confirm that a model based only on perceptions of individual control is insufficient, and that distinguishing between the perceived knowability and randomness of changes in financial well-being allows for more complete understanding and better predictive ability.

Despite the commonly held wisdom that support for welfare policies depends on political attitudes, we show that belief-compatible messages can increase support for redistribution policies and voting intentions for the politicians proposing these policies, across the entire political spectrum. When people disagree about a certain distribution policy, this disagreement may stem from a failure to jointly define what exactly the policy entails–who it helps, on what basis, and with what purpose. Whenever such disagreements arise, a slight reframing of the policy, guided by an understanding of beliefs about the uncertainty in financial well-being, may bring opinions on the matter closer together.

How Probability Information Impacts Outcome Judgments

EXTENDED ABSTRACT

Consumers' decisions about which foods they eat and which health products they utilize influence their welfare and well-being. When consumers believe these products may produce greater benefit, they are more likely to consume them; when they believe these products may cause greater harm, they are less likely to consume them (Slovic 1964). When judging the size of products' benefits and harms, consumers are often aware of these outcomes' probability of occurring. In fact, this information is often highlighted in product advertisements, product packaging, and product websites.

Imagine that a side effect increases a consumer's eosinophil count from 397 to 435 per microliter. Of note, the side effect's prior probability of increasing eosinophils provides no objective insight into the degree to which that consumer's eosinophil count has now increased, and thus this prior probability should not inform the individual's decision about whether to incur a cost (e.g., buy a medical treatment) to remedy that increase. Nevertheless, we theorize that such objectively irrelevant information biases magnitude judgments: Consumers forecast that more probable product outcomes will be larger in magnitude, and also perceive them as larger in magnitude after those outcomes unfold. We propose that this bias emerges because people believe larger prior probabilities emanate from more powerful causal antecedents that produce outcomes with larger magnitudes.

In Study 1, undergraduates were randomly assigned to either a *Smaller Probability* or *Larger Probability* condition, and viewed a Claritin drug advertisement which noted that Claritin causes 6% (vs. 68%) of users to experience a side effect of coughing. When participants learned that someone experienced coughing as a result of taking Claritin, they forecasted that the person experienced a larger number of coughs, $t(108) = 3.35$, $p < .001$. Study 2 replicated this phenomenon when the probability information was communicated via frequencies rather than percentages, $t(198) = 4.23$, $p < .001$.

Studies 3-4 found that probability information also distorts *perceptions* of objective magnitude information. In Study 3, participants in the *Smaller* (vs. *Larger*) *Probability* condition read that when a person eats an orange, the orange has a 14% (vs. 66%) chance of increasing the concentration of trypsin in the body. Next, participants read that someone's trypsin count increased from 397 to 435 per microliter after eating an orange. Participants entered the percentage by which the person's trypsin increased when it increased from 397 to 435 per microliter. Participants were incentivized for accuracy. Participants in the *Larger* (vs. *Smaller*) *Probability* condition perceived that this increase constituted a larger percent increase, $t(198) = 4.14$, $p < .001$.

Study 4 examined an anchoring explanation. Participants in the *Smaller* (vs. *Larger*) *Probability* condition read that consuming a banana has a .03% (vs. 22%) chance of increasing people's eyelash length. Participants then read that a woman's lashes increased in length after she ate a banana, and viewed pictures of her lashes before and after she ate the banana. Participants further read that her lashes were now .75 inches *after* eating the banana; beneath this information and the before-and-after pictures, participants indicated the length of her lashes *before* she ate the banana. Whereas an anchoring alternative predicts that participants who viewed the larger prior probability would report a *larger* initial magnitude, we found that participants who viewed the larger prior probability reported a *smaller* initial magnitude (which indicated that they perceived more

growth depicted in the before-and-after pictures), $t(198) = 2.56$, $p = .011$.

Study 5 found this bias emerges because people believe larger probabilities emanate from more powerful causal antecedents that produce outcomes with larger magnitudes. In addition, it found that the current phenomenon impacts intended behavior. Specifically, participants in Study 5 read that consuming pumpkin seeds has a chance of increasing bone density. Participants viewed a bar graph which depicted that eating one pound of pumpkin seeds has a 6% chance of increasing bone density (and "6%" was printed above the bar). The only difference between conditions was the y-axis, which ranged from 0% to 5% (vs. 100%) in the *Larger* (vs. *Smaller*) *Probability* condition. A pretest revealed that this manipulation caused participants to perceive that the 6% probability was larger in the *Larger* (vs. *Smaller*) *Probability* condition. Participants in the *Larger* (vs. *Smaller*) *Probability* condition judged that pumpkin seeds were more powerful ($t(202) = 5.49$, $p < .001$), that pumpkin seeds would more greatly increase bone density if it did increase a person's bone density ($t(202) = 5.04$, $p < .001$), and were more likely to eat pumpkin seeds ($t(202) = 3.76$, $p < .001$). A serial mediation with bootstrapping indicated that participants in the *Larger* (vs. *Smaller*) *Probability* condition were more likely to eat the seeds because they perceived them to be more powerful and thus would produce a larger boost in bone density. Study 6 leveraged a similar design in the field, and found that the current phenomenon shifts consumers' likelihood of clicking on online ads to purchase a promoted product ($\chi^2 = 5.64$, $p = .018$).

Study 5 found that this bias emerges because people believe larger probabilities emanate from more powerful causal antecedents that produce outcomes with larger magnitudes. As a result, Study 7 found that probability information no longer influences magnitude judgments when people believe that the antecedent that determines an outcome's magnitude is different than the antecedent that determines that outcome's probability. A 2 (Probability: Smaller vs. Larger) × 2 (Antecedent: Connected vs. Disconnected) ANOVA revealed a significant interaction ($F(1, 396) = 7.67$, $p = .006$): Probability information influenced magnitude perceptions when participants believed that the same antecedent determined both an outcome's probability and its magnitude ($F(1, 396) = 18.84$, $p < .001$), but not when they did not ($F(1, 396) = .14$, $p = .708$).

These findings provide novel insight into the inferences consumers draw from probabilities and the architecture of consumers' causal schemas. Importantly, the perceived magnitude of products' benefits is a dominant input into consumers' decisions about whether to purchase those products (Rundmo and Nordfjjaern 2017; Slovic 1964). Thus, our findings have numerous strategic implications.

How Uncertainty Boosts Confidence in Consumption Decisions

EXTENDED ABSTRACT

Could feeling uncertain increase consumers' confidence in their preferential choices? The answer to this question is not obvious. But it is important because decision confidence increases consumers' willingness to pay (Thomas and Menon 2007) and their likelihood to complete a purchase (Huang, Korfiatis, and Chang 2018), and it promotes favorable post-consumption evaluations (Heitmann, Lehmann, and Herrmann 2007).

According to prior research, incidental feelings of uncertainty undermine confidence in understanding (Clore and Parrott 1994), memory (Jacobson, Weary, and Lin 2008), predictions (Tiedens and Linton 2001), and causal judgments (Wichman, Brunner, and Weary 2008). Nevertheless, little is known about the influence of incidental uncertainty on consumers' confidence in their consumption decisions. The present research reveals that the impact of incidental uncertainty on confidence is not limited to the congruency effects demonstrated in other domains, but rather is context dependent. Evidence from three studies shows that the negative effect of incidental uncertainty on confidence vanishes, and even turns positive, when consumers make subjective (i.e., matters of taste) consumption decisions.

Intuitively, decision confidence is a belief in the correctness of a decision. But evidence points to cues from processing—fluency, speed, degree of deliberation and conflict—as the key drivers of decision confidence (Koriat 2012). We propose that the effect of incidental uncertainty on cues from processing differs depending on the context of the decision. Given the self-referential nature of subjective consumption decisions, we posit that increased processing motivation (Tiedens and Linton 2001) and greater semantic clustering (Bass, de Dreu, and Nijstad 2011, 2012) that arise under conditions of uncertainty prompt the generation of thoughts more favorable to the chosen alternative and lead to faster decision making. Rather than feeling more difficult, these cues signal greater confidence.

In Study 1, participants ($N = 405$) read a research abstract that manipulated incidental uncertainty vs. certainty (used in all studies; adapted from Faraji-Rad and Pham 2017). Participants decided between renting a functionally superior or an emotionally appealing apartment (Faraji-Rad and Pham 2017) and reported their confidence in and reasons for their decision. Participants' selection served as proxy for the objectivity of the decision (supported by analysis of reported reasons; significantly greater objectivity for the functionally superior apartment, $p < .001$). The congruency effect evidenced in past research emerges when the functionally superior apartment is chosen ($p = .018$) but vanishes when the emotionally appealing apartment is selected ($F_{1,402} = 0.04$), demonstrating that incidental uncertainty need not always undermine decision confidence.

In Study 2 we directly manipulated context to test our hypothesis that, unlike the judgments studied in the past, confidence in subjective preferential choices is boosted by incidental uncertainty. Participants ($N = 374$) either selected a painting from four alternatives (subjective choice) or responded to a reasoning problem (judgment). A directional congruency effect emerges in the judgment context, whereas uncertainty boosts decision confidence in the subjective choice, ($F_{1,371} = 3.97$, $p < .047$). Uncertainty increases the perceived difficulty of the judgment ($p = .031$), but not of the subjective choice ($t_{195} = 0.08$), suggesting decision difficulty does not explain the positive effects of uncertainty and pointing to a difference in the nature of processing between these two contexts.

Study 3 generalizes the positive effect of uncertainty to another consumption domain and probes the nature of decision processing in matters of subjective taste. Participants ($N = 118$) selected a video to watch from five comedy video screenshots (unknown to participants, all segments from the same video), reported decision confidence, decision difficulty, and thoughts they had about the selected video while making the decision, then watched the video. Uncertainty boosts decision confidence ($p = .012$) but has no detectable effect on difficulty ($t_{116} = 0.25$). Participants were asked if they recommend including the video in a collection of enjoyable videos for future research. Uncertainty increases recommendation ($p = .026$), an effect mediated by decision confidence ($b = .359$, 95% CI:[.045, .733]). Absence of a significant interaction with scores on the causal uncertainty scale ($\alpha = .90$; Weary and Edwards 1994) suggests the boundary condition found in prior research (effects limited to those scoring high; e.g., Jacobson et al. 2008) is not present in this context.

Critically, incidental uncertainty leads to thoughts that are marginally more semantically clustered ($p = .068$; Bhatia 2017, 2019; Hass 2017) and favorable to the chosen alternative ($p = .077$), and to faster decision making ($p = .038$).

This paper sheds new light on how feelings of uncertainty influence consumers' beliefs about the quality of their consumption decisions. In matters of subjective taste, consumers gain confidence from incidental feelings of uncertainty. These findings inject nuance into our understanding of the context dependent dynamics of decision processing, offering initial support for the novel proposal that engaging in more systematic subjective evaluation of choice alternatives may boost the fluency, speed, and favorability of decision processing.

SESSION OVERVIEW

Decades of work in consumer research and psychology provides evidence that consumers' preferences depend on the context in which they are constructed. Classic work on context effects shows that, contrary to normative theory, preference for a given product can depend on the presence (vs. absence) of other—often irrelevant—options in the choice set. Recent research has challenged the robustness of these effects (Evangelidis et al., 2018; Frederick et al., 2014; Yang and Lynn, 2014), while introducing important boundary conditions of their occurrence. In this session, we collectively build on this work by advancing novel factors that drive the occurrence of context effects, ad demonstrate entirely new context effects.

Shennib, Evangelidis, and Jung investigate the occurrence of context effects in two common elicitation procedures: choice and willingness-to-pay. They demonstrate that attraction and compromise effects replicate in choice, but are eliminated (attraction) or reversed (compromise) in willingness-to-pay because the latter is predominantly driven by price perceptions that are stable across contexts.

Shaddy, Fishbach, and Simonson find that identity expression systematically attenuates variety seeking, the compromise effect, and balancing (vs. highlighting) between goals. The authors identify a mechanism: that, when it comes to identity, consumers want to avoid sending mixed signals. Identify expression, therefore, influences consumers' tradeoffs by reducing the appeal of mixed solutions, which partially satisfies multiple considerations or goals.

Evangelidis, Levav, and Simonson demonstrate a novel context effect, symmetric dominance, whereby preference between a high-quality high-price option and a low-quality low-price alternative can be influenced by the addition of a decoy option that is dominated by both alternatives (i.e., a low-quality high-price option). They show that this effect is observed because consumers will feel better about—and anticipate lower feelings of regret from—choosing the high-quality high-price option in the presence (vs. absence) of the decoy.

Finally, contrary to earlier research (Frederick et al. 2014; Yang and Lynn, 2014), Alman and Urminsky provide evidence for the attraction effect using visual stimuli. They show that the attraction effect can be observed when making size judgments between visually-presented product packages and when choosing between equally-priced products. They also find that package orientation biases size judgments, moderating the attraction effect.

Taken together, this session contributes to the understanding of how consumers construct their preferences as a function of the decision context. Our work expands the understanding of drivers that influence consumers' tendencies to rely on the context during decision-making.

The Contingent Impact of Context on Choice versus Valuation

EXTENDED ABSTRACT

Consumers' preferences are often swayed by the decision context. Context effects, in which the addition of a new option to a binary set affects preferences for a (target) option, have been well established across social-science disciplines (e.g., Huber, Payne, and Puto 1982; Simonson 1989). Using two frequently employed elicitation methods—choice and willingness-to-pay (WTP), we demonstrate that the occurrence of context effects critically depends on the elicitation procedures used.

We conjecture that the elicitation method impacts how preferences are constructed (Tversky, Sattath, and Slovic 1988). In choice, consumers predominantly rely on attribute weights to construct preferences. In WTP tasks, consumers rely on price perceptions rather than attribute weights. In turn, they report higher WTP amounts for options perceived to be more expensive, reversing preferences from the same compromise set in a choice task. Further, we propose that consumers will be less likely to prefer asymmetrically dominating options in WTP than choice, because dominance should not influence price perceptions. In two pre-registered studies, we test our predictions using classic compromise and attraction effect paradigms.

In Study 1, participants (N=400) were randomly assigned to one of four conditions in a 2 (elicitation: Choice vs WTP) x 2 (options: AB vs ABC) between-subjects design. Participants in the AB conditions made a choice between two options or reported the maximum price they would be WTP for both options, separately. Similarly, participants in the ABC conditions made one choice among three options, which included the same AB options in addition to a C option, or expressed their WTP for all options, separately. Prior literature has demonstrated greater choice preferences for the compromise/middle option in the ABC set relative to the same option in the AB set (Simonson, 1989). To create comparable metrics between choice and WTP, we converted WTP into a binary (AB) or trinary (ABC) preference indicator, such that, in each set, preferences were coded as the option that participants were WTP most for. Preferences in the choice conditions were participants' choices of one option in the set.

Participants in each condition responded to two product sets, randomly ordered: BBQ grills and flashlights. Each product included two attributes (e.g., a flashlight's brightness and battery life). One attribute increased in superiority while the other attribute decreased.

Results showed that, in choice, participants selected the compromise options more so in the ABC sets (61.3%) than the AB sets (58.6%). In WTP, however, participants preferred the compromise option strikingly less in the ABC sets (*9.9%*) than the AB sets (*82.0%*) resulting in a highly significant interaction (β = -3.85, SE = .41, Z = -9.35, p < .001). That is, in the ABC WTP conditions, participants were rarely WTP most for the middle options despite their ABC choice counterparts preferring this option more than 60% of the time.

Study 2 (N = 546) was identical to Study 1 except that we also tested (a) the attraction effect and (b) two mechanisms underlying the effects in WTP and choice. In the attraction effect, options A and B are the same as in compromise sets, but C is known as a "decoy" that is asymmetrically dominated by—and thus increases preference for—one of the two options (Huber et al. 1982). Participants responded to four randomized products: two compromise sets that included BBQ grills and headphones and two attraction sets that included water bottles and flashlights.

For the compromise sets, we replicated the interaction from Study 1 (β = 1.76, SE = .31, Z = 5.67, p < .001). Regarding the attraction sets, in choice, participants selected the dominating options more so in the ABC set (80.1%) than the AB set (57.7%). In WTP, however, participants valued the dominating option less in the ABC set (40.5%) than the AB set (57.6%). The interaction was highly significant (β = 1.76, SE = .30, Z = 5.87, p < .001).

We then examined the mechanisms underlying the observed preference reversals. We hypothesize that WTP amounts are driven by perceived prices, explaining higher WTP amounts for extreme options when there is one dominating attribute the set. In choice, however, we hypothesize that individuals select options that rely more so on subjective attribute weights. We tested our predictions by having participants select the option in each set that they believed was the most expensive and to rate how important each attribute was in determining their responses from 1(not important at all) to 7(extremely important).

Across the compromise and attraction sets, separately, we found that, in WTP, preferences were significantly more associated with price perceptions than in choice. Put differently, those who were WTP most for the compromise/attractive or extreme/non-dominating option were also more likely to perceive that option to be the most expensive, whereas in choice, preferences were unrelated to price perceptions (Elicitation X Price Perception in compromise sets: β = 1.37, SE = .58, Z = 2.37, p = .018; in attraction sets: β = 1.67, SE = .38, Z = 4.43, p < .001).

For the attribute weights mechanism, the results were, again, consistent with our predictions: in choice, attribute weight scores predicted preferences for the compromise/attractive options. However, in WTP, preferences were unrelated to attribute weights. Put simply, in choice, individuals factor in the attributes and their levels in the option-sets significantly more so than in WTP (Elicitation X Attribute Weights in compromise sets: β = .97, SE = .25, Z = 3.91, p < .001; in attraction sets: β = -.27, SE = .12, z = -2.30, p = .021).

Our results highlight that the extent to which consumers rely on context is contingent on the elicitation procedure. To researchers and practitioners, this suggests using precaution when selecting a method to elicit consumer preferences, as the generalizability of the results may vary as a function of the elicitation procedure. Behavioral researchers have studied context effects primarily using choice procedures. Given the normative assumption of procedural invariance, one would expect context effects to replicate across other procedures, yet our data pose a challenge to this assumption.

Invoking Identity Changes How Consumers Resolve Tradeoffs

EXTENDED ABSTRACT

"We are what we repeatedly do."
–Aristotle (allegedly)

Marketers frequently invoke identity. For example, the makers of Jim Beam bourbon declare: "Guys never change. Neither do we." The fast food restaurant Wendy's explains: "Paul does the Paul burger, not a generic John Doe burger—don't compromise." Mercedes-Benz claims its SLK roadster is "as extreme as you." Is it simply coincidental that these references to specific identities (e.g., "guys") are often paired with appeals like "never change"? Or might invoking identity actually increase the likelihood that consumers will refuse to "compromise" and instead choose to be "extreme"?

In this research, we answer this question by documenting how identity expression systematically changes the way consumers resolve tradeoffs. Specifically, we find that it reduces the appeal of mixed solutions—outcomes that partially satisfy multiple considerations (e.g., tastes, attributes, goals, etc.). This is because when people view decisions as expressions of identity, they are uncomfortable sending mixed signals—both to themselves and to others (Berger and Heath 2007; Rifkin and Etkin 2019; White and Dahl 2006).

We explore the consequences shifting consumers' tradeoff resolution strategies by examining several seemingly unrelated and well-known choice effects. Variety seeking, the compromise effect, and balancing between goals all represent outcomes that partially satisfy multiple considerations—competing tastes, in the case of variety seeking (Kahn 1995; Simonson 1990); competing attributes, in the case of the compromise effect (Simonson 1989); and competing goals, in the case of balancing (Fishbach and Dhar 2005). Consequently, if invoking identity reduces the appeal of mixed solutions—because people are uncomfortable sending mixed signals—then it should systematically attenuate all three.

Importantly, while previous research has documented the various ways in which identity changes *what* people choose—someone with a "rugged" identity, for example, might opt for a similarly "rugged" Jeep (Aaker 1997; Belk 1988; Escalas and Bettman 2005; LaBeouf, Shafir, and Bayuk 2010; Reed 2004)—we examine the way in which identity changes *how* people choose.

Seven studies (*N*=2,213) tested this account. In S1, a field study, we offered two free snacks to passers-by in a university student union: potato chips (indulgent) and pea crisps (healthy). Participants could choose one of each or two of the same snacks, and we manipulated the contents of the signs advertising the snacks. The identity-invoking sign read: "Who are you? I am a health-conscious snacker" vs. "I am an indulgent fun-loving snacker." The control sign read: "Which snacks will you choose?" Research assistants surreptitiously recorded actual choices, observing less variety seeking (i.e., choice of one of each snack) in the identity condition (26% vs. 43%; *b*=—.94, SE=.33, *z*=—2.82, *p*=.005).

In S2–4 (all preregistered), we modified a single basic scenario (e.g., choosing a car) to test all three choice effects, predicting that prompting participants to express their identity would attenuate variety seeking (S2), the compromise effect (S3), and balancing (S4).

In S2, participants were less likely to rent different cars on each of two different weekends (i.e., seek variety) when prompted to consider their identity (e.g., "Which type of car best reflects your identity?"; 17% vs. 46%; χ²(1)=19.34, *p*<.001). In S3, participants were similarly less likely to choose the middle option when purchas-

ing one of three cars when prompted to consider their identity (e.g., "Which car…best reflects your identity?"; 47% vs. 64%; χ²(1)=5.38, *p*=.020). Finally, in S4, participants imagined having recently saved money. Those who reflected on their identity (e.g., "Does [saving money] make you feel like the kind of person who is financially responsible?") were less likely to subsequently spend extra money upgrading a rental car (i.e., balance between saving and spending goals; *M*=2.32 vs. *M*=3.35; *F*(1, 398)=12.39, *p*<.001).

We next designed S5–7 to test for process. Specifically, we measured participants' tradeoff resolution strategies directly with a scale that we developed. Participants indicated agreement or disagreement (e.g., "To what extent does each statement below describe how you made your choice?") with statements like: "try to get a little bit of everything," "set priorities and go with the top priority," and "find the middle ground." We predicted that the reduced appeal of mixed solutions (as measured by our scale) would mediate the attenuating effect of invoking identity on variety seeking, the compromise effect, and balancing.

In S5, participants were less likely to vacation in different countries each of two different years (i.e., seek variety) when prompted to consider their identity (e.g., "These trips will help define and reinforce your identity"; 58% vs. 78%; χ²(1)=19.31, *p*<.001). In S6, participants were similarly less likely to choose the middle option when renting one of three apartments when prompted to consider their identity (e.g., "If you were trying to communicate [your] identity… which apartment would you choose?"; 42% vs. 55%; χ²(1)=6.40, *p*=.011). Finally, in S7, participants imagined having recently helped clean a park (i.e., making progress toward an environmental goal). Those who viewed environmental consciousness as part of their identity were less likely to subsequently purchase an environmentally *un*friendly, but cheaper and more effective cleaning spray (i.e., balance between hedonic and utilitarian goals; *M*=2.93 vs. *M*=3.44; *t*(397)=2.57, *p*=.011). Moreover, in all three of S5–7, the reduced appeal of mixed solutions mediated the attenuating effect of identity expression on variety seeking, the compromise effect, and balancing.

This work (1) contributes a new insight to the literature explicating the role of identity in consumer decision making, (2) provides a unique theoretical lens with which to reconcile potentially competing predictions for when opposite choice effects will arise (e.g., variety seeking vs. consistency seeking), and (3) illuminates the psychological processes governing tradeoff resolution, more broadly. And with respect to marketing practice, we offer that managers would be wise to use these findings to strategically attenuate or amplify these choice effects in the marketplace—especially given that our results suggest many well-known decision phenomena may not be as universal (or unique) as previously assumed.

Symmetric Dominance

EXTENDED ABSTRACT

Decades of research in marketing and psychology corroborate that—contrary to normative theory—preference for a given option is contingent on the decision context. Perhaps the most prominent empirical finding from this research is the asymmetric dominance effect (Huber, Payne, & Puto, 1982). Asymmetric dominance describes the finding that adding a decoy option that is dominated by only one of two alternatives in a binary set increases the choice share of the dominating (target) option. In this paper, we demonstrate another context effect—symmetric dominance—that has surprisingly eluded earlier research. Symmetric dominance pertains to the case of adding a symmetrically dominated option to a binary set characterized by a tradeoff between price and quality. Intuitively, the introduction of the symmetric decoy should not influence relative preference because the decoy is dominated by both alternatives. For example, consider the following experiment. In the control condition, participants are asked to choose between a 1TB hard drive that costs $40 and a 2TB drive that costs $80. In the experimental condition, participants are presented with the same two options, as well as a symmetrically dominated option: a 1TB drive priced at $80. Here, the decoy is dominated by both of the original alternatives. It has the same capacity as the 1TB drive but is more expensive, while it has the same price but less capacity compared to the 2TB drive. Although the symmetric decoy does not seem to favor one of the dominating alternatives over the other, we posit that it can actually exert a systematic impact on preference. In the absence of the decoy option, individuals may covet the 2TB drive, but may find it difficult to justify paying $40 more (vs. the 1TB drive). Consequently, individuals may defer choice. However, the introduction of the decoy provides a compelling reason for choosing the 2TB drive: compared to the decoy, choice of the 2TB implies getting more capacity without incurring additional costs. Thus, we argue that consumers, who have an innate preference for the 2TB drive may find it easier to justify its purchase—and thus select that option more frequently—when choosing from the trinary compared to the binary set. Symmetric dominance may seem rather unintuitive because, in theory, the presence of the decoy provides a reason for choosing either one of the two dominating options. To allow for symmetric dominance, we posit that consumers will be more likely to rely on the comparison between the high-quality high-price option (e.g., the 2TB drive) and the decoy compared to the comparison between the low-quality low-price option (e.g., the 1TB drive) and the decoy when choosing from the trinary set. In turn, the symmetrically dominated decoy option will provide an asymmetric advantage to the high-quality high-price option over the low-quality low-price competitor. Consumers will feel better about—and anticipate lower regret from—choosing the high-quality high-price option in the presence (vs. absence) of the decoy.

We provide evidence for symmetric dominance in five well-powered preregistered experimental studies (total N = 5,888). Study 1 shows robust evidence for the effects using five different sets of stimuli: backpacks, Bluetooth speakers, external hard drives, hotels, and TVs. Participants were more likely to select the high-quality high-price options when the symmetrically dominated decoys were added to the choice sets compared to the control two-option conditions (p < .001). Further, participants were less likely to defer choice (i.e., search for other options) when the symmetrically dominated options were introduced to the set compared to the two-option conditions (p < .001). Both effects were robust across stimuli.

Study 2 provides further evidence of the effect using actual purchase decisions of laptop bags. Participants were more likely to select a high-quality high-price laptop bag when a symmetrically dominated decoy bag was added to the choice set compared to the control two-option condition (p = .048). Further, participants were less likely to defer choice (i.e., not purchase a bag) when the decoy option was introduced to the set compared to the two-option condition (p = .014).

Study 3 provides evidence for the process underlying the effects. First, we replicate our basic results (p < .006). Further, we show that our effect is mediated by feelings of regret (ab = .053, 91% LLCI = .001, ULCI = .124) rather than changes in the importance that participants afford to the different attributes (ab = -.029, 91% LLCI = -.224, ULCI = .165). In the presence (vs. absence) of the decoy, participants anticipate weaker feelings of regret from the choice of the high-quality high-price option relative to the choice of

the low-quality low-price alternative. In turn, the decrease in anticipated regret leads to a higher incidence of choice of the high-quality high-price option. Our process evidence suggests that consumers desire, but are reluctant to choose the high-quality high-price option in the absence of the decoy. However, in the presence of the decoy, consumers tend to use that option in order to support choice of the desired high-quality high-price alternative, leading to lower feelings of anticipated regret.

Further studies provide evidence for two moderators of the effect. Study 4 shows that the symmetric dominance effect is larger in magnitude when the decoy is located next to the high-quality high-price option (p < .001) compared to when it is located next to the low-price low-quality alternative (p < .001; interaction p = .013). Presumably, it is easier for people to rely on the comparison between the high-quality high-price option and the decoy when the two options are adjacent to each other. Finally, Study 5 shows that symmetric dominance replicates when there is a trade-off between price and quality (p < .001), but is eliminated when the two focal options present a trade-off on two attributes, both of which are associated with product quality (p = .187; interaction p = .055). Thus, symmetric dominance is more likely to manifest in consumer decisions that involve price-quality tradeoffs.

Overall, our work has important implications for decision-making theory because no extant theoretical framework or model can accommodate these effects.

The Attraction Effect in Product Size Judgments

EXTENDED ABSTRACT

Marketers attempt to present products so that they appear more attractive than competing products. Context effects have been widely studied as influencing the relative appeal of consumer products. In particular, the attraction effect occurs when a decoy option that is asymmetrically dominated by a target option increases the choice share of that dominating target option when the decoy is added to a binary choice set (Huber, Payne, and Puto, 1982; Huber and Puto, 1983). While the attraction effect has been observed in a large range of contexts when stimuli are depicted as stylized or numeric (Tversky, 1972; Pan, O'Curry, and Pitts, 1995; Simonson, 1989; Huber et al.,1982), the robustness of the attraction effect with perceptual stimuli has recently been called into question (Frederick et al., 2014; Yang and Lynn, 2014). Across four pre-registered studies, including paper and pencil and online studies, we demonstrate that the attraction effect is observed when making size judgments between visually presented product packages and when choosing between equally priced products. We also identify important factors influencing the robustness of the effect, particularly the importance of vertical vs. horizontal package orientation.

In our first experiment, building on recent research demonstrating context effects with geometric shapes (Trueblood et al., 2013), we tested whether the attraction effect is observed when making size judgments between product packages. Front-facing mock product packages were created for eight different brands; Barilla penne pasta, Ritz crackers, Cheezits crackers, Cheerios cereal, Chips Ahoy cookies, Jell-O mix, Domino sugar, and Tootsie Pops. For each brand, equal-area horizontally and vertically oriented boxes were created, which had the same dimensions with width and height reversed (except for Chips Ahoy).

A range-decoy image was then created for each package. Vertical range decoys were less wide than vertical targets, and horizontal decoys were shorter than horizontal targets. Each image was also produced in an alternative color scheme, not used in the market. For each brand, participants were shown binary trials with identically sized vertical and horizontal packages and ternary trials in which a decoy option was added, asymmetrically dominated by one of the packages. The order of options from left to right, their orientations, and colors were all randomized. The attraction effect would be observed if the probability of selecting the target option in a ternary trial was significantly greater than the probability of selecting the same option in a binary trial.

Results from Experiment 1 ($N = 376$) revealed an overall attraction effect for size judgments among visually presented consumer goods packages ($\chi^2(1, N = 2107) = 20.20$, p < 0.001, $d = 0.11$).

This was generally consistent across brands except for the differently shaped Chips Ahoy packages, where the addition of a decoy decreased the choice share of the associated target option ($\chi^2(1, N = 266) = 6.33$, p = 0.012, $d = -0.19$). Importantly, analyses revealed that the attraction effect, across all brands aside from Chips Ahoy, was only observed when the target and decoy options were vertical ($\chi^2(1, N = 923) = 76.77$, p < 0.001, $d = 0.49$) but not horizontal ($\chi^2(1, N = 918) = 1.29$, p = 0.26, $d = -0.05$). We also found a strong horizontal bias, such that people viewed the horizontal package as larger than the equally-sized vertical package the majority (77%) of the time. Thus, the attraction effect being moderated by target package orientation is consistent with Evangelidis, Levav, and Simonson (2018), which finds stronger attraction effects when the decoy is dominated by the less preferred option.

In experiment 2 ($N = 278$), we replicated the visual package-size attraction effect in an in-person, paper and pencil survey in which participants selected the largest Cheez-Its box from either a binary set or from a ternary set with a decoy, which increased selection of the target option as larger ($t(274.89) = 3.49$, p < 0.001, $d = 0.42$).

In Experiment 3 ($N = 352$), we systematically varied the package dimensions and orientation as potential moderators of the attraction effect. Participants judged the largest in binary or ternary sets of packages, with eight different dimensions, ranging from near square to highly elongated (e.g., as in the Chips Ahoy boxes in Experiment 1). In each binary pair, the two packages (one vertical, one horizontal) had the same surface area. In the ternary sets, a decoy package was added. We again found an overall attraction effect ($\chi^2(1, N = 1994) = 34.47$, p < 0.001, $d = 0.15$), significant when the target was vertical ($\chi^2(1, N = 979) = 49.31$, p < 0.001, $d = 0.28$) but not when the target was horizontal ($\chi^2(1, N = 1015) = 0.65$, p = 0.422, $d = 0.03$), as in Experiment 1. However, the degree of elongation of the packages did not moderate the attraction effect, either as a main effect ($\beta = -0.07$, p = 0.800) or in a non-linear relationship ($\beta = 0.04$, p = 0.290). Results were robust to different types of decoys (e.g., range vs. frequency).

In Experiment 4 ($N = 446$), we extended our findings from size judgments to product choices in which size was the primary basis for decision. We asked participants to choose which hypothetical package of crackers to purchase (from either the binary set or ternary set), with all options priced equally at $3.29. Participants made multiple choices, varying the elongation of the packages across choice sets as in Experiment 3. We observed an overall attraction effect ($\chi^2(1, N = 2166) = 20.49$, p = < 0.001, $d = 0.10$) which was significant for both vertical trials ($\chi^2(1, N = 1082) = 16.50$, p = < 0.001, $d = 0.13$) and horizontal trials ($\chi^2(1, N = 1084) = 5.10$, p = 0.02, $d = 0.07$), albeit with small effect sizes when the target was horizontal.

Overall, these findings demonstrate that the attraction effect occurs for visual stimuli, affecting both prompted size judgments and choices among equally priced options. These findings provide robust

support for the practical application of the attraction effect in consumer settings.

Paper #3: Precisely Unique: Semantic Precision Increases Perceived Uniqueness of Cultural Products
Vincent Xie, University of Massachusetts, Boston, USA
Ann Kronrod, University of Massachusetts, Lowell, USA

SESSION OVERVIEW

This session embraces the rendez-vous conference theme by examining the role of language and culture in consumer behavior. Each paper takes a slightly different focus—on consumer perceptions, evaluations, or decisions—using experimental and field data to provide a rich understanding of the following topics: How does country personality influence brand perceptions via cultural stereotypes? Why do brand names ending in vowels trigger cultural associations with gender and warmth, increasing loyalty attitudes? And why does semantic precision increase perceived uniqueness of cultural products?

Karat and Kronrod introduce Country Personality DNA—the unique combination of human traits that are associated with a country—and explore how it influences perceptions of brands whose names sound typical of a specific country. Their results suggest that countries possess a distinct set of four "core gene" personality traits, and that new brands whose names sound like they originated from a particular country "inherit" these traits. This topic is of particular importance given the growing global marketplace.

Pogacar, Angle, Shrum, Kardes, and Lowrey focus on the cultural effect of gender perceptions activated by brand names. The authors demonstrate that brand name length, stress, and vowel ending influence perceptions of brand name gender. Feminine name gender in turn leads to cultural inferences of warmth, which results in enhanced loyalty. The authors use both experimental and observational data, real and invented brands, and consequential and hypothetical choices. These findings have important implications for naming products that should seem 'warm' (and those that shouldn't).

Lastly, Xie and Kronrod's work reveals the novel link between semantic precision and perceptions of uniqueness of cultural products. The mere presence of more precise language, even about non-central product attributes, influences the perceived cognitive distance of the words, and increases perceived product uniqueness for cultural products like international tourism. This finding is relevant given the demand for unique consumer experiences, and the saturation of competing products vying to meet these demands.

Together the papers in this session highlight the important role of language and culture in consumer behavior. Each work addresses a unique aspect of this topic: foreign language brand names; brand names and gender associations; language precision and cultural products. Given the array of questions addressed, we expect to draw a broad audience and to spark an interesting rendez-vous among attendees interested in language, culture, marketing communication, advertising, and branding.

Brand Names and Country Brand Personality DNA

EXTENDED ABSTRACT

This work introduces "Country Personality DNA" – the unique combination of human characteristics that are associated with a country – and explores the way it influences perceptions of new brands whose names sound typical to a specific country. Drawing from literature on branding, country of origin and country stereotypes, the work tests how spelling a brand name in a foreign language triggers associations with that country, and more specifically, with the specific set of human personality traits that belongs to that country.

In this study, we treat "Country Personality DNA" as a metaphor for a country's hereditary brand personality. Through this lens, we examine the way countries with high brand equity, such as France, Germany or Japan, can pass on their recognizable personality traits to new brands with names that sound as if they originated from these countries. This is done through the process of instant activation of stereotypical personality traits associated with these countries. Based on these logical links we first theorize that countries have unique and identifiable combinations of humanlike personality traits (Country Personality DNA) in people's perceptions. Further, following the DNA metaphor, we suggest that the country acts as a "parent" to the "child" brand, and the child brand inherits this unique set of personality traits, which we call the "core genes".

"Core genes" are the country's *highest ranking four personality* traits. Just like the four genes that make up the human DNA, these genes have the strongest association with the "parent" country, and have the highest potential of being inherited by the "child" brand.

Based on this reasoning, we next predict that a brand name that sounds like it originated from a particular country should "inherit" that country's personality DNA — its unique combination of personality traits—and consequently consumers associate similar traits with that brand. Thus, we predict that new brand names that resemble a particular country-of-origin language—even if they are fictitious—carry the same perceived "genetic make-up" (DNA traits) of their parent country's brand.

Method

In our studies we focused on two of the G7 European countries (France, Germany) and one East Asian country (Japan), mainly because they are well-known countries which are similar to each other in terms of industrial and economic growth (Laš, 2018). In addition, these countries have identifiable different languages. Study 1 identifies the 'core genes' that make up the unique combination of country personality DNA for France, Germany and Japan. We first selected 29 personality traits from a pool identified in studies by Aaker *et al.,* (2001), and Ferrandi *et al.,* (2000) and Bosnjak *et al.,* (2007). These traits were: Sincere, Kind, Spirited, Optimistic, Independent, Reliable, Intelligent, Confident, Glamorous, Charming, Sophisticated, Good-looking, Shy, Sentimental, Affectionate, Tender, Genuine, Stable, Aggressive, Tough, Elegant, Romantic, Peaceful, Naïve, Dependent, Dignified, Funny, Happy, Energetic. Next, 305 MTurk participants ranked these 29 personality traits on the extent to which

each of them described each of the 3 countries (France, Germany and Japan) if they were a person (1 = strongly disagree; 7 = strongly agree). Each participants ranked one country, in a 3-cell between subjects design. Results of Factor Analyses suggest that each of the three countries has a unique set of four 'core genes' in people's minds. We defined this set as the country's Personality DNA. The identified 'core genes' were:

France: glamorous, sophisticated, elegant, and romantic;
Germany they are: independent, intelligent, confident, and tough;
Japan: reliable, intelligent, stable and dignified.

Study 2 demonstrates that these 'core genes' are 'inherited' by brands whose names sound original to the associated country. First, a pretest was conducted in order to identify fictitious brand names that are correctly identified with France, Germany and Japan. 14 brand names were tested against 17 countries (Albania, Bulgaria, China, Egypt, France, Germany, Greece, Italy, Japan, Mexico, Netherlands, Portugal, Romania, Russia, Spain, Turkey and USA). The fictitious names, included filler names from Turkish, Greek and Russian, looked and sounded like they came from a specific country of origin and were: Doğanoğlu, Μίαπαρέα, Bleusàur, L'Noir, Duprêté, Ne-mashi, Miyoshi, Takitomo Bäumtät, Müssler, Schaumbern, Süchtig, Экрейс, Клятва. Based on the pretest, six brand names, that showed strong associations with France, Germany and Japan, were chosen (two for each country): L'Noir (81.2%), Duprêté (42.6%), Scha-umbern (76.2%), Süchtig (63.4%) and Miyoshi (80.2%), Takitomo (82.2%). These names were chosen for the main study.

In the main study, 392 MTurk participants ranked the 29 human personality traits from study 1 on the extent to which they described each of the six brand names. Subsequently, participants guessed the country of origin for each of the six names. 280 participants guessed the country correctly, and analyses were conducted with this sub-sample. Overall the results showed, as predicted, that there is a sig-nificant overlap between the four traits of country personality DNA for each of the three focal countries, and the human traits that partici-pants assigned to each of the brand names. Factor analyses showed similar factor loadings for the brand names, as we found for their "parent" countries. The means were strikingly similar.

To sum, we show that when brand names are recognized as being from a particular country, they evoke perceptions associated with humanlike personality traits associated with that country. This study is the first to identify inheritable country personality traits, and link them to branding. Theoretically, the findings contribute to our understanding of the way brand names with languages which sug-gest country origin, influence perceptions of brand origin, in return influence brand perceptions, via country stereotyping. As a market-ing implication, utilizing the new Country Personality DNA model allows marketers, brand managers and entrepreneurs to create brand names that can instantly signal brand personality – which is espe-cially important for new brands.

Is Nestlé a Lady? Brand Name Gender and Loyalty Attitudes

EXTENDED ABSTRACT

There are many ways a name can convey information about a brand, including semantics (Klink, 2001) and individual sounds (Lowrey & Shrum 2007). Brand names can also suggest gender. Names sound masculine or feminine due to length, sounds, and stress (Barry and Harper 1995). Specifically, feminine names tend to be longer, with stress on the second or later syllable, and often end in a vowel, especially the "a" sound (e.g., Lisa, Visa). Conversely, masculine names tend to have fewer syllables and end in a consonant (e.g., Brad, Ford).

We examine when brand names with feminine versus masculine linguistic characteristics are advantageous. Beyond simply matching brand name gender to product category or user, we posit a process based on the Stereotype Content Model (Fiske et al., 2002) by which feminine brand names convey warmth (tolerance, good-naturedness, friendliness, sincerity). Because attributes like warmth are primary drivers of loyalty attitudes (Chaudhury and Holbrook 2001) we pro-pose a link between brand names with feminine linguistic attributes, perceived warmth, and loyalty attitudes such that feminine brand names will enhance perceived warmth, which will enhance brand loyalty attitudes.

We test these predictions in seven studies, varying types of brands (real, invented, Interbrand top brands), methodology (obser-vational, experimental), stakes (hypothetical, economic, temporal), and participant population (MTurk, college students). In Study 1 we investigate whether brand name femininity is positively related to loyalty-based brand performance by examining the linguistic charac-teristics of a real-world sample of Interbrand top brand names. Study 2 examines whether brand name gender influences actual product choices with consequences for time (Study 2a) and money (Study 2b). Study 3 tests the hypothesis that brand warmth mediates the relationship between brand name gender and self-reported brand loyalty using a sample of real-world brands. Study 4 tests the propo-sition that brand warmth mediates the effect of brand name gender on brand loyalty attitudes for hypothetical brands in a controlled experi-ment. Studies 5 and 6 test theoretically relevant boundary conditions, showing that the feminine brand name advantage is moderated by product category (hedonic vs. utilitarian; Study 5) and typical user gender (men vs. women; Study 6).

Study 1 tested the proposed association between feminine brand name linguistics and brand loyalty attitudes using a sample of Inter-brand's "Global Top Brands," which are designated, in part, based on consumer loyalty. We coded 171 of Interbrand's top brands for a twenty-year period from 2000-2019 using a validated name gender normative scale that quantifies the degree of linguistic masculinity or femininity from -2 (most masculine) to +2 (most feminine; Barry and Harper, 1980). Interbrand top brands have, on average, feminine names ($p < .001$); feminine names gender is positively associated with average rank on the Interbrand list ($p = .01$); and feminine brand names spent more years on the list than did masculine names ($p = .008$). Finally, comparing the Interbrand names with 171 randomly selected companies from Thomson Reuter's Eikon database, and controlling for net income, net revenue, years in business, and num-ber of employees, feminine brand name gender predicted Interbrands top brand status ($p = .02$).

In Studies 2a and 2b we explore whether brand name gender influences product choices with real-world consequences. Study 2a used a common consumer domain—streaming videos (N = 300 mTurkers). Participants were told they would be evaluating a short video produced by one of two channels and then chose whether to spend their time watching a video from a feminine-named channel (Nimilia) or a masculine-named channel (Nimeld). A significant ma-jority chose to watching a video from the feminine-named "Nimilia Channel" (71% versus Nimeld: 29%, $p < .001$). Study 2b replicates these results with economic consequences by offering participants (N = 150 students) either monetary compensation or a choice of product: Nimilia or Nimeld brand hand sanitizer. Participants were significantly more likely to choose the feminine-named product than any other option (49% Nimilia hand sanitizer; 36% monetary com-pensation; 14% Nimeld hand sanitizer; $p < .001$).

Study 3 tested the hypothesized effect of brand name gender on perceived warmth and self-reported loyalty using a sample of real brands. We elicited a sample of relevant brands and coded their name gender using the scale from Study 1. We then asked a separate sample from the same mTurk population (N = 517) to evaluate each brands' warmth and report their loyalty toward each brand. Hayes PROCESS model 4 showed that feminine brand name gender predicts warmth (p = .03), which predicts brand loyalty (p < .001), and the mediating role of warmth is significant (95% CI = [.001, .066]).

Study 4 provides causal evidence by experimentally manipulating brand name gender using a one-factor (name gender: feminine, masculine) between-subjects design and the same stimuli used in Studies 2a and 2b. Participants (N = 250 mTurkers) evaluated the feminine brand name as warmer (p < .001); warmth increased brand loyalty attitudes (p < .001); and warmth mediated the effect of brand name gender on loyalty attitudes (95% CI = [.52, .91]).

In Study 5 we tested the moderating role of product category (hedonic vs. utilitarian) using a 2x2 between-subject experiment (N = 781 mTurkers) and the same names used in Studies 2a, 2b, and 4. We find that feminine brand names benefit hedonic products (chocolate) more than utilitarian products (bathroom scale; p = .02). This suggests that warmth is a more valued attribute for hedonic than utilitarian products.

Study 6 used a 2-factor between-subject design (N = 695 mTurkers) and expanded stimuli set (Woldard; Stelad; Wolda; Steda) to examine the moderating role of typical user gender. Results show an interaction between name gender and typical user gender (p = .03) such that the feminine brand name advantage is neutralized when the typical user is male (e.g., stout beer; p = .43) but intact when the typical user is female (e.g., strawberry daquiri; p < .001).

This research has important implications for brand managers and best-naming practices, as well as our theoretical understanding of brand loyalty, warmth, and linguistics.

Precisely Unique: Semantic Precision Increases Perceived Uniqueness of Cultural Products

EXTENDED ABSTRACT

Consumers often value uniqueness of cultural products such as a folk artifact or a tour (Kasey 2019). We suggest that product uniqueness can be evoked via a "precise-unique" heuristic, whereby more precise language increases perceptions of product uniqueness. Semantic precision is the extent to which the use of language conveys subject matters exactly as they are. We draw on the psycholinguistic literature suggesting that more precise words (e.g., *scarlet* versus *red*) are less prototypical members of their category (e.g., *colors*) (Rosch 1983; Rosch and Mervis 1975), and consumers are less likely to think of more precise words when they process product information within their semantic category (Hamby and Levine 2015). We suggest that as a result, more precise words evoke perceptions that the product is more unique. This effect can be salient even when the words do not directly describe a product attribute. For example, a product review for a tour abroad that uses the word "robin" would elicit higher perceived uniqueness of the tour than if it uses the word "bird."

Four experiments provide empirical support for our predictions. Study 1 shows that semantic precision evokes reduced perceived category typicality. Study 2 tests the precise-unique heuristic in a cultural product context. Study 3 demonstrates that cultural products appear more(less) unique when their description is more(less) precise, and that the effect is mediated by category typicality such that the more(less) precise description resembles the same seman-

tic category to a lesser(greater) extent. Finally, Study 4 introduces a moderator and finds the precise-unique heuristic is moderated when a product is perceived as atypical by default.

In Study 1 participants (n=162) first composed sentences from a list of 10 precise/non-precise words (e.g. bake/make, spotless/clean, cider/beverage). Next, participants indicated the category typicality of each word to its corresponding category ("when you think of the category, how likely are you to think of that particular word?"-1: not likely at all; 7: very likely). We used the mean of the ratings of the ten words (α=.91) as a composite measure of category typicality. Finally, participants indicated how precise were the ten words on four items (definite/exact/precise/specific, α=.91).

Results. The high-precision words were rated as significantly more precise (M=5.33) than the low-precision words (M=4.90, $F(1,160)$=4.06, p=.046). As predicted, the aggregated category typicality was significantly lower for the high-precision (M=5.00) than the low precision words (M=5.32, $F(1,160)$=3.98, p=.048). These results provided evidence that more precise words elicit lower perceived category typicality.

Study 2 (n=284) tested the effect of semantic precision on perceived uniqueness. Participants read one of two ad texts promoting a t-shirt as imported from Europe/or Netherlands and rated the T-shirt uniqueness (distinct/original/special/unique, α=.90) and ad precision (α=.91).

Results. "Netherlands" was rated as significantly more precise (M=4.14, $t(282)$=6.63, p<.001) than "Europe" (M=3.01). As predicted, a T-shirt imported from the Netherlands was perceived as significantly more unique (M=3.09, $t(282)$=2.53, p=.01) than when it was from Europe (M=2.60). Study 2 supported the prediction that semantic precision of product descriptions increases perceived uniqueness of cultural products.

Study 3 (n=200) examined the effect of semantic precision on consumer perception of product uniqueness driven by category typicality. Participants read an excerpt from a more/less precise review of a boat tour (e.g., "The dinner(meal) included soup(appetizer), fish(entrée), and pudding(dessert)"). Participants rated the tour's uniqueness, category typicality of each of the high(low) precision words (e.g., pudding/dessert - dish), and how precise those twelve words were as a whole (α=.91).

Results. The review was rated as significantly more precise in the high-precision condition (M=5.30) than the low-precision condition (M=4.85, $F(1,198)$=6.73, p=.01). As predicted, category typicality was significantly lower in the high-precision condition (M=4.69) than the low precision condition (M=5.33, $F(1,198)$=18.25, p<.001). Perceived uniqueness of the high-precision (M=5.48) and low-precision (M=5.29) conditions did not significantly differ ($F(1,198)$=1.15, p=.29). A mediation analysis (Hayes 2018) suggested that the effect of semantic precision on perceived uniqueness was fully mediated by perceived category typicality. Semantic precision was a significant predictor of category typicality (β=.65, p <.001), and category typicality was a significant predictor of perceived uniqueness (β=.38, p <.001). Importantly, semantic precision was a significant predictor of perceived uniqueness (β=-.43, p=.01). The mediation pathway from semantic precision to perceived uniqueness via category typicality was significant (95% CI:[0.11,0.41]).

Study 3 provided evidence that semantic precision reduces category typicality, which in turn increases perceived product uniqueness. The insignificant direct effect of semantic precision on perceived uniqueness can be attributed to the high inherent uniqueness of the tour experience. Study 4 addressed this issue specifically.

Study 4 (n=125) examined the moderation effect of product inherent uniqueness on the "precise-unique" heuristic. Participants

were randomly assigned to one of four conditions representing a 2 (more/less precise description) x2 (typical/atypical product) between-subjects design. They first rated perceived uniqueness of an ice-cream flavor (typical-Berry/Raspberry; atypical-Spice/Ginger). Next, they rated perceived precision of the flavor word, and the extent to which the flavor was typical on three 7-point scale semantic differential items (atypical/typical, unusual/usual, uncommon/common; α=.98).

Results. We found two main effects: Berry flavors were rated significantly more typical (M=4.32) than Spice flavors (M=2.13, $F(1,123)$=50.21, p<.001). Raspberry/Ginger was significantly more precise (M=5.88) than Berry/Spice in describing the flavors (M=4.02, $F(1,123)$=54.93, p<.001). We also found a significant interaction between precision and typicality on perceived uniqueness ($F(1,121)$=5.32, p=.02). Within typical flavors, Raspberry (M=4.88) was significantly more unique than Berry (M=3.48, $F(1,60)$=13.24, p=.001). By contrast, for atypical flavors, Spice (M=5.40) and Ginger (M=5.63) were not significantly different in perceived uniqueness ($F(1,61)$=.49, p=.49). Study 4 demonstrated further that semantic precision increases perceived product uniqueness, but also that the "precise-unique heuristic" is not salient for inherently atypical products.

To sum, our findings demonstrate the potential benefit of describing cultural products more precisely, as precise descriptions increase perceived uniqueness of the products. In a consumption world valuing unique cultural experiences, the use of semantic precision can be an effective and costless tool to enhance consumer sense of product uniqueness.

SESSION OVERVIEW

Understanding how consumers make health decisions is theoretically and pragmatically important. Why do consumers avoid going to their health practitioners? What causes consumers to have positive interactions with a provider and therefore become a repeat customer? Why do consumers seek illegal treatments? In part because of the important implications of these types of questions, a great deal of research has been devoted to understanding health decision-making in the fields of marketing, medical decision-making, and psychology, among others. This series of papers contributes to these literatures by offering novel insights about the drivers of (sometimes suboptimal) health decision-making.

Currently, the medical decision-making literature emphasizes giving patients autonomy and the ability to choose their own treatments, in a movement for "patient-centered decision making." Kassirer, Levine and Gaertig (paper 1) show the downsides of decisional autonomy. In a series of studies, they compare advisers who give decisional autonomy to patients (by providing information but no explicit recommendations) to advisers who give paternalistic advice (by providing information and explicit recommendations). Advisers who give decisional autonomy are penalized—viewed as less competent, less helpful, and are less likely to be recommended.

The medical decision-making literature also suggests that patients want their doctors to be socially warm during doctor-patient interactions. Goksel, Berman and Scott (paper 2) suggest that this may not always be the case. In particular, when patients have embarrassing symptoms, they prefer doctor-patient interactions that are socially cold or mediated by technology. Patients expect socially warm interactions will cause more discomfort when disclosing embarrassing symptoms.

Together, the first two papers look at how social intuitions and beliefs can drive consumers to dislike an interaction with their healthcare provider. The last two papers look at the heuristics and biases in consumers beliefs about the severity of symptoms and the efficacy of treatments.

Goksel, Faro and Puntoni (paper 3) examine how the cause of symptoms affects perceived severity of symptoms. The same physical symptom (e.g., a rash displayed in a photograph) is judged to be less severe and painful when people think it was caused by psychological (vs. physiological) factors. Additionally, people are less likely to recommend a person seek medical help for a physical symptom when it was caused by a psychological (vs. physical) reason.

Finally, Gershon, Lieberman and Scott (paper 4) examine one reason why consumers might seek an illegal treatment. The authors demonstrate an illegal=effective heuristic, where consumers think the same drug will be more potent, strong and effective if it is illegal (vs. legal). Consumers even infer this when the drug is not legal for reasons unrelated to the safety and efficacy (e.g., a paperwork error).

Collectively, these papers provide new insights into health decision-making. In particular, these papers examine social intuitions and lay beliefs that might lead consumers to avoid going to a doctor, dislike an interaction with their doctor, or even seek illegal treatments. Such insights contribute to theories in marketing, psychology, and medical decision-making, among other fields, and therefore should be of interest to a broad audience of scientists.

The Costs of Autonomy: Decisional Autonomy Undermines Advisees' Judgments of Experts

EXTENDED ABSTRACT

Imagine that you were recently diagnosed with a serious illness and you face a very difficult medical decision. You must choose between two medical treatments: Treatment A and Treatment B. Each treatment could potentially halt the progress of your illness, but they each are associated with different side effects. Even though your doctor has provided you with all of the available information on each of the treatments, you still remain confused about which is the better choice. Thus, you ask your doctor what you should do. Your doctor reviews the potential costs and benefits of both treatments and reminds you that there is no objectively right answer. Ultimately, your doctor says that she cannot tell you what you should do and you will have to make the final decision. How would this make you feel about your doctor? How would this make you feel about the decision?

Over the past several decades, the United States medical system has increasingly prioritized patient autonomy. Physicians routinely encourage patients to come to their own decisions about their medical care rather than providing patients with clearer, yet more paternalistic, advice. Political theorists, bioethicists, and philosophers generally see this as a positive trend. In the current research, we challenge the philosophical and practical assumptions about the benefits of autonomy by exploring decision makers' reactions to autonomy-oriented versus paternalistic advice when making difficult decisions under uncertainty. We define autonomy-oriented advice as any advice that ultimately leaves the final decision to the advisee and is not accompanied by an explicit recommendation. We define paternalistic advice as any advice that contains an explicit recommendation.

In a pilot study with a sample of employed physicians (N=127), we found that physicians were torn about whether autonomy or paternalism would be seen more positively by patients. Specifically, 56%, 49%, 52%, and 48% of physicians believed that patients would find them to be more competent, more helpful, would be more likely to return to them, and more likely to recommend them, respectively,

for providing decisional autonomy instead of paternalistic advice (for all judgments, doctors' expectations regarding which communication tactic would be favored by patients did not significantly differ from the null of an equal 50%/50% distribution, all $ps \geq .214$). However, as we reveal across 6 studies ($N=3,867$), patients are not torn. Patients, and advisees in general, show a strong preference for paternalism. That is, they have more positive impressions of advisers who offer paternalistic rather than autonomy-oriented advice.

In Study 1, participants ($N=196$) read a scenario that was similar to the opening example. Participants were asked to imagine that they were a patient who had a very difficult medical decision to make. They had to decide between two procedures and imagined that they asked their doctor what to do. Participants were randomly assigned to one of two conditions: autonomy or paternalism. Participants in both conditions read that their doctor reminded them that both procedures had different risks and that either could lead to a favorable outcome. Their doctor then either gave them a clear recommendation and said that they should choose procedure A (or B) (paternalism) or did not give them a recommendation and told them that the choice was theirs to make (autonomy). Participants who received paternalistic advice evaluated the doctor as more competent ($F (1,194) = 5.93$, $p = .016$) and more helpful ($F (1,194) = 6.11$, $p = .014$) than participants who received full decisional autonomy. Moreover, participants who received paternalistic advice indicated that they would be more likely to return to and recommend the doctor than those who received full decisional autonomy ($F (1,194) = 5.66$, $p = .018$). That is, participants who imagined themselves as patients showed a preference for paternalistic advice over full decisional autonomy. In Study 2 ($N=451$), we largely replicated these effects for medical, financial, and workplace advice.

In Study 3 ($N=802$), we randomly assigned participants to a separate or joint evaluation condition (Hsee, 1996), and we examined how advice type influenced doctor choice. In both separate evaluation (89.1% vs. 77.9%, $X^2 (1) = 9.06$, $p = .003$) and joint evaluation (67.5% vs. 33.5%), $X^2 (1) = 46.57$, $p < .001$), we found that patients were more likely to choose the doctor who offered paternalistic advice. Consistent with Study 1, we again found that doctors who provided paternalistic advice were viewed as more helpful ($ps < .001$) and competent ($ps \leq .065$).

In Studies 4 ($N=807$) and 5 ($N=806$), we furthermore showed that the results hold regardless of whether an explicit recommendation was solicited or unsolicited and whether or not the advice was accompanied by more expert guidance.

Finally, in Study 6 ($N = 805$), we extended our investigation to an abstracted context in which participants had to choose between two raffles, which entailed different risks and benefits. Participants were paired with a raffle expert, who provided participants with some information about the raffles and then delivered either autonomy-oriented or paternalistic advice. Before participants received the advice, they also evaluated how difficult the choice was for them to make. There was no main effect of advice type for any of our dependent measures (all $ps \geq .416$). Importantly, however, there were significant interactions between advice type and decision difficulty for three of the four measures (competence, use again, and wages assigned; all $ps \leq .049$), and a marginally significant interaction for helpfulness ($p = .096$). Paternalistic advisers were seen more favorably than advisers who offered full decisional autonomy when decision difficulty was high, but this preference was attenuated (and sometimes reversed) when decision difficulty was low. These results suggest that advisees evaluate paternalistic advisers more favorably than advisers who provide decisional autonomy, but only when decision makers experience decision difficulty.

Taken together, our results demonstrate that decision makers evaluate advisers who give paternalistic advice more favorably than those who give autonomy-oriented advice. These results deepen our understanding of preferences for autonomy and paternalism and challenge the benefits of recently adopted practices in medical decision-making that prioritize autonomy.

Communication Preferences in Medical Advice Seeking

EXTENDED ABSTRACT

What types of interactions do people want with healthcare providers when seeking medical advice? There is a growing conventional wisdom that patients benefit from interacting with practitioners who display interpersonal warmth towards their patients (e.g., Di Blasi et al., 2001; Howe, et al., 2019; Kraft-Todd et. al, 2017; Verheul, et al., 2010, etc.), and prefer to receive advice from humans rather than technology (e.g., Longoni et al., 2019; Promberger & Baron, 2006, etc.).

In this paper, we challenge this conventional wisdom that people always prefer to consult with interpersonally warm healthcare providers, and explore consumers' preferences for interpersonal warmth when seeking care. We argue that when patients have embarrassing symptoms, they become averse to interpersonally warm interactions with healthcare providers. We demonstrate an aversion to interpersonal warmth both as a preference for doctors who hold an interpersonally colder demeanor towards patients (Studies 1-4), as well as a preference for technology-mediated mediums of communication (Studies 5-6).

Study 1 (N=446, hospital patients) establishes an aversion to interpersonal warmth in an externally valid, real-world context. We approached patients at a hospital waiting room to complete a survey. Patients wrote down the symptom they had, and chose which doctor they would like to see among two options: an interpersonally warm (facially expressive) doctor, or an interpersonally cold (facially expressionless) doctor. The more patients perceived their symptoms to be embarrassing, the more likely they were to choose the interpersonally cold doctor ($\beta = .25$, $p < .001$).

Study 2 (pre-registered: https://aspredicted.org/blind.php?x=8r5yg8, N=737, MTurk) replicates these results using a different manipulation of interpersonal warmth, and investigates the relationship between interpersonal warmth and anticipated discomfort in communication. Participants imagined either having symptoms that are embarrassing (e.g., diarrhea, hand warts) or non-embarrassing (e.g., sore throat, knee pain), and calling their clinic for an appointment. Participants chose between two doctors: an interpersonally cold (strictly professional) doctor and an interpersonally warm (more casual) doctor. Participants were more likely to choose the interpersonally cold doctor for embarrassing symptoms (51.8%) than for non-embarrassing symptoms (40.4%, p < .001). Moreover, whereas those who felt embarrassed by their symptoms anticipated more discomfort speaking to an interpersonally warm (vs. cold) doctor (p < .001), those do not feel embarrassed by their symptoms felt equally comfortable talking with two types of doctors (p = .29).

Study 3 (pre-registered: https://aspredicted.org/blind.php?x=n5mk4c, N=550, MTurk) demonstrates a boundary condition for aversion to social warmth. It manipulates the perspective of the decision maker and shows that third parties underestimate patient preferences for socially cold communicators. Participants either took the perspective of a patient and chose a doctor for themselves (Self condition), or the perspective of a nurse and assigned a patient to a doctor (Other condition). In both conditions, patients had an embarrassing symptom. As predicted, participants were less likely to assign

a patient to the interpersonally cold doctor (38.1%) than they were to choose the interpersonally cold doctor for themselves (49.4%, p = .007). Moreover, participants in the Self condition anticipated more discomfort with the interpersonally warm doctor, while participants in the Other condition expected patients to feel greater discomfort with the interpersonally cold doctor (p < .001).

In order to disentangle the mechanism behind these preferences, Study 4 (pre-registered: https://aspredicted.org/blind.php?x=j6wz4u, N=141, Behavioral Lab) examines two opposite intuitions about interpersonal warmth in doctor-patient interactions. We manipulated the intuition people considered before choosing a doctor: participants either evaluated how much discomfort they anticipated when talking to a doctor (Discomfort condition), or how reassured they thought a doctor would make them feel regarding their embarrassing symptoms (Reassurance condition). While participants anticipated greater discomfort with the interpersonally warm doctor (p < .001), they also expected this doctor to provide greater reassurance (p < .001). Moreover, participants were more likely to choose the interpersonally warm doctor in the Discomfort condition (65.7%) compared to the Reassurance condition (45.1%, p = .014). Thus, even though people expect the interpersonally warm doctor to provide them with greater reassurance about their condition, the fact that they would feel uncomfortable when revealing their symptoms leads them to avoid interpersonal warmth.

Studies 1-4 demonstrate consumer preferences for interpersonally colder doctor-patient interactions. Studies 5 and 6 explore the role of technology in mediating these interactions and test an implication of the previous findings: Consumers may prefer colder mediums of communicating with doctors when they have embarrassing symptoms. Study 5 (N=385, MTurk) investigates consumer discomfort associated with using a variety of technology-mediated communication mediums when seeking medical information for either embarrassing or non-embarrassing symptoms. Participants rated the extent to which different mediums of communication were perceived to facilitate interpersonally warm interactions (e.g., email, online-chat, video call). They also reported their discomfort in using each medium to get information about either an embarrassing or non-embarrassing symptom. A linear regression predicting discomfort revealed a symptom X warmth interaction (β = .57, *p < .001*): warmer mediums of communication elicited more discomfort, but only when symptoms were embarrassing (embarrassing symptoms: β = .51, *p < .001*; non-embarrassing symptoms: β = -.06, *p = .22*).

Lastly, Study 6 (N=252, Behavioral Lab) demonstrates the effect of embarrassment on the preference for using technology in order to avoid speaking to experts. Participants imagined going to a pharmacy to search for medicine either for an embarrassing or non-embarrassing symptom. They then chose between using a mobile app and speaking to a pharmacist to get more information. As predicted, participants were more likely to choose to use the app for embarrassing symptoms (37.9%) compared to non-embarrassing symptoms (22.6%, *p = .009*).

In sum, this research shows that not only are consumers averse to interpersonal warmth in doctor-patient interactions, this aversion also encourages them to use technology in order to avoid interacting with experts when they have embarrassing symptoms. These findings suggest that, as opposed to the conventional wisdom, setting an interpersonally colder doctor-patient relationships can mitigate the effect of embarrassment on the avoidance of contacting experts.

The Effect of Causal Explanations on Judgments of Medical Symptoms

EXTENDED ABSTRACT

Many medical conditions are complex in nature which makes it difficult for lay people to understand their causes and consequences. For instance, chronic conditions such as fibromyalgia, psoriasis, or irritable bowel syndrome diseases still lack awareness and understanding in society although millions of people have their everyday lives severely affected by their symptoms (e.g., Brody, 2017; Hayes et al., 2010; Horn et al., 2007; Stern et al., 2004; Wardle, 2017, etc.). One common factor to these illnesses is that they are believed to involve both the psychological and the physical states of individuals (e.g., Kellner, 1994; Perrott et al., 2000; Stojanovich & Marisavljevich, 2008, etc.).

An extensive line of research on mind-body dualism has shown that people tend to think of the mind and the body as two separate entities (Forstman & Burgmer, 2015, 2017). While in reality the mind and the body are often closely linked in the demonstration of illnesses (Ray, 2004), it is unclear whether lay people appreciate this connection or whether they fall prey to dualistic reasoning instead when making judgments regarding different medical symptoms.

In the present research, we argue that beliefs about the underlying causes of medical symptoms influence lay people's perceptions of the severity of medical symptoms, and their intentions to take medical action regarding these conditions. While previous research looked at judgments regarding medical symptoms in the absence versus presence of medical evidence (Asbring & Narvanen, 2002; Looper & Kirmayer, 2004; Ruddere et. al, 2012; 2013), we instead contrast lay people's perceptions of medical symptoms when these are driven by different types of causes. In particular, we investigate whether people perceive *the same observable* medical symptom differently when they believe that it is caused by a psychological as opposed to a physical reason. Across three studies, we demonstrate that having a psychological (versus physical) cause to a medical symptom decreases (1) its perceived severity, (2) people's tendency to recommend medical care for it, and (3) their likelihood to examine its cause.

Study 1 (N = 488, pre-registered) investigates people's perceptions of a skin rash when it is caused by psychological reasons or physical reasons. Participants saw a picture of a skin rash and were told that it developed either as a reaction to temporary stress (psychological cause), or food (physical cause). They made a choice about whether they would recommend a patient to go to a doctor, or wait for a few days which was our dependent measure. Participants then completed a six-item measure of severity (e.g., how red the rash looks, how itchy it feels, etc.). Participants were less likely to recommend the patient to see a doctor when the rash had a psychological cause as opposed to a physical cause (β = -.38, *p* = .05). Additionally, they thought that the rash with a psychological cause was less severe (*p* < .001). Severity ratings mediated the effect of the cause type on their tendency to recommend medical care (*IE* = -.39, *95% CI* = [-.64, -.18]).

Study 2 (N = 487, pre-registered) shows the robustness of the previous findings for another observable symptom. Participants listened to an audio of a patient coughing and were told that the cough developed as a reaction to either anxiety (psychological cause) or being exposed to chemicals in the air (physical cause). They then made the same choice of recommendation, and completed a measure of severity (e.g., how loud the cough sounds, how scratchy it feels, etc.). Participants were less likely to recommend the patient to see a doctor (β = -.57, *p* = .003) and perceived the cough to be less severe

(*p* = .005) when it had a psychological cause. As before, severity ratings mediated the tendency to recommend medical care (*IE* = -.27, *95% CI* = [-.47, -.08]).

Study 3 (N = 898) looked at the influence of temporal primacy in judgements of medical conditions. Specifically, it explored cases when an individual suffers from multiple medical symptoms, and investigated how causal belief influence the extent to which individuals prioritize seeking care for the causally central medical condition among two symptoms. We predicted that individuals have an overall tendency to treat the causally central symptom, but that this tendency would decrease when a psychological symptom leads to a physical symptom. Participants imagined a person developing two different medical symptoms. We had two focal conditions, where we described an individual developing a skin rash and anxiety. In one condition, anxiety was described as the central cause leading to a skin rash, and in the second condition a skin rash was described as the central cause leading to anxiety. In addition, we had two control conditions. In one of the conditions, a person was described of having two psychological symptoms (i.e. anxiety and sleeplessness), while in the other condition a person was described of having two physical symptoms (i.e. sore throat and skin rash). In all experimental conditions, participants were highly likely to treat the symptom that appeared first (86%-97%) except for the condition in which a psychological symptom caused a physical symptom (67%). In particular, participants were less likely to treat the causally central symptom when it was a psychological symptom, leading to a physical symptom, compared to all other conditions (*ps* < .001).

In sum, these studies show that casual beliefs about the underlying cause of medical symptoms influences both perceptions of severity and the intentions of providing medical care. Symptoms caused by psychological illness are perceived to be less severe and less likely to warrant medical care.

The Illegal = Effective Heuristic

EXTENDED ABSTRACT

When deciding whether to try a drug or treatment, whether for recreational, medical, or other purposes, two of the most important factors for consumers to consider are safety (i.e., how likely is the drug to cause side-effects?) and efficacy (i.e., how potent and effective is the drug?). This work looks at consumer perceptions of illegal (vs. legal) products. When discouraging the use of illegal substances, public health campaigns often highlight safety concerns. Our research finds that people already tend to believe that illegal substances are less safe than legal substances, but surprisingly, they also perceive illegal substances as more effective. Three studies establish the existence of this illegal = effective heuristic; across a range of substances, illegal products are viewed as stronger, more potent, and more effective than legal products. This effect holds even when the product is illegal for reasons explicitly unrelated to efficacy or safety (i.e., a paperwork error).

Consumers often lack complete information about their product choices, either because attributes cannot be observed or because procuring attribute information is prohibitively costly. In all these situations, consumers make inferences about product attributes based on their *lay beliefs*. For example, a consumer might infer that a product is high quality because it has a warranty, or infer that a healthy food will be less tasty (Srivasta & Mitra, 1998; Raghunathan, Naylor, & Hoyer, 2006). Oftentimes, these lay beliefs involve looking at an easily observable attribute (e.g., whether there is a warranty) to make an inference about a difficult to observe attribute (e.g., quality). Here

we look at an important new lay belief surrounding legality. We posit that illegal drugs are viewed as more effective.

As an initial test of the illegal = effective heuristic (Study 1, N=404), participants evaluated a fictional product that was either described as legal or illegal. To test for robustness, we also manipulated whether the drug was a utilitarian (sleep aid) or hedonic (intoxicant) product, in a 2x2 between-subjects design. Participants were asked to imagine the following: "Stava is a beverage made from Piper Methysticum, a plant native to the western Pacific Islands." Those in the utilitarian condition further read, "Stava is typically used as a **medicinal sleep aid,**" while those in the hedonic condition read, "Stava is typically used as a social drink and makes its users intoxicated." Finally, participants read, "Stava is legal [not legal]". Participants then responded to the following items: effectiveness (3-item scale: strength, potency, effectiveness; alpha = .86) and safety (2-item scale: safety and concern about side-effects [reverse-scored]; alpha =.76). We found a non-significant interaction of condition (utilitarian/hedonic) and treatment (legal/illegal) on effectiveness. For both conditions, participants believed the illegal drug was indeed less safe (Ps<.01), but more importantly, also more effective (Ps<.01).

Study 2 (pre-registered, N=754) was designed as an additional demonstration and robustness check of the illegal = effective heuristic. As in study 1, our key manipulation was whether a product was described as illegal or legal, and we tested for robustness across different products (a stimulant, an exercise supplement, or a weight-loss drug). Therefore, this study followed a 2x3 between-subjects design. Participants responded to the same effectiveness and safety items used in Study 1. There was a significant effect of the legality treatment (p<.001), but no effect of the product type condition. That is, across all three products, participants who were told that the product is illegal rated it as not only less safe, but also significantly more effective.

Study 3 (N=401) was designed to test whether the illegal = effective heuristic persists when the drug (in this case, a sleep aid) is illegal for reasons explicitly unrelated to efficacy or safety. This study had 5 between-subjects conditions: 1) Legal, 2) Illegal (no reason provided), 3) Illegal due to paperwork error, 4) Illegal due to side-effects, and 5) illegal even though it is as safe as the leading sleep-aids. All illegal conditions were perceived as more effective than the legal treatment (p<.001). For an additional effectiveness measure, we asked how many people (out of 100) would likely find relief using the treatment. For all treatments, participants believed that more people would find relief from illegal (vs. legal) treatments. Beliefs about safety remained higher for the legal condition compared to the illegal conditions. Study 3 shows that individuals continue to believe that an illegal treatment will be more effective, even when the drug is illegal for reasons unrelated to strength, potency, or even safety.

We find that illegal products are indeed viewed as less safe than legal products, but surprisingly we also find that they are perceived to be more effective. As with other heuristics, the illegal = effective heuristic may at times be an accurate inference. For example, the healthy = expensive intuition finds that while healthier foods are certainly more expensive at times, consumers overgeneralize this belief to contexts where it is not the case (Haws, Reczek, & Sample, 2017). There are many possible reasons for a drug to be illegal, ranging from safety concerns to issues related to politics, sourcing, and history. We demonstrate that the illegal = effective heuristic holds even when the product in question is illegal for reasons unrelated to efficacy or safety. This finding has implications for public health and marketing. For example, the legalization of products such as CBD (a cannabis derived product) may lead consumers to infer reduced potency compared to when the product was not available legally.

Additionally, individuals with lower concern about legal repercussions and high concern about potency (e.g., people suffering from addiction or other mental illness) may assume that illegal products are more effective at treating their suffering than legal alternatives offered by their doctor. While many public health campaigns educate individuals about the safety concerns of illegal drugs, we hope to further explore this effect by studying whether we can reduce interest in illegal substances by reducing perceived effectiveness instead.

Americus Reed, University of Pennsylvania, USA

SESSION OVERVIEW

We all have a sense of who we are in the context of our social roles, ethnic or national affiliations, and character traits (Reed et al. 2012). Self-identity—defined as one's overall sense of self—guides our thoughts and feelings and influences our behavior (Kleine et al. 1993). Early self-identity research has primarily focused on how priming specific identities or constructs influences identity-relevant attitudes through self-esteem or self-consistency (Kettle and Häubl 2011; Reed et al. 2012). However, much remains unknown about the mechanisms responsible for the effects of self-identity on consumption decisions and behaviors. The papers in this session aim to address this gap by examining two important questions: 1) how does self-identity activated by contextual cues affect product evaluations and consumption decisions? and 2) how does a multifaceted view of self-identity influence identity-relevant choices?

The first two papers in this session examine the influence of self-identity prompted by contextual cues. Kettle and Mantonakis show that adding a personal signature to marketing stimuli affects consumption behavior. They find that a personal signature could be an identity prime and enhance product evaluations when the consumer's relevant identity is associative to the signer's identity but lowers evaluations when the identity is dissociative. In the second paper, Kim and Häubl argue that the timing of identity salience is critical when self-identity is involved in the activation of an implemental mindset. They find that an identification request that taps into self-identity at the beginning of a shopping process induces an implemental mindset (e.g., planning which product to buy), which renders consumers more likely to make a purchase.

The next two papers focus on how a multifaceted view of self-identity influences identity-relevant actions. Dommer and Winterich show that consumers' perceptions of the similarity between two identity options depend on self-variety—the extent to which the self is composed of many different and diverse identities. They find that individuals with low (vs. high) self-variety perceive two identity goods as more similar (vs. dissimilar) to one another, which makes it easier (vs. harder) for them to choose between the options. The final paper examines how consumers' decision confidence varies as a function

of a salient identity's agentic properties. Morgan, Kettle, and Reed show that an identity's agentic properties derive from the tendency for individuals to let others choose for them in situations where that identity is relevant and diagnostic. They examine that making an autonomous (vs. heteronomous) identity salient induces self-product connections and thus reduces the likelihood of post-choice switching.

Together, these four papers examine mechanisms by which consumers' self-identity influences how they evaluate products, make choices, and act upon those choices. The research presented in this session has implications for researchers interested in consumer identity, self-variety, agency, and judgment and decision-making.

Look for the Signature: Personal Signatures on Marketing Stimuli Affect Consumption by Making Identities Salient

EXTENDED ABSTRACT

Management at Niagara's Riverview Cellars once added a facsimile of the winemaker's personal signature to the back label of a wine sold exclusively at their retail store. Adding the signature was associated with an (statistically significant) 80% sales increase – remarkable given that the signature was printed on the bottle's back label. What could explain this?

Marketers intuit that signatures signal quality (Smith 2012). Yet, people sign their name to represent their identity in writing (Hawkins 2011), and a personal signature is thus a meaningful symbol of a person's identity (Koo and Fishbach 2016). As an identity symbol for the signer, we hypothesize that a personal signature serves as an identity prime and thus makes salient identities within a consumer's self-concept that are relevant to the signer's identity. This implies that a personal signature on marketing stimuli (e.g., label, advertisement) should enhance (attenuate) product evaluations and preference among consumers with an associative (dissociative) identity relevant to the signer's identity.

For clarity, identity self-importance describes the chronic role of an identity within the individual's self-concept, identity salience describes the current activity of an identity in one's thoughts, and identity prime is an intervention that generates identity salience (Kettle 2019); Reed 2012). An associative identity is one possessed by the signer that the consumer also sees in themselves (e.g., consumer and signer are both American), whereas dissociative identity is an identity possessed by the signer that conflicts with the consumer's identity (e.g., consumer is American, signer is Canadian).

Studies 1-2 were retail field experiments. In study 1, we manipulated whether the winemaker's personal signature was printed on a display sign located next to one type of wine in the store. We had a control condition with no display sign, a second control condition with a display sign featuring no personal signature, and a third condition with a display sign featuring a facsimile of the personal signature. The personal signature was associated with significantly greater sales as compared to the control conditions.

We conducted study 2 during a wine tasting: we manipulated whether the winemaker's personal signature was printed on the bottle's back label. Participants rated the taste and quality of the wine. We operationalized relevant self-important identity as whether the

consumer self-identified as Ontario. The personal signature generated more favourable product evaluations and greater product sales among consumers with an associative identity, but less favourable evaluations (with no effect on sales) among consumers with a dissociative identity.

Studies 3-5 were online experiments. In study 3, we crafted fictitious signatures for the founders of two unfamiliar brands (Bluebird Farms, Farm Boy) and we independently manipulated whether a personal signature was present on (versus absent from) the product label and whether the signer's identity was associative (versus dissociative) relative to the participant's home state. Replicating study 2, the personal signature on the product label led to more (less) favorable evaluations of products in the associative (dissociative) identity condition, but only among consumers with high identity self-importance.

Study 4 tested the mental mechanism (identity salience) by manipulating the diagnosticity of a subsequent hypothetical donation scenario (ostensibly) unrelated to either the personal signature or the marketing stimuli. Using an associative identity (home state) in all conditions, we independently manipulated the presence (versus absence) of a fictitious personal signature on the label of an unfamiliar brand (Organic Valley), and whether a subsequent donation scenario was identity-diagnostic (versus non-diagnostic). In the identity-diagnostic condition, we described donation recipients as originating from the participant's home state: in the non-diagnostic condition we provided no information about recipients' origins. As hypothesized, the self-importance of the consumer's associative identity only predicted donation amount in one condition: the personal signature present and identity-diagnostic condition. In all other conditions, identity self-importance did not predict donations.

Study 5 examined generalizability by manipulating whether the personal signature of baseball legend Derek Jeter appeared on Modavo watch advertisements. We asked 300 American men to rate the watches, indicate purchase interest, and rate the self-importance of their baseball identity. Replicating studies 2-4, the signature enhanced (lowered) product evaluations among passionate baseball fans (men who dislike baseball), and identity self-importance moderated the mediating role of product evaluations in the effect of personal signatures on purchase interest.

Our research contributes to our understanding of consumer identity by showing that an identity within a consumer's self-concept can be made salient by a cue that is not specific to that particular identity – the personal signature of another person who possesses a relevant identity.

The Logged-In Shopper: How Consumer Authentication Influences Purchase Behavior

EXTENDED ABSTRACT

With the rise of digital retail platforms, authentication (e.g., login) has become an important topic for both firms and researchers (Schaupp and Belanger 2005; Lee et al. 2012). Authentication is defined as the process or action of verifying the identity of a user (Basu and Muylle 2003) and it generally requires the user to enter identifying credentials (e.g., email address, fingerprint, etc.). Intuitively, authentication is irritating to consumers. Prior research shows that breaking the continuity of online shopping can reduce consumers' purchase motivation (McDowell et al. 2016). Therefore, it is in a firm's best interest to minimize consumers' effort associated with authentication until time for checkout (e.g., Expedia's login recommendation at checkout). In contrast to this view, we propose that encountering a request to authenticate when entering a store increases consumers' likelihood of making a purchase. This is because "on-entry" authentication requests activate an implemental mindset (i.e., focusing on the implementation of a goal-directed behavior), which in turn increases consumers' likelihood of purchasing a product. On the other hand, when entering a store without such authentication, consumers are more likely to be in a deliberative mindset (i.e., considering the pros and cons of pursuing a specific goal), and therefore, they tend to be less certain about whether they should make a purchase. In this case, encountering a request to authenticate just before completing a purchase does not activate an implemental mindset, which in turn reduces their likelihood of purchasing a product. Moreover, we propose that salience of self-identity during the authentication process is critical to activate an implemental mindset. Prior literature implies that an implemental mindset is induced when the sense of self is made salient during goal pursuit (Bayer and Gollwitzer 2005). Consistent with this, we examine how making an identity salient (vs. CAPTCHA) during the authentication process activates an implemental mindset, rendering consumers more likely to purchase. Three experiments support our theorizing.

In Experiment 1 (N=318), MTurk participants were randomly assigned to one of two conditions (authentication request: at the beginning vs. near the end). Participants were instructed that they were considering purchasing a new backpack in an online store and that there would be a draw at the end of the study in which one participant would be chosen as the winner. Before beginning the shopping task, participants were asked to provide their email address so that they could be contacted if they are the winner. In the authentication-request-at-the-beginning condition, participants were required to log in by confirming their (previously typed) email address to enter the store, whereas participants in the authentication-request-near-the-end condition entered the store without the login request. If participants chose not to enter the store, they proceeded to an unrelated study. Once participants entered the store, they had the opportunity to purchase one of eight different backpacks, but were free to exit the store without making a purchase. In the authentication-request-at-the-beginning condition, participants completed their purchase without additional authentication at checkout, whereas in the authentication-request-near-the-end condition, participants were required to log in by confirming their email address in order to complete their purchase. The dependent variable was whether a participant completed the purchase of a backpack. We showed that when consumers encountered an authentication request at the beginning (vs. near the end) of a shopping process, they were more (vs. less) likely to make a purchase (=20% vs. =10%; (1)=4.89, p=.03).

In Experiment 2 (N=150), we replicated our previous findings and tested whether an implemental mindset mediates the early authentication effect by introducing a procedure that offsets a deliberative-implemental mindset. MTurk participants were randomly assigned to a 2 (authentication request: at the beginning vs. near the end) x 2 (cross mindset manipulation: present vs. absent) between-participants design. In the cross-mindset-manipulation-present condition, there was an additional procedure after the manipulation of authentication which was the same as in Experiment 1. In the authentication-request-at-the-beginning condition, after participants logged in and entered the store, a deliberative mindset was activated by listing five potentially positive and five potentially negative consequences of switching banks. By contrast, in the authentication-request-near-the-end condition, after participants entered the store, an implemental mindset was activated by planning the implementation of switching banks and listing five steps to execute the plan. In the cross-mindset-manipulation-absent condition, there was no additional procedure after the manipulation of authentication. The depen-

dent variable was whether a participant completed the purchase of a backpack. We showed that the early authentication effect was attenuated in the cross-mindset-manipulation-present condition (=10% vs. =15%; (1)=7.48, *p*=.39), but not in the cross-mindset-manipulation-absent condition (=31% vs. =6%; (1)=4.70, *p*=.03).

In Experiment 3 (N=398), we tested an important boundary condition: identity salience. MTurk participants were randomly assigned to a 2 (authentication request: at the beginning vs. near the end) x 2 (identity salience: authentication vs. CAPTCHA) between-participants design. In the authentication condition, the manipulation of authentication at the beginning versus authentication near the end was the same as in Experiment 1. In the CAPTCHA condition, on the other hand, participants proved that they were not a robot at the beginning (vs. near the end). The dependent variable was whether a participant completed the purchase of a water bottle. We showed that the early authentication effect held in the authentication condition (=25% vs. =13%; (1)=4.56, *p*=.03), but not in the CAPTCHA condition (=21% vs. =19%; (1)=.25, *p*=.61). This experiment rules out an alternative explanation based on the sunk cost fallacy. If the increase of the purchase rate in the authentication-at-the-beginning condition is driven by the mere effort that consumers invest in the purchase process, then the purchase rate in the CAPTCHA-at-the-beginning condition should also have increased. However, as demonstrated, this was not the case.

This research examines how the timing of consumer authentication influences shopping behavior. It contributes to prior literature on how contextual cues that consumers encounter while shopping activate deliberative versus implemental mindsets and thereby influence their purchase behaviors. Our findings have an important managerial implication: firms can benefit from providing authentication requests first in a shopping environment.

Choosing Between "Me's": Why Greater Self-Variety Makes It More Difficult to Choose Between Identity Goods

EXTENDED ABSTRACT

Consumers are motivated to behave in identity-congruent ways (Oyserman 2009). As such, prior research has established consumers' preference for identity products, especially when the identity is salient (Reed et al. 2012). But these paradigms have traditionally pitted goods that express or are linked to one's identity ("identity goods") with neutral (no identity) goods, prompting the question – what happens when an individual must choose between two identity goods?

In the typical choice model, choosing creates conflict because the chosen option is never perfect, and the forgone option has some desirable aspects that are lost (Festinger 1964; Shultz, Léveillé, and Lepper 1999). The more features shared by choice options, however, the less time needed to make the decision (Chernev 1997; Houston, Sherman, and Baker 1991; Nagpal et al. 2011). In the extreme case, choosing between two identical goods should be very easy. On the other hand, choosing between two very distinct goods is more difficult, as consumers experience conflict when choice involves trade-offs among different attributes (Shugan 1980). Thus, the difficulty experienced when choosing between two identity goods should depend on the similarity between the two identity options. We believe that consumers' perceptions of the similarity between two identity options will depend on how much similarity (or distinctiveness) they have within their self—a measure we are calling "self-variety."

The self links various aspects of self-knowledge, including roles, identities, and traits based on associative relations (Campbell,

Assanand, and Di Paula 2000; Gramzow et al. 2000; Greenwald et al. 2000; Reed and Forehand 2016; Reed et al. 2012). The amount of variety within the self essentially assesses how distinctive each identity is from others within the global self, based on the degree of shared associations between each identity (Campbell et al. 2000). At one end of the spectrum, low self-variety, the self can contain a few identities with many associations, creating an amorphous whole with little differentiation. At the other end of the spectrum, high self-variety, the self can contain a greater number of identities with few associations, indicating that the self is multifaceted and unique across identities, contexts, and situations.

Identities share more in common for individuals with low self-variety than individuals with high self-variety. Such identity integration can help reduce conflict across identities (Benet-Martínez et al. 2002; Zou, Morris, and Benet-Martínez 2008). Thus, we believe that individuals with low self-variety will perceive two identity goods as more similar to one another, which should make it easier for them to choose between the options (Chernev 1997; Houston et al. 1991; Nagpal et al. 2011). On the other hand, because their identities are distinct from one another, individuals with high self-variety should view identity goods as being more dissimilar to one another. Without a dominant option, it should be difficult for them to choose between two identity goods (Dhar 1997; Shugan 1980; Tversky and Shafir 1992).

Six studies support our theorizing. In study 1a, a panel of parents made a hypotehtical choice between two pairs of socks and completed our measure of self-variety. Participants with high self-variety took longer to make a choice when their choice set contained two identity-related socks compared to individuals with low self-variety, and relative to when their choice set contained only one pair of identity socks. Study 1b replicated the results of study 1a in a lab experiment where students made a real choice between canvas bags.

In study 2, we manipulated self-variety through a writing task. Participants then made a hypothetical choice between two t-shirts. In addition to capturing the time they took to make the decision, we also included an explicit measure of choice difficulty. Individuals in the high self-variety condition took longer to decide and reported greater decision difficulty when two identity options were present in a choice set compared to those in the low self-variety condition, and relative to when their choice set contained only one identity option.

In study 3, in addition to the two identity goods, we also included a non-identity (i.e., neutral) good the choice set. In support of our theorizing that deciding between two identity goods is especially difficult for individuals with high self-variety, these individuals were more likely to "opt-out" of the decision and choose the neutral option compared to individuals with low self-variety.

Study 4 included a condition where instead of choosing between goods, participants simply rated them. We find our effect of self-variety and the number of identity goods on the length of time it took participants to choose between products, but not on the length of time it took participants to evaluate products, suggesting that decision time is not measuring information processing or involvement.

In Study 5 participants made a real choice between two different stress balls. We measured both the time they took to make their decision as well as perceptions of similarity between the two stress balls. We once again replicated our effect and demonstrate that perceptions of similarity mediates the effect.

Finally, in study 6, we primed either a maximizing or satisficing mindset (Ma and Roese 2014). A satisficing mind-set reduced decision difficulty among individuals with high self-variety, suggesting that these individuals have a tendency to engage in greater comparison of options. Priming a maximizing mind-set, however, encour-

ages such comparison and thus increased decision difficulty among those with low self-variety.

In examining the effect of self-variety on a choice set consisting of more than one identity good, we make two important contributions. First, we contribute to work on identity-based motivation (Oyserman 2009) by examining a context in which consumers must choose between two actions, each of which is congruent with one of their identities. Second, while only few papers in marketing have examined multiple identities (Saint Clair and Forehand 2019; Winterich and Barone 2011; Winterich, Mittal, and Ross 2009), even fewer have looked at the structure among an individual's multiple identities (Savary and Dhar 2020). By demonstrating the effect of high self-variety on choosing between two identity goods, we offer a more comprehensive understanding of how one's self influences consumer behavior.

Autonomous Properties of Identity

EXTENDED ABSTRACT

We all possess different identities that comprise our overall sense of who we are (Reed et al. 2012). It is well-established that different identities, ranging from gender to athlete, musician to soldier, predictably influence consumer decisions in identity-diagnostic contexts (Reed and Forehand 2016). But how might identities influence decisional autonomy in contexts that are not identity-diagnostic? And what downstream consequences might these effects have?

Though autonomy is central to an individual's sense of self (Deci and Ryan 2002), not all identities are equally centered on autonomy. We examine how the *autonomous properties* of an identity – the centrality of autonomous decision-making in shaping that identity – vary across identities, and predictably affect consumer choice and post-choice behavior. First, we establish that autonomy is more central to certain identities, and we pinpoint the key determinant of an identity's autonomous property as the extent to which one lets others make choices for them when that identity is relevant. Then, we demonstrate that triggering an autonomous (versus heteronomous) identity in a choice context strengthens self-product connection, and leads consumers to stick with their choice in the face of disconfirming information.

We began our investigation by developing a 4-item autonomous properties (AP) scale inspired by the autonomy literature (Hong and Faedda 1996; Moller et al. 2007). This scale examines identity-specific associations with autonomous versus constrained behavior (e.g., "When in a context where my [target identity] is relevant, my freedom of choice is restricted."). Each item was on a 7-point scale (1 = strongly disagree, 7 = strongly disagree). Scale reliability was high across all four studies ($\alpha \geq .78$).

We conducted studies 1-2 to examine how autonomous properties vary across different identities within the same individual's self-concept. In study 1 we examined peoples' perceptions for autonomous properties of common identities: family identity (son, daughter), gender identity (man, woman), university student, and Greek member (fraternity, sorority). We were particularly interested in contrasting pairs of identities that would both reside within a single consumer's self-concept: man vs. son, woman vs. daughter, and university student vs. Greek member. Within these pairs, participants perceived greater autonomy for (1) the man identity versus the son identity, (2) the female identity versus the daughter identity, and (3) the university student identity versus the Greek (fraternity, sorority) identities.

In study 2, using a within-subject design, we examined the autonomous properties for two of each participant's own identities:

their gender identity (man, woman) and their family identity (son, daughter). Consistent with study 1, both male and female participants considered their gender identity to be more autonomous than their family (son, daughter) identity. Together, studies 1 and 2 provide convincing evidence that identities have distinct autonomous properties.

Having established that autonomous properties differ across identities, in studies 3 and 4 we investigated the extent to which autonomous (vs. heteronomous) identities might influence product choice and self-product connection. In study 3, we asked participants to describe an identity they possessed. We manipulated (between-subject) whether that identity was autonomous ("an identity with which you feel you have very few restrictions on your actions and behavior") or heteronomous ("… very many restrictions …"). We then asked participants to think of a physical item that they associate with that identity. Participants in the autonomous identity condition indicated a stronger self-product connection to their self-generated item than participants in the heteronomous identity condition. The relationship between the autonomous (versus heteronomous) identity and the self-product connection was fully mediated by the autonomous properties of the identity.

Study 4 used a similar task as study 3: we asked participants to describe an identity they possess (autonomous versus heteronomous) and a physical item that they associate with that identity. Replicating study 3, self-product connection was stronger in the autonomous (versus heteronomous) identity condition. We then asked participants to imagine a scenario in which a better alternative was available to replaced their existing product. Participants were less likely to switch in the autonomous (versus heteronomous) identity condition, and this effect was fully mediated by self-product connection.

In study 5, we turned our attention to pinpointing the key characteristic underlying the difference between autonomous versus heteronomous identities. We examined six potential characteristics, such as how much one considers others when that identity is relevant, and how often they are faced with difficult decisions. We examined four identities (family, gender, student, Greek member). Replicating studies 1-2, the gender and student identities had stronger autonomous properties than the family and Greek member identities. Importantly, only one characteristic explained the difference in autonomous properties across all identities: for autonomous (vs. heteronomous) identities, participants were less likely to have other people make decisions on their behalf: this fully mediated the relationship.

Our work provides an important contribution to the identity and decision-making literatures. Where prior findings identify interpersonal differences in autonomous behavior, we demonstrate an intrapersonal factor – the autonomous properties of distinct identities within one's self-concept – that predictably impacts self-product connection and willingness to forego a previously chosen option. While prior work on consumer autonomy highlights differences in agentic behavior across individuals, we demonstrate intra-individual differences in autonomy that directly impact consumer decision-making.

SESSION OVERVIEW

Nobel Prize-winning economic theory suggests that consumer's choices are guided by an implicit or explicit calculation of expected value (Becker, 1993). However, consumers may sometimes have mistaken expectations. Such misunderstandings based on erroneous beliefs or miscalibrated perceptions can result in consumers theoretically acting rationally—that is, consistent with their expectations—but nevertheless behaving suboptimally.

This session integrates four papers examining these sorts of consumer misunderstandings in daily life. These advanced projects (involving highly-powered field, laboratory, and online experiments) span topics of broad interest to consumer behavior researchers—from prosocial behavior to advice to conversation to engagement during consumption. And yet, they are highly connected: Each talk reveals a tendency for consumers to miscalculate the complexities of their everyday interactions, from the surprising depth of one's own and others' emotional reactions to the surprising pleasures of stepping outside one's comfort zone. Together, they elucidate the need for better understanding how to enhance consumer welfare.

Kumar and Epley investigate the beliefs about and reality following prosocial acts. Participants in their experiments predict how recipients will respond to their prosociality and recipients report their actual experience. They find that, due to an egocentric bias, those performing an act of kindness consistently underestimate how positive their recipients will feel. Consumers not recognizing the impact of their prosociality on others can stand in the way of themselves and others being better off.

Sezer et al. explore what they call the "I Told You So Effect" in the domain of advice. Hearing someone say "I told you so" after a misstep has been made can hurt relationships, decrease the likelihood of following subsequent advice, and thereby serve as a barrier to effective learning. Nonetheless, people often mistakenly choose to use this common phrase when giving advice.

Kardas, Schroeder, and O'Brien study mispredictions about the hedonic trajectory of conversation. Participants in these studies report believing that conversations with another person will become less enjoyable over time, but actually experience more positive outcomes as discussions continue. As a result, people may under-exploit very effective opportunities to enrich themselves through interactions with others.

Goor, Donnelley, and Norton examine how unfamiliarity can lead to feelings of self-discovery. Specifically, they demonstrate that although consumers tend to like familiar products and experiences, unfamiliar products and experiences can foster greater consumer engagement. Engagement with the unfamiliar promotes a clearer understanding of who one really is. Importantly, they document evidence for a particular zone of proximal discovery: Moderately unfamiliar consumption experiences are most likely to facilitate self-discovery.

Notably, this work showcases several topics consistent with the theme of this year's conference, including gift-giving, identity, and interpersonal communication. In the City of Light, we hope to shine a light on some mistaken beliefs that appear to exist in consumers' minds. Our field is uniquely suited to understanding causes and consequences that can suggest steps consumers might take in order to make themselves better off. A better understanding of these misperceptions, we believe, can suggest ways for consumers to improve the quality of their day-to-day lives.

A Little Good Goes an Unexpectedly Long Way: Underestimating the Positive Impact of Kindness on Recipients

EXTENDED ABSTRACT

Positive interpersonal contact promotes well-being (Kahneman & Deaton, 2010). For example, consumers who spend money on others are happier those who spend on themselves (Dunn, Aknin, & Norton, 2008). Prosociality, then, can improve consumer welfare. Consumers have many opportunities to act prosocially but may not engage in prosocial behavior as often in everyday life as might be optimal. It is sometimes said that "a little good goes a long way." We find that it goes an *unexpectedly* long way: Performers of acts of kindness systematically underestimate the positive impact they have on recipients. These miscalibrated expectations matter because they create a barrier to prosocial engagement (Kumar & Epley, 2018). Decisions are guided partly by the expected value of action; the expected impact of a prosocial act on others may therefore guide one's behavior.

We first tested, on a broad range of participants, whether recipients of a prosocial act feel more positive than performers of the act anticipate. In **Experiment 1a**, MBA students (N = 106) in a field experiment performed a variety of self-chosen acts of kindness and predicted how their recipients would react. Participants engaged in many different acts, including purchasing coffee, buying flowers, and delivering baked goods to others. We compared performer expectations to recipients' actual experience. Performers reported that their act was not as "big" as recipients perceived it to be, and reported expending less time, money, and energy than recipients believed performers had expended (ps < .001). Performers also expected recipients to feel positive, but recipients reported feeling even more positive than performers anticipated (p < .001). Consistent with prior research, performing a prosocial act was a significantly positive experience for performers as well, in this and all experiments (ps <

.001). Performers additionally indicated that they perform prosocial acts less often than they'd like (*p* < .001).

Experiment 1b replicated these findings holding the act itself relatively constant. The standardized prosocial behavior was sending a card to someone "just because." One hundred undergraduates did this and predicted how recipients would feel. We followed-up with recipients and measured how they actually felt. Performers again reported that their act was not as "big" as recipients perceived it to be, and also reported expending less time and energy than recipients believed performers had expended (*p*s < .001). They also significantly underestimated how positive recipients would feel (*p* < .05).

Experiments 2a and 2b provided tests of our hypotheses in designs enabling perfect response rates from recipients, something we could not obtain in the field settings of Experiments 1a-1b. We achieved this by having participants perform a prosocial act for a stranger nearby. Experiment 2a involved members of the public (N = 84) who were visiting an attraction in a large urban field setting. Participants at a park gave hot chocolate to another person near an ice-skating rink. Givers again reported that their act was not as "big" as recipients perceived it to be, and significantly underestimated how positive it made recipients feel (*p*s < .001). Experiment 2b (N = 102) replicated these effects in a controlled laboratory setting, with participants giving away gifts from a "lab store" as the act of kindness (*p*s again < .001).

We hypothesized that people undervalue the impact of prosociality due to a perspective-based asymmetry in attention paid to competence versus warmth in evaluating interpersonal behavior (Wojciszke, 1994). People focus more on competence when evaluating their own behavior but more on warmth when evaluating others' behavior. This could cause givers to focus inordinately on the details of the act itself: what one is giving and its objective value. Recipients of an act of kindness, however, care about what is given but also the positive intention and warmth that the act signifies. **Experiment 3** tested this explanation by comparing an act of kindness condition to a control condition in which participants received the same objective item but without it resulting from a prosocial act. Forty-nine participants gave a cupcake to 49 strangers in a park and predicted their reactions, while another 50 participants predicted the actual responses of 50 participants who received a cupcake from an experimenter (not as an act of kindness). Recipients reported a more positive and valuable experience in the kindness condition than in the control condition (p_{big} < .001; p_{mood} = .06), but those predicting their responses anticipated similar experiences for recipients in these two conditions (*p*s > .1). A recipient's reaction to a prosocial act comes from the objective value of the act itself, plus the warmth conveyed by it. Here, performers may have attended to how much someone would like a cupcake, but not to the fact the cupcake was also a gift given in kindness.

Experiment 4 (N = 200) examined whether underestimating a recipient's emotional reaction also leads to underestimating their behavioral reaction. Kindness can spread through indirect reciprocity (Gray, Ward, & Norton, 2014). Those who receive kindness are more likely to behave kindly to others in the future. If people undervalue the positive impact of prosociality on others, they should also underestimate the magnitude of indirect reciprocity it produces in others. Participants completed a laboratory version of Experiment 3 (using gifts from Experiment 2b), and recipients were later assigned the role of "decider" in a dictator game (Camerer, 2003). Performers of the act predicted their recipient's behavior. They again underestimated the positive impact their prosocial act had on the recipient, both on the recipient's emotional experience and on their increased kindness towards a third party (*p*s < .05).

Whereas those who perform an act of kindness might construe their act as relatively "little," as if they are not doing much at all, recipients construe it to be significantly "bigger" and of greater value than performers expect. Misunderstanding how recipients will respond may leave people choosing to engage in prosociality less often than they want to, thereby representing a barrier to prosocial interactions. Undervaluing the positive impact of a prosocial action can therefore keep people from being prosocial *enough* for both their own and others' well-being.

The I Told You So Effect

EXTENDED ABSTRACT

From solving complex problems to making purchases, people often rely on advice from others. In fact, consumers rarely make critical decisions in isolation. Prior research has identified multiple factors that influence individuals' use of advice. For instance, decision-makers weigh advice more heavily when the advice is costly to get (Patt, Bowles, & Cash, 2006), or when the task is difficult (Gino & Moore, 2007). When people feel confident or experience anger (Bonaccio & Dalal, 2006; Gino & Schweitzer, 2008), they are less likely to rely on advice. Similarly, advisor characteristics also impact whether people follow their advice. When the advisors are more experienced (Feng & MacGeorge, 2006; Goldsmith & Fitch, 1997; Harvey & Fischer, 1997; Sniezek, Schrah, & Dalal, 2004; Soll & Larrick, 2009; Yaniv, 2004; Yaniv & Milyavsky, 2007) and have greater confidence (Phillips, 1999; Sniezek & Buckley, 1995; Sniezek & Van Swol, 2001; Soll & Larrick, 2009; Van Swol & Sniezek, 2005; Yaniv & Foster, 1997), the advice is weighted more heavily.

At the same time, however, the consequences of expressions that advisors use depend on the psychological and emotional reaction of the targets, and critically on their appraisal of the advisor statements as helpful or not, because interpersonal aspects in advice exchange are as important as the quality of the advice (Blunden, Logg, Brooks, John, & Gino, 2019). While previous research has focused on expressions that prompt advisor credibility and confidence (Soll & Larrick, 2009), little is known about the effects of statements that backfire. In the current research, we investigate a common and a universal statement that is of critical importance in advice-giving contexts: "I told you so."

Building on past research on advice-giving and learning, we conceptualize "I told you so" as a statement that stems from the satisfaction of being right. We propose that individuals who hear this statement view the advice giver as more condescending, less empathic, and less trustworthy. We suggest that although it is a very common statement that exists in all languages across the world, and is a universal phenomenon, saying I told you so backfires as it harms trust in advice exchange and hurts learning.

In **Study 1** (*N* = 302), participants estimated an individual's weight from a photograph for three rounds. Out of 302 participants, 133 of them ignored their advisor's estimate in Round 1, and 169 of them took the advice. In Round 2, those who didn't follow the advice in Round 1, got another piece of advice, but half of them heard the new advice with "I told you so" while the other half only heard just the advice. Among the ones who ignored their partner's advice in the first round, those who received Round 2 advice with "I told you so" perceived the advice to be lower quality than those who received the same advice without the I told you so statement, *t* (131) = 2.64, *p* = .009, *M* = 4.11 vs *M* = 4.75. Similarly, the group that received "I told you so" perceived their advisor to be more condescending, *t* (131) = 7.69, *p* = < .001, *M* = 4.89 vs *M* = 2.53, and less empathic *t* (131) = 3.43, *p* = .0008, *M* = 3.54 vs *M* = 4.24.

In **Study 2** (*N*=500), we employed the same design as Study 1, and randomly assigned participants to one of two between-participants conditions: *"I told you so" vs "You were wrong.".* When participants didn't follow their partners' advice, in Round 2, they either received "I told you so" or "You were wrong" as a message in addition to advice for the new round. Out of 500 participants, 276 of them ignored the advice from their partner in Round 1. Among the group who ignored their partner's advice, those who received "I told you so" perceived their partners to be more condescending *t* (274) = 8.07, *p* = < 001, *M* = 5.01 vs *M* = 3.71, and less empathic *t* (274) = 4.32, *p* = .002, *M* = 1.81 vs *M* = 2.37, than those who received "You were wrong" from their partners.

In **Study 3** (*N*=102), participants in the lab completed the same weight estimation task, and those who received "I told you so" in Round 2, along with the advice, perceived their partner to be more condescending, *t* (100) = 9.67, *p* < 001, *M* = 5.03 vs *M* = 2.87, less empathic *t* (100) = 7.23, *p* < 001, *M* = 1.81 vs *M* = 3.56, and less trustworthy *t* (100) = 3.89, *p* = .004, *M* = 3.56 vs *M* = 4.35 than the participants who didn't hear I told you so but received the same advice. More importantly, those who received "I told you so" were less likely to choose the same partner for the subsequent round, *p* = .03.

In **Study 4** (*N*=200), participants engaged in 10 rounds of the same task, but as an advisor this time. After each round, they found out they were right, and their partner was wrong, and they could either send "Bummer!" or "Bummer, I told you so!" as a message. 142 out of 200 participants (71%) chose to send the "I told you so" message at least once across 10 rounds, and on average, participants chose to send this message 3.235 times of the possible 10. About 23% of participants chose to say I told you so after only Round 1. In other words, despite not liking this statement (as found in Studies 1, 2, and 3), when given a chance, participants use the opportunity to say "I told you so."

We contribute to the advice literature by focusing on interpersonal effects, as opposed to decision accuracy and quality, which has been the primary focus of previous research (Bonaccio & Dalal, 2006). We introduce and examine the psychology underlying a common advice statement "I told you so" and shed light on the importance of empathy and trust in learning and building an advisor-advisee relationship.

Keep Talking: (Mis)Understanding the Hedonic Trajectory of Conversation

EXTENDED ABSTRACT

People engage in conversation every day, from small-talking with colleagues to checking in with close others. We explore one common but consequential conversation opportunity: talking with new acquaintances. People encounter far more opportunities to interact with new acquaintances than they take (Hill & Dunbar, 2003), yet doing so forms the basis of richer relationships. Typically, the more people talk, the more they learn, the closer they feel, and the more they like each other (Aron et al., 1997; Quoidbach et al., 2019; Reis, 2012). Only by continuing the conversation do two strangers have a chance of becoming two friends.

Why might people forego such opportunities? On the one hand, people cannot always tell whether others are willing to engage at all. Thus, people often fail to initially approach others to start any conversation (Boothby et al., 2018; Dunn et al., 2007; Epley & Schroeder, 2014). We build on this idea by examining another barrier that may rise *after* people have officially met and enjoyed some initial conversation. Specifically, even after enjoying the start of a conversation, people may believe the experience will quickly grow dull as they and their partner must *maintain* a conversation—despite the aforementioned research suggesting the opposite.

Two other literatures support this possibility. First, predictions about future experiences reflect one's mental simulations of those experiences, but mental simulations are "mere cardboard cutouts of reality" (Gilbert & Wilson, 2007, p. 1354). As a result, after people initially experience an enjoyable stimulus, they tend to underappreciate the extent to which repeat exposures can reveal exciting new information (O'Brien, 2019). People notoriously misunderstand how experiences build and grow over time. Second, people are especially prone to misunderstand the depth and complexity of *other people,* given the inaccessibility of others' elaborate mental lives from an observer perspective (Waytz et al., 2013). For example, people tend to underestimate others' capacities to generate nuanced opinions and experience intense emotions (Pronin, 2008).

Put succinctly, these literatures suggest people may underappreciate the extent to which they and a new acquaintance will continue to find new things to discuss beyond their initial interaction, leading people to underappreciate their enjoyment as they continue conversing—*even if* they enjoyed chatting initially.

In **Experiment 1**, pairs of strangers (*N* = 100 pairs) conversed for one round (3 minutes). Some pairs then predicted their trajectory of enjoyment over four additional rounds. Others actually continued conversing and reported their enjoyment round-by-round. We observed the hypothesized Role × Round interaction (*p* < .001): Whereas *Predictors* expected enjoyment to decline over time (*p* < .001), *Experiencers* reported that enjoyment actually increased (*p* = .010).

Experiment 2 utilized a within-participant design, with the same participants first making predictions and then reporting their experiences. We also tested mechanism: Whether people misunderstand the hedonic trajectory of conversation because they underestimate how much their pair will have to discuss. Pairs of strangers (*N* = 50 pairs) completed a similar experiment to Experiment 1. We also measured conversation material ("How much will you [did you] have to discuss during this round?"). For enjoyment, we again observed the hypothesized Phase × Round interaction (*p* = .017): Participants predicted that enjoyment would decline (*p* < .001), yet those same participants then experienced similarly high enjoyment (*p* = .920). This interaction also emerged for conversation material (*p* < .001): Participants predicted that conversation material would diminish (*p* < .001), yet then maintained ample material (*p* = .797). The effect of Phase on changes in enjoyment, via changes in conversation material, was significant (*b* = -0.38, 95% CI = [-0.80, -0.15]).

If people underestimate enjoyment because they underestimate their pair's ability to sustain material, they might underestimate enjoyment more when having one long conversation with the same person (deepening one relationship) versus having multiple shorter conversations with different people (broadening their network). **Experiment 3** tested this possibility (*N* = 395 individuals). Procedures were identical to Experiment 2, except participants were randomly assigned to either have five rounds of conversation with the same partner, or five rounds of conversation each with new partners. Again, there were significant Phase × Round interactions for enjoyment and conversation material (*p*s < .001), with participants generally underestimating both. Most interesting, we observed split evidence for Partner effects. There was *no* 3-way interaction for enjoyment (*p* = .584): All participants (regardless of partner) predicted declining enjoyment (*p*s < .001) yet then experienced increasing enjoyment (*p*s < .019). However, there *was* a 3-way interaction for conversation material: Same-partner participants were *especially* likely to underestimate conversation material as compared to different-partner

participants ($p < .001$). Conversation material again served as the mediator ($b = -0.44$, 95% CI = [-0.61, -0.28]).

These experiments reveal that people misunderstand the hedonic trajectory of conversation. Even after enjoying some initial conversation, people imagined that further conversation would quickly grow dull—yet experienced similar or greater enjoyment in reality.

Our findings advance research on social forecasting errors. Conversation provides feedback about others and thus should calibrate expectations. However, our paradigm compares predictions to experiences *after* one round of conversation and finds that people still underestimate enjoyment under these conservative conditions. Social forecasting errors may arise not only from lack of knowledge about one's initial approach but also from misunderstanding how the experience will change as they *keep* talking.

Additionally, our participants underestimated enjoyment because they underestimated their pair's ability to sustain material, but also underestimated enjoyment before speaking with multiple partners, when material should be ample. Perhaps people are also (mistakenly) worried about how fatiguing social interaction is (Zelenski et al., 2013). Future research should further unpack whether people are concerned that they themselves (versus their partner) will struggle to generate material. Finally, future research should examine downstream effects. People may exit conversations earlier than they should for their own happiness, just as our participants underappreciated how much further conversation would measure up to initial conversation. Accordingly, people may keep to themselves or pursue impoverished interactions through social media (Kross et al., 2013), while returning to those we already know may prove more rewarding.

The Road Not Taken: Consumption of Unfamiliar Products Increases Feelings of Self-Discovery and Product Engagement

EXTENDED ABSTRACT

As consumers, our identity and roles in life are intertwined with our possessions and consumption behaviors (Belk, 1988). The types of products we purchase are influenced by our personality and values (Donnelly, Iyer, & Howell, 2012; Matz, Gladstone, & Stillwell, 2016) and consumers often turn to durable goods like clothing and accessories to construct and convey an actual, nostalgic, or aspirational self to others (Chernev, Hamilton, & Gal, 2011; Goor, Ordabayeva, Keinan, & Crener, 2019). This research examines a different perspective of consumption experience and argues that products not only facilitate self-expression, but can also help consumers discover who they are. Specifically, we demonstrate that unfamiliar (vs. familiar) consumption experiences may increase the sense of self-discovery, and thus lead to greater engagement with the unfamiliar product.

Prior research demonstrates that consumers seek extraordinary experiences to signal status (Keinan & Kivetz, 2010) or to feel intensely alive (Arnould & Price, 1993). Furthermore, major life events, like starting a new job or starting a new relationship, can encourage consumers to question previous values and ideas and bring about new roles in life (Schouten, 1991). Conversely, repeated consumption can increase satiation and adaptation, and reduce consumer enjoyment and product evaluation (Bhattacharjee & Mogilner, 2014; Frederick & Loewenstein, 1999; Gershon & Smith, 2019). Contributing to this literature, we find that basic albeit unfamiliar consumption experiences, such as listening to an unfamiliar song, eating unfamiliar food, or using an unfamiliar product, provide consumers opportunities to discover more about themselves (as opposed to merely discovering more about an unfamiliar product), which in turn, increases engagement.

Three studies demonstrate our effect and suggest a zone of proximal discovery – moderate rather than extreme levels of unfamiliarity facilitate the process of self-discovery. Consistent with theories in developmental psychology (Vygotsky, 1978), which suggest that children have a successful and positive experience when learning skills that can be directly applied to previously developed knowledge, we demonstrate that some level of familiarity is needed to increase consumers' self-discovery and further interest in the product.

In **Study 1** (*N*=176, MTurk), participants described a recent purchase of a product that was unfamiliar to them (vs. a new product that replaced an existing one) and indicated the extent to which the product made them discover and learn about themselves using a 3-item index ("Using this product I discovered new parts within myself," "Purchasing this product felt like a discovery," "This product helped me to learn about myself"; α=.82). In both conditions, participants wrote about similar purchase categories (clothing, cleaning supplies, yard tools, and electronics). Importantly, as expected, unfamiliar products increased self-discovery ($M_{unfamiliar}$=4.23, SD=1.47) compared to new products (M_{new}=3.76, SD=1.61; $F(1,174)$=3.94, p=.049).

In **Study 2** (*N*=274), undergraduates were randomly assigned to drink a small sample of Watermelon (unfamiliar flavor) vs. Orange (familiar flavor) juice. A pre-test (*N*=100) confirmed that Watermelon is a less familiar juice flavor than orange (p<.001). After tasting the juice, participants indicated how interested and engaged they were by the juice using a 6-item scale (e.g., "I feel engaged in the experience of drinking," "I stopped several times to examine the juice and how it's served," "I'd be curious to try it again in the future"; α=.79). They also indicated how much they like the juice in general (one-item), and the extent to which drinking the juice made them discover and learn about themselves using a 6-item scale (e.g., the juice "elicited some self-reflection," "opened me to new experiences and a new aspect within me," "made me reevaluate my preferences," and "felt like a part of a journey of self-discovery"; α=.85). The results revealed that the unfamiliar juice increased interest and engagement ($M_{unfamiliar}$=3.62, SD=1.28) compared to the familiar flavor ($M_{familiar}$=3.05, SD=1.21; $F(1,272)$=14.70, p<.001) and this effect was mediated by feelings of self-discovery ($a \times b$=.3287, SE=.0953, 95% CI=[.1452,.5202]. Interestingly, the unfamiliar experience decreased liking ($M_{unfamiliar}$=3.75, SD=1.82) compared to the familiar juice ($M_{familiar}$=4.49, SD=1.59; $F(1,272)$=12.66, p<.001).

Study 3 tested an important boundary condition: the potential zone of proximal discovery. Participants (*N*=303, MTurk) ranked their familiarity with five music genres: country, rock, rap, jazz, and classical. They were then randomly assigned to one of three conditions: listening to a song from a familiar genre (ranked 1/5), slightly unfamiliar genre (ranked 3/5), or a very unfamiliar genre (ranked 5/5). After listening to a brief 60-second music clip, participants indicated the extent to which listening to the music helped them discover and learn about themselves using a 5-item scale (e.g., "felt like a part of a journey of self-discovery," "made me reevaluate my music preferences," and "advanced my self-knowledge"; α=.86). They also evaluated how much listening to the song helped them learn about music using 3-item scale (listening to that song "is like taking a music lesson," "made me feel like I know more about music," "made me realize that music has subtle nuances"; α=.87). The results indicated that the slightly unfamiliar genre increased feelings of self-discovery ($M_{3/5}$=3.13, SD=1.49) compared to the familiar genre ($M_{1/5}$=2.71, SD=1.34; p=.047). The effect of listening to a very unfamiliar genre was non-significant compared to the other conditions

($M_{5/5}$=2.93, SD=1.63, p's>.300). Importantly, the effect of genre familiarity on music-discovery was not significant across conditions (p's>.488).

Our work contributes to the literature on consumer psychology, suggesting that consumers might be more engaged using unfamiliar (vs. familiar) products in order to learn about themselves through interacting with the products. Preliminary results further suggest that older consumers are more susceptible to self-discovery using unfamiliar products. Our research has also important practical implications. Today, marketers often use big-data analyses to provide consumers recommendations that are based on product familiarity and similarity (Linden, Smith, & York, 2003), even though consumers regularly express preferences for a greater variety of products (Ratner and Kahn 2002; Simonson 1990) and unique experiences (Keinan & Kivetz, 2010). Our research demonstrates that marketers could increase engagement and interest in their products by giving consumers the opportunity to experience new products (e.g., new collections, samples, extensions) that encourage greater self-discovery.

Paper #4: Consumers' Responses to Brand Transgressions: Role of Brand Type and Materialism

Sylvia S. Chang, University of Washington, USA

Shailendra Pratap Jain, University of Washington, USA

SESSION OVERVIEW

The instances when brands violate consumers' expectations and commit misbehavior attract ever-increasing attention and possess omnipresent damage potential which is amplified by social channels proliferation, consumer activism, and viral dissemination of content. This session centers around the following questions: 1) how do consumers react to misbehaving brands, 2) how do these reactions vary as a function of different factors related to the consumer, brand, and consumer-brand connection, and 3) what is the downstream impact of brand misbehavior on consumers' brand perceptions and brand-related behaviors? Collectively, the four papers shed light on consumers' differential responses to explicit or perceived brand transgressions in terms of their attitudes, forgiveness, purchase intentions, and behaviors toward those brands. The session contributes to the emerging literature on consumer reactions to brand misbehavior by highlighting novel multiplex research drawing on concepts and theories from interpersonal relationships psychology, construal level theory, the dark triad of personality, brand relationship, commitment, and materialism theories.

In the first paper, Kumbargeri et al. demonstrate the impact of brand heritage on consumer responses to brand transgressions. The authors find that consumers are more likely to forgive heritage (vs. non-heritage) brands and exhibit less negative attitudes, word-of-mouth and unethical punishment behaviors toward such brands, which is mediated by differentially induced construal level. In the second paper, Malär et al. find that misbehaving brands possess distinct negative brand personality traits. Transferring the dark triad of narcissism, machiavellianism, and psychopathy to the branding context, the paper measures dark brand personality with a novel thirty-item scale and assesses its downstream consequences on consumers attitudes and behavioral intentions. In the third paper, Garg

et al. reconcile prior literature on misbehaving brands by documenting that depending on the transgression agency responsible, type of transgression, brand remedial measures, and brand apology, affective commitment can predictably 'buffer' versus 'amplify' consumer backlash against the misbehaving brand. The effect is mediated by shame. In the final paper, Chang and Jain zoom in on self-brand connection to examine whether consumer materialism and brand type can mitigate the negative impact of brand transgressions. In particular, materialism influences the extent to which consumers forgive material versus experiential brands following quality-related brand transgressions.

This year's conference theme is "Rendez-Vous in the City of Light" with different approaches, paradigm perspectives, and multiple interests called to come together to focus on consumer research questions. This session embodies the spirit of integrating multiple perspectives on the topic of brand misbehavior. Specifically, the four papers elucidate how consumer responses to brand misbehavior are impacted by a series of consumer-related factors (materialism), brand-related factors (brand heritage, brand personality, brand type, brand transgression type and responsibility, brand remedial measures), and consumer-brand connection factors (affective commitment, self-brand connection). To this end, the proposed special session brings together researchers from nine universities in six countries across all stages of an academic researcher: doctoral student, assistant, associate, full, and chaired professor. We expect this session to appeal to a broad audience, including researchers interested in brand transgressions, product/service failures, consumer-brand relationships, loyalty, marketplace ethics and morality.

Wilt Thou Forgive That Sin? – The Influence of Brand Heritage on Consumer Reactions to Brand Transgressions

EXTENDED ABSTRACT

Introduction

On April 20, 2010, a methane gas release triggered an explosion on the British Petroleum (BP)-run Macondo Prospect site killing 11 workers and causing incalculable damage to surrounding wildlife. BP, a British company with an origin dating back to 1909, was found guilty of this environmental catastrophe. This incident constitutes an act of transgression, defined as any violation of rules guiding consumer-brand relationships (Aaker et al. 2004). In this research, we ask the question: When a brand commits a transgression, are consumers more willing to forgive heritage brands than non-heritage ones? Brand transgressions often induce negative reactions from consumers, which if not managed appropriately, can severely tarnish brand reputation putting the very existence of a brand at risk (Bechwati and Morrin 2003; Khamitov, Grégoire, and Suri 2020; Rotman, Khamitov, and Connors 2018).

Theoretical Framework

Urde, Greyser, and Balmer (2007, pp. 4-5) define brand heritage as "a dimension of a brand's identity found in its track record, longevity, core values, use of symbols and particularly in an organizational belief that its history is important." Brand heritage draws on consumer's distinct cognitive ability to think temporally in terms of a

brand's track record, longevity, and history as important components of its identity (Urde et al. 2007). Here, we advance this view by focusing on construal level associated with heritage brands.

Construal level theory suggests that temporal distance (vs. proximity) is linked to a more abstract (vs. concrete) representation of information (Kyung et al. 2010; Liberman et al. 2002; Trope and Liberman 2003, 2010). Applied to our context, heritage (vs. non-heritage) brands, owing to their emphasis on temporal distance, should, by extension, induce a psychologically distal (vs. proximal) perspective and, therefore, an abstract (vs. concrete) construal. We pose that this is likely to help them reduce negative outcomes resulting from brand transgressions. Some preliminary support for this proposition originates from McGraw and Warren (2010) and McGraw et al. (2012), who found that psychologically distant tragedies induce humor as they are perceived less threatening and benign violations. Furthermore, Gong and Medin (2012) demonstrated that abstract (vs. concrete) construal level leads to more positive judgments of moral transgressions. Taken together, we expect consumers to perceive the transgressions by heritage (vs. non-heritage) brands less negatively due to the abstract (vs. concrete) construal that such brands induce. Consequently, we expect consumers to be more forgiving of heritage (vs. non-heritage) brands and exhibit less negative attitudes, reduced negative word-of-mouth and unethical punishment behaviors towards heritage (vs. non-heritage) brands in the event of a transgression. And this effect of brand heritage should be mediated by the abstract construal induced by the heritage brand.

Methodology

Six experiments across five different product categories and real as well as hypothetical brands investigate the impact of brand heritage on consumer responses to brand transgressions. Experiment 1A was designed as a single factor (brand type: heritage vs. non-heritage) between-subjects study with post-transgression attitudes toward a transgressing university brand and negative word-of-mouth as the dependent variables. Experiment 1B sought to extend findings of Experiment 1A in a different setting (health drink) and with an additional dependent variable (consumer forgiveness) to establish the robustness of the hypothesized effects. Experiment 2 investigated the mechanism underlying the hypothesized effect by establishing construal level mediation. This study measured the construal level using the BIF scale (Vallacher and Wegner 1989) and included consumer forgiveness and post-transgression attitudes toward the brand as the dependent variables and brand heritage as the independent variable. Experiment 3 sought to further substantiate the mechanism by testing for moderation by construal level. If the focal effect is indeed mediated by construal level, then the effect should be manifest (attenuated) when the abstract (concrete) construal is independently manipulated. This study was conceived as a 2 (brand type: heritage vs. non-heritage) x 2 (construal: abstract vs. concrete) between-subjects design study. In Experiment 4, using the unethical punishment matrix task adapted from Mazar, Amir, and Ariely (2008), we aimed to provide behavioral evidence for our hypothesized effect in the context of two real brands – one heritage and the other non-heritage. Finally, experiment 5 tests the robustness of the hypothesized effect using a single brand positioned along the heritage vs. non-heritage lines. In this experiment, as an additional behavioral measure, respondents were asked to provide their email IDs if they wished to express their concern about the transgression.

Results

Experiments 1A and 1B demonstrated that consumers are more likely to forgive heritage (vs. non-heritage) brands and exhibit less

negative attitudes and negative word-of-mouth toward them in the event of a brand transgression, thus providing evidence in support of the core effects. Experiment 2 replicated the main effect and further demonstrated that the impact of brand heritage on consumer forgiveness and post-transgression attitudes is mediated by construal level (b = .134, SE = .079, 95% CI [.004, .319]). Experiment 3 provided additional evidence for the proposed mechanism by showing moderation by construal levels. Experiment 4 showed that consumers are less likely to unethically punish the transgressing heritage brand as compared to a non-heritage brand and additionally replicated the results of experiments 1A and 1B. Experiment 5 showed respondents are less likely to express concern in case of a transgression by a heritage brand as compared to a non-heritage brand along with replicating findings of the previous experiments.

Contributions and Implications

We contribute to the academic literature on the psychology of brand transgressions and brand heritage by highlighting brand heritage as one of the strategies to diminish the negative impact of brand transgressions on consumer responses (Khamitov et al. 2020). We also contribute back to construal level theory (Trope and Liberman 2010) by showing that the influence of construal level extends to the evaluation of brands in the wake of a brand transgression. The current set of studies has substantial managerial implications as it sheds light on brand heritage as an effective strategy to buffer the negative consumer attitudinal and behavioral reactions in the increasingly prevalent event of a brand transgression.

The Dirty Thirty of Brand Personality: Narcissistic, Machiavellian, and Psychopathic Brands

EXTENDED ABSTRACT

"Boeing is a silver-haired, middle aged white man in a $3000 suit. He is well-connected and respected in important social and political circles that help him grow his business. Due to his obsession with quarterly profits, he fails to spend time with his own family. His wife is unsatisfied and takes opiods to cope with her lost sense of self, his teenage daughter hates him, and his son is spiraling out of control via drug abuse."

This description of the Boeing brand from a consumer interview provides preliminary evidence that certain brands are not associated with positive personality attributes (e.g., "exciting", "down-to-earth", "cool"; Aaker 1997), but rather with a dark personality in a similar way that humans have dark personalities.

In our hyperconnected world, firms disseminate branded information increasingly quickly and broadly (Swaminathan et al. 2020). This has led to more transparency where bombarded and frustrated consumers increasingly use their power to attack brands (e.g., consumer brand sabotage; Kähr et al. 2016). These developments have elevated the likelihood that consumers witness brands' undesirable behaviors (e.g., manipulation of consumers, exploitation of employees, pushy or arrogant messages) and, consequently, attribute negative personality characteristics to such brands.

Despite the sheer prevalence of dark brand personalities in the marketplace, prior research has primarily focused on positive and favorable brand personalities (e.g., Aaker 1997; Warren and Campbell 2014). Nevertheless, there are some initial studies that hint at existence and magnitude of negative brand personality dimensions. For example, Geuens, Weijters and De Wulf (2009) include aggressiveness, Grohmann (2009) examines some negatively-valenced traits pertaining to gender dimensions of brand personality (e.g., aggres-

sive and dominant), and Rojas-Méndez and Papadopoulos (2012) add brand neuroticism to their brand personality measure. Relatedly, Awad and Youn (2018) show that narcissistic consumers love narcissistic, anthropomorphized brands. However, to date, a systematic understanding of the dark traits of brand personality is missing as virtually all prior studies have only peripherally focused on the dark side of brand personality and/or treated those as rather an afterthought.

Against this backdrop, the current research conducted six studies to systematically examine the dark side of brand personality primarily drawing on the important concept of dark triad from personality psychology that consists of narcissism (i.e., admiration seeking, feelings of superiority; Morf and Rhodewalt 2001), machiavellianism (i.e., immoral beliefs, pursuit of self-beneficial goals and manipulation tactics; Rauthmann and Will 2011), and psychopathy (i.e., cold affect and antisocial behaviors; Neumann, Hare, and Newman 2007).

As a first step in the dark triad (DT) of brand personality item generation (Study 1a), we developed an extensive battery of 567 items primarily based on limited negative brand personality items in the literature, personality psychology scales, and a series of qualitative consumer interviews. We eliminated items that were overlapping or not applicable to brands. In the second stage (Study 1b), we had six branding and personality psychology experts rate the items in terms of their conceptual map on their respective trait and applicability to the branding context.

Next, we initially administered and validated our remaining set of items. In Study 2a, 900 MTurk US participants were randomly assigned to one brand from a sample of 13 pretested brands and indicated their level of agreement with the initial DT items (1 strongly disagree-7 strongly agree). In an exploratory factor analysis, a three-factor solution emerged. We tested the three-dimensional structure in a confirmatory factor analysis using AMOS. Items were removed one at a time based on modification indices and squared multiple correlations (below .6). These processes resulted in a final set of 30 items. Examination of different alternative measurement models (e.g., two factors) indicated that the three-factor correlated model fits the data best ($\chi2(402)=1460$, $\chi2/df=3.63$, NNFI=.96, CFI=.96, GFI=.88, SRMR=.03, RMSEA=.06, SRMR=.03). Study 2b validated our shortlisted set of items with a new sample and a self-selected brand approach. The final items reflect three dark-sided brand personality dimensions: narcissism (e.g., BRAND pretends to be more important than it actually is; demonstrates arrogant behavior), machiavellianism (e.g., BRAND does not care about others unless it benefits its bottom line; manipulates others to get ahead), and psychopathy (e.g., BRAND tends to be unconcerned with the morality of its actions; appears not to care about the well-being of others).

To establish discriminant validity, Study 3 tested brand attitudes, Aaker's five brand personality dimensions, and brand reputation against a second-order factor model of DT. Discriminant validity was supported according to the Fornell-Larcker criterion for all comparisons.

Study 4 provides a preliminarily investigation of the DT dimensions' impact on downstream brand attitudes and behavioral intentions. More specifically, we posit that a highly dark brand personality has leads to a) greater hostile and unethical intentions as well as dishonesty towards the brand and b) decreased brand attitudes and purchase intentions. We manipulated DT using fictitious brand descriptions with two conditions: a brand high vs. low on dark traits. Our 30 items served as a manipulation check.

Results confirm the expected effects: a) the higher the DT, the greater consumers' hostile intentions towards this brand are ($M_{high}=2.5$, SD=1.30; $M_{low}=1.22$, SD=.51; t(282)=-10.92, *p*=.001)

as are unethical punishment intentions ($M_{high}=1.52$, SD=1.00; $M_{low}=1.11$, SD=.41; t(282)=-4.52, *p*=.001). Also, the higher the DT, the more likely a consumer behaves dishonestly ($M_{high}=1.32$, SD=.47; $M_{low}=1.19$, SD=.39; t(282)=-2.47, *p*=.001). Lastly, the brand was evaluated less favorably in the high DT condition than in the low DT condition: brand attitudes ($M_{high}=1.60$, SD=.90; $M_{low}=5.35$, SD=1.26; t(282)= 28.82, p=.001) and purchase intentions ($M_{high}=1.70$, SD=.93; $M_{low}=5.27$ SD=1.33; t(282)=26.26, p=.001).

In sum, this research contributes to the brand personality literature (Aaker 1997; Geuens et al. 2009) by providing a first systematic empirical examination of the dark traits of brand personality along with an effective, reliable measure to capture dark brand personality. Specifically, we draw on the important concept of the dark triad from personality psychology (i.e., narcissism, machiavellianism, and psychopathy) and bring it to the context of brands, showing that DT impacts a series of downstream consequences. So doing, we also contribute back to the dark triad literature in personality psychology (Morf and Rhodewalt 2001; Neumann et al. 2007; Rauthmann and Will 2011) by demonstrating that the influence of dark triad dimensions meaningfully extend to the branding context. These contributions are managerially relevant: a more detailed understanding and effective measurement of the dark side of a brand's personality may support managers in assessing whether their brand suffers from such a personality and provide an opportunity to intervene and counteract.

Does it Hurt or Protect? The Effect of Affective Commitment on Unethical Behavior toward Transgressing Brands

EXTENDED ABSTRACT

Brand transgressions seem to have become more prevalent and receive greater media coverage, in recent times (Dick 2019). When brands transgress, consumers can become punitive by engaging in negative behaviors including spreading negative word-of-mouth (Grégoire and Fisher 2008; Wangenheim 2005), withdrawing from interactions with the brand (Grégoire and Fisher 2008; Huber et al. 2010), brand boycotting (Klein, Smith, and John 2004), switching to rival brands (Bechwati and Morrin 2003), and even engaging in brand sabotage (Kähr et al. 2016; Nyffenegger et al. 2018).

One potential protective mechanism against the possible negative responses in the face of such incidents might be *affective commitment* towards the brand. Affective commitment is defined as the customer's emotional attachment to a particular brand based on consumers' identification with that brand (Allen and Meyer 1990) and reflects their desire to maintain an on-going relationship with the brand (Jones et al. 2010). Recent research has suggested that one of the key antecedents of affective commitment is self-brand connection (Turri et al. 2013) while as a consequence, it is a strong driver of re-purchase intentions toward the preferred brand (Fullerton, 2005; Jones et al. 2010) and brand loyalty (Evanschitzky et al. 2006; Kim et al. 2008).

While prior literature has extensively documented the positive outcomes of affective commitment, it is less definitive on how it might impact consumer response when a brand transgresses. Research suggests that affective commitment could grant the transgressing brand a certain level of immunity or 'buffering' as strong brand relationship supports the brand during a service failure (De-Witt and Brady 2003; Hess, Ganesan, and Klein 2003). In contrast, literature also presents evidence of an 'amplifying' effect where high commitment leads to significantly lower brand evaluations after a service failure (Gregoire et al. 2009) because committed consumers consider brand transgression as a normative violation, leading to

an increased desire for retaliation (Grégoire and Fisher 2006, 2008; Grégoire et al. 2009). In a series of four studies, the current research seeks to address this paradox in the novel context of unethical consumer behavior toward the transgressing brand and importantly, establishes ecologically valid moderators such as transgression agency, transgression type, and brand responses, of this effect along with the mediating role of shame which arises due to high affective commitment toward the transgressing brand. The studies use real brands (Coca-Cola/ Nike), their transgressions, and measure 'actual cheating behavior' (Winterich, Mittal, and Morales 2014) (except Study 2).

Studies 1 and 2 test the moderating effect of transgression-related factors; agency responsible for the transgression (direct – brand vs. indirect – franchisee) and the type of transgression (performance-based (PBT) vs. value-based (VBT)), respectively. **Study 1** employed a continuous (affective commitment) x 2 (transgression agency: direct, indirect) between-subjects design (n=158). Analysis reveals a significant interactive effect on the amount of cheating () such that the amount of cheating varies across affective commitment but only in the direct transgression condition ($M_{high\text{-}direct}$ = 5.94 vs. $M_{low\text{-}direct}$ = .66, $p < .001$) and not in the indirect condition ($M_{low\text{-}indirect}$ = 3.38 vs. $M_{high\text{-}indirect}$ = 2.33, ns). **Study 2** (n=147) uses purchase intentions as the dependent variable and finds a significant interaction between transgression type (VBT vs. PBT) and affective commitment . Importantly, it shows that affective commitment *amplifies* punitive action for VBT (lowered purchase intentions)[1]), but has a *buffering* effect for PBT). Further, higher levels of shame emerge for high (vs. low) affective commitment), and for VBT (vs. PBT)). As predicted, there is no evidence of mediation through shame for PBT (but it is significant for VBT (.

Studies 3 and 4 examine the role of brand response as moderators of the impact of affective commitment on unethical behavior; brand remedial measures (vague vs. specific (concrete)) in Study 3 (n=230) and brand apology (present vs. absent) in Study 4 (n=233). In **Study 3**, the interaction between remedial measures and affective commitment is significant. Specifically, we find that high affective commitment leads to *more unethical* behavior when the remedial measures were vague (vs. specific) () Contrary to the conventional wisdom, even with specific remedial measures, high (vs. low) affective commitment leads to more punitive behavior (). Thus, while specific response is more effective, the backlash effect of high affective commitment is robust and persists. Finally, **Study 4** finds that there is a significant interaction between brand apology and affective commitment While high affective commitment is associated with more unethical behavior in the no-apology condition), this effect is non-significant in the apology condition). As predicted, there is evidence of mediation through shame in the no-apology condition (but not in the apology condition (.

Overall, our findings make four important contributions. First, we extend our understanding about the effect of brand transgressions in the context of unethical consumer behavior. Unethical consumer behavior has significant short- and long-term costs for firms and thus, this is an important question. Further, existing research has focused on performance-based (vs. value-based) transgressions. We contribute by examining VBT but additionally, contrast its effects with those of PBT. Second, we resolve the affective commitment paradox in the literature for transgressing brands by identifying some of the key moderating factors which might explain when commitment might have a buffering versus an amplifying effect. Third, we examine sev-

eral theoretically and managerially relevant moderators; both transgression- and brand-related factors. This is an important contribution because not only do these provide a more nuanced understanding of affective commitment's effect but also suggest actionable response strategies to a brand. Finally, we establish a unique mediator of the relationship between affective commitment and unethical behavior toward the transgressing brand – shame, while ruling out alternative explanations such as anger and betrayal for consumer retaliation.

Consumers' Responses to Brand Transgressions: Role of Brand Type and Materialism

EXTENDED ABSTRACT

Marketing literature on consumer-brand relationships has found that a strong brand relationship is beneficial for the brand, such that consumers strongly connected to a brand are less likely to lower their judgments of the brand when faced with negative brand information (Ahluwalia et al. 2000; Swaminathan, Page, and Gürhan-Canli 2007). Research has found that when a brand negatively violates consumers' expectations, consumers process and respond to such transgressions differently, depending on the extent to which the brand is tied to their identity. In particular, the degree to which consumers view the brand as part of themselves (i.e., self-brand connection) mitigate the impact of negative brand information (Cheng, White, and Chaplin 2012). When consumers view a brand as part of who they are, they construe negative information about the brand as a self-threat, which in turn elicits efforts to defend their self-views, including minimizing the brand transgression event.

Building on these findings, the current research examines situations when the buffering effect of self-brand connection is likely to occur. We identify two variables that help address this research question, one relating to the transgressing brand and one relating to the consumer. Specific to the brand-related variable, research has shown different implications such as consumer happiness and satisfaction (Gilovich, Kumar, and Jampol 2015), depending on the type of purchase—whether it is material or experiential. Applying this distinction to brands, we posit that brands can be perceived as more experiential or material as well, depending on which aspect of the brand is salient. The consumer-related variable we include in our framework is materialism, or the level of importance a person places on their possessions (Richins and Dawson 1992; Richins, Mick, and Monroe 2004). We propose that materialism influences the extent of consumer forgiveness of different type of brands (material vs. experiential) subsequent to a transgression. Consistent with prior work, we propose that the underlying mechanism for such effects is the difference in self-brand connection consumers form with material and experiential brands.

We tested our hypotheses across six studies using different brands and varying product categories. In study 1, we examined our proposed interaction effect of brand type and materialism on brand evaluations by manipulating materialism and asking participants to recall a past brand transgression episode of a material versus experiential brand. We find that there was a significant interaction effect of brand type and materialism on brand evaluation, $F(1, 182) = 4.64$, $p = .03$. Specifically, within the high materialism condition, material brands ($M_{material} = 6.01$, SD = .83) were evaluated higher than experiential brands ($M_{experiential} = 5.30$, SD = 1.51). Within the low materialism condition, there was no difference in brand evaluations between material brands ($M_{material} = 5.67$, SD = .91) and experiential brands ($M_{experiential} = 5.66$, SD = 1.11). In study 2, we replicate study 1 findings by employing a different brand type manipulation; we present a single brand and frame

---

1   Note: All t-tests are conducted on groups with ±1sd of affective commitment means.

the brand to be more material or experiential by highlighting different aspects of the brand.

In studies 3 and 4, we demonstrated that the interaction effect of brand type and materialism replicates with our proposed mediator of self-brand connection, the extent to which consumers incorporate brands into their self-concept. Study 3 manipulated participants' materialistic mindset and then presented a single brand Nike to be seen as experiential or material. Results revealed a significant interaction between the two factors, $F(1, 173) = 3.87$, $p = .051$. When Nike was viewed as a material brand, participants in the high materialism condition indicated higher self-brand connection with Nike ($M = 47.00$, $SD = 23.83$) versus those in the low materialism condition ($M = 35.99$, $SD = 23.44$; $F(1, 175) = 4.46$, $p = .036$). On the other hand, there was no difference between high and low materialism conditions when Nike was viewed as an experiential brand ($F(1, 175) = 1.94$, $p = .165$. Study 4 conceptually replicates study 3 findings but using a different brand.

Study 5 and 6 tested our full theoretical model by investigating whether the interaction effect of brand type and materialism on brand evaluation is mediated by self-brand connection. Specifically, study 6 replicated study 5 by using a fictitious brand to control for any prior beliefs about and attitudes toward the featured brand. Results revealed a significant moderated mediation (index = 26.65, SE = 19.23, 95% CI [.13, 76.78] such that the indirect effect of self-brand connection was significant at one SD above the mean level of materialism (a x b = 21.43, 95% CI [1.09, 54.81]) but not one SD below the mean (a x b = -8.22, 95% CI [-37.01, 14.42]). That is, self-brand connection was a significant mediator only among high (and not low) materialistic individuals.

Overall, our findings make several theoretical contributions. We extend the brand transgression literature in showing that subsequent to a brand committing a violation, consumer materialism influences evaluations of material versus experiential brands by increasing the self-brand connection consumers form with brands. In doing so, we add to the body of work that studies how consumer identity influences judgments after a transgression by identifying two novel antecedents of material/experiential brands and materialism. Moreover, we contribute to the purchase type literature in demonstrating that the material versus experiential dichotomy can be applied to perception of brands. This enables us to bring together the purchase type and the brand transgression literatures and proposes a novel dimension that brands that can be differentiated on, which is important in understanding how consumers respond to negative brand information. Finally, we contribute to the materialism literature by identifying a novel consequence of materialistic mindset. While past work suggests that a materialistic mindset generally has negative consequences (Bauer et al. 2012; Dittmar et al. 2014), our work demonstrates that high materialism buffers against negative information for material (vs. experiential) brand. This finding suggests that materialism does not always result in negative outcomes, particularly in the context of brand transgressions.

SESSION OVERVIEW

Text analytics is becoming increasingly popular. From consumer reviews to social media posts, marketers are realizing the value of language and beginning to collect and analyze massive amounts of text.

Despite this, many researchers use only the most basic approaches, pairing simple word counts with t-tests or regression. What unique approaches are researchers developing? And how might we combine existing text analytics with novel methods to cultivate fresh insights?

This session draws on researchers from marketing to computer science to answer important questions using new approaches. How do we model the flow of conversation and its consequences? How might we trace consumer trajectories over time as they gain expertise? What words best reveal distinct groups of consumers and their vocabularies? Can we use text analytics to capture networks of online influencers and competing brands?

Li, Packard, and Berger show the power of functional data analysis and machine learning for parsing and understanding conversational dynamics. Across 200 real-world customer service calls, they find there are pivotal moments within a conversation where employees must emphasize warmth or competence. Increasing emotion at both the beginning and ending of a conversation predicts positive customer perceptions, whereas cognitive language should be emphasized in the middle.

Rocklage, Rucker, and Nordgren demonstrate how growth curve modeling can be used to trace emotional trajectories as consumers gain expertise. Across 70,000 individuals, for each additional wine or beer they taste, consumers' language becomes more emotionally numb. These results replicate comparing professional movie critics and lay consumers across 3 million Rotten Tomatoes reviews. Experiments show this numbness can be explained by cognitive frameworks experts develop and then apply to the domain.

Hovy, Melumad, and Inman introduce a text analytics tool called *Wordify*, which uses machine learning to identify words that best discriminate between groups of interest. As one way of demonstrating its unique value, the authors analyze 60,000 TripAdvisor reviews that were written either on a PC or smartphone. Using their bottom-up approach, they find that reviewers on smartphones not only use more emotional language than those using PCs, but emotional language that is also more intense.

Junqué de Fortuny and Lee use a combination of machine learning, network analysis, and text analytics to identify and track networks of influencers. Their bottom-up approach allows them to understand how brand reference groups are dynamically created and how the new age of online celebrities imbue brands with cultural meaning. For example, they identify a "moms" social influencer network that appears to be driven primarily by brand sponsorship, thereby highlighting firms' ability to successfully influence brand meanings and reference groups.

With a special focus on text analytics, these papers answer the call to introduce novel methodologies and perspectives. This session should have wide appeal to researchers interested in text analysis, language, and real-world big data as well as those studying emotion, brands, word-of-mouth, and consumer networks. We invite others to join us in peering beneath the calm surface of text analytics in order to spark ideas for collaboration and gain unique consumer insights.

Dynamically Solving the Self-Presenter's Paradox: *When* Customer Care Should be Warm vs. Competent

EXTENDED ABSTRACT

Consumer conversations are dynamic. People chat with each other online (discussion boards, texting, social media) and debate word of mouth opinions in the "real world." Salespeople try to persuade potential buyers who sometimes push back, while call centre workers talk with customers to help resolve their issues. These important consumer interactions are not monologues, but dynamic dialogues between people.

While conversations are a central feature of consumer life, they can be remarkably difficult to analyze. They entail a messy series of conversational turns with dramatic variation in content and importance. These challenges may be why most prior language research examines texts or speech acts as singular, static events (e.g., Kronrod et al. 2011; Packard, Moore, and McFerran 2018).

But a more granular view may be important. Clearly some parts of conversations may matter more than others, but which parts might those be, and how can researchers identify them? We introduce a novel method allowing researchers to not only examine whether language matters, but *when* it matters. Specifically, when different linguistics features in different parts of conversations play a larger role.

To demonstrate this approach, we explore a test case around what are said to be the two most important dimensions of person perception—warmth and competence (Abele and Wojciszke 2007; Fiske, Cuddy and Glick 2007). It's difficult to seem both warm and competent. Trying to be more emotionally-concerned impedes perceptions of competence, while acting in a more rational, cognitively-

oriented manner makes people seem less warm (the warmth / competence trade off or "self-presenter's paradox"; Godfrey, Jones and Lord 1986; Holoien and Fiske 2013; Wang et al. 2019). As a result, prior work suggests people should prioritize just one of these two modes in a given social interaction.

However, speaking only warmly or competently may not be ideal. For example, service agents are supposed to show they care, but also that they are thinking through and trying to solve the customer's problems (e.g., de Ruyter and Wetzels 2000; Parasuraman et al. 1985; Spiro and Weitz 1990).

We suggest that *when* agents speak warmly vs. competently is important. Specifically, more affective language at the beginning of an interaction may be important to build rapport over the customer's issue. That said, it is also important to turn to a more analytic, cognitive style when trying to competently solve that issue. Finally, given the work on recency or end effects (Greene 1986), closing with affective language may be key to leaving the customer feeling positive about the interaction. Our approach uses dynamic quantitative modeling to test this possibility.

Data. We obtained 200 audio recordings of customer service calls from a large American retailer. As a dependent measure, the firm provided end-of-call perceptions of employee helpfulness (1 = not at all helpful, 4 = very helpful). A transcription company converted the recordings to text. Each conversational turn was treated as a separate record (e.g., turn 1 (agent): "How can I help you?", turn 2 (customer): "I can't find (…)"), resulting in 12,410 turns for analysis. The time-series of turns is standardized over all calls (time = 0-1).

For our independent measures, we captured affective versus cognitive language using validated linguistic dictionaries (affective processes, cognitive processes; LIWC; Pennebaker et al. 2015) for both the employee and customer. Controls included customer attributes (e.g., gender, lifetime expenditures), employee attributes (e.g., tenure, quality ratings), customer language, and conversation features (e.g., issue, severity, linguistic synchronicity).

Method. We use methods from functional data analysis (FDA; Ramsay and Silverman 2007) and machine learning (Yang and Zou 2015; Kong et al. 2016) to address the challenges of analyzing conversational language. This integrated approach enables data-driven identification of time-based functions (curves) of conversational features (e.g., language) significantly linked to the outcome of interest (e.g., perception of the other speaker). For any set of conversation feature(s), this method produces sensitivity curves that can deviate over time either positively or negatively from non-significance (zero line) in relation to the outcome of interest.

Results. Results support our theorizing. Areas shaded in blue reveal the importance of more cognitive language in the middle 50% of the call. That said, as shown by the negative effect of cognitive language at the beginning of the call, employees who try to jump straight into using cognitive language at the call's opening-- perhaps attempting to quickly and competently solve the customer's problem-- generate significantly negative social perceptions (blue shaded area below the zero line). Instead, affective language has the most positive effect at the beginning and end of the call.

The average employee's use of both affective and cognitive language does not follow the optimal functional forms. Instead, the agent's use of affective language is at its lowest point at the start of the call, when it is particularly important, while cognitive language is near its lowest point between 12.5% and 40% into the conversation, which our method reveals is when it offers its most positive impact on social perceptions.

Discussion. This research begins to shed light on a richer theory of conversational dynamics. While a great deal of work has looked at word of mouth in general, *when* different linguistic approaches are most useful in conversation has received little attention.

Our results show that customer service employees should try to be warm and competent, but at different times in the conversation. Further, this is just one example of how this approach can be used to understand conversational dynamics. The same approach could be used to understand other linguistic features thought to be beneficial such as concreteness, asking questions, or using long sentences (Castleberry et al. 1999; de Ruyter and Wetzels 2000; Schellekens et al. 2010) in customer service, or studying word of mouth, negotiation, message recall, or other important marketing subjects.

The Numbness of Expertise: Emotional Trajectories in the Development of Expertise

EXTENDED ABSTRACT

Expertise provides numerous benefits. Experts process information more efficiently (Johnson and Mervis 1997), remember information better (LaTour and LaTour 2010), and often make better decisions (Mitchell and Dacin 1996).

Yet, expertise may also carry a cost. Specifically, we propose that as consumers accrue expertise in a hedonic domain, they become increasingly emotionally numb to their experiences.

Building expertise leads to cognitive structure – i.e., knowledge – for how to understand a domain (Alba and Hutchinson 1987). Though this knowledge is often beneficial, it may also lead consumers to engage in an analytical dissection of their experience and thereby detract from it. Take, for example, the movie critic who uses their knowledge to analyze and decompose a comedy, thereby undermining the experience. Given that people engage in consumption for the very feelings it evokes (Holbrook and Hirschman 1982), expertise may have the ironic effect of decreasing feelings for those consumers most interested in a domain.

Study 1 provided initial evidence in a naturalistic setting. We obtained all reviews from the movie website RottenTomatoes.com, which includes reviews from both professional critics ($n_{critics}$ = 5,780) and lay consumers ($n_{consumers}$ = 642,681) across 8,627 movies ($n_{reviews}$ = 3,009,095□). We quantified the positivity and emotionality of reviewers' language using the Evaluative Lexicon (EL; Rocklage, Rucker, and Nordgren 2018; Rocklage and Fazio 2020). Using mixed modeling and controlling for how positive or negative a review was (its extremity), critics expressed less feeling than consumers. This result held controlling for review length, movie genre, and the normative emotion evoked by the movie. For this and all studies, results held across positive and negative emotion.

Studies 2 and 3 used advances in statistical modeling to trace the accumulation of expertise across time via growth curve modeling (see Bolger and Laurenceau 2013). Using CellarTracker.com and BeerAdvocate.com reviews (McAuley and Leskovec 2013), we followed 71,610 consumers as they developed expertise in wine and beer, respectively ($n_{reviews}$ = 3,175,143). Controlling for review extremity, consumers showed consistent decreases in feeling toward each additional wine or beer they reviewed. These results held controlling for review length, the total reviews that user wrote, gender, age, and the normative emotion evoked by each item. They also held for reviewers' *most* emotional reaction in each review, indicating that experts did not reach the same emotional heights as when they first began.

Study 4 examined this phenomenon in the lab and generalized it to professional photography. We showed participants (n = 102) 10

randomly-selected photographs (5 positive and 5 negative; Kurdi, Lozano, and Banaji 2017). After each photograph, participants indicated the emotionality and extremity of their reaction using an EL adjective checklist (Rocklage and Fazio 2015, 2016)the adjectives – individuals use can be harnessed to understand the different aspects of their attitudes. The present research introduces a novel approach to measuring attitudes that allows researchers to quantify these aspects. In Study 1, we created a list of 94 evaluative adjectives and asked participant judges to rate the implied valence, extremity, and emotionality of each adjective. This approach allowed us to quantify each adjective along these dimensions and thereby create the Evaluative Lexicon (EL. They then reported their expertise in photography (Carlson et al. 2009). This study and all the following use mixed modeling and control for extremity. The more expertise consumers had, the less feeling they had in reaction to each photograph.

Study 5 tested the proposed mechanism: experts develop a cognitive framework that, when applied, leads to decreases in feeling. It also generalized the effect using a different emotion measure. We used the same design as Study 4, but participants (n = 452) were randomly assigned to one of three conditions. Those in the Expertise condition went through a learning module on the characteristics that experts use to understand the quality of a photograph (e.g., the message it is attempting to convey, lighting, etc; Sethna 1992) and asked to apply that learning. As a control condition, those in the Expertise-Without-Learning condition were asked to engage with the photographs as if they were an expert photographer, but not provided any learning. Another control condition was not provided the framework nor any specific instructions. After each photograph, individuals indicated the intensity of their emotions using the Self-Assessment Manikin (Bradley and Lang 1994)arousal, and dominance associated with a person's affective reaction to a wide variety of stimuli. In this experiment, we compare reports of affective experience obtained using SAM, which requires only three simple judgments, to the Semantic Differential scale devised by Mehrabian and Russell (An approach to environmental psychology, 1974. Those in the Expertise condition experienced less feeling after each photograph versus control. Expertise-Without-Learning participants showed no difference from the Control or Expertise conditions, indicating that the cognitive framework was key for emotional numbness.

Study 6 was preregistered (https://bit.ly/32cZMvh) and examined whether mere knowledge of the cognitive framework was enough to decrease emotion or whether individuals must actively apply it. Participants (n = 605) were assigned to one of three conditions. Those in the Mere Knowledge condition went through the learning module from Study 5, but not instructed to apply their learning. Instead, they were told we simply wanted to understand how clear the module was for future research. Those in the Application condition were instructed to apply their learning. Control participants were not given the framework nor any specific instructions. Participants used EL checklists to indicate their reactions. As preregistered, those in the Application condition felt less emotion toward each photograph compared to Control. Those in the Mere Knowledge condition showed no difference from Control. These results indicate consumers must apply the framework and that mere knowledge is not sufficient.

Across multiple domains, as consumers develop expertise, they become increasingly emotionally numb. This was evident using both traditional experimental approaches and growth curve modeling, which allowed us to track consumers' emotional trajectories as they gained expertise. Though this effect could be the result of multiple processes (e.g., hedonic satiation), we show that it can result from the cognitive structure experts develop and apply. Whereas past research has focused nearly exclusively on the benefits of expertise, we show that expertise can also have negative side effects: the pursuit of expertise can detract from the very experiences experts chased in the first place.

Wordify: A Tool for Discovering Consumer Vocabularies

EXTENDED ABSTRACT

There is currently growing interest in how consumers use words to express thoughts, feelings, and preferences. In this work we describe a new, easy-to-use online tool for automatic vocabulary discovery named *Wordify* that identifies the words most associated with different *a priori* categorizations of text. Unlike other text-analysis tools that may be familiar to consumer researchers (such as LIWC or LDA), *Wordify* does not seek to provide a summary measure of sentiment or a characterization of latent topics, but rather a list of words that are most predictive of different classifications that are of *a priori* interest to researchers. The tool has multiple domains of potential application, including:

1. *Exploratory analysis*: Discovering the vocabularies that consumers use when discussing a given topic (e.g., products, service experiences);
2. *Hypothesis testing:* A means of testing hypotheses about differences in word use across contexts (e.g., are the words most commonly used in reviews written on phones more emotional than those most commonly used in PC-generated reviews?);
3. *Augmentation:* When used in conjunction with tools such as LIWC and LDA, *Wordify* can yield deeper insights into the words that drive classifications produced by such methods; and
4. *Dictionary expansion:* The tool can be used to expand the dictionaries of bag-of-words text-analysis tools (such as LIWC) so that they provide more accurate measure of sentiment.

One of the main advantages of Wordify is its usability. The tool is freely available online (https://wordify.unibocconi.it/index; temporary user password 0981), and requires only the upload of a .csv file that includes text and a dichotomous classification variable of interest. The resulting output is a list of words that are most predictive of the classification, along with a measure of their degree of predictive validity. In this way, the tool can be seen as analogous to discriminant analysis, but applied to a setting where the predictors are potentially tens of thousands of words in a corpus.

The statistical basis of *Wordify* is randomized logistic regression (RLR, Meinshausen and Bühlmann 2010). Applied here RLR is a method of machine learning that repeatedly fits logistic models to random samples of words in a corpus, and then applies shrinkage or regularization methods to correct for overfitting of these models. The algorithm then computes the relative frequency with which each word in the corpus appears as a significant predictor in each of these models. The final output is the set of words that are most often able to discriminate between categories of interest. By relying on repeated sampling and randomized regularization, the method approximates an "ideal" world where all possible models are estimated, and the model with the best fit is selected (something that is computationally infeasible).

To illustrate the use and output of *Wordify*, consider a recent work by Melumad, Inman, and Pham (2019), who hypothesized that consumer reviews written on smartphones will often be more emotional than that written on personal computers (PCs). The hypothesis is that, because smartphones have a smaller keyboard and screen,

content written on smartphones will tend to be shorter, leading users to convey the gist or essential elements of an experience (in lieu of specific details). Since the gist of one's experience is usually based on the writer's emotional evaluation of that experience, this results in the creation of content that is more selectively emotional when written on smartphones versus PCs.

To test this, we applied *Wordify* to the same corpus of 61,642 *TripAdvisor* reviews analyzed by Melumad et al. (2019). We estimated two sets of *Wordify* models: one identifying the words most predictive of a review being written on a smartphone, and another of those most predictive of a review being written on a PC. The smartphone results yielded a vocabulary of 269 words that were significant predictors in more than 30% of RLR models, and the PC results yielded a vocabulary of 389 words (reflective of the greater number of PC-generated reviews). The partial output from the *Wordify* analysis is reported below.

The results illustrate that, indeed, consumers use different vocabularies when writing reviews on their smartphones compared to PCs. As hypothesized, reviews written on smartphones tended to contain a greater proportion of emotional words. Of the 269 words most predictive of a smartphone-generated review, 18.22% expressed emotionality or an evaluation, while of the 389 words most predictive of a PC review, only 6.43% were emotional or evaluative (Wald Chi-Square = 20.44, $p < .001$).

Perhaps more interestingly, the results reveal that the emotional words used in smartphone-generated reviews tended to be more intense in character than the emotional words used in PC-generated reviews. For example, of the emotional words used, the three that were most predictive of a smartphone-generated review were "amazing", "awesome", and "delicious" (appearing in 59%, 56%, and 53% of all models, respectively), while the three emotional words most predictive of a PC-generated review were "excellent", "wonderful", and "fine" (appearing in 54%, 46%, and 40% of all models, respectively).

While the words used in PC-generated reviews may have conveyed less intense emotionality, more generally, such reviews made greater use of words that were descriptive of the details surrounding the experience itself. For example, the three words that were overall most predictive of a PC-generated review were "restaurant", "dining", and "time" (significant in 58%, 57%, and 57% of models, respectively). In contrast, the three words overall most predictive of a smartphone were "recommend", "amazing", and "awesome" (significant in 59%, 59%, and 56% of models, respectively).

As shown in the above illustration, *Wordify* fills a gap in the growing array of text-analysis tools available to consumer researchers interested in the study of language. Here, the focus is on the individual words that consumers use in different contexts rather than overall patterns such as sentiment (e.g., LIWC) or topics (e.g., LDA). As interest in language grows in the consumer research community, there will be a growing need for similar turnkey tools that can be used by researchers without advanced training in natural language processing. *Wordify* exemplifies such a contribution.

Influencer-Generated Reference Groups

EXTENDED ABSTRACT

In a new "hyperconnected world" where consumers help co-create brand meaning on digital platforms (e.g., Swaminathan et al. 2020), an economy of consumer influencers has developed, where influencers with substantial followings are solicited by brands for mentions on social media (Khamis, Ang, and Welling 2017; Marwick 2015; Senft 2013). Differing from the celebrities in previous marketing research (e.g., McCracken 1989), consumer influencers in digital environments can vary dramatically in terms of their audience, and even consumers with less than 5,000 followers on social media (e.g., "micro-influencers") can now be tapped to support brands. Additionally, these consumer influencers have ultimate control in the publishing of content where they promote brands (Hughes, Swaminathan and Brooks 2019). Finally, these consumer influencers not only provide influence via sponsored engagements, but also through unsolicited opinions on brands and products (i.e. via earned media).

Notably, because of the emergence of the consumer influencer, the potential for brand reference group associations has never been greater. As multiple, similar consumer influencers mention a given brand, followers may repeatedly associate this brand with a certain "type" of person. Decades of research (e.g., Bearden and Etzel 1982; Escalas and Bettman 2005; Berger and Heath 2007; White, Argo, and Sengupta, 2012) have explored how reference groups can influence consumer behavior for brands or products with pre-existing group associations. At the same time, recent commentary suggests that our understanding of *how* cultural meanings are transferred to brands (e.g., how brands gain reference group associations) is still underdeveloped (Batra 2019), particularly from a quantitative, empirical perspective. Because consumers now have digital "megaphones" (McQuarrie, Miller, and Phillips 2013) and are more empowered than ever to shape brand meanings, we chose to explore (1) how influencers might transfer reference group meanings to brands at scale on social media, along with (2) the role of brand sponsorship and endorsement in instigating this meaning creation.

We analyzed a dataset of over 377,404 social media posts by 745 US-based consumer influencers on Instagram, generated through a major social media influencer search engine. First, we identified potential reference group categories by analyzing the text of all influencers' *Instagram* profile bios, which provide self-description of key roles and identities (e.g., "fitness enthusiast", "dog mom"). We consolidated the most frequent self-descriptions and used crowdsourced tagging (via an mTurk survey of 317 participants) to identify additional reference group categorizations for each influencer. We also processed users' bio photos through Microsoft Azure's deep learning FACE API to generate demo-faceo descriptives for the influencers in our dataset. Finally, using a series of nested (hierarchical) logistic regressions alongside a bi-partite network graph (containing 24,518 nodes and 94,807 edges), which we reduced via a Singular Value Decomposition exercise (SVD), we confirmed that several of our identified reference groups were uniquely different in terms of their social media tagging and mentioning behavior.

We then analyzed the brands that were uniquely associated with specific, discernable reference groups in our dataset. As an example, we considered the reference group category of "moms" mentioning the apparel brands in our network graph. We developed a weighted bi-partite graph to provide a visual representation of the connection between apparel brands and our mom reference group. This graph was weighted based on the following size of each influencer, such that macro-influencers exerted greater "pull" than micro-influencers on the positioning of each brand in the graph. A Fisher exact test with Bonferroni correction revealed five brands (Gap, Gap Kids, Express, Old Navy, and J.Crew) significantly associated with the mom reference group. To explore the underlying mechanism of this association, we applied keyword detection (Anderson and Simester 2013) to identify call-to-action and sponsorship signals (CTAs) which signal intent to advertise. Adapted mediation analyses using a Poisson generalized linear model suggested that these unique brand-reference group associations appear to be driven by brand sponsorship and

endorsements of these influencers. At the same time, evidence of unpaid chatter (e.g., for Gap Kids by mom influencers) was also evident based on our mediation analyses.

Our work builds on major ideas in consumer research on branding and social groups (e.g., Bearden and Etzel 1982; McCracken 1986; Solomon 1983), particularly on how brands gain cultural meanings from celebrities (e.g., McCracken 1989) and other cultural artifacts. We extend this research to a new era of social media, in order to quantitatively explore the emerging relationship between brands and consumer influencers. Leveraging tools from Natural Language Processing, network analysis and computer vision, we find that brands are connecting to distinct reference groups in social media, and that these brand-reference group associations can be driven not only by organic brand chatter (e.g., brand mentions in everyday conversation), by also by brand sponsorship and endorsement as part of a reference group branding strategy. Through this work, we hope to help build a bridge between longstanding cultural and sociological theories in consumer research and novel computer science methods, to provide new insights into the emerging digital era of influencer-driven marketing.

Paper #4: Offline *Is* The New Luxury? Consuming Digital Detoxing
Mariam Humayun, University of Ottawa, Canada

SESSION OVERVIEW

Embracing this year's ACR theme of enlightenment, we would like to critically examine the complexities of human-object interactions in modern consumers' lives (Epp and Price 2010; Hoffman and Novak 2018). In this special session we are exploring counter trends to abundance and excess in various contexts, e.g. digital and physical decluttering, home organization, and home renovation.

Consumers' lives are stuffed with 'things', be it offline or online (Miller 2008; Johnson 2010). While some consumers still follow a consumerist logic and accumulate objects, there has been a counter quest for *letting go,* reducing*,* and curation of spaces and belongings – be they physical or mental. The need for reducing chaos in our lives has remained consistent, be it in the ethos of voluntary simplicity or going off to live in the hippie communes of the 1960s (Schor 1998). This need to "make sense" and to reach a "better place" has become more pressing.

Drawing on various theoretical lenses ranging from the themes of pollution, conflict, implacement, to consumer resistance, the papers in this session bring up manifold questions: How are consumers in various contexts letting go of objects in their offline and online lives? Some of these consumers are focused on improving their homes to become idealized spaces. Others are engaged in reducing the clutter from their digital lives following the ethos of digital minimalism. What are the differences and similarities of these practices? Decluttering can range from permanent dispossession such as selling off a house to live off-the-grid, to more temporal states such as turning off all social media for a day. What role does temporality play? This de-cluttering takes place in "spaces" that are constituted as tangible (offline) to the more ephemeral (online). What is the role of materiality? How has the Covid19 pandemic affected some of these acts of *"letting go"*?

The first paper *"Consuming Order & Discipline"* derives the key concepts of order and pollution to understand the rise of consumer disciplinary mechanisms in professional home organization services. Findings show how two contesting regimes – the polluting ingestion regime of consumption and the disciplinary dietetic regime of organization – govern consumers' perceptions of self, home, and life.

Next, the paper *"Home Sweet Home: How Consumers Regain Implacement in Creating the Place of Home"* contributes to the theory of place through an examination of how consumers return to a more balanced equilibrium by way of the transformation of renovat-ing a home. The study analyzes the rituals consumers engage in to reach "implacement" – feeling "at home."

The third paper *"Freed from Desire: Consumers' Escape from Market Ideologies Through Decluttering Practices?"* highlights the conflicts that consumers face when dispossessing objects and explores consumer motives for divestment processes that focus rather on the societal consumption ideologies that may hinder the disposal process.

The final paper *"Offline Is The New Luxury? Consuming Digital Detoxing"* examines the emptiness and entanglements of the digital world and how consumers are engaging in digital detoxes and letting go of their digital devices and social media as a new form of consumer resistance.

Consuming Order and Discipline

EXTENDED ABSTRACT

Consumerism and materialism are placed under a strict dietetic regime through the institutionalized insistence that we own too much stuff (e.g., Bennett, 2012; Czarniawska and Lofgren 2013; Herring, 2014; Löfgren, 2012). Consumers continue to buy and accumulate material objects in order to feel secure or to compete with referent others (Schor, 1998). Whybrow (2006) argues that American consumers accumulate experiences and possessions at a rapid and unhealthy pace due to the accelerating work-spend-consume cycle. Similarly, longing for something more is often our response to a sense of imbalance and insecurity as well as the desire for more passion in life (Barton, 2014; Charland, 2014; Williamson, 1985). One response is to acquire and accumulate ever more possessions (Flanders, 2007).

No matter what drives us to buy more and possess more, our increasing inventories of possessions lead to the formation of what we and others perceive as clutter and chaos in our homes and offices. Consumer advocates and market agents have begun problematizing and stigmatizing over-consumption and excessive accumulation, and at the same time medicalizing and destigmatizing practices now called hoarding, obsessive compulsive disorder, and addiction, equating these practices with mental disorders (Belk, 1985; Frost and Steketee 2014; Hirschman, 1992; Kasser, 2002; O'Guinn & Faber, 1989; Richins & Dawson, 1992; Rook, 1987; Schor, 1998; Van Ameringen et al., 2014). Hoarding joined the others as a psychological disorder in DSM-5 (American Psychiatric Publishing, 2013).

Recent and ongoing criticism of consumerism and hoarding behaviors has revised societal definitions of order and disorder, cleanliness and dirtiness in North America. Such criticism also promotes a new desire for order and discipline. As well it has renewed social expectations and definitions of the ideal consumer-citizen.

Based on our research with a professional organizing firm and its clients, the aim of this paper is to unpack their co-constructed disciplinary processes. As consumers become bound by these new practices, the institutionalized regimes of order and discipline act as a domestic "diet." Our analysis of this intersection of materiality, home dietetics, and consumerism, shows that the vicious cycle of discipline/order and regression/disorder binds our self-image and mental health to the way we manage our over-stuffed homes and bodies.

Our collaborative study of professional organizers and their clients, also shows that the construction of order and discipline is

actively mediated by the interactions between these market agents and consumers. We find that transitions within a person's life create a psychological burden and increase levels of uncertainty and instability in their lives. Too much consumption, too many possessions, and too much failure in multi-tasking are other sources of domestic disorganization. Like dietary restrictions, home organization in the current study is viewed as a learnable skill and a "consumer-intensive" practice (Fischer et al., 2009), since consumers have to engage and commit to keeping up with prescribed new tasks and ordering systems to achieve desirable outcomes.

The societal obsession with home order and organization is similar to our obsession with slim and well-kept bodies. A cluttered home is seen as synonymous with an overweight body. In both cases programmatic dietary restriction is promoted as one way to achieve societal ideals. Professionals (e.g., dietitians and professional organizers) act as coaches who help in structuring and implementing these regimes. Disorganization becomes misconduct and therefore is seen to require regulation and treatment. Our findings also show that new organizational practices demand a new lifestyle for consumers who desire disciplined lives that consolidate their "good citizen-consumer" identities.

We find that the order-construction process encourages self-governance while simultaneously setting norms that are difficult or impossible to realistically achieve. The reinforcement of organizational concepts not only alters consumer practices but also introduces a new and harsh regime to their everyday lives. A clutter-free home is first collaboratively staged by professional organizers and clients through purging and ordering. Order and disorder as well as cleanliness and dirtiness are not purely abstract and depersonalized constructs. Rather, they are suffused with moralization, empathy, and sorrow (Herz, 2012; Kelly, 2011). When inevitable backsliding into clutter, disorder, and chaos occurs, a medicalized rationalization of disease averts blame and self-disparagement.

Being organized is now framed as a life choice. Society sets new standards, rules, and regulations. The market responds with systems to discipline and monitor our bodies and homes. Marketplace organizing services are offered to administer and reinforce these standards. Despite their empathetic intervention, new disciplines generate fear, anxiety, and discomfort. We discuss the discursive formation of these disciplinary discourses and show how dietetic principles render our homes, minds, and bodies as "disciplined spaces."

Home Sweet Home: How Consumers Regain Implacement in Creating the Place of Home

EXTENDED ABSTRACT

The home is an important consumer place. Historically, consumer researchers have come to understand the importance of the home as foundational in building "the good life" (Belk and Pollay 1985, 891), which at its core involves the quest for 'homeyness'—a culturally constructed state that consumers create through a constellation of material resources within the home (McCracken 1989). The home is where consumers enact authentic personal and family identities and practices (Epp and Price 2008, 2010; Tian and Belk 2005; Wallendorf and Arnould 1991), such as the identity of 'father' (Coskuner-Balli and Thompson 2012) and other gendered identities (Moisio, Arnould, and Gentry 2013). Within the home, consumers also enact taste regimes as they build social distinction and high cultural capital through the display of fashion, wealth, and elite tastes (Arsel and Bean 2013; Holt 1998; Üstüner and Holt 2009) while communicating and negotiating cultural norms and moral beliefs (Dion, Sabri, and Guillard 2014).

Throughout this literature, the home emerges ubiquitously as a place in Western culture where consumers act out identities, relationships, and build social distinction. However, this perspective portrays the home as an inert entity, a "receptacle for material and social objects… an arena in which objects [are] socially arranged and re-arranged" (Prior 1988, 88). For example, Bourdieu (1973, 102) adopted a Newtonian worldview of space in which "the house is organized according to a set of homologous oppositions," meaning that the home comes to stand as an objectified reflector of social life (Prior 1988). Such is the "disenchantment of place and its reconfiguration as a mere subdivision of universal space, inert and homogeneous" (Sherry 2000, 274). This prior literature tends to regard place as an inert platform upon which consumers engage in social activity, but overlooks the human condition that is entwined with place. The philosopher Edward Casey sensitizes us to this dynamic.

In his theory of place, Edward Casey (1993; 1998, 6) directs our attention to a predicament of the human condition in which people seek a feeling of being in place, or "to achieve the assurance offered by plenitude of place" as an antidote to "place panic; depression or terror even at the idea, and still more in the experience, of an empty place." The quest to achieve a "plenitude of place" is driven by a fear of "the void of no-place [which] is to be avoided at almost any cost" (Casey 1998, 6). At the extreme, this void of no-place, or "terror of the void" (Sherry 2000, 274), is evident when considering, for example, the trope of immigrants as an uprooted people (Bodnar 1985) who are obliged to "leave the place of [one's] birth to seek safety, opportunity, or even basic necessities of life" (Peñaloza 1995, 83); the struggles of homeless people who fantasize about living in a permanent home while coping with their displacement (Hill 1991); or the vulnerability of people who lose their homes as a result of a natural disaster (Baker, Hunt and Rittenburg 2007). Just as Roux and Belk (2019) note that one's body is the ultimate place of origin and destination that one cannot escape, Casey's work sensitizes us to the idea that having a place we call home is not an option.

To build an understanding of the dynamic of the human condition that is entwined with place, we engaged in an ethnographic exploration of the home renovation marketplace in which consumers find themselves on seemingly endless quests to modify their well-functioning homes. This paper examines how the quest for plenitude of place—implacement—which is grounded in the existential threat of no-place, shapes the home renovation marketplace and consumers' behavior around the modification of their homes. In so doing, we address three research questions: How does the fear of no-place manifest in a context in which the consumer does not fear literal physical displacement from one's home? How do modifications to the home help the consumer address this fear of no-place? What role do media and marketers play in our understanding of the place of home and the consumer quest to modify this place?

We contribute to the theory of place with an in-depth examination of the home renovation marketplace that comprises media observation, participant observation in home renovation shows, and longitudinal depth interviews with consumers engaging in home renovations. We draw on Edward Casey's (1993; 1998; 2009; 2017) theory of place as the lens through which to understand our data. We find that through media portrayals of the home, consumers are confronted with an anonymous gaze that admonishes them for portrayals of uniqueness within the home. The cosmogenic origins to which the home is thought to align is dysplaced—socially re-engineered—through this anonymous gaze. This invisible presence leaves consumers with an uneasy feeling within one's home, setting the consumer on a path of renovation and subsequent displacement—physical dislocation—during the renovation. As such, the home emerges as

a place where the consumer's quest for implacement is constantly impeded by forces of dysplacement and displacement.

Freed from Desire – Consumers' Escape from Market Ideologies Through Decluttering Practices?

EXTENDED ABSTRACT

Consumers in western countries have come to a place of material abundance. In 2019 Americans spent, on average, $ 1.497 per month or nearly $ 18,000 per year on non-essential goods (Backman, 2019). This material abundance has left many consumers living in cluttered environments (Arnold, Graesch, Ragazzini, & Ochs, 2019). One estimate suggests that the average American home is filled with about 300,000 things (MacVean, 2014). Clutter is defined as an "… overabundance of material possessions that collectively create disorderly and chaotic home environments" (Roster, Ferrari, & Peter Jurkat, 2016, 32). As a solution to the problem of abundance, consumers start the disposal of objects, which has grown into a consumption trend (Cwerner & Metcalfe, 2003; Löfgren, 2017).

Prior research on disposal focused on the role of consumer's identity (Lastovicka & Fernandez, 2005; Price, Arnould, & Folkman Curasi, 2000) and the transfer of meaning trough divestment processes (McCracken, 1986). Building on the theory of the extended self, Belk (1988) it is theorized that consumers let go of objects that no longer serve the purpose of maintaining or extending the self-concept (Kleine, Kleine, & Allen, 1995; Lastovicka & Fernandez, 2005; Trudel, Arg, & Meng, 2016).

Thompson and Haytko (1997) see personal identity as variable and cultural meanings as appropriated in a dynamic field of social relations through dialogue. Often consumers make an effort to live up to culturally prescribed standards of living and being (Schouten, 1991). However, consumers may also engage in modes of resistance against prevailing market ideologies and consumption practices (Gollnhofer, Weijo, & Schouten, 2019; Martin & Schouten, 2014). Resisting certain cultural meanings may cause a greater sense of personal identity than unconsciously embraced meanings (Thompson & Haytko, 1997). Research has shown that disposal processes can be accompanied by internal identity conflicts, feelings of guilt, and ambiguity (Phillips & Sego, 2011). Overall, consumers strive to resolve conflicts around their identity (Ahuvia, 2005). Therefore, we explore the conflicts encountered during the decluttering process.

We draw on the concept of acculturation to explain why consumers move away from market ideologies about object ownership during a decluttering process. The concept of acculturation has previously been applied to the process of risk acculturation for skydivers (Celsi, Rose, & Leigh, 1993), but more often in the context of migration and minorities (Askegaard, Arnould, & Kjeldgaard, 2005; Luedicke, 2015; Üstüner & Holt, 2007). In the context of changed consumer-object-relations and the rise of more liquid consumption, Bardhi et al (2012) started to critically reflect on the role of acculturation and we would like to build on this discussion. The phenomenological experience of consumer's object ownership (e.g. being overwhelmed by abundance and clutter) and dominant Western market ideologies are in conflict, and these conflicts are materialized in a decluttering process. As these conflicts are resolved during the decluttering process, consumers adapt their ideas around consumption, consumer identity, and object ownership.

To understand the conflicts consumers face during the decluttering process, we conducted 8 in-depth interviews with recent declutters and decluttering coaches, resulting in 177 pages of interview transcripts (1.5 spaced). For contextualization and triangulation, we examined series, documentaries, and YouTube videos, popular books, and articles in blogs, and magazines on the decluttering phenomenon. The interviews were systematically coded and analyzed.

From our research, we first distinguished two types of disposal processes. The first type of disposal process has already been studied: Consumers interact with the object and assess whether the individual meaning is still relevant to them. The second type of disposal process involves a reflection, not only on personal meanings but also on market ideologies, which can be materialized in the ownership of certain products (e.g. Zanette & Scaraboto, 2019). So far, we identified four consumer ideologies that consumers may let go of during a decluttering process: ownership, process professionalization, the pursuit of ideals, fear of scarcity. The first market ideology of ownership has already been discussed by Bardhi et al (2017; 2012) and also Belk (2010). During decluttering process consumers reflect on whether they need a physical object. Sometimes they take photos as digital representations or switch to access based services to let go of their physical objects. When consumers let go of process professionalization, they may dispose of the desire to own specialized equipment for certain tasks or events and overall simplify their consumption practices and the belongings involved. Consumers, who let go of the pursuit of ideals, let go of societal expectations regarding trendiness or looking fashionable. Instead they opt for more durable, timeless classic objects after their disposal experience. Consumers may also let go of the expectation to lose weight and adhere to a societal standard of beauty by keeping clothes size to small or very uncomfortable clothes that 'look nice'. Despite living in a world of abundance, consumers may still hold onto a fear of scarcity. Consumers may be prone to respond to deals, special offers, and freebies on the one side and/ or keep consumption objects 'just in case'. They start to realize in the process of decluttering that there is no need to be prepared for every instance in advance.

This study contributes to consumer research by providing insights on conflicting personal and market ideologies. Further, we introduce the concept of acculturation into the debate around disposal. Lastly, we contribute to identity theory by highlighting the role of disposal for the identity process as prior research only saw acquisition as relevant for perpetuating and creating a consistent-self-concept.

"Offline *Is* The New Luxury? Consuming Digital Detoxing"

EXTENDED ABSTRACT

"Take the phone off the hook and disappear for a while" – Vienna by Billy Joel.

Back in the day, it was possible to escape the daily grind of life by simply disconnecting one's phone. There was a time in the early days of the internet and the world wide web when there was a difference between offline and online lives. However, these boundaries have become ever more porous especially in the developed world. When once people used terms such as "BRB" (Be Right Back) or "IRL" (In Real Life), today the infiltration of the digital into our lives is ubiquitous where we are constantly connected and rarely – if ever – *exit* the system.

While social media was once hailed as a utopian technology connecting many, today there has been growing concern about the polarization and tribalism it has created (Lanier 2014; O'Neil 2016; Bauman 2017). Democracies and individual freedom have been threatened by the same technologies that once held the promise of consumer empowerment and liberation (Zuckerman 2019). Social media was designed to hijack our attention by inviting us down vari-

ous rabbit holes led by algorithmic systems (Sandvig et al. 2014; Harris 2016). Social media and our phones were in fact built to be addictive devices that keep us coming back for more content. We as consumers have taken to using free products offered by the likes of Google, Facebook, and TikTok, but there has always been an invisible hefty price to pay. As the saying goes, "if you are not paying for the product, you *are* the product" (Molla 2020).

We live in an era of big data where consumer-generated content has been one of the key drivers of innovation in marketing (Kozinets et al. 2010). While every facet of our lives is becoming ever more digitized, tracked, and monetized (Belk 2013; Kozinets et al. 2017; DuFault and Schouten 2018), there have been growing concerns over our digital futures, be it ethical concerns over AI, the rise of fake news, extensive surveillance through the social credit system, facial recognition technologies, or different forms of trolling and targeting enabled by social media (O'Neil 2016; Eubanks 2017; Noble 2018). Social media and the internet by their ubiquitous nature have become a part of the *background* or the digital *banal* (Dinnen 2018).

Technology often creates a paradoxical relationship where consumers feel connected to each other constantly and at the same time feel alienated by these interactions (Mick and Fournier 1998; Kozinets 2008; Turkle 2011). There has also been a significant erosion of trust in digital technologies of late (Zuboff 2015; Confessore and Kang 2018; Karppi 2018; Zuboff 2019). Consumers are seeking to escape the relentless march of the digital through postdigital consumption (Cramer 2015; Humayun and Belk 2017, 2020). Consumer resistance has found a new meaning online (Penaloza and Price 1993; Heath and Potter 2004; Kozinets and Handelman 2004).

Given that consumers' data is the "new oil" (Lanier 2014; Zuboff 2019) and the recognition that we have given up our privacy in return for free products, many consumers are seeking to resist complete surveillance and reclaim their privacy through engaging in digital detoxes or "going offline". Escaping the digital realm through postdigital consumption has become one form of such mundane resistance. These consumers are to an extent evangelical in their opposition to the cannibalization of the digital realm. Digital detoxing refers to the practice of purging of digital technologies from daily lives for either permanent or temporal periods (Syvertsen and Enli 2019).

This research is based on ethnographic data drawn from consumer interviews, participant observation, archival data, and a netnography focused on subreddits, podcasts, YouTube, social media announcements (e.g. Instagram, Twitter, Facebook posts of "going offline"), alongside blogposts focused on digital detoxing. While these consumers are engaging in digital detoxes, an important part of the experience, ironically enough is sharing the experience online.

There are various degrees to which consumers engage in digital detoxing. Some might give up social media for a week – or even a day – while other consumers are choosing to give up using cellphones or go completely "off the grid" by moving away from cities and living in ecovillages. Consumers often announce their "offline weeks" on their social media accounts and return to post about their offline experiences – be it through blogposts or through email newsletters which have made a comeback. They connect these conversations across disparate social media accounts by using #digitaldetox #offline or #unplugging. Others are also relying on their podcast network to engage in connected digital detoxes hinting at an entanglement (Lupton 2015). Many influencers and gig economy workers in fact have been some of the key figures leading the digital detox movement as they experience burnout from being constantly connected and entangled with the online world. Sharing the digital detox encounter often constitutes an important part of the experience.

Some consumers brand themselves as modern day *luddites* shunning technologies to find life at its core. Others are inspired by the principles of digital minimalism and mindfulness discourses (Newport 2019). Many take to digital detoxing simply because their lives have reached burnout points, especially gig-economy workers or 'influencers' (consumers-turned-entrepreneurs) for whom digital media is their main source of livelihood. At the other extreme are those who are considered "data fundamentalists" who are completely reclaiming privacy by living off-the-grid (Rosen 2010). Marketers are increasingly jumping on the digital detoxing bandwagon by sponsoring events encouraging "no Wi-Fi". For example, Lululemon promoting mindfulness through digital cleansing, the rising popularity of "digital wellness" apps, lifestyle brands like Goop extolling the benefits of being offline, or cities positioning themselves as places to engage in digital detox.

Being offline has become a new form of luxury and status symbol. Ironically enough, it is the tech elites who can afford to take off for offline retreats in the wake of the world they created. The Covid19 pandemic has in fact revealed some of these digital inequalities where only a few can really afford to truly disconnect. Others remain embedded in the vortex of "doomscrolling" or "zooming". Digital detoxes raise important questions about our digital lives and the possibly dystopian futures and the ever-changing social imaginaries that lie ahead.

SESSION OVERVIEW

People often face choices between what they *want* to do and what they think they *should* do. The aim of this session is to explore the consequences of this intrapersonal conflict and to address ways in which consumer behavior can be shifted to better align with what consumers think they should do. In particular, we consider this discrepancy from two angles: first, the impact of the discrepancy on interpersonal judgments and behaviors; and second, the potential nudges that can be utilized to encourage behaviors in line with the "should" self.

The session will open with two papers that examine the interpersonal consequences of want/should conflicts. The first paper will focus on how the want vs. should conflict influences consumers' public vs. private behavior. Specifically, **Lin, Woolley, and Liu** discuss self-discrepancy in health goal motivations. Across seven studies, they show that consumers hide their appearance motivations from others because they feel that they should be less driven by physical appearance than they actually are. In the second paper, **Durso and Haws** discuss observers' perceptions of an agent experiencing a want/should conflict. Whereas prior literature largely deems indulgences as normatively "bad," the authors show that indulgences still generally result in positive evaluations (albeit with greater ambivalence). Thus, they suggest that social judgments of indulgent behavior are less severe and more nuanced than consumers generally perceive them to be.

In line with this year's theme of integrating multiple paradigm perspectives, the final two papers in this session utilize unique methods to nudge consumers into pursuing actions in line with their "should" selves. The third paper, by **Khambatta, Mariadassou, Morris, and Wheeler,** utilizes machine learning models to generate real-time, personalized predictions tailored to consumers' actual or ideal preferences. The authors find that consumers who receive recommendations in line with their ideal (vs. actual) preferences are more likely to report that their time is well-spent after they follow the

recommendation and that they are better off as a result, demonstrating the effectiveness of personalized nudges in improving consumer well-being. Last, **Mehr, Silverman, Sharif, Barasch, and Milkman** take a behavioral economic approach by using an economic game to model the motivational power of attaining a streak. Across five studies, they find that streak-rewarding payments increase persistence in effortful tasks, even relative to higher-paying incentives. These results provide implications for assisting consumers in initiating and achieving "should" goals.

Combined, these four papers examine how want/should conflicts affect both self-presentation and interpersonal perception and also how firms can motivate behaviors in line with what consumers feel they should want. We believe that this session is well-suited to this year's theme of integrating multiple perspectives as these papers draw on a variety of different methods and literatures, including attitude discrepancies, signaling, goal pursuit, self-control, and nudges. We hope that this session will attract a diverse audience and provide fruitful discussion for innovative research regarding this fundamental conflict in consumer behavior.

To Look Good or to Be Good? Holding (but Hiding) Viceful Motivations for Health Goals

EXTENDED ABSTRACT

Academic research treats health behaviors (e.g., dieting, exercise) as virtuous (Berman and Small 2018; Dhar and Wertenbroch 2012; Khan, Dhar, and Wertenbroch 2005; Wertenbroch 1998). We challenge this healthy=virtuous assumption and propose that consumers believe that health behaviors can be vicefully motivated from a moral perspective, with implications for consumers' public (vs. private) consumption behaviors.

We propose that appearance motivations for health are viewed as relatively viceful, as they violate internally held moral values (e.g., humility, concern for society, Beatty et al. 1985; Gurel-Atay et al. 2010; Schwartz 1994) by reflecting excessive pride and self-involvement (Cafaro 2005; Netemeyer, Burton, and Lichtenstein 1995), and perpetuating unhealthy societal standards. However, given the prominence of idealized societal standards for beauty (Richins 1991), consumers cannot avoid internalizing appearance motivations, leading to a moral conflict: although they are actually motivated to engage in diet and exercise to improve their physical appearance, this violates their internally held moral values. We document this self-discrepancy and examine its implications for consumers' public (vs. private) behavior.

Studies 1a and 1b (pre-registered; Ns=86, 100) documented this moral conflict in Asian and Western populations. Participants viewed multiple motivations for pursuing health goals (physical appearance, long-term health, mental health, and physical capabilities). Participants reported how much each motivation reflected their "virtuous" and "actual" motivations. Participants believed that appearance was less virtuous than all other motivations, $ps<.02$. Furthermore, participants indicated that appearance motivations reflected their actual more than their virtuous motivations, $ps<.001$, revealing the predicted moral conflict; by contrast, all other motivations reflected their virtuous motivations equally or more than their actual motivations.

The remaining studies test implications of this self-discrepancy for consumers' public (vs. private) behavior. Because consumers are more likely to act in line with their virtuous "ought" self-standards

in public than private (Baumeister 1982; Goffman 1978; Gollwitzer and Wicklund 1982; Peloza, White, and Shang 2013), we predicted that consumers hide their non-virtuous appearance motivations from others.

Study 2a (pre-registered; N=326) tested the basic effect. Participants chose hashtags for two health photographs (food, gym) to post as part of a private or public review. Those who considered posting in private chose more appearance-related hashtags (e.g., #bikini-body) (M=1.35) than those posting in public (M=.98), p<.001.

Study 2b (N=302) examined real choice in the lab. Participants believed their choices would be observed live by others in the lab session or that they would be private. They chose three articles to read from a set of six (three appearance, three non-appearance) articles. Participants chose fewer appearance articles to read in public (M=1.24) than in private (M=1.50), p = .013.

In Study 3a (N=138), participants were randomly assigned to imagine posting to a private or public Pinterest board. They indicated their likelihood of posting three appearance-related articles (e.g., Beach Body Challenge) and three non-appearance-related articles (e.g., Strategies for Running). Participants were less likely to post appearance-related articles in the public condition (M=1.78) than the private condition (M=2.44), p=.039; this did not occur for non-appearance articles (M$_{public}$=2.91; M$_{private}$=2.90); $t_{interaction}$(296)=2.45, p=.014. We further assessed how much appearance motivations reflected participants' actual and virtuous motivations (as in studies 1a and 1b). This effect was stronger for those with more moral conflict (i.e., who had a greater discrepancy between how much appearance reflects their actual and virtuous motivations), $t_{interation}$(686)=2.00, p=.046.

Study 3b (pre-registered, N=401) examined posting behavior of real Pinterest users. Participants created real private and public boards for health articles. They chose three articles to post from six appearance or six non-appearance related articles, randomly assigned. Participants indicated whether they would post these articles to their private or public boards. Participants posted more pins to their private board when the posts were appearance-related (M=1.66) versus appearance-unrelated (M=1.08), p<.001. This effect was again (directionally) stronger for those higher in moral conflict, $t_{interation}$(397)=1.64, p=.101.

Study 4 (pre-registered, N=594) tested whether framing appearance as secondary to an overarching health motivation increases public sharing. Participants imagined receiving a discount for posting about a healthy meal plan subscription to Facebook. The post described appearance as a primary motivation ("We help you be healthier, so that you can achieve your ultimate goal to look good!"), secondary motivation ("We help you look good, so that you can achieve your ultimate goal of being healthier!"), or did not mention appearance ("We help you be healthier!"). Participants decided whether to incur (a real) 30-second cost to privatize the post (i.e., to make the post not viewable by Facebook friends). Participants privatized the post more in the appearance-primary condition (62.3%) than the other two conditions (collapsed 53.2%), p=.034.

Study 5 (N=324) tested whether people privatize their appearance motivations because they desire to act in line with their moral value systems. Participants were given an ostensibly real choice between two fitness subscription programs that would post daily workouts to their Facebook timelines: "Trim Body Program," (appearance) and "Heart Health Program" (non-appearance). Participants were assigned to one of three conditions: private, public, or private-with-values-reminder. Those in the private-with-values-reminder condition first wrote about why they should or ought to pursue their health goals, as dictated by their moral values. Those in the public

condition were told that the program title would be visible to others. Those in the private conditions were told the workout would appear with a generic "Your Fitness Program" title. Participants were more likely to choose the appearance program in the private condition (56.48%) than either the public (41.28%), p=.026, or private-with-values-reminder (42.99%), p=.049, conditions.

Overall, this research contributes theoretically to the vice-virtue literature, challenging the notion that health pursuits are inherently virtuous. This research also offers practical implications for how marketers should frame health programs to encourage private attention versus public sharing.

No Diet, No Problem: Social Judgments of Consumers' Indulgences

EXTENDED ABSTRACT

How do people judge the consumer who indulges however they "want", rather than restricts as they "should"? Consumption decisions are a common basis for rendering judgments about oneself and others (Belk 1988; Vartanian, Herman and Polivy 2007), especially when decisions involve conflict (i.e., ambivalent feelings; Durso, Brinol and Petty 2016; Keller and Siegrist 2015; Ramanathan and Williams 2007). Research on self-control conflicts and "hedonic consumption," however, has often made strong assumptions that indulgences (e.g., eating pizza) are normatively "bad" whereas restrictions (eating salad) are "good" (Haws, Davis and Dholakia 2016; Shiv and Fedorikhin 1999; cf. Vosgerau, Scopelliti and Huh 2020).

Do consumers evaluate others' indulgent "wants" so negatively compared to restrictive "should" choices? Or, similar to many judgments of their own decision conflicts, do consumers instead feel *ambivalent* about others' indulgences? If so, when? This is critical for predicting consumer behavior, as social judgments of *others* provide invaluable information toward understanding *personal* self-control decisions (Fishbach, Eyal and Finkelstein 2010).

We examine these questions here. Across three studies, participants learned about a target, "Bob," who eats indulgently or restrictively. We manipulated the presence versus absence of a dieting goal (Study 1), the relevance of the behavior (eating vs. spending) to a dieting goal (Study 2), and whether an extraordinary opportunity was present or not (Study 3) when Bob indulged. We focus on two outcomes: How is Bob evaluated (positively vs. negatively), and how ambivalent (e.g., conflicted) do they feel about him?

In Study 1, we examined judgments of Bob in a 2 (dieting goal: present vs. absent) x 2 (behavior: indulgent vs. restrictive) between-participants design. Our findings revealed significant interactions on evaluations, F(1,403)=52.43, and ambivalence, F(1,403)=38.77, ps<.001. *Absent* a diet, evaluations were equally positive whether Bob indulged on pizza (M=7.90) or restricted by eating salad (M=8.22), t(200)=1.30, p=.195. Ambivalence was marginally greater when he indulged (M=4.35) versus restricted (M=3.73), t(200)=1.76, p=.079.

When dieting was *present*, however, evaluations were less positive following indulgence (M=6.31) versus restriction (M=9.25), t(203)=11.48, p<.001. Ambivalence was greater when he indulged (M=6.67) versus restricted (M=3.16), t(203)=11.33, p<.001. In all, participants evaluated Bob less positively (and more ambivalently) when he indulged (vs. restricted) when dieting goals were present. However, Bob was judged equally positively *absent* a dieting goal, regardless of indulging versus restricting.

In Study 2, we examined whether evaluations and ambivalence toward Bob might differ as a function of normative indulgence versus restriction, but now depending on whether his behavior was relevant or irrelevant to dieting in particular. Prior research suggests that

self-control often manifests domain-specifically (Haws et al. 2016) rather than generally (cf. Tangney et al. 2004). As such, Bob was always presented as dieting, but was observed either as eating (goal-relevant) or spending (goal-irrelevant) in a normatively indulgent or restrictive manner.

Results revealed that significant interactions of context (eating vs. spending) by behavior (indulgent vs. restrictive) again emerged on evaluations, $F(1,403)=71.09$, and ambivalence, $F(1,403)=40.94$, ps<.001. Spending was evaluated equally positively regardless of its normative indulgence (buying designer clothing with next-day delivery; M=8.09) or restriction (saving it on his wish list; M=8.43), $t(201)=1.43$, p=.155, with equal ambivalence (Ms=4.27, 4.61), $t(201)=0.98$, p=.328.

When eating, however, his indulgence (ordering "loaded fries") was evaluated less positively (M=6.18) and more ambivalently (M=6.29) than restriction (ordering salad; Ms=9.35, 2.84), ts(202)=13.26, 10.45, ps<.001. Thus, while participants had less positive evaluations (and more ambivalence) toward Bob when he indulged (vs. restricted) in his food choice, this was *not* the case when Bob indulged or restricted himself when *spending* (goal-irrelevant), where he was viewed equally positively and (un)ambivalently.

Finally, in Study 3 we tested another boundary condition by providing a rationalization for indulgent behavior within the domain of dieting. In this case, Bob was *always dieting and always indulging* as in Study 2—whether his indulgence was goal-relevant (eating) or not (spending) and whether his birthday was mentioned (vs. unmentioned) were manipulated orthogonally. Significant interactions of context (eating vs. spending) by situation (birthday vs. unmentioned) emerged on evaluations, $F(1,395)=11.86$, p=.001, and ambivalence, $F(1,395)=5.47$, p=.020. When Bob shopped indulgently, evaluations were equally positive whether his birthday was not mentioned (M=8.45) or mentioned (M=8.47), $t(197)=0.12$, p=.907, with equally low ambivalence (Ms=3.84, 3.91), $t(197)=0.21$, p=.836.

When Bob *ate* indulgently, however, evaluations were less positive when his birthday was not mentioned (M=5.76) versus mentioned (M=6.98), $t(198)=4.45$, p<.001, and reflected greater ambivalence (Ms=6.33, 5.29), $t(198)=3.08$, p=.002. As such, we again found that when the behavior was unrelated to the stated goal, participants evaluated Bob equally positively and with low ambivalence. But, when an extraordinary circumstance was provided (versus not provided), even indulgent behavior directly in contrast to a stated goal was more positively evaluated and with less ambivalence.

In sum, contrary to common assumptions that indulgences represent normatively negative outcomes—via established perspectives in self-control, hedonic consumption, and licensing (Vosgerau et al. 2020)—these studies reveal that even indulgences result in positive evaluations overall. More specifically, the degree of positivity and ambivalence were found to vary as a function of relevant goal information being present versus absent (Study 1) and whether the dieting target indulged in a relevant (eating) or not (shopping) manner (Study 2). Even an extraordinary situational attribution used explicitly to justify the indulgence (Study 3) *improved* evaluations while reducing ambivalence, rather than being negatively evaluated as "excuse-making" (Kivetz and Zheng 2006).

Variation in ambivalence is an especially interesting contribution from these studies, as this is a critical and unique predictor of decision making and social comparison compared with outright negativity (Durso et al. 2016; Petty 2006; van Harreveld et al. 2009; Zemborain and Johar 2007), with clear implications for self-control (Keller and Siegrist 2015). This represents an unappreciated discrepancy between what consumers (and researchers) have characterized as a supposedly "negative" outcome of indulgence based on how

they *ought* to behave (prudently) compared to how they *desire* to behave (indulgently). Overall, we suggest that social judgments of others indulgent behaviors are perhaps less severe and more nuanced than has been assumed.

Customizing Algorithmic Recommendations to Actual and Ideal Preferences

EXTENDED ABSTRACT

Many of people's decisions for what to read, what to watch, where to eat, and what to buy are made on digital platforms. Given the abundance of available options, algorithms often curate the choice set presented to consumers by learning consumers' preferences and providing them with recommendations. Such recommendations can be helpful but can sometimes increase risks to consumer well-being, particularly in cases of biased recommendations (Banker and Khetani 2019; Yeomans et al. 2019). An additional challenge these algorithms face is that consumers often demonstrate discrepancies between what they *actually* want and what they *ideally* want. For instance, consumers might actually want to read about celebrity gossip but ideally want to learn more about personal finance. Both evaluations have been shown to independently influence subsequent information processing and behavior (DeMarree et al. 2017; DeMarree et al. 2014; Milkman, Rogers, and Bazerman 2009).

In this research, we expand on the effectiveness of personalized nudges (Peer et al. 2019) and show that the decisions of recommendation algorithms regarding which types of preferences to target can have important consequences for individuals' consumption patterns and consumer well-being. Specifically, we examine how people respond to personalized recommendations tailored to actual preferences versus ideal preferences. To test this, we built an online recommendation agent that inferred consumer preferences using pre-trained machine learning models hosted on a cloud computing platform.

In the training study (N = 1,003), we collected the data needed to generate machine learning model predictions. We collected participants' actual and ideal preferences for stimuli from a naturalistic context: articles posted on Twitter. For 52 tweets about news articles, we asked participants how likely they were to read each article now and how likely they were to read each article later on 100-point slider scales. Additionally, participants reported how much they actually and ideally wanted to read each article. Using data from these participants, we built machine learning models (random forests) to predict actual and ideal ratings for the ten articles with the largest preference discrepancies. To evaluate the accuracy of our models, we used 10-fold cross-validation, a method in which we generated predictions for 10% of the data at a time using the remaining 90% of the data to train the models. We evaluated the accuracy by comparing the predicted and true values using the following metrics: the average correlations (r), the square root of the average squared difference (*RMSE*), and the average absolute difference (*MAE*). The average accuracy (r) for actual ratings was 0.54 (*RMSE* = 29.93, *MAE* = 25.15), and the average accuracy for the ideal ratings was 0.60 (*RMSE* = 29.52, *MAE* = 24.36). We used these models to generate real-time predictions in the main study.

In the main, pre-registered study (N = 6,488), participants were presented with 42 tweets about news articles and reported how likely they were to read each article now and later. Employing an online cloud computing platform, we used our previously validated machine learning models to generate a real-time personalized recommendation for each participant based on their responses. The study employed three conditions. Participants in the actual (*ideal*) condi-

tion received a recommendation for the article that we predicted they actually (*ideally*) wanted to read the most from the set of ten possible articles. Participants in the control condition were recommended a randomly selected article from the set of ten articles. Participants were asked to report their reactions to the recommendations and were asked if they would rather read their recommended article or an alternative article. Nevertheless, to avoid self-selection effects, all participants read their recommended article and subsequently reported their reactions to the article.

For our initial analysis, we compared both the actual and ideal conditions to the control condition. We found that customized recommendations (vs. random recommendations) resulted in more favorable impressions of the recommendation system and the article along all reported measures. This confirms that the recommendations were customized to participants' unique preferences.

For our primary analysis, we compared the actual and ideal conditions to each other. As predicted, participants whose recommendations aligned with their actual preferences were more likely to choose to read the article than participants whose recommendations aligned with their ideal preferences (52% vs. 40%, $p < .001$). These participants also found more pleasure in reading the article: they reported that they liked reading the article more ($M_{actual} = 4.12$, $M_{ideal} = 3.77$, $p < .001$) and found the article more enjoyable than participants in the ideal condition ($M_{actual} = 4.02$, $M_{ideal} = 3.52$, $p < .001$). However, participants in the ideal condition found the recommendations to be more helpful ($M_{actual} = 3.83$, $M_{ideal} = 4.32$, $p < .001$) than participants in the actual condition and also felt more positively about the recommendation agent. They were more likely to report that the organization generating the recommendation had people's best interest at heart ($M_{actual} = 3.43$, $M_{ideal} = 4.02$, $p < .001$). Finally, after reading the recommended articles, participants who received recommendations tailored to their ideal preferences were more likely to report that their time was well-spent ($M_{actual} = 3.87$, $M_{ideal} = 4.26$, $p < .001$) and that they were better off as a result ($M_{actual} = 3.20$, $M_{ideal} = 4.91$, $p < .001$). Perhaps most importantly for a recommendation service, contrary to the notion that companies must exploit people's actual preferences to increase engagement, we found that those who received recommendations in line with their ideal preferences were more inclined to use the recommendation service again ($M_{actual} = 3.48$, $M_{ideal} = 3.30$, $p = .028$). These results were robust to analyzing the data of only participants who self-selected to read the article.

In conclusion, this research suggests that, rather than exploit people's base desires and recommend content they want to consume (but wish they did not), organizations can benefit from training recommendation algorithms to cater to people's ideal preferences. In doing so, they can also improve overall consumer well-being by assisting individuals in narrowing the gap between who they are and who they ideally want to be.

The Motivating Power of Streaks: Incentivizing Streaks Increases Engagement in Effortful Tasks

EXTENDED ABSTRACT

When faced with a choice between instantly-gratifying distractions (e.g., watching television, browsing Facebook) and exerting effort to obtain delayed rewards (e.g., studying for tests, staying focused at the office), people often favor distractions, only to later regret their choices (Bazerman, Tenbrunsel, and Wade-Benzoni 1998; Kotabe and Hofmann 2015; Milkman, Rogers, and Bazerman 2008; Thaler and Shefrin 1981). One way to increase engagement in effortful behaviors is to make initiation of goal-related behaviors more appealing (Milkman, Minson, and Volpp 2014). Across five incen-

tive-compatible, pre-registered experiments, we find that encouraging consumers to complete streaks via incentives (i.e., paying people for completing three or more effortful tasks consecutively) increases engagement in effortful tasks because doing so feels more game-like.

In Study 1, participants (N=1,104) made five decisions to either engage in a lengthy, effortful task for a bonus payment (looking up the definition of three words) or a shorter, fun task (watching a clip of a popular television show) without a bonus. In the streak-rewarding payment condition, participants were paid for choosing to complete vocabulary tasks consecutively. Participants received a lower reward for the first vocabulary task they completed, then a higher amount for the second and third vocabulary tasks they completed in a row, but returned to lowest amount for the next vocabulary task completed after watching a video. In the flat payment condition, participants received the maximum payment amount from the streak-rewarding payment condition each time they completed a vocabulary task; thus, holding the number of vocabulary tasks completed constant, payment in the flat payment condition was always larger than payment in the streak payment condition. Using a t-test, we found that participants in the streak-rewarding payment condition completed significantly more vocabulary tasks ($M = 2.65$, $SD = 2.30$) than those in the flat payment condition ($M = 2.15$, $SD = 2.17$; $d = 0.22$, $t(1068.1) = 3.69$, $p < .001$).

In Study 2 (N = 421), all participants made 10 choices between completing CAPTCHA tasks (decoding 6 CAPTCHAs) and watching funny videos. Payment amount was varied to establish robustness. Using linear regressions, we found that participants in the streak-rewarding payment condition completed more CAPTCHA tasks ($M = 6.36$, $SD = 3.82$) than those in the flat payment condition ($M = 5.40$, $SD = 4.04$; $b = 1.04$, $t(418) = 2.77$, $p = .006$), and there was no significant interaction with incentive size ($b = 0.93$, $t(417) = 1.23$, $p = .218$). Thus, regardless of magnitude, streak-rewarding incentives encouraged participants to complete more unappealing tasks than larger, flat incentives.

In Studies 3 and 4, we use the same basic paradigm to test which features of streak-rewarding payments lead participants to complete more effortful tasks. In Study 3 (N=712), we compare the two earlier conditions to an increasing payment scheme (i.e., increasing payments for completing non-consecutive CAPTCHA sets). We replicated our finding that streak-rewarding payments ($M = 6.71$, $SD = 3.43$) outperformed flat payments ($M = 5.38$, $SD = 4.29$; $b = 1.33$, $t(709) = 3.62$, $p < .001$). In addition, participants in the streak-rewarding payment condition completed more CAPTCHA sets than those in the increasing-payment condition ($M = 5.98$, $SD = 3.71$; $b = 0.74$, $\chi^2 = 4.76$ $p = .029$), and there was a marginally significant difference between the flat and increasing payment conditions ($b = 0.60$, $t(709) = 1.70$, $p = .089$). Thus, the increasing nature of streak-rewarding payments does not explain the observed difference between streak-rewarding and flat payments.

In Study 4 (N=702), we examine the costly nature of skipping a CAPTCHA set by adding a third streak-without-penalty condition in which payments remained the same, instead of decreasing, after a skipped CAPTCHA task. Again, streak-rewarding payments ($M = 7.03$, $SD = 3.34$) outperformed flat payments ($M = 5.89$, $SD = 4.25$; $b = 1.15$, $t(699) = 3.36$, $p < .001$). Additionally, there was no difference between performance in the streak-without-penalty condition ($M = 6.88$, $SD = 3.38$) and our standard streak-rewarding payment condition ($b = 0.16$, $\chi^2 = 0.18$, $p = .670$). This suggests that decreasing payments after a broken streak is not necessary to harness the motivating power of streak-rewarding payments.

In Study 5 (N = 1,204), we test if streak-rewarding incentives increase persistence in effortful tasks because they make the tasks

more game-like. Participants were again randomly assigned to either the streak-rewarding or flat payment condition. After completing the tasks, participants were asked two items regarding the extent to which the tasks felt game-like (e.g., how much completing the survey felt like a game; $r = .74$). Importantly, we once again replicated the effect of payment condition on number of tasks completed ($M_{\text{streak-rewarding}} = 5.25$, $SD = 4.12$ vs. $M_{\text{flat}} = 4.52$, SD =4.10; $b = 0.727$, $t(1201.90) = -3.07$, $p = .002$). Averaging responses to both questions, participants in the streak-rewarding payment condition indicated that the study felt marginally more game-like ($M = 3.98$, $SD = 2.12$) than those in the flat payment condition ($M = 3.74$, $SD = 1.96$; $d = 0.12$, $t(974.75) = 1.87$, $p = .061$). We also found that the positive effect of the streak-rewarding payments on number of tasks completed was mediated at the 90% confidence level by how game-like the tasks felt (indirect effect = .13, 95% CI = [-0.004, 0.14]; 90% CI = [0.01, 0.25]).

In sum, our work suggests that incentivizing consumers to initiate streaks can increase persistence in effortful tasks, even relative to higher-paying incentives. The results of our research have several practical implications. For example, marketers can offer incentives that encourage streaks via loyalty programs to increase consumer engagement at a lower cost. More broadly, policy makers could harness the power of encouraging streaks to help people initiate and meet important goals, such as those related to health and savings.

Paper #4: Luxury and Consumer Well-being: Using Luxury Products Impairs Women's Self-Control

Yajin Wang, University of Maryland, USA
Deborah Roedder John, University of Minnesota, USA

SESSION OVERVIEW

Conspicuous consumption has been on the rise around the world (Deloitte, 2019). Some consumers buy visible and expensive products to communicate their social status (Han et al. 2010), while others are motivated to bridge the gap between their current and ideal selves through such purchases (Mandel et al., 2017). This special session comprises four papers that examine the causes and consequences of status signaling via product purchases and compensatory aspect of conspicuous consumption. The session broadly contributes to our understanding of how consumers' self-discrepancies affect conspicuous consumption activity, and whether consumers' status signaling efforts actually work and at what cost. The session also helps expand the current scope of research on status-driven and compensatory consumption by examining novel characteristics such as product noise and body-related products as well as by investigating some unintended social and personal implications of engaging in such consumption activity.

The first paper by Lowe, Ward and Ozturk analyzes the status signaling effect of product noise. This examination is important because related research to date has focused primarily on the role of product visibility and brand in status signaling. The authors demonstrate that a product's sound also plays an important role how observers make inferences about consumers' personal qualities and status. Specifically, the authors find that relatively louder products help consumers signal their social dominance to others, whereas relatively quieter products communicate social prestige.

The second paper by Kurt examines the compensatory consumption motivation behind people's jewelry purchases. Based on the compensatory consumer behavior model, this paper argues that jewelry shopping interest and spending will be higher in places with greater obesity rate because wearing jewelry can help people feel better about their looks and reduce their appearance-related self-discrepancy. The data obtained from Google Trends, the U.S. Economic Census on jewelry retail sales, the U.S. Consumer Expenditure Survey, and Twitter support this theory.

The third paper by Blair, Rucker and Lisjak highlights the risk that observers may actually perceive conspicuous consumption as a compensation for one's insecurities rather than as a signal of their achievements. This risk, however, depends on observers' feelings of insecurity. The authors show that when observers feel insecure about their power, they perceive the driver of a more conspicuous car as having lower status than that of a less conspicuous car. As such, taking the perspective of an observer helps consumers realize this unexpected consequence of conspicuous consumption (i.e., being seen as engaging in compensatory consumption), preventing them from paying a premium for a conspicuous item when they feel insecure.

Finally, the fourth paper by Wang and John demonstrates another unwanted cost of conspicuous consumption: self-control impairment after the use of luxury products. The authors argue that using luxury products makes women feel more entitled to fulfill their wants, resulting in lower self-control. Their experiments involving the use of real luxury products and consumption of unhealthy snack lend support for their thesis.

Overall, this session brings together papers that use a variety of methods—experiments, field studies, and archival data analysis— to shed more light on the benefits and costs of conspicuous consumption and status signaling via product purchases.

I am Product, Hear Me Roar: Social Dominance and Preference for Loud Products

EXTENDED ABSTRACT

A billboard advertising Porsche shows a picture of the iconic luxury car and the words "*IT'S LOUD*." On the other hand, Bosch, a luxury appliance brand, positions its dishwasher as the 'quietest model' in the US. It is evident that the sounds products emit contribute to consumers' perceptions of them. In this research, we examine how products' auditory noises function as signals of status.

Expressions of dominance and prestige represent social strategies used to achieve status within a group. The dominance-prestige account of status-striving (Henrich and Gil-White 2001) suggests that social hierarchies arise from two systems of rank allocation: prestige and dominance. The theory states that individuals may increase their social status by engaging in behaviors that express one or both of these qualities. Expressing dominance usually entails behaviors that induce fear through intimidation (Chase et al. 2002), while expressing prestige refers to individuals who influence others by being "considered worthy of emulation" for their skills, access to material resources, or knowledge (Cheng et al. 2013, pg. 105; Cheng and Tracy 2014).

In this research, we relate loud and quiet sounds to these two status-striving strategies. Prior research on non-human primates has established that having a particularly loud call or roar may establish an animal as being more dominant and consequently, having higher status within the pack (Neumann et al., 2010; Kitchen et al., 2003). Likewise, amongst humans, speaking louder or in a deeper voice may afford one a more dominant position in a group (Carney 2020), however, status may also be conferred to those who speak quietly insofar as it signals the refined demeanor of the speaker. To be sure, quiet sounds are more easily ignored or overlooked than loud sounds, however, they are equally effective at signaling product attributes, including high quality (Lageat, Czellar, and Laurent 2003).

Because consumers use products strategically to send desired social signals about themselves, we predict that consumers wishing to express dominance will show a marked preference for louder product sounds, while those wishing to express prestige will prefer quieter products.

The purpose of Study 1 is to demonstrate that using loud products serves as a signal of social dominance, but not necessarily of social prestige. In a 2 (product: loud vs. quiet) by 2 (user intent: purposeful vs. unintended) factorial design, participants imagined observing another individual using a product in public (a truck or a radio). In one condition, participants read that this product was extremely loud, while in the other condition the product is described as quiet. Participants also read that the reason for the unusual volume of the product was either intentional on the part of the driver (a purposeful modification or setting), or unintentional (the result of manufacturer's setting). After reading the scenario, participants were asked about their impressions of the other consumer (i.e. likeable, dominant, submissive, humble, aggressive, high-status, and important they perceived this consumer to be).

An ANOVA interacting intent and product loudness on perceived social dominance was significant ($F(1,443) = 5.66$, $p = .018$). Specifically, when the volume of the product was seen as unintentional, there was no difference between the loud and quiet conditions ($M_{Loud} = 3.61$, $M_{Quiet} = 3.58$; $F(1,443) = .018$, $p = .89$). When product volume was seen as intentional, however, there was a significant difference in perceptions of social dominance between two conditions such that the individual was seen as more dominant when the individual used the louder product ($M_{Loud} = 4.61$, $M_{Quiet} = 3.95$; $F(1,443) = 12.08$, $p = .001$).

In Study 2, we tested whether consumers use auditory sounds to express social status. First, student participants were instructed to imagine that that they were preparing a presentation that they would give at a later date to win a Business Leaders of America competition. They were instructed to design the look (e.g. colors, fonts) and feel of the presentation. Additionally, they were asked them how quiet or loud they would set their 'walk in' music to be (scale of 1 – 100). They listened to some EDM music and adjusted the volume to their preferred audio level for the presentation and recorded the numeric value. Lastly, they indicated whether they thought the winner of this contest was likely to be more prestigious or more dominant (1-7 scale). The results confirm that that those indicating the winner should be more prestigious (vs. dominant) set their walk in music volume lower than those who thought that the winner would be a dominant individual ($F(1,144) = 4.73$, $p = .031$).

In Study 3, we conducted an empirical model to show support for these predictions using real marketplace data. Using a data set a 2014 aggregation of Facebook data capturing consumers' college football team allegiances at a zip code level, we identified 482 zip codes where fan allegiances were the relatively homogenous among the area's population. For each zip code, data was provided indicating the 3 most popular teams in that area. Then team performance data (win percentage) was gathered for all teams across 4 years (2011 to 2014). This data was matched with a complete dataset of car sales at the zip code level. Another dataset was used to find the actual operating volume (dB) of each model of automobile present in the dataset. Finally, control variables including population, education and income were collected.

We predicted that the better a zip codes' preferred college football team performs, the more this population should feel relatively dominant, sharing in their team's success. As such, more dominant zip codes should show a preference for louder vehicles, all else held equal. The results show that overall, that the better a college football team performed (resulting in increased feelings of dominance in the fans), the more zip codes that associated themselves with that team, sought out louder cars. In addition, there was a main effect such that more educated zip codes (individuals who strive for status using prestige signals) showed a preference for quieter vehicles overall.

Obesity and Compensatory Consumption: Evidence from Jewelry Shopping

EXTENDED ABSTRACT

Obesity rates have been rising across the U.S. over the years, with four out of every ten adults having obesity (Hales et al., 2017). Yet, there is limited research on the link between obesity and consumption behavior in non-health domains. In particular, higher obesity may fuel appearance-related compensatory consumption because prior studies highlight that individuals with obesity exhibit greater disparagement of body image and report lower self-esteem than normal weight individuals (e.g., Wadden and Stunkard 1985; Miller and Downey 1999; Wang et al. 2009). Motivated by this observation, the present research examines whether shopping interest and spending on jewelry, which is regarded as the architecture of the body (Beckett 2015), are higher in places with high versus low obesity rates.

Obesity stigma is a well-documented effect (e.g., Crandall 1994; Miller et al. 1995; Hebl and Heatherton 1998; Carr and Friedman 2005; Puhl and Heuer 2009). Prior research has shown that people view obese individuals and those around them less favorably than others with normal weight (Hebl and Mannix 2003) and that obese individuals face discrimination due to weight (Sutin, Stephan, and Terracciano 2015; Daly, Sutin, and Robinson 2019). People also tend to associate obesity with disease and approach overweight individuals with disgust (Hoyt, Burnette, and Auster-Gussman 2014). In turn, overweight individuals try to mitigate disease threats by choosing to wear clean clothes (Neel, Neufeld, and Neuberg 2013). Despite the growing interest on obesity-focused consumer research, there has not been much progress on understanding whether and how obesity plays a role in shaping people's shopping interest and decisions pertaining to visible products that may help boost their body images. Jewelry, for instance, has historically been viewed as a tool for transforming human body (Gomelsky 2018). With over $68 billion annual sales in the U.S. (Branstrator 2019), jewelry consumption is therefore a suitable study setting in testing the compensatory consumer behavior model (CCBM; Mandel et al., 2017) with a focus on appearance and body image threats (Park and Maner 2009; Hoegg et al. 2014).

According to the CCBM, self-esteem represents an important psychological asset that consumers desire to maintain at a certain level. When consumers' self-esteem is threatened by social stigmas and other external factors, they try to enhance the self via different compensatory consumption strategies. Because wearing jewelry can help people feel better about their physical appearance and boost their self-esteem, one would expect that jewelry shopping interest and spending in a locality increases with obesity rate. The present research tests this hypothesis across four archival studies using online and field data. All the studies in the paper utilize U.S. data and measure obesity rate either at the state- or county-level depending on data availability.

Study 1 uses data obtained from Google Trends for the period 2010-2017 to test whether people's search interest in jewelry stores increases with obesity rate. The dependent variable is annual state-level interest score for the search term "jewelry stores". By construction, the online search interest score is standardized by the total volume of online searches in a given state and year. The independent variable of interest is state-level obesity rate. The control variables are median resident income, median resident age, the proportion of female residents, the proportion of white residents, the proportion of college-graduate residents, and year dummies. The OLS regression results show that for a one-standard-deviation increase in obesity

rate, online search interest for jewelry stores goes up by 12.9% ($p < .01$). The results also show that people's interest in the search term "lose weight"—a proxy for weight- and appearance-related self-discrepancy— mediates the positive relation between obesity rate and search interest in jewelry stores. Falsification tests conducted with alternative search terms such as "appliance stores" and "hardware stores" did not yield any significant results.

Study 2 analyzes the 2012 U.S. Economic Census data on retail sales (2017 data is not available yet) and tests the relationship between jewelry store sales and obesity rate across counties. The dependent variable is the total sales volume for jewelry stores in a county (log-transformed). The independent variable of interest is county-level obesity rate. The control variables include the number of jewelry stores in a county and the same controls from Study 1 (measured at the county-level). The OLS regression results reveal that a one-standard-deviation increase in obesity rate is associated with a 13.0% increase in jewelry store sales ($p < .01$). Falsification tests based on sales volume for different types of stores such as electronics and appliance stores and hardware stores did not generate any significant results.

Study 3 employs the U.S. Consumer Expenditure Survey data for the period 2010-2017 to investigate whether consumers living in states with greater obesity rates are more likely to buy jewelry. The data were collected through quarterly interviews with households. Gift purchases were excluded from the analysis. After controlling for total spending and various state and household characteristics, the logistic regression results show that for a one-standard-deviation increase in obesity rate, the likelihood of jewelry purchase goes up by 6.4% ($p < .01$). The OLS regression of dollar amount of jewelry spending yields similar results.

Study 4 performs a textual analysis of a large sample of jewelry-related tweets downloaded between January, 2019 and April, 2019 to understand whether people from states with greater obesity rates use more self and body words in their tweets. Tobit regression results show that the use of self and body words increases by 5.6% and 3.1%, respectively, when obesity rate is higher by one standard deviation (p's $< .05$). This evidence suggests that as obesity becomes more prevalent, self- and body-related themes stand out as more important themes in consumers' expressions about jewelry.

The present research demonstrates an additional cost of obesity. Unlike weight loss, engaging in compensatory consumption through jewelry purchases does not provide a direct resolution to appearance-related self-discrepancy stemming from obesity. Thus, resorting to jewelry shopping as a compensatory consumption activity is likely to be detrimental to consumers' financial, physical, and psychological well-being in the long-run.

Conspicuously Insecure: When Conspicuous Consumption Backfires

EXTENDED ABSTRACT

Shrek: "So, that must be Lord Farquaad's castle."
Donkey: "Uh-huh, that's the place."
Shrek: "Do you think maybe he's compensating for something?"

In this scene from the movie Shrek, the eponymous hero and his companion Donkey are approaching the evil Lord Farquaad's castle. Having been powerless to prevent the relocation of grating fairytale creatures to his once-tranquil swamp, Shrek has come to the formidable fortress to confront the man responsible. Laughter ensues, however, when Shrek suggests that the large and conspicuous castle is an indication of the despot's personal shortcomings. Although the

audience is never explicitly told what he means, it is readily understood that Shrek is suggesting that the massive monument is compensating for Farquaad's petite physique.

Both common sense and prior literature suggest that conspicuous consumption is often viewed as a symbol of an individual's achievements. For example, merely wearing luxury brands can lead people to view individuals as having greater status (Cannon and Rucker 2019; Nelissen and Meijers 2011). Yet, Shrek's observation, and the audience's response to it, suggests that conspicuous consumption can sometimes be viewed as a symbol of an individual's shortcomings instead. The present research explores this latter possibility. Specifically, this work tests when observers interpret conspicuous consumption as an attempt to compensate for a deficit as opposed to a signal of achievement (Cutright 2012; Gao, Wheeler, and Shiv 2009). To illustrate, consider a middle-aged man purchasing a sports car. Do observers believe the purchase represents his success and status as an elite businessman, or do they infer that the purchase is driven by the psychological insecurities of a man in midlife crisis?

We suggest that observers' inferences are often influenced by their own psychological insecurities. Specifically, we propose that observers are more likely to attribute an actor's conspicuous consumption to compensatory motives when they feel insecure (vs. not). This prediction builds on prior research showing that insecure individuals desire conspicuous products primarily because they believe the products will make them feel more confident in a desired self-view (Rucker and Galinsky 2008). Because people often impute their own thoughts and feelings to others when making attributions (Gordon 1986; Nickerson 1999), we argue that insecure (vs. secure) observers are more likely to believe that an actor's conspicuous consumption is similarly motivated by feelings of insecurity. Ironically, this suggests that although feelings of insecurity make actors more likely to use conspicuous products to gain social acknowledgment, it simultaneously makes observers less likely to provide it.

Study 1 tested our hypotheses by having participants complete a recall task manipulating power (insecure vs. secure vs. baseline). Subsequently, respondents were shown two Mercedes-Benz cars that differed in terms of how conspicuously they were branded. Respondents were asked which driver they thought had more status. Consistent with our theorizing, participants thought that the driver of the more conspicuous car had less status when they felt insecure about their power but more status when they felt secure about their power ($p < .05$). This study provides initial support for our theorizing that observers are more likely to attribute an actor's conspicuous consumption to compensatory motives when feeling insecure (vs. secure).

Study 2 explored the proposed psychological mechanism by showing that the focal effect is attenuated when observers take the perspective of the actor rather than their own perspective, as perspective-taking reduces the tendency to impute one's own mental states to others. After completing a recall task manipulating security of their intelligence (insecure vs. secure), respondents were shown two Yale University t-shirts that varied in terms of the conspicuousness of the university's logo. Respondents were told to imagine they saw two people wearing the shirts and were asked to rate which person felt more secure about his intelligence. Before responding, half the respondents were first asked to take the perspective of the actor. As expected, observers were more likely to report the conspicuous t-shirt signaled insecurity when they themselves were insecure than when they were secure ($p < .05$). However, this effect was eliminated when observers engaged in perspective taking (interaction $p < .05$).

Study 3 tested an implication of observers' attributions of compensatory consumption. Specifically, if insecure observers are more

likely to see conspicuous consumption as driven by compensatory motives, then insecure *actors* should be less likely to engage in conspicuous consumption if they take the perspective of the observer. The idea is that calling an actor's attention to the observer's perspective might make salient the possibility that the purchase would be seen as compensatory. Thus, the actor might reduce their own compensatory behavior to avoid looking like a compensator. To test this idea, we first manipulated participants' power (insecure vs. baseline). Next, respondents were shown a picture of an executive pen and were asked either how powerful and respected owning the pen would make them feel (actor condition) or how powerful and respected *others* would think owning the pen would make them feel (observer condition). Respondents then provided their reservation price for the pen. Replicating previous findings in the literature, respondents in the actor condition tended to pay more for the pen if they were first led to experience insecurity about their power. However, as predicted, this effect was eliminated when respondents took the perspective of the observer (interaction $p < .05$).

In conclusion, we find that while engaging in conspicuous consumption may help actors feel more secure, it can also send the exact opposite signal to observers. For consumers seeking to compensate for a self-threat, this finding suggests that conspicuous consumption may actually backfire if observers see it as reflecting psychological insecurity and thus treat them as compensators. Furthermore, this finding suggests that even when an actor's behavior is *not* driven by compensatory motives, observers may nevertheless make such an inference. In doing so, this research sheds light on potentially unwanted costs of conspicuous consumption and highlights the importance of considering the social context when studying both conspicuous and compensatory consumption.

Luxury and Consumer Well-being: Using Luxury Products Impairs Women's Self-Control

EXTENDED ABSTRACT

The growth of luxury consumption is one of the most important consumer trends in the last decade. Sales of luxury goods have skyrocketed to over $1.3 trillion globally, and luxury goods are in the hands of more consumers than ever. Despite the explosion of luxury consumption, there is a paucity of research aimed at understanding how the use of luxury goods affects our lives, especially how it might negatively affect aspects of our well-being.

We provide women with an opportunity to use real luxury products, and find this experience makes them feel more entitled, more deserving of whatever they want and entitled to more than other people. Entitlement is known to be associated with a number of negative psychological traits, such as narcissism and selfishness, but we focus on an under researched consequence of entitlement that has particular relevance for consumer behavior—loss of self-control. We theorize that feelings of entitlement run counter to exercising self-control, where one depresses their immediate wants and desires to meet higher-order goals. Four studies are presented to test our hypothesis.

In Study 1, 121 female students were assigned to one of three conditions: Chosen Luxury vs. Given Luxury vs. Non-Luxury. In the Chosen Luxury condition, women were shown a luxury handbag (Louis Vuitton) and a non-luxury handbag and were asked to choose one of the handbags for the study. Participants in the Given Luxury condition were given the Louis Vuitton handbag and were asked to use it for the study. Participants in the Non-Luxury condition were given a non-luxury cross-body handbag and were asked to use it for the study. Participants were asked to imagine that they owned

the handbag and were instructed to walk around the building with the handbag. Next, each participant was directed to an individual room which had a computer and a bowl of M&M's candies on the desk. The participants were then left alone in the room to complete the survey. As predicted, we found that participants in the Chosen Luxury condition consumed significantly more M&M's (M = 23.33 grams, SD = 20.28) than participants in the Non-Luxury condition (M = 12.38 grams, SD = 11.93; $t(118) = 2.31$, $p = .023$, ηp2 = .043). Women in the Given Luxury condition consumed significantly more M&M's (M = 21.81 grams, SD = 24.33) than women in the Non-Luxury condition (M = 12.38 grams, SD = 11.93, $t(118) = 2.08$, $p = .039$, ηp2 = .35). Finally, the amount of M&M's consumed did not differ for women in the Chosen Luxury versus Given Luxury conditions ($p = .73$, ηp2 = .001). Study 1 also tested the role of mood and feelings of authenticity and did not find evidences for these effects.

In Study 2, 174 (M_{age} = 20.28, SD = 1.57) female students from a large North American university participated and were randomly assigned to one of the conditions in a 2 (Product Type: Luxury vs. Non-Luxury) by 2 (Food Type: Healthy vs. Unhealthy) between-subjects design. The procedure was similar to study 1 except two types of food were provided. The results revealed that participants in the Luxury condition ate significantly more unhealthy food (M = 30.12, SD = 17.08) than participants in the Non-Luxury condition (M = 22.12, SD = 23.84, ($F(1,170) = 4.34$, p = .039, ηp2 = .025). However, for healthy food consumption, there was no significant difference between participants in the Luxury condition (M = 13.98, SD = 17.34) and Non-Luxury condition (M = 16.47, SD = 20.85, ($F(1,170) = .347$, $p = .56$, ηp2 = .002).

In Study 3, 126 women (M_{age} = 39.81, SD = 16.72) attending the State Fair were recruited to participate in the study. After participants walked around at the State Fair with a Louis Vuitton bag or a non-luxury bag, snacks were provided while they filled out the survey. Entitlement was also measured (adopted from Campbell, et al. 2004). A one-way ANOVA revealed that women in the Luxury condition ate significantly more M&M's (M = 21.16, SD = 22.68) than women in the Non-Luxury condition (M = 13.49, SD = 17.99; $F(1,124) = 4.45$, $p = .037$, ηp2 = .035). Women in the Luxury condition felt more entitled (M = 3.04, SD = 1.21) than women in the Non-Luxury condition (M = 2.56, SD = 1.19; $F(1,124) = 5.00$, $p = .027$, ηp2 = .039). Finally, a 5000 resample bootstrap test of the indirect effect of luxury use on the amount of M&M's consumed revealed that feelings of entitlement statistically mediated this effect (b = 2.07, SE = 1.74, 95% CI: [.0297, 6.8526]).

In our final study, we examine an intervention that luxury consumers can undertake to counteract the negative effects of luxury use on self-control. The key is to identify an intervention that reduces feelings of entitlement. We propose and test that encouraging a grateful disposition among luxury users would serve this purpose, by reducing feelings of entitlement that lessen self-control. 143 female students (Mage = 19.73, SD = 1.54) from a large North American university were assigned to one of three conditions: Luxury vs. Luxury with Gratitude vs. Non-Luxury. Replicating prior studies, we found that participants in the Luxury condition consumed significantly more M&M's (M = 17.75, SD = 19.82) than participants in the Non-Luxury condition (M = 10.71, SD = 14.51; $F(1,140) = 4.26$, $p = .041$, ηp2 =.030). Next, women in the Luxury with Gratitude condition consumed significantly less M&M's (M = 9.79, SD = 10.80) than women in the Luxury condition (M = 17.75, SD = 19.82; $F(1,140) = 4.05$, $p = .008$; ηp2 =.049). In fact, the gratitude intervention was so successful that consumption of M&M's for women in the Luxury with Gratitude condition was similar to that of women in the Non-Luxury condition (M = 9.79 vs. 10.71; $F(1,140) = .10$, $p = .92$).

Taken together, our results show that the experience of using a luxury product can have unanticipated negative consequences—it can lower consumer's ability to exert self-control in everyday life.

SESSION OVERVIEW

George Orwell's *Down and Out in Paris and London* describes how he managed to live in Paris on pennies a day, a tale that stands in sharp contrast to the City of Lights' reputation for luxury and elegance. In Paris, Orwell found himself deciding between paying rent (and sleeping comfortably indoors) or sleeping on park benches to afford wine on the weekends. Although few people experience the extremes Orwell faced, tradeoffs are inherent to any consumer choice, as people decide which options to consider, which ones to choose, and how much to pay for those chosen options. For example, when planning vacations we decide whether to stay in expensive premium hotels or cheaper budget ones, or when commuting we decide whether to rely on public transportation or less ecofriendly single passenger rides.

Collectively, these papers seek to add to the literature on how consumers' goals shape their management of tradeoffs. To kick things off, in "*Meaning Comes Cheap...*" the authors show that participants who were induced to derive meaning (vs. pleasure) from consumption tend to cheap out – that is, they displayed a preference for lower-end (vs. higher-end) products. The authors of the second paper "*Hurts So Good...*" provide novel insight into why consumers sometimes want luxury products that are not only financially costly but also environmentally costly. They show that consumers who are motivated to achieve high status desire luxury products that are environmentally costly because those products symbolically express consumers' desire for dominance. Following on the status theme, in "*Status Pivoting...*" the authors provide new insight into why and where consumers splash out when they experience a status threat. In reaction to an upward status comparison, consumers are less likely to engage in within-domain compensatory consumption than they are to pivot to high status products in alternative domains. Finally, in "*I'll Have What She's Having...*" the authors examine how social influence changes households' economic decisions regarding mortgage

loans. They find that refinancing and loan-type decisions are influenced by the decisions of their neighbors. In particular, households that are relatively higher in value are more likely to exhibit the social influence effects as compared to relatively cheaper households, suggesting that expensive houses exert a greater social influence effect.

Questions emerging from this session might include the following:

- Which social processes are more likely to move consumers toward luxury versus frugality?
- How might the pursuit of meaning (vs. pleasure) interact with the felt need for status to drive consumption decisions?
- How might households' status concerns interact with normative social influences to drive economic decision-making?

Importantly, this collection of papers utilizes a diverse array of methods to explore how consumers' goals shape the tradeoffs they make, including field studies, lab experiments, incentive compatible choice designs, observational methods, interviews, and large-scale panel data analysis. Given its multimethod nature, this session provides ideal conditions for a productive meeting of the minds, where researchers of different stripes can come together to generate new insight into when and why consumers splash out versus cheap out.

Meaning Comes Cheap: The Pursuit of Meaning and the Preference for Low Price Options

EXTENDED ABSTRACT

Consumers strive to find and create meaning in their daily lives. Yet, despite this fundamental need, there is a paucity of research that has examined how consumers use the marketplace to help them in their pursuit of meaning. When consumers wish to add meaning to their lives, what do they want?

Past research suggests that pursuing meaning may cause people to "splash out' by seeking higher-quality, more expensive products. Meaning is associated with a desire for self-growth (Baumeister et al. 2013) and the belief that larger investments will provide longer-lasting benefits (Percival Carter and Williams 2017). Those desires are best fulfilled by high-quality products because those products can be incorporated into consumers' sense of self over time (Belk 1988).

In this research, we posit (and find) the opposite: meaning causes people to "cheap out" by gravitating toward less expensive options. This effect is robust across a variety of usage situations and diverse material goods, experiences, and services, and this effect is explained by an enhanced focus on opportunity costs. The distinct thought processes associated with meaning (increased thoughtfulness, thinking about non-monetary ways to generate meaning, and a focus on the future) encourage people pursuing meaning to think about opportunity costs – the alternative ways they can spend their limited time, energy, and money – which in turn makes them reluctant to devote their resources to any given high-price option.

We report five studies which provided support for our hypotheses. Consistent with previous research studying meaning, we contrasted the pursuit of meaning with the pursuit of pleasure. Not only is this a conceptually and empirically valid approach, it is also eco-

logically valid as pleasure is a related but distinct motivation that is considered to be one of the most important drivers of consumer choice (Alba and Williams 2013; Holbrook and Hirschman 1982).

In experiments 1a (N=173; undergraduate participants) and 1b (N=181; Amazon Mechanical Turk (mTurk) workers), respondents induced to purse meaning (vs. pleasure) reported a stronger preference for the less-expensive alternatives across multiple product categories (cars, coffee, skiing, dining, cameras, and water) and within single-use products (e.g., a cup of coffee) and multiple-use products (e.g., a coffee maker) of each product category (experiment 1a: $F(1,171)=14.86$, $p<.001$; experiment 1b: $F(1,179)=20.460$, $p<.001$).

To check the robustness and external validity of our findings, we conducted an incentive-compatible study which was pre-registered (experiment 2; N=193 MTurkers). Participants were asked to go shopping on Amazon.com, and they were randomly assigned to choose something to create meaning (or pleasure). Participants were given a budget of $100, but otherwise they were free to select whatever they wished. To make this study incentive compatible, participants were told they would be entered into a draw to win the product selected, and that if they spent less than $100 on the product, they would receive the remainder in cash (i.e., MTurk bonus). This lottery was executed. Conceptually replicating experiments 1a-1b, participants who were induced to pursue meaning chose a less expensive product (M=$38.23, SD=$23.52) as compared to those induced to pursue pleasure (M=$49.71, SD=$27.72), $t(191)=3.100$, $p=.002$.

In experiment 3 (N=437; Prolific workers), we tested the hypothesis that pursuing meaning (vs. pleasure) causes people to "cheap out" because the pursuit of meaning heightens consumers' focus on alternative uses for their resources (i.e., opportunity costs). Consistent with predictions, we observed an indirect effect of the meaning (vs. pleasure) manipulation on increased preference for less-expensive products through heightened focus on opportunity costs for both single-use products (c'=.1666, SE=.0464, 95%CI [.0820, .2631]) and multiple-use products (c'=.1815, SE=.0514, 95%CI [.0877, .2867]).

In experiment 4 (N=344; Prolific workers), we tested a theoretically relevant boundary condition. If pursuing meaning heightens consumers' focus on opportunity costs, then they may neglect to think of the longer-term benefits of more expensive products – namely, that high-quality products last longer. In this way, reminding consumers that higher-quality products tend to last longer should mitigate the effect of meaning (vs. pleasure) on increased preferences for less-expensive products, but only when products can be used over time (i.e., multiple-use products not single-use products). In this way, the experiment was a 2 (pleasure vs. meaning) by 2 (durability reminder: yes vs. no) by 2 (single-use product vs. multiple-use product) mixed design, with consumption goal and durability reminder as between-subjects factors and product longevity as a within-subjects factor.

We observed the predicted three-way interaction between consumption goal, durability, and product longevity ($F(1, 340) = 7.022$, $p = .008$). Examining preferences for *single-use products*, we observed the predicted main effect of the goal manipulation ($F(1, 340)=32.046$, $p<.001$). Conceptually replicating the previous studies, participants in the meaning (vs. pleasure) condition reported a stronger preference for the lower-quality products.

When predicting preferences for *multiple-use products*, we observed the predicted interaction between the durability reminder and the consumption goal manipulation ($F(1, 340)=8.149$, $p=.005$). The results of pairwise comparisons supported our theorizing. When participants were *not* reminded that higher-quality products last longer, we replicated our previous findings: meaning (vs. pleasure)

participants reported a higher preference for less expensive products ($p<.001$). More important, this effect was mitigated when the link between quality and durability was made salient to participants ($p=.330$). This attenuation was due to the durability reminder (vs. no reminder) increasing preferences for more expensive products among meaning participants ($p<.001$). Confirming that the moderator was having an effect on meaning participants specifically, the durability reminder did not have an effect on participants in the pleasure condition ($p = .740$).

This research provides a first look at how the pursuit of meaning guides marketplace choices. Across five studies, we find that the pursuit of meaning (vs. pleasure) causes consumers to gravitate toward less expensive options because of a heightened focus on opportunity costs. The findings thus point to a disconnect between what people say they want when engaged in meaningful consumption (more expensive products that last longer) and what they choose when pursuing meaningful consumption (less expensive products that fail sooner).

Hurts So Good: Status Products that Incur Environmental Costs Are Preferred by Status Striving Consumers

EXTENDED ABSTRACT

The motivation to strive for elevated status within one's social circle is evident across cultures (Barkow 1989). Although the particular behaviors and objects that enable upward mobility differ considerably across culture (Bian and Forsythe 2012), the behavioral strategies used to achieve high-status are universal. The dominance-prestige account of status-striving (Henrich and Gil-White 2001) states that individuals may increase their social status by expressing dominance, which usually entails displaying products or engaging in behaviors that represent an individual's control over other entities through force or aggression (e.g. individuals, animals, surroundings; Maeng and Aggrawal 2017; Chase et al. 2002) and by expressing prestige, which is accomplished by displaying material resources or knowledge considered "worthy of emulation" (Cheng et al. 2013, pg. 105; Cheng and Tracy 2014).

Both prestige and dominance are effectively signaled to others vis a vis the products consumers use and display. Although modern consumers seldom procure products via physical force, symbols of dominance are embedded in certain luxury products via the "environmental costs" that they incur in their sourcing or production (i.e. the physical destruction, or damage that occurs to an environmental entity as an outcome of the procurement of a material or the production of a good). Environmentally costly products symbolically express the producer's (and by extension, the consumer's) dominance over another living being or resource.

We contend that products that incur environmental costs are particularly desirable to those engaged in status-striving. We theorize that goods that are symbolic of both paths (i.e. prestige and dominance) are particularly appealing to individuals who are seeking higher social status. The ego-enhancing benefits of luxury coupled with the signals of physical threat makes the consumption of environmentally costly luxury items particularly effective tools in upward mobility (Sivanathan and Pettit 2010).

While some might view scarcity as the inevitable result of the environmental costs inherent in the production of luxury products, scarcity and environmental costs are orthogonal constructs. Thus, we acknowledge the importance of scarcity in consumers' desire for luxury but control for scarcity perceptions in our studies.

Study 1 was a 2 (environmental costs: high vs. low) x 2 (status-striving: high vs. low) behavioral study (n = 205). First, participants were instructed to write about why choosing status goods makes sense (high status-striving condition) or does not make sense (low status-striving condition). Next, an RA asked participants to take part in a taste test for a luxury cold-pressed juice brand. Those who agreed read about juice made from Camu Camu fruit. Only in the high environmental cost condition were participants told that harvesting the fruit has a detrimental effect on the fauna and flora surrounding it. Participants were then given samples of the juice. Participants endorsed the degree to which they liked the juice, found it desirable and thought it tasted good (1 = not at all/ 9 = very much; α = .94). Participants in the high status-striving condition found the juice with high environmental costs more appealing compared to the juice with low environmental costs (M_{HEC} = 6.97 vs. M_{LEC} = 5.93, $F(1, 202)$ = 9.38, p = .002). This pattern was reversed in the low status-striving condition (M_{HEC} = 6.01 vs. M_{LEC} = 6.59, $F(1, 202)$ = 2.64, p =.10).

Study 2 manipulated one between-subjects factor (environmental costs: high vs. low) and measured status-striving (Eastman et al. 1999). Participants (n = 131) were told that the marketing department was working with the university bookstore to determine which kind of luxury chocolate squares they should carry. At each computer was 10 chocolate samples and a booklet offering information about the luxury chocolate. In the high environmental cost condition participants read that cocoa farming contributes to deforestation and damage to wildlife habitats. Before leaving, participants were told they could take as many chocolate samples from their stations as they liked. RAs recorded how many chocolates participants took (0-10). Two weeks later, a follow-up email survey measured status-striving (Eastman et al. 1999). For high status-strivers (+1 SD), the presence of high environmental costs caused an increase in the number of chocolate samples taken (β = .43, p = .0002). For low status-strivers (-1 SD), the presence of high environmental costs caused a decrease in the number of chocolate samples taken (β = -.33, p = .03).

Study 3 examines our hypothesized dominance process via moderation. We conducted a 2 (environmental cost: high vs. low) X 2 (dominance: validated vs control) between subjects design with status-striving measured. Participants (n = 323) were primed by writing about a time that they had felt dominant (dominance validated condition) or to describe their typical morning routine (control). Then, they were instructed to read a passage about how snakeskin is procured for luxury accessories. In the high (low) environmental cost condition we included information that snakes were killed for their skins (molted their skins). Next, participants rated a luxury snakeskin bag on how attractive, appealing, and desirable the bag was (1 = not at all/ 9 = very much; α = .91) and completed the same status-striving scale used in Study 2 (Eastman et al. 1999).

In the control condition, where dominance had not been validated, we continue to find a significant and positive effect of environmental costs at high status-striving (JN point at +1.66 SD), and significant and negative effect of environmental costs at low status-striving (JN point at -.45 SD). In the high environmental cost condition, the effect of the dominance manipulation on product appeal was negative and significant at high levels of status-striving (JN point at +.42 SD).

In sum, we contend that certain consumers (those striving for status) are drawn to status products *because* they are destructive to environmental resources. Consuming these products enables consumers to access an object that represents an additional path to high social status: dominance. Thus, we find support for our prediction that objects that embody both signals (prestige and dominance) are a stronger representation of status and, as such, are particularly appealing to status-striving consumers.

Status Pivoting: Coping with Status Threats through Motivated Trade-off Beliefs and Consumption in Alternative Domains

EXTENDED ABSTRACT

Prior research suggests that consumers cope with status threats by engaging in compensatory consumption, i.e. by purchasing and displaying status-related products and brands that signal professional success and affluence to restore their "shaken self" (Gao et al. 2009; Mandel et al. 2017). Going beyond compensatory consumption in the domain of the status threat, we examine when and how consumers cope with status threat by choosing to pivot to alternative domains. We argue that upward comparisons to higher-status individuals motivate consumers to adopt beliefs about trade-offs between success in the domain of the threat (e.g., professional or financial success) and alternative domains (e.g., personal life or physical fitness). These motivated trade-off beliefs, which are specifically pronounced when consumers experience a status threat, fuel consumption and display of brands associated with accomplishments in these alternative domains. We investigate the domains consumers pivot to, compare the prevalence and appeal of the "status pivoting" behavior to compensatory consumption within the threat domain, and examine when consumers are more or less likely to engage in status pivoting.

Eight studies combining field and lab experiments, observational methods, incentive-compatible designs, and an analysis of social media posts, explore the status pivoting phenomenon.

Study 1 examined the prevalence and appeal of status pivoting in a real-world natural setting. We recorded and coded 217 responses to a question posted on an online platform Quora.com: "How can you overcome your envy of people who are your age but are far more successful?" A greater proportion of posts mentioned pivoting to an alternative domain (48.8%) than restoring status within the threat domain (25.3%; c^2=6.031, p=.014). The most frequently mentioned alternative domain was social life and relationships (30.2%), followed by mental wellness (23.6%), personal character and moral values (20.8%), and physical health (15.1%). Furthermore, comments about status pivoting were viewed (p<.001) and liked (p=.006) more than those about restoring status within the threat domain, indicating its greater prevalence and appeal.

In Studies 2A-C, we explored how car bumper stickers can be consumed as a form of status pivoting. In Study 2A, we examined cars at golf club parking lots in Crans-Montana, a luxurious resort town in Switzerland. Analysis of the cars that had bumper stickers (N=98) revealed that, compared to owners of luxury cars, owners of non-luxury cars were more motivated to signal status in alternative domains using stickers associated with collectable experiences (e.g., extreme sports; c^2=28.63, p<.001) or social causes (c^2=48.17; p<.001) over stickers associated with the status threat domain – golf.

To test causality, in Study 2B, we surveyed 73 runners (M_{age}=45.1, 55.4% males) in the Boston Marathon pre-race exposition. Runners who described someone they knew with a very expensive car (status threat) were more interested in displaying the "26.2" sticker on their car, laptop, or at work (1-7 scale; α=.56) (M=4.51) than runners who did not describe such an individual (control) (M=3.65; $F(1,72)$=13.84, p=.045).

Study 2C manipulated status threat in a controlled setting and tested the mediating role of motivated trade-off beliefs. Car owners (N=179; M_{age}= 37.9; 47.5% female; MTurk) imagined that one of their coworkers had won a large amount of money ($100,000; status threat) vs. a smaller amount of money ($1,000; no threat) in the lottery. Participants were more interested in putting stickers that display alternative domains on their cars in the threat (vs. no threat) condi-

tion (*p*=.030). The effect was mediated by motivated trade-off beliefs (that financial success leads to problems in alternative life domains; *a×b*=.8421, 95% CI=[.4947,1.2206]).

The following studies tested the effect of status threat on choice between status pivoting to an alternative domain versus status restoration within the threat domain.

In Study 3, participants (N=203, M_{age}=35.9, 41% female, MTurk) imagined they met a former classmate at a high-school reunion. In the status threat (vs. no threat) condition, the classmate was described as more (vs. less) professionally successful than them. Afterwards, participants chose which mug they would like to win a real raffle. Participants were more likely to choose a mug that highlighted an alternative domain ("Keep Calm and Be a Friend") over a mug that highlighted the domain of the status threat ("Keep Calm and Back to Work") in the status threat (vs. no threat) condition (c^2=4.51, *p*=.024).

Studies 4A-B tested a boundary condition of status pivoting – attainability of high status in the domain of the threat. Study 4A (N=355; M_{age}=34.7; 36.2% female; MTurk) showed that subjectively perceiving the success of the higher status person in the domain of the threat as attainable can attenuate the effect of status threat on status pivoting and lead consumers to signal status in the threat domain (c^2(3)=10.00, *p*=.019). Study 4B (N=236; M_{age}=48.6; males; Qualtrics panelists) revealed that consumers' actual ability to attain high status within the threat domain (i.e. income) attenuates the effect of status threat on status pivoting, as status threat (vs. no threat) increased status pivoting only at annual income levels below $107,768 ($b_{jn}$=.4057, *p*=.05).

Study 5 examined an alternative possibility that pivoting could occur because people merely want to escape the status threat. It also further tested the process (trade-off beliefs) by manipulating the salience of trade-offs across domains. 180 women (M_{age}=35, MTurk) imagined that their friend enrolled in a professional course. She either felt disadvantaged because her classmates were more accomplished (status threat), felt that she was doing well (no threat), or felt disadvantaged compared to her classmates who were more accomplished but did not have rewarding relationships (trade-off between domains highlighted). Participants evaluated bracelet charms to gift to their friend. Participants were more likely to prefer charms associated with an alternative domain (relationships) in the status threat and the trade-off salient conditions than in the no-threat condition (*p*=.028; *p*=.011), but their preferences for charms associated with the threat domain (*p*>.11) and neutral domains (*p*>.491) did not differ across conditions.

Our work adds to theory on status-signaling and compensatory consumption by enhancing the understanding of status pivoting, and it contributes to prior work on lay theories about cost-benefit heuristics by demonstrating that beliefs about trade-offs may be pronounced under status threat.

'I'll Have What She's Having:' Neighbors Socially Influence Households' Mortgage Decisions

EXTENDED ABSTRACT

A mortgage is the largest and most consequential financial contract that the typical household makes. For most families, their house is their largest asset and their mortgage their largest liability. Understanding the drivers of household mortgage choices therefore remains critical to the study of consumer behavior and household finance. A growing body of work shows that decision-making and risk-taking behavior can be influenced by various contextual factors, including social influence. However, neighbors have been largely unexamined in this research agenda. While this may be partially due to identification challenges that necessitate linking high-quality and precisely located geographic data to outcome variables of interest, recent literature and labor trends have pointed to other concerns diminishing the importance of this group.

In his influential book, *Bowling Alone*, Putnam (2000) argues that Americans are largely disconnected from their neighbors and local communities. Recent trends also find that Americans are increasingly spending more time working and online (O'Boyle and Harter, 2013; Perrin, 2015). Yet there are clear reasons that neighbors should not be overlooked as a consequential source of influence, particularly in household mortgage decisions. Americans live in their homes for an average of thirteen years, more than twice the average workplace tenure, and are living in their homes increasingly longer (BLS, 2019; Modestino and Dennett, 2013). And, finally, while people are working longer hours, more and more of these hours are spent working from home (BLS, 2017). Consequently, do social interactions from our neighbors have a meaningful impact on households' economic decisions? If so, by what mechanism? Do they improve decision-making or lead to worse outcomes? And in particular, does living in a relatively more expensive home lead you to be more or less likely to be socially influenced that those in relatively cheaper homes?

We build a comprehensive panel dataset that details the owners, outstanding mortgages, and characteristics of every property in Los Angeles between 1992 and 2012. Crucially, we know the precise latitude and longitude of each property and can therefore map households and their hyperlocal neighbors. With this fine level of detail, we can isolate and identify social influence effects occurring at a hyperlocal level. This level of precision affords the ability to identify hyperlocal sources of influence in a way that is not possible using zip code-level or county-level data alone, where endogenous group formation concerns prevail. Our empirical strategy tests whether decisions made by a household's block peers, the sixteen neighbors on the household's residential block, exert a significant influence on its mortgage decisions even when controlling for the decisions made by the household's larger set of neighborhood peers, the 130 neighbors on the household's census block and those blocks adjacent to it, and controlling for borrower and lender-specific fixed effects as well as time quarter-by neighborhood level fixed effects.

We find households make refinancing and loan-type decisions especially like those of their hyperlocal, block-level neighbors, even after controlling for the decisions of those neighbors who live just slightly farther away, on adjacent blocks. Specifically, we estimate that households are 4% more likely to refinance and 2% more likely to choose an adjustable rate mortgage (ARM) if the count of block peers who have recently refinanced or the share of their block peers with an ARM for their last loan increases from the 10th percentile block to the 90th percentile block, respectively. We further find that households making purchase loan decisions, who have not lived in the neighborhood before and therefore had no opportunity to socially interact with their new neighbors, show no signs of being socially influenced. However, though not initially socially influenced, we show that movers who later refinance become socially influenced over time.

Unlike real estate listings, adding solar panels (Bollinger and Gillingham, 2012), and foreclosure (Gupta, 2018), refinancing and ARM choice are not decisions typically visible at the hyperlocal level, ruling out the possibility of a visual salience mechanism. Instead, these hyperlocal social influence effects are more consistent with a word-of-mouth mechanism. To provide further support of a word-of-mouth transmission mechanism, we investigate whether hyperlocal peer effects change as the likelihood of social interac-

tions among neighbors increases. To do so, we estimate our model across areas with varying walkability scores. Walkability scores measure accessibility to public transportation, the presence and quality of footpaths, and traffic and road conditions, among other factors, therefore serving as a proxy for the likelihood that households living in that zip code interact with their neighbors, particularly those beyond their specific block. We find that the estimated effect of block peer influence is steady and similar across all ten deciles of walkability score. Social interactions between block neighbors are no more likely to occur as areas become more walkable. This is unsurprising since interactions between block-neighbors are already almost a certainty. Getting mail, taking out the trash, and shoveling snow all happen regardless of the area's walkability. Importantly, this also means that block-level social interaction effects are always in play, regardless of neighborhood attributes correlated with walkability. We also find that the estimated effect of adjacent-block peers' decisions do increase as a function of increased walkability. While we cannot attribute all of this increase to an increase in social interactions as there are other correlated unobservable forces, the notion that more walkable neighborhoods increase the neighborhood-level social influence effect is consistent, once again, with a word-of-mouth, social interaction mechanism.

Finally, we use our data to speak to the welfare implications of hyperlocal neighbor social interactions. First, we examine whether households are better/worse off from social interaction by examining optimal refinancing. We do this by determining what the current prevailing interest rate to the interest rate prevailing when the loan was originated and measure how long it has been since the house has refinanced. By looking just at the extremes, we can say what a given household "ought" or "ought not" to do (Keys et al., 2016). We find that the effects of hyperlocal social influence are significantly stronger for households who ought to refinance compared to households who ought not to. This indicates that interacting with neighbors might encourage learning whereby households who ought to be making a certain choice are more likely to do so if their block peers have recently made that same decision. Second, we examine whether there is heterogeneity in the 'type' of households who are more likely to be socially influenced. We find that relatively larger households on a block (as determined by estimated value) are, in fact, *more* likely to exhibit social influence effects while households that are relatively cheaper on a block are *less* likely to show these effects. This implies that households who are relatively wealthier in terms of visual salience are more likely to show hyperlocal social influence effects in their refinance decisions relative to those households whose visual display of wealth is comparatively less.

In summary, we demonstrate hyperlocal social interactions may be an important mechanism for information flow in household finance and mortgage markets, spurring households to learn about prevailing interest rates and new mortgage products, leading them towards "better" decisions.

Paper #4: Not-so Easy Listening: Roots and Repercussions of Auditory Choice Difficulty in Voice Commerce

Kurt P. Munz, Bocconi University, Italy
Vicki G. Morwitz, Columbia University, USA

SESSION OVERVIEW

Voice-enabled technologies enjoy widespread popularity and are being adopted at a staggering rate. Sixty-six million US adults own a smart speaker (Levin and Lowitz 2019), 49% of US smartphone users use voice-technology at least once a week (Statista 2018), and 20% of mobile Google searches are done by voice (Sterling 2016). Some industry experts predict that in the coming decade 30% of online browsing will be done entirely without screens (Gartner 2016), and it cannot be disputed that voice-enabled technologies are becoming a part of consumers' daily lives with myriad marketing implications (Dawar 2018).

As we are entering the era of voice (Campos 2017), this session combines four papers that shed light on various dimensions on consumer interactions with voice technology with important downstream consequences for advertising effectiveness, product preferences, and choice.

The first paper investigates differential privacy perceptions in online interactions with technology as a function of communication modality. Specifically, Melzner, Bonezzi, and Meyvis find that consumers expect oral versus written interactions with technology to be more private with negative consequences for the receptivity of targeted advertising based on orally as compared to written disclosed information.

The second paper by Valenzuela, Luna, Hildebrand, and Du explores the use of imperative language while interacting with voice assistants. Experienced voice assistant users adapt their speech toward greater use of commands, while inexperienced users feel uncomfortable doing so, making them less likely to seek status products.

Next, Chae, Mourey, and Yoon show that a subtle cue, such as a programmed accent in the voice of an artificial intelligence agent can influence willingness to pay and purchase intention–an effect not intuited by consumers. That is, accents in smart technology voices can elicit country of origin associations that boost evaluations of products from that country.

Finally, Munz and Morwitz explore the cognitive consequences of shopping by voice. Voice shoppers have greater difficulty making comparisons, leading them to choose recommended items more often, but also making them more likely to choose nothing. They rely more heavily on information they can understand apart from a comparative context.

This session should be of interest to a broad audience of researchers with substantive interests in voice technology, human-technology communication as well as a theoretical interest in normative beliefs, associative processes, and information processing. The consequential nature of the dependent variables provides insights for practitioners.

Verba Volant Scripta Manent: Communication Modality Affects Privacy Expectations

EXTENDED ABSTRACT

Consumers increasingly interact with technology by speaking instead of typing. This voice technology boom is predicted to affect marketing on many levels (Dawar 2018). In this research, we focus on targeted advertising. Specifically, we propose that oral versus written communication increases consumers' privacy expectations with negative effects for targeted advertising.

Privacy expectations are social norms about how information should flow within and outside of the contextual boundaries of an information exchange (Nissenbaum 2009). Oral communication is ephemeral and transient and thus tends to be contextually bounded. That is, spoken content typically remains within the social (i.e., with the audience involved directly in the communication), spatial (i.e., in the same location), and temporal (i.e., no record) boundaries of the information exchange setting (Jahandarie 1999). Written communication, however, is a contextually impoverished modality, as content can easily be saved and transmitted to third-parties at remote place at later times (Sproull and Kiesler 1986). Thus, consumers may have internalized the norm that orally versus written disclosed information should not be accessible to parties not involved in the immediate information exchange and not be transmitted to other places or saved and later used. Even though, ephemerality of the spoken word does not hold in online communications with technology (as content is recorded, sent to remote servers, and often disseminated; e.g., Acquisti, Brandimarte, and Loewenstein 2015), the physical ephemerality of consumers' spoken output is highly salient to consumers, while the digital translation of the disclosed information is arguably not. Furthermore, consumers tend to apply well-established offline norms to interactions with technology online (Moon 2000) even though they do not apply in this context.

In four studies, we show that consumers display increased privacy expectations in oral versus written communication with technology online. Furthermore, consumers perceive contextual boundary breaches as higher privacy violation in oral versus written communication with negative downstream consequences for the effectiveness of targeted ads, which necessitate contextual boundary breaches of provided information. For brevity, we report two studies in this report.

Study 1: Undergraduate students were each seated in private rooms and presented with an online survey on a topic of relevance to them, namely dating. Participants were assigned to one of three conditions. In the oral (written) condition, participants heard (read) the questions recorded with a female Google Assistant voice and responded by speaking into a built-in laptop-microphone (typing). The oral transcription condition closely resembled the oral condition, with the exception that participants were specifically notified that no audio files of their recordings are saved and that their responses will be automatically transcribed (participants in the oral condition received no further information even though no voice files were saved either).

Measures. As measures of privacy expectations, participants were presented with the following five statements and asked to indicate the extent they would find social (three items: the researchers get access to their answers, the researchers give others access to their answers, a third-party company gets access to their answers), temporal (their answers are stored indefinitely), and spatial (their answers are transmitted to remote servers) boundary breaches acceptable. Since all items show highly similar results and load on a single factor, they will be reported as a single composite measure of privacy expectations for brevity. Next participants indicated the degree to which they felt that their answers made them identifiable as individual.

Results. Conditions differed in acceptability of contextual boundary breaches, such that participants in the oral condition indicated lower acceptability (and thus higher privacy expectations) than participants in both the oral transcription than written condition) with no difference between the latter two conditions. Additionally, conditions differed in perceived identifiability, with the oral condition indicating higher identifiability than the oral transcription and marginally higher identifiability than the written condition with no difference between the latter two conditions. However, identifiability did not mediate the effect of oral versus oral transcription and written condition on acceptability.

Discussion. The results support the hypothesis that consumers find boundary breaches less acceptable in oral versus written communication. The effect does not seem to be a function of feeling more identifiable through speaking than writing. Furthermore, it is not the act of speaking itself that evokes increased privacy expectations but the ephemerality of spoken output as indicated by the fact that participants in the oral transcription condition displayed privacy expectations similar to the written condition.

Study 2: Undergraduate students were seated in private rooms and asked to imagine that they had to Google things to do for a weekend-trip (amongst which was eating at a restaurant). Participants were assigned to one of two conditions (oral and written) and entered search terms either by typing or by speaking into the built-in laptop-microphone using the Google voice functionality. The keyboard was disabled in the latter condition. Afterwards, participants completed unrelated studies for about 30 minutes. On a different laptop, participants were informed that the search terms they entered previously were used to generate a personalized ad for them and were then presented with an ad for a restaurant.

Measures. Upon seeing the ad, participants were asked to indicate the degree to which they felt like their privacy has been violated. They further indicated the degree to which they were interested in visiting the website of and eating at the advertised restaurant. These items were averaged into measure of ad effectiveness. Additionally, they were asked how identifiable they felt based on the search terms they provided and how good a match the ad was for them.

Results. Participants indicated marginally higher privacy violations in the oral than written condition. Conversely, participants indicated lower ad effectiveness in the oral than written condition. However, the indirect effect of oral versus written condition via privacy violation on ad effectiveness was only marginally significant.

Discussion. The results provide first evidence in an ecologically valid context that targeted ads based on oral versus written information from consumers are received less favorably due to increased consumer privacy expectations in oral communication.

Experiential Effects of Device-Dependent Voice Interactions: Resolving the Power Imbalance between Voice-assistants and Users

EXTENDED ABSTRACT

Amazon's Echo (a voice-activated device) is a smart home speaker embedded with artificial intelligence. Dubbed Alexa, Amazon's Artificial Intelligence has gained popularity in many households. The U.S. installed base of smart speakers has hit 66 million in 2018 (Levin and Lowitz 2019) with 252 million U.S. adults using voice-assistants in their homes or cars (Voicebot 2019). Alexa only responds when summoned, and consumers usually talk to her using imperative language. In this paper, we investigate how the consumer's experience originating from device-dependent voice interactions may have an effect on downstream decisions.

The chameleon effect is a specific form of synchrony that takes place among dyads rather than within and between groups (for a review, see Chartrand & Lakin 2013). As adults, we engage in mimicry to establish and maintain social relations with others (Chartrand & Bargh 1999). In linguistics, accommodation theory investigates the mechanism underlying verbal mimicry (Gallois, Ogay, and Giles 2005; Koslow, Shamdasani, and Touchstone 1994). Convergence, within linguistic accommodation, explores the motivation for verbal imitation. Convergence arises when speakers alter their linguistic patterns to adopt styles more like that of their interaction partners (Wisniewski, Mantell and Pfordresher 2013).

In this paper, we focus on the dynamics of language accommodation in the dyad "consumer - voice activated assistant" (assemblage theory; Hoffman and Novak 2018). We posit that technology devices' inherent constraints make digital assistants less conversational, and, consequently they potentially limit consumers' use of language. Specifically, in their working paper, Hildebrand, Hoffman and Novak (2019) link phonetic signals in the human voice when interacting with voice-activated assistants with consumer experiences, and differentiate between command-based ("Alexa, length of marathon") and request-based ("Alexa, can you tell me the length of a marathon?") voice inputs.

Our research question centers on the idea that differential experiences of the interaction with a voice interface may have downstream consequences. Consumers may experience this interaction differently depending on whether they have already started their accommodation process towards talking "with a Machine". Consumers that already use voice-activated devices would be accommodated to using Commands instead of Requests, while the opposite would be true for those that have never used such devices. This differential extent of accommodation may create friction in their experience, which may lead to compensatory processes to resolving the power imbalance between the voice-assistant and the user. In this paper, we examine the impact of device-dependent voice Interactions on consequential marketing outcomes like the evaluation of "status"-related cues. A set of three studies tests these ideas.

In the first study (N= 114), participants worked in individual lab rooms with an Amazon Echo dubbed "Computer." Participants were given a 3-minute practice run. At that point, participants were given 8 tasks to fulfill with their Echo and told they would get rewarded by their performance. We then measured their level of language accommodation ("I changed the way I spoke to make it easier for X to understand me"; 0-100) and their success communicating (1-7). Individual differences in their experience (yes/no) with Alexa and with voice-activated phone systems were recorded.

Study 1: We identify a significant two-way interaction between whether participants had prior experience with Alexa or with other voice-operated systems in the extent of language accommodation (F $(1,113)=3.87$, p <0.05) and communication effectiveness (F $(1,113)=6.73$, $p<.01$). Participants accommodated less and experienced less effectiveness in their communication when they had not used Alexa or Siri before ($M_{accommod;success}$ = 45; 5.7) or had used Siri but not Alexa ($M_{accommod;success}$ = 35; 6.2), compared with when they had already used Alexa and other voice-activated systems ($M_{accommod;success}$ = 55; 6.6).

Study 2 (N= 159) and 3 (N= 80) followed a similar procedure as study 1. Participants were given 8 tasks to fulfill. However, when interacting with the voice-activated assistant (either just repeating the sentence to the screen - study 2 - or interacting with the actual Echo dubbed "Computer" - study 3), participants were directed to use either Commands or Requests (e.g. "Alex, Turn on the TV" instead of "Alex, Can you turn on the TV?"). After that, they answered a set of questions about language accommodation, communication effectiveness, and prior experience with Alexa and other voice-activated devices. In study 2, they also rated whether their experience was that of a 1 = Master; 7 = Servant. In study 3, we included some downstream DVs: a) Attitude towards status-cuing ads ("A symbol of status. The Office Pen is designed to attract attention with its sophisticated design") vs. a non-status driven ad ("A symbol of quality. The Office Pen is designed to perform consistency with its extraordinary quality"; 7-point scale: "I would like/share this ad"); b) Evaluation of status-cuing products (*WTP* (10% to 120% of retail price) for status (e.g. briefcase, silk tie) vs. non-status (e.g. sofa, washing machine)).

Study 2: We identify a significant two-way interaction between whether participants had prior experience with Alexa and whether they were using Commands/Requests in the extent in which they felt like a Servant (F $(1,158)=3.49$, $p<0.05$), their language accommodation (F $(1,158)=8.66$, $p<0.01$) and communication effectiveness (F $(1,113)=3.41$, $p<.07$). With prior Alexa experience, participants felt more like a Master using Commands ($M_{Command}$ = 5 vs. $M_{Request}$ = 3.8), while those without experience using Requests ($M_{Command}$ = 4.2 vs. $M_{Request}$ = 4.6). When using Commands, those with experience accommodated much less than those without experience ($M_{Alexa\_experience}$ = 35 vs. $M_{Alexa\_no\_experience}$ = 62).

Study 3: We identify a significant two-way interaction between whether participants had prior experience with Alexa and were using Commands/Requests in their relative evaluation of status items (F $(1,80)=4.09$, $p<0.05$) and marginal for attitude towards status claims (F $(1,80)=2.40$, $p<.10$). Without prior Alexa experience, participants exhibited lower relative evaluations towards status items when using Commands ($M_{Command}$= .85 vs. $M_{Request}$ = 1.15), while those with experience when using Requests ($M_{Command}$= 1 vs. $M_{Request}$ = .90).

Taken together, device-dependent voice Interactions like the evaluation of "status"-related items. This results could be driven by the pattern of language accommodation when talking to voice-activated assistants, which may lead to compensatory behavior based on the consumers' conversational experience.

Is That an Accent I Hear?
How a Digital Voice Assistant's Accent Affects Consumer Perceptions and Intentions

EXTENDED ABSTRACT

Is a Chinese horoscope more likely to come true if the fortune teller speaks with a Mandarin accent? The country-of-origin (COO) literature (Hong and Wyer 1989, 1990) suggests it is possible to produce positive market outcomes by leveraging existing associations between cultures and products, such as the French and wine. However, when most digital devices–like Amazon's Alexa–feature standard voices in a user's native language, would adding accents to particular responses help or hurt user perceptions? Two studies suggest that a native accent can dominate, but that deliberately adding accents to particular responses can affect user-related outcomes via perceptions of fit and competence.

To date, the majority of smart devices feature female voices speaking a user's native language without any regional accent (Kinsella 2019; West, Kraut, and Chew 2019). For some devices, consumers are able to customize the specific language and gender of a device's voice, but regional accents, foreign accents, and dialects are not yet customizable features (Fingas 2018). For English-speaking consumers, the fact that English tends to be perceived as the "international" language and even as the expected voice for companies engaged in global business may explain why English is the default language setting for most smart devices (Krishna and Ahluwalia 2008). When it comes to smart devices, English is the *expected* voice.

However, English as the default language ignores the vast literature on the COO effect in which consumers link positive associations between particular products and their source country (Bilkey and Nes 1982; Erickson, Johansson, and Chao 1984; Han 1989, Hastak and Hong 1991). These associations typically result in greater liking, purchase intentions, and satisfaction for the product, such as paying more for pasta from Italy (Hong and Wyer 1989, 1990; Johansson, Douglas, and Nonaka 1985). Once a particular COO association has been established, deviations or incongruities with that association can produce negative outcomes that could have been avoided by omitting any COO reference in the first place (Melnyk, Klein, and Volckner 2012).

That English is generally considered the default "voice" for global business poses an interesting question with respect to smart device voices: what happens when a smart device response, provided in English, is delivered with a foreign accent? The goal of the current research is to explore the extent to which an accent for a smart device's voice predictably affects consumer outcomes. We predict that the standard, American English accent--recognized as the default, global business language and accent--is likely to yield positive outcomes given its ubiquitousness and familiarity. However, we argue that English spoken with particular foreign accents--like Mandarin or French--can help or hinder consumer outcomes depending on context. Specifically, when a positive COO association exists, the relevant accent should bolster consumer outcomes; when no such association exists, the accent should harm consumer outcomes.

A pilot study tested people's beliefs about our predictions. Participants (N =198) rated whether they thought accents could affect their perceptions and behaviors. Participants were significantly likely to say that accent, gender, and vocal age would certainly *not* affect their perceptions of truth, product quality, or behavioral intentions.

We next tested how accents actually influence people's perceptions and behavioral intentions.

In Study 1, participants (N = 183) heard a vocal instruction that was created using Amazon's Polly Artificial Intelligence. A smart home device gave recipe instructions for grilled cheese or French toast in a voice with an American or French accent. As predicted, the interaction of recipe and accent was significant on participants' recommendations (p = .02). When the AI had an American accent, French toast (M = 4.79) versus grilled cheese (M = 5.23) recipes did not influence recommendations (p = .12). However, speaking with a French accent for French toast (vs. grilled cheese) increased recommendations (M = 4.53 vs. M = 3.99; p = .05). The interaction effect was also significant on the perceived fit of voice (p < .001). While a French accent increased the perceived fit with French toast more than with grilled cheese (M = 4.51 vs. M = 3.21; p < .001), an American accent increased the perceived fit with grilled cheese more than with French toast (M = 5.62 vs. M = 4.69; p = .001). Importantly, the perceived fit was a significant underlying mechanism for a French, not American, accent (95% CI for index of moderated mediation = [.83, 1.78]). Only when the AI spoke with a French accent, providing the French (vs. American) recipe increased the perceived fit between product and voice and subsequently increased participants' recommendations.

Study 2 further examined the underlying processes in a new context. Participants (N = 193) heard an audio clip of a Chinese or Zodiac horoscope read in a voice with either a Chinese accent or an American accent. They rated the extent to which they believe the horoscope would come true, the amount they are willing to pay for a 1-year subscription, the perceived fit of voice, and the perceived competence of the AI. As predicted, horoscope and accent resulted in a significant interactive pattern that was similar to Study 1, on all of the measures (ps < .04). A significant moderated serial mediation showed that only when the AI had a Chinese accent, reading the Chinese (vs. Zodiac) horoscope increased the perceived fit, which enhanced the perceived competence and subsequently the level of belief and willing to pay.

Despite the fact that individuals do not think a smart device's accent can affect their perceptions and behavioral intentions, two experiments provide initial evidence to the contrary. Although an American English accent consistently yielded positive effects on consumer outcomes and intentions, ethnic accents bolstered consumer outcomes in COO-relevant contexts and diminished those outcomes in non-COO-relevant contexts. Further, the better the perceived fit of the voice, the higher the perceived competence of the smart device. This better fit and greater competence had important consequences on consumer outcomes that users did not think were possible. Together, results suggest that simply altering the accent of a smart device's voice can have interesting consumer implications.

Not-so Easy Listening:
Roots and Repercussions of Auditory Choice Difficulty in Voice Commerce

EXTENDED ABSTRACT

Will shopping by voice resonate with consumers or will the many upbeat forecasts (e.g. Hayllar and Coode 2018; Simms 2019) prove to be mostly chatter? We take an information-processing perspective to suggest that voice shopping can be cognitively challenging for consumers, particularly when they need to make comparisons.

While presenting information to consumers by voice is not new (e.g. radio advertisements or spoken daily specials), interest in this area has boomed since voice assistants like Amazon Alexa opened a new shopping channel. Yet research into auditory consumer behavior is relatively scarce (Krishna 2010; Meyers-Levy, Bublitz, and Peracchio 2010). While there are undoubtedly aspects to shopping by voice that make it more like a human *social* interaction (e.g. Schroeder and Epley 2016), we compare text presented visually (in writing) to the same text spoken aloud and explore the underlying *cognitive* processes.

In the context of persuasive messaging, some studies have directly compared spoken words to their equivalent written form, as we do in this research (e.g. Chaiken and Eagly 1976, 1983; Sparrow 2007; Unnava, Burnkrant, and Erevelles 1994). However, we focus on the novel circumstance of choices made from options presented by voice, suggesting that this context may be particularly challenging for consumers.

It is not necessarily the case that spoken information is always harder to process. Indeed, processing auditory information is generally easier than reading text (Liberman 1989)prior to all others: why is it easier to perceive speech than to read, and why is it easier to speak a word than to spell it? My aim is to repair these omissions. To that end, I divide my talk into two parts. First, I say why we should consider that the greater ease of perceiving and producing speech is paradoxical, by which I mean to suggest that the reasons are not to be found among surface appearances. Then I propose how, by going beneath the surface, we can find the reasons, and so resolve the paradox. THE PARADOX Before developing the paradox. I should first remind you that perceiving and produCing speech are easier than reading or writing. for thiS is the point from which I depart and to which I will. at the end. return. The relevant facts include the following. (1, a sentiment anyone who has hesitated to read subtitles in a foreign-language film can appreciate. For proficient readers however, differences in processing difficulty between text and speech may be minimal, with comprehension of written text (books) and auditory text (audiobooks) being generally similar (Gernsbacher, Varner, and Faust 1990). However, for particularly difficult passages, reading can be easier than listening due to an ability to re-read (Daniel and Woody 2010).

We propose that voice shopping is challenging due to difficulty making auditory comparisons. Voice comparisons require a greater reliance on memory. Spoken words persist only in the instant of their utterance while typeset words can be re-visited with ease. A rich literature in consumer behavior has demonstrated that holding information in memory can interfere with processing new information due to increased cognitive load (Shiv and Fedorikhin 1999)compared to a second (fruit salad. Limitations on memory may also enhance the likelihood of ignoring some of the information (e.g. Tversky 1972) an aspect is selected (with probability proportional to its weight, and consumers might rely on summary information or on important attributes when choosing, rather than integrate all available information.

We predict that these processes will lead auditory consumers to have greater difficulty processing choice options compared to visual consumers with three consequences. First, auditory difficulty may make accepting a recommendation more likely, as difficulty while choosing can increase acceptance of advice (Gino and Moore 2007). Second, auditory consumers may be more likely to "defer" choice by choosing none of the available options, which also becomes more likely as choice difficulty increases (Dhar 1997) or even as the subjective feeling of choice difficulty increases (Novemsky et al. 2007). Third, because cognitive load disrupts attitude formation (Cronley, Mantel, and Kardes 2010), we predict that auditory consumers will have less polarized attitudes toward items they evaluate in a comparative context.

Experiments 1a-1i confirmed the above hypotheses. In Experiment 1a, in-lab participants chose a lip balm as a free gift. One of two options was recommended. Based on random assignment, half the participants heard the options read aloud to them in the voice of "Alexa" and half read the same information. Participants chose one and were given it to keep. As predicted, a significantly greater percentage of auditory participants chose the recommended option ($\chi^2(1;N=74)=6.77,p=.009$).

In Experiment 1b (preregistered), participants faced a similar (hypothetical) choice, but could also defer. Auditory participants were more likely to choose the recommended option ($\chi^2(1;N=603)=17.06,p<.001$). They also deferred more often $\chi^2(1;N=603)=15.43,p<.001$), as predicted. Attitudes toward both choices revealed less polarized attitudes among auditory consumers ($F(1,601)=19.24,p<.001$), also as predicted. A processing difficulty scale ("complex," "complicated," "easy to comprehend" (reverse); Anand & Sternthal, 2006) mediated the effect of presentation mode on choice. Additional measures suggested the effects were not due differences in anthropomorphism or trust.

Experiments 1c through 1i demonstrated robustness across various stimuli and voices, controlling for order effects, and when the visual stimuli were presented sequentially or in an ephemeral manner mimicking speech.

Experiments 2 through 4 provided evidence that the effects are specifically related to difficulty making comparisons in auditory mode. In Experiment 2, we crossed presentation mode (voice vs. text) with a classic joint versus separate evaluation paradigm (Hsee 1996), reasoning that preference reversals should be less likely by voice due to difficulty learning from context. As predicted, we replicated the classic preference reversal only in visual mode. Auditory consumers' evaluations were similar whether considering the options jointly or each option separately. Experiment 3 (preregistered) extended this idea to comparisons of items previously encountered. Consumers rated a single novel product less favorably when it was described by voice and they compared to one they had encountered previously, but evaluations were similar when consumers were not making comparisons. In experiment 4, manipulating the difficulty of making comparisons eliminated the differences that naturally exist between the conditions and provided stronger causal evidence.

Experiments 5 and 6 explored the role of memory. In experiment 5, working memory was measured with a "digit span" task (recalling strings of numbers). As consumers' working memory capacity improved, the differences in choice outcomes between auditory and visual consumers diminished. Experiments 6a and 6b used the insight that the effects are related to memory to design interventions useful for marketing managers. Negative effects of voice presentation can be mitigated by explicitly stating the comparative value of an option, eliminating the need to make comparisons (Experiment 6a) or by describing the choice options in a by-feature (rather than by-option) manner (Experiment 6b), which reduces the time and amount of information needed to be held in memory.

This research represents one of the first explorations of voice commerce and contributes to our understanding of auditory judgment and decision making.

SESSION OVERVIEW

Consumers produce written content for themselves or other consumers every day. They write reviews, enter search queries, and create information on websites like Wikipedia. Doing this, people use words alone or in combination with visuals to express their opinions or goals. Past research shows that the words people use can reveal important aspects of their social and psychological worlds (Pennebaker, Mehl, and Niederhoffer 2003). With advances in computer technology, text analysis allows researchers to reliably and quickly gain insights into what people say. In this session, we examine how people choose the words they use as a function of their *supplementary use of visuals* and their *goals,* and examine novel consequences of verbal-visual communication. Jointly, these presentations uncover insights about antecedents and consequences of consumers' word choices as they move through their decision journey, contribute to discussion forums, and write recommendations for others. Papers in this session ask: Do consumers express themselves differently when they use emoji (presentation1) or pictures (presentation2) together with text? Do consumers' internal goals impact their word choice when they create search queries (presentation3) or generate Wikipedia entries (presentation4)? Jointly, these papers examine novel factors that affect consumers' word choices when using different ways to express themselves and their subsequent decision.

Moore, Das, and Mukhopadhyay distinguish how people use emojis to complement or substitute text when responding to others' posts. They find when people respond to posts with mixed emotions, the emoji predominantly used by previous posters drives their own emoji choice and felt emotions. Further, the emotional contagion from such an anchor emoji increases the likelihood of using both text and emoji when responding.

Ceylan and Diehl examine whether people use photos to complement or substitute text when communicating their experiences. They find that photos complement text the more people focus on visual aspects of the experience. Internal factors (i.e., caring about visual aspects) or external factors (i.e., choosing photos ahead of text) heighten visual focus in consumers' writing and increase the likelihood of sharing a photo.

Humphreys, Isaac, and Wang examine how people's transactional (vs. informational) goals impact their word choice in online search queries. They find that people use more concrete words when they are in a concrete mindset. Further, consumers respond more favorably to search engine results and ad content whose language matches their construal level.

Yeomans et al. explores how words indicating receptiveness to opposing opinions can affect readers' perceptions, engagement, and willingness to cooperate. While using receptiveness words fosters trust and cooperation, this effect is often underappreciated by writers who do not anticipated the positive consequences of receptiveness.

Taken together, these presentations identify the antecedents and consequences of consumers' word choices by adopting novel methodologies in a variety of consumption settings. All papers are at an advanced stage, employing a range of methodologies and contexts. None of these papers has been previously presented at ACR. We expect this session will generate significant interest among researchers studying word of mouth, online sharing, natural language processing, and social media.

Emotional Echo Chambers: Observed Emoji Clarify Individuals' Emotions and Responses to Social Media Posts

EXTENDED ABSTRACT

Imagine an individual browsing on Facebook—a daily activity for more than 1.5 billion people (Facebook 2019). This individual sees a friend's post expressing mixed emotions about their grandmother's passing. She notes that others have already responded to the post, some with a sad emoji, and some with a love emoji. How are her feelings and responses to the post shaped by others' prior responses? We find that if others have responded to the post with predominantly sad (love) emoji, the individual in question—and subsequent others—will feel sadder (happier), will be more likely to respond to the post, and will be more likely to respond with a sad (love) emoji. This process may create "emotional echo chambers," contributing to the polarization of opinion and emotion on social media (Toubiana and Zietsma 2017).

Emoji are icons used to convey emotion (e.g., ☺; Oxford English Dictionary 2018), and are a form of textual paralanguage (TPL), which expresses audible, tactile, or visual elements of face-to-face communication in text (Luangrath, Peck, and Barger 2017). In 2016, in addition to the like emoji, Facebook began offering love, haha, wow, sad, and angry emoji reactions to posts. In the subsequent twelve months, these emoji were used 800 million times per day (Cohen 2017). Further, nearly half of Americans (48.9%) use emoji on social media or in text messages (Pilon 2015), and over half of Instagram posts contain emoji (Morrison 2017).

Despite their popularity, it is unclear how use of—or exposure to—emoji affects consumers. Thus, we examine how social media users are impacted by "anchor emoji"—others' prior emoji responses to a post. In doing so, we identify the potential for anchor emoji to

create emotional echo chambers—a substantive issue for consumers, firms, and policy makers. Further, we investigate emoji as a unique type of TPL, which can be used independent of text. Finally, we contribute to theory on emotional contagion. Recent work has established that emoji can lead to contagion (Smith and Rose 2019). The online context allows us to build on this work by: 1) exploring contagion arising from multiple, anonymous emoji; 2) investigating contagion from mixed emotions; 3) testing a new source of contagion: others' emoji responses to a post, rather the post's content. Our results establish anchor emoji as a novel form of unintended and indirect contagion.

We predict that consumers will use the distribution of anchor emoji in response to a given social media post as an input to their own responses. Hence, the same post may generate different emotional and emoji responses from consumers, depending on the distribution of anchor emoji. We suggest that anchor emoji (e.g., sad vs. love) clarify consumers' emotions in response to mixed emotional content (e.g., sad and happy), resulting in felt emotions and emoji choices that correspond with the anchor emoji. A field data sample of 100 posts (with ~200,000 emoji reactions) from CNN's Facebook page supported this conjecture: the first emoji response to a post significantly predicted subsequent emoji reactions.

Study 1 provided a causal test of this notion. Participants (N = 389; MTurk) imagined viewing a friend's mixed emotional Facebook post about their grandmother's passing (i.e., happy and sad; Williams and Aaker 2002). We manipulated the anchor emoji that appeared with the post. Participants saw no anchor emoji (all emoji were zero), one heart anchor emoji (all others zero), or one sad anchor emoji (all others zero). They indicated which of the six emoji they would choose if they were to respond to their friend's post, and reported their feelings on 14 emotion items. Anchor emoji condition predicted participants' chosen emoji: those in the sad (love) anchor condition were more likely to select a sad (love) emoji. Further, participants in the love (sad) anchor emoji conditions felt more (less) positive and less (more) negative emotion than those in the control condition. Felt emotion mediated the relationship between anchor emoji condition and emoji choice. A supplementary study (1A) replicated these effects and demonstrated that anchor emoji impacted not only emoji choice, but participants' overall likelihood of responding.

Using the same mixed emotional post as Study 1, Study 2 aimed to replicate these effects using multiple anchor emoji (N = 311; undergraduates). In the sad (love) anchor emoji condition, participants saw a like emoji and a sad (love) emoji with the number 107, indicating that 107 others had responded to the post, some with like reactions and some with sad (love) reactions. The control condition showed no anchor emoji. This study also manipulated the order in which participants chose an emoji and reported felt emotion, to confirm that choices were driven by felt emotion (and not vice versa). We found that regardless of order, participants in the sad (love) anchor emoji condition were more likely to choose a sad (love) emoji, relative to the control condition and to the other anchor emoji condition. Felt emotion showed corresponding effects, and mediated participants' emoji choices.

Study 3 (N = 484; MTurk) explored the relationship between emoji and text responses. We tested whether emoji responses supplement or replace commenting on a post (Luangrath et al. 2017). Our prediction was that the emotional contagion from anchor emoji would increase the likelihood of responding with both. Using a different mixed emotional post (a dog dying), we manipulated anchor emoji condition (control, sad) and whether participants were: 1) forced to choose either an emoji or a comment as a response; or 2) free to choose either response, or both. We found that participants in

the free choice condition who were exposed to a sad anchor emoji felt the most negative emotion, and were the most likely to select both an emoji and a comment as a response. This suggests that when anchor emoji are present, observers' felt emotions mirror the anchor, and that emoji and text responses supplement one another.

To sum, consumers' emotional responses to mixed emotional posts are clarified by anchor emoji, leading them to make corresponding emoji choices and potentially creating "emotional echo chambers".

Is a Photo Worth a 1000 Words? The Usage of Images and Text to Express One's Opinions

EXTENDED ABSTRACT

People have more ways than ever to share and communicate thoughts and experiences to other people. In particular, camera-enabled phones have created the ability to easily share experiences not just verbally but also visually. Hence our research asks: How do people use visual and verbal information when communicating their experiences? Specifically, we examine whether people use pictures to *complement* or *substitute* text. Lay belief may suggest that "a picture is worth 1000 words" and hence that pictures may *substitute* text. Alternatively, people may want to "show and tell", in which case pictures may *complement* text (and vice versa). In this project, we investigate how and why people combine these different forms of expression.

Study 1 examines the relationship between text and pictures in the context of online reviews. We examined whether greater focus on visual aspects of the experience would increase or decrease the usage of photos in two large restaurant review datasets (from Yelp! and TripAdvisor). We found that people were more likely to post a photo when they provided greater *visual* detail (measured by the number of words from the "see" category in LIWC) in both the Yelp! ($\beta = 0.11$, $t = 44.5$, $p < .001$) and TripAdvisor ($\beta = 0.05$, $t = 15.9$, $p < .001$) datasets. This relationship also occurred for the number of photos included (Yelp!: $\beta = 0.06$, $t = 27.7$, $p < .001$; TripAdvisor: $\beta = 0.03$, $t = 15.3$, $p < .001$) and held for expert and non-expert reviewers and controlling for word-count (excluding see words) as well as restaurant-specific factors. These analyses suggest that reviewers use pictures to *complement* words when they focus more on visual aspects of the experience.

In **study 2**, we manipulated the number of see words in a product review and tested whether greater focus on visual aspects heightens photo use. This study followed a three-group design. We recruited 598 participants (41.2% female; mean$_{age}$ = 35.8) on MTurk (preregistration: osf.io/jd23r/). Participants imagined they had written a review of a computer mouse and read "their" 140 words- review. Participants in the no-see words condition read a review that included no words from LIWC's "see" category. In the low-see [high-see] words condition "see" words constituted 10% [30%] of the review. Participants indicated whether they would consider adding a photo when posting this review (Yes = 1, No = 0), our independent variable. In line with the correlational data, a greater percentage of participants in the high-see words condition (86%) indicated that they would include a photo compared to the no-see words condition (75%), $t(598) = 3.09$, $p = .002$. Participants in the low-see words condition were directionally but not statistically significantly more likely to include a photo with their review (82%) compared the no-see words condition (75%), $t(598)=1.4$, $p=.16$. This study provides causal evidence that using more visually-focused words heightens photo sharing.

Studies 1 and 2 suggest a complementary relationship between text and photos. In study 3, we manipulated people's focus within an experience. We recruited 400 respondents on MTurk (41.2% female; meanage = 35.8) but excluded 66 people due to non-compliance with instructions (preregistration: https://osf.io/472xy). Participants imagined writing an email to a friend about their positive experience at a restaurant. Participants first identified 3-5 elements that positively influenced their experience that either related to the look of the food and the design of the restaurant (visual-focus condition) or to the staff and service (human-focus condition). Subsequently, all participants wrote an email to their friend focusing on these elements and then indicated whether they would consider adding a photo to this email (Yes = 1, No = 0). Importantly, participants were more likely to share a photo in the visual-focus (63%) than the human-focus condition (46%), z=3.1, p=.002, again pointing to a complementary relationship.

One aspect inherent to the real-world data but also the lab studies is the order in which text versus pictures are produced: text is written first, then photos are added. This structure may have contributed to the observed complementary relationship which may not exist if photos are selected first. In study 4, we manipulated the order of writing (text-first vs. picture-first) and altered whether text and pictures were produced on the same page or different pages. We recruited 466 participants on MTurk (preregistration: https://osf.io/hmfzc). Procedures followed those of study 3 except that participants indicated 3-5 elements of their choice that impacted their experience positively. In the text-first condition, participants first wrote an email to their friend and subsequently picked a photo of that restaurant (available on Yelp!) to include in their email. In the picture-first condition, these steps were reversed. In the different pages condition, these steps were requested on separate pages, in the same page condition they were requested on one page. We measured participants' focus by their usage of "see" category words. Participants themselves also indicated to what extent they focused on the look of the food and design elements when writing the email. Participants used more see words in the picture-first (M=0.73) than the text-first condition (M=0.65, t(466)=1.83, p=.06), suggesting again a complementary relationship. They also used more see words when text and picture were presented on the same (M=0.77) than on different pages (M=0.61, t(466)=2.14, p=.03). Self-reported measures of visual focus parallel these findings.

Taken together, we find that people use photos complementary to text in communicating their experiences. This is particularly true when they focus on visual aspects of an experience, either due to an internal or external focus. While much research has examined how purely verbal communications are perceived by readers, our findings shed light on an important but unexplored area, namely how both visual and verbal information are used jointly by communicators.

Construal Matching in Online Search: Applying Text Analysis to Illuminate the Consumer Decision Journey

EXTENDED ABSTRACT

This research incorporates Construal Level Theory (Liberman and Trope 1998; Trope, Liberman, and Wakslak 2007) and text analysis (e.g., Humphreys and Wang 2017; Berger et al. 2020) in order to improve outcomes in online search. We propose that as consumers move through the decision journey, they adopt different goals that can be detected through text analysis of their search queries. We hypothesize that consumers with informational [transactional] goals are likely to generate search queries that exhibit different levels of mental construal, or mindsets, i.e., abstract [concrete]. We further posit a fluency-driven matching effect in online search such that consumers respond more favorably to search engine results and ad content containing language that matches their mindset.

In the pilot study, we analyzed a data set of 24,039 search queries. We calculated a concreteness score for each search query in our database using the concreteness dictionary developed by Paetzold and Specia (2016). Our analysis established that, contrary to conventional wisdom, substantial variation exists in the abstractness/concreteness of language used by consumers when performing an online search.

Study 1 is a survey in which university students (N = 369) reflected on the last query they made using a search engine. We found that participants with a transactional goal executed queries that were more concrete (less abstract) than participants with an informational goal. Furthermore, we obtained correlational evidence that participants at an earlier stage of the decision journey (i.e., informational goals) are relatively less likely to visit e-commerce websites and corporate websites than consumers at a later stage (i.e., transactional goals).

Study 2 tests our proposition that construal matching between consumers' stage in the decision journey and the concreteness of the language in a search result will increase their engagement. In this 2 (journey stage: informational vs. transactional) x 2 (search results: abstract vs. concrete) between-participants design, we informed 490 MTurkers that they were repainting their living room. The language used in the description of their journey stage or in the search results was either abstract or concrete. Results confirmed our prediction that participants were more likely to choose a search result whose concreteness matched with the consumer journey stage.

Study 3 assesses how construal level varies for multiple stages of the decision journey. Recruited by a market research firm, 357 U.S. participants were informed that they were considering purchasing a laptop computer, and that consumers tend to progress through three sequential stages – information, comparison, transaction – when making a purchase decision. We assigned the participants to one of the three stages, asked them to execute an online search, and showed them advertisements whose language varied in concreteness. We found that participants in the transactional stage executed searches that were more concrete (less abstract) and preferred more concrete results than participants in the other two stages.

Study 4 explores how the construal matching effect influences consumers' perceived progression through the decision journey. In a 2x2 design, 427 MTurkers were informed that they wanted to learn more about grilling (informational stage) or that they needed to choose a charcoal grill (transactional stage). Then, after being shown a list of either abstract or concrete results, they were asked to indicate the amount of progress they would make on their decision journey if they visited these websites. Participants in the informational stage reported that they would make greater progress when they encountered abstract search results as opposed to concrete search results. However, participants in the transactional stage reported that they would make greater progress when they encountered concrete search results.

Finally, in a field experiment with over 128,000 ad impressions, we investigated actual click behavior in a real-world context. We bid on a set of abstract and concrete keywords that appeared in search queries for a particular product category. We created two versions of an online advertisement that were written using either abstract or concrete language. The field study corroborated the construal matching effect; click-through rates were higher when the language of the search query matched the concreteness of language in the advertisement.

We make three contributions to research on search and consumer journey. First, we demonstrate the influence of construal level in online search and show that firms can increase engagement by matching their content to consumers' mindsets. Second, we illustrate the important substantive consequences of matching construal for improving the search experience and making search advertising more cost- and time-efficient. This work outlines a scalable method for firms to identify consumers' search goals in text and facilitate their progression through the consumer journey. Finally, we highlight the contextual and changing nature of the decision journey. By outlining a straightforward and implementable process by which consumers' mindsets can be reliably categorized based on their own search queries, we add to the burgeoning literature in marketing that shows how text analysis can provide nuanced insight into consumer needs and goals. Digital marketers can leverage this newfound knowledge to serve content that corresponds with consumers' construal level, resulting in greater, customized consumer engagement at a lower cost to advertisers.

Conversational Receptiveness: Improving Engagement with Opposing Views

EXTENDED ABSTRACT

Disagreement is a fundamental feature of social life, in civic spaces, in professional organizations, and in personal relationships at home. Opposing viewpoints are often inevitable in the pursuit of more important organizational and interpersonal goals. Engagement with diverse perspectives can also help us increase the accuracy of our own belief. However, disagreement can also give rise to biased processing, negative inferences, and conflict. While engagement with opposing viewpoints can be beneficial, its effects will be tempered by the contents of those interactions (see Bail et al. 2019; Paluck, Green and Green 2018). Here we examine whether "conversational receptiveness" can foster co-operative goals during disagreement and prevent conversational conflict spirals.

In this research we conduct four studies, and all data, analysis code, stimuli, and preregistrations from each study are available (anonymously) at https://bit.ly/2QwyiuL. In Study 1 we instructed 1,102 participants to write responses to statements written by people with whom they disagree, on one of two controversial issues. A separate group of 1,322 participants read responses from people with opposing viewpoints, and evaluated how receptive the writer had been. We parsed the text of the responses into features from the politeness R package (Yeomans, Kantor and Tingley 2018), and we trained a supervised machine learning algorithm (Friedman, Hastie and Tibshirani 2010) to build a receptiveness detection model that was generalizable (for datasets from other domains) and interpretable (to design interventions). This model was just as accurate (pairwise accuracy = 66.8%; p<.001), as any one human rater (65.2%; p<.001). The model focuses on the structural, domain-general elements of the language (hedges, acknowledgment, negation, reasoning), and the model's accuracy was unaffected when it was trained and tested on different topics (65.2%; p<.001). In Studies 2 and 3, we apply the model in conversations from organizational contexts where disagreement naturally arises.

In Study 2, we collected conversations between 238 senior local government officials in an executive education program, who were paired up to discuss controversial policy topics (using a negative assortative matching algorithm to ensure they all disagreed with their partner). After the conversation, participants rated their own and their partner's receptiveness. Partner-rated receptiveness was associated with a range of positive interpersonal benefits, like trust in judgment and willingness to work together (r=.289, p<.001). Furthermore, the receptiveness model from Study 1 predicted these positive interpersonal outcomes (r=.232, p<.001), and also showed that partners' receptiveness converges over time, indicating that one of the benefits of receptiveness is that it is returned in kind (r=.335, p<.001). However, people could not predict how receptive their partner would rate them (r=.048, ns). Our language model held their own speech to a different standard than their partner's speech, focusing more on formality (titles, gratitude, etc.) than demonstrations of listening.

In Study 3 we extend this result to conversations within globally-distributed organizations where disagreement naturally arises, and where people are free talk about many different topics, with many different people. In Study 3A we examine receptiveness among 3,303 students in policy-themed massive open online courses at HarvardX. We collect ideology measures and compare them to the contents of the class discussion forums. We find that on average, students were less receptive to students they disagreed with (r= .099, p < .05). However, the receptiveness of students' posts predicted the receptiveness of the replies they received from other students who disagreed with them (r= .226; p<.001). This suggests that receptiveness is often, and individual choices to be more receptive can foster a more receptive dialogue going forward. In Study 3B, we measure receptiveness during the editorial process of correcting Wikipedia articles. We borrowed a dataset of talk page threads, in which 585 threads ending in personal attacks were each matched to similar thread without an attack (Zhang et al., 2018). We found that editors who were less receptive were more likely to be attacked themselves (59.9%; p<.001).

Study 4 was similar to Study 1 except that some writers were first taught a "recipe for receptiveness", which was developed as a 100-word summary that can be cheaply deployed as a nudge during conversation. Opponents who read the responses from writer who saw the recipe thought they were more trustworthy and persuasive than writers who responded naturally. However, writers did not always predict this effect, and expressed surprising hesitation to be receptive in the future.

Overall, our results suggest that receptiveness is measurable and has meaningful interpersonal consequences but can be under-utilized in part because speakers can misjudge their own receptiveness. Our results also highlight an under-discussed element of recent efforts to improve civic discourse: The linguistic behavior that people exhibit in conversation can powerfully affect their partners' perceptions, engagement, and willingness to cooperate.

SESSION OVERVIEW

Price can arguably be considered one of the most important attributes for consumers' purchase decisions. Importantly, besides actual prices, consumer price perceptions play a crucial role in impacting purchase decisions (Zeithaml 1988; Gupta 1988; Monroe 2003; Krishna et al. 2002). This session was put together with the aim of deepening our understanding of how consumers' decisions and behaviors are influenced by factors related to pricing. Each paper will approach this from a different theoretical angle—making the session as a whole highly relevant and appealing to a wide range of consumer researchers. Importantly, on top of using data from behavioral experiments, the papers also present evidence drawn from incentive-compatible paradigms or field studies, large-scale panel data, and secondary data from various industries. We contend that this contributes to the overall robustness and eventual generalizability of our collective findings.

The first two papers focus on how purchase decisions are guided by how consumers make use of price information. When engaging in purchases, consumers can rely on narrow or broad bracketing. **Morwitz, Hadar,** and **Danziger** document conditions under which choice is likely to be guided by average price perceptions versus predictions of specific future prices, and how these perceptions and predictions impact purchase for consumers of frequency or depth pricing retailers.

Next, **Gunadi** and **Evangelidis** evaluate how consumers' purchase decisions are influenced by historic price information. They focus on the interaction between frequency and direction of past price changes on purchase decisions for a given product.

In the third paper, we turn to examine whether the purchase of a specific product could be influenced by price promotional information for another product. **Kan, Lichtenstein, Janiszewski** and **Liu** document the deal proximity effect, and find that this crucially depends on substitutability of the respective products.

We round out the session with a longitudinal assessment of how consumers behave under a consumer elective pricing scheme

'pay-what-you-want.' Using a large-scale panel dataset, **Jung, Liu,** and **Nelson** found that consumers voluntarily contribute a positive amount, but that this contribution gradually declines over time.

Collectively, this session strives to answer two broad questions. Firstly, how are consumer purchase decisions influenced by price information, be it past prices, aggregate price perceptions, or prices of other, related products? Secondly, how do consumers behave under specific pricing schemes and strategies? The papers arguably show the multidimensionality of pricing, and how diverse research on this topic can be. While price plays a key role in the consumers' decision-making process, at the same time, it is also an important instrument that retailers have managerial control over. Accordingly, we believe these papers—which are wide-ranging but complementary in nature—offer important theoretical and practical insights. Whether companies are choosing to use an elective pricing scheme, or to incorporate price promotional deals, or to convey price changes, or to opt for depth or frequency pricing strategies—this session highlights how they could all have substantial impact on consumers' purchasing behavior.

Choice Bracketing and Consumer Choice under Uncertainty

EXTENDED ABSTRACT

Consumers' inclination to use narrow bracketing, that is, to consider choices independently of other similar choices, or broad bracketing, that is, to consider multiple, similar choices jointly, may systematically influence choice. For example, consumers may choose between two retailers based on an isolated assessment regarding which retailer will be cheaper on a particular purchase or based on an aggregate assessment of which retailer will be cheaper on average, across multiple purchases. These choices may differ because the retailer more likely to be cheaper on a particular purchase is not necessarily the one that will be cheaper on average. We examine the effect of choice bracketing on preference for retailers using frequency (i.e., offering many small discounts) versus depth pricing strategies (i.e., offering fewer, but larger discounts).

Consumers generally buy more often at frequency retailers than at depth retailers because they rely on trial-by-trial predictions of which retailer will be cheaper on the next shopping trip, rather than on their beliefs regarding which retailer is cheaper on average (Danziger, Hadar, and Morwitz 2014). We examine conditions under which choice is likely to be guided by average price perceptions. We find that consumer reward programs that reward multiple purchases or set minimum purchase requirements encourage broad bracketing, prompt reliance on average price judgments and preference for retailers who consumers believe offer a lower price on average, whether it is the depth or frequency retailer.

Participants in our studies were incentivized to minimize overall costs when making multiple choices between two options. Choices were made without knowing the options' prices in advance. In study 1, 120 students made 21 daily choices between two fictitious coffee shops and received an incentive-compatible payoff. Unbeknownst to participants, one coffee shop used frequency pricing while the other used depth pricing. We manipulated, between-subjects, which coffee shop was cheaper on average. After participants completed 20 choices between the two coffee shops the bracketing manipulation was introduced. Participants in the *narrow bracketing* condition received

10 coupons offering a 10% discount on the price of coffee. Each coupon could be redeemed at either coffee shop; participants in the *broad bracketing* condition received one coupon offering a 10% discount on the price of coffee, for *one* of the coffee shops, valid for the next 10 purchases. They indicated which coffee shops' coupon they wanted and received the discount only if they chose to buy at this shop. Supporting our hypothesis, we found a Bracketing by Cheaper distribution interaction effect ($\chi^2(1)$=4.95; *p*=.026): participants were more likely to shop at the cheaper shop in the broad bracketing condition ($\chi^2(1)$=1.9, b=1.4, *p*=.057), but not in the narrow bracketing condition ($\chi^2(1)$=-1.3, b=-.97, *p*=.184).

Study 2 (N=202) examines the effect of choice bracketing on the propensity to choose the option consumers *judge* as cheaper on average. Broad bracketing is prompted by having participants made multiple choices before receiving any feedback (while in the narrow bracketing condition feedback is provided following every choice; Read, Loewenstein, and Rabin 1999). Actual average prices were the same across the depth and the everyday low price (EDLP) retailers. The Bracketing by judged average price difference interaction was significant ($\chi^2(1)$=5.09; *p*=.024): in the broad bracketing condition the cheaper the judged average price of the depth grocer, relative to the EDLP grocer, the higher the choice likelihood of the depth grocer (B =.34; 95% CI=.05,.64). In the narrow bracketing conditon, however, average price difference did not predict choice (B= .004; 95% CI=-.01,.02).

Study 3 replicated this effect with non-dichotomous distributions of time. Participants (N=201) made repeated choices between two roads and were instructed to minimize overall commute time. One road was associated with a frequency time distribution and the other with a constantly short time distribution. In the narrow bracketing condition participants received 10 vouchers to a fast lane that reduces the commute time by up to five minutes; participants in the broad bracketing condition chose a single voucher for the fast lane, valid for the next 10 trips, for one of the roads. We, again, found a Bracketing condition by judged average time difference interaction (B=.008; 95% CI=.002,.01; *p*=.015): in the broad bracketing condition, the lower the judged average time of the frequency road, relative to the constant road, the higher the choice proportion of the frequency road (B =.012; 95% CI=.008,.017; *p*<.0001). In the narrow bracketing conditon, however, the judged average time difference did not predict choice (B=.004; 95% CI=-.001,.009; *p*=.082).

In Study 4 (N=400), holding reward magnitude constant, participants in the narrow bracketing condition were rewarded for individual choices whereas participants in the broad bracketing condition were rewarded only if they completed a fixed number of purchases at a given retailer. We manipulated which option was cheaper on average. Our hypothesis was supported by a moderated mediation analysis (PROCESS model 14; Hayes 2013) in which the independent variable was the Cheaper Retailer, the mediator was judged average price difference, the dependent variable was Depth choices, and the moderator was Bracketing. We found a significant Bracketing by judged average price difference interaction (B=.03, 95% CI=.01,.05; *p*=.008) and a significant moderated mediation effect (B=.05, 95% CI=.01,.11): average price difference mediated the effect of Cheaper price on choice in the broad bracketing condition (B=.04, 95% CI=.01,.07), such that the the judged average price of the depth retailer relative to the frequency retailer was lower when the depth grocer was cheaper than when the frequency grocer was cheaper. In addition, the lower the average price of the depth grocer was judged to be (relative to the frequency retailer), the more the depth grocer was chosen. In contrast, in the narrow bracketing condi-

tion, the judged average price difference did not mediate the effect of Cheaper price on choice on choice (B=-.02, 95% CI=-.06,.02).

Our results suggest that companies whose products or services are perceived as relatively cheaper on average should offer reward programs that trigger broad bracketing, for example, by rewarding multiple purchases. In contrast, companies whose products or services are perceived as relatively expensive on average are better off rewarding individual purchases.

The Impact of Historic Price Information on Purchase Deferral

EXTENDED ABSTRACT

In current retail settings, prices of goods in the market change frequently over time and consumers now have increasing access to historical prices. We examine how frequency and direction of past price changes influence consumers' decision to buy later versus now. We advance an expectation-based framework—proposing that frequency of price changes impacts the expectations people form about future price changes. We set forth two key predictions. For price decreases, we predict that consumers would be more likely to defer purchase upon observing a higher frequency of past decreases in price. For price increases, consumers would be less likely to defer upon seeing a higher frequency of past increases.

Research shows that consumers tend to expect a sequence of events to represent alternations instead of runs (Tversky and Kahneman 1974). Upon observing a series of identical outcomes, consumers may believe an alternative outcome would be due. However, in the price changes context, we predict that consumers may be more likely to expect the same change (decrease or increase) as previously observed to repeat in the future (Gilovich et al. 1985; Carlson and Shu 2007). We posit that these expectations will be stronger, the *more* changes in the same direction consumers have previously encountered. Specifically, for price decreases, consumers will hold stronger beliefs that the price will decrease further in the future, upon observing relatively higher frequency of decreases in price. Similarly, for price increases, consumers will hold stronger beliefs that the price will increase further, upon observing higher frequency of increases. In turn, these expectations that consumers form about future price changes will affect their decision to make or defer purchase. Consumers should be more (less) likely to defer purchase, the more they believe that the price of the product they consider purchasing will decrease (increase) in the future.

We found collective support for our predictions in eight preregistered experiments (N=5933) and three studies using secondary data (N=3537). In most of the studies, we employed a 2 (direction of price change: decrease vs. increase) by 2 (frequency of change: low vs. high) between-participants design. Participants were asked to imagine that they were buying a specific product, and were provided with historic price information (in numeric form) based on the experimental condition. We manipulated frequency of change by altering how many changes in the ticket price were communicated to the participants. In the low frequency condition, there was one change in price. In the high frequency condition, there were four changes. Importantly, the final price and the absolute magnitude of change were held constant across conditions. Our dependent variable was participants' decision to buy the product now or later.

Study 1a established the expected interaction between frequency and direction of change on purchase deferral in the context of flight tickets. As predicted, when price decreased, participants were more likely to defer purchase when the frequency of price changes was high (27.4%), compared to low (10%), Waldχ^2 = 18.50, *p*<.001.

When price increased, participants were less likely to defer purchase when the frequency of price changes was high (26.4%) versus low (46.3%), Waldχ^2 = 16.87, p<.001. We replicated this pattern of results when holding the amount of information constant across low/high frequency conditions (Study 1b) and when price information was presented visually in graphs (Study 1c).

Study 2 tested our expectations-based account. Consistent with our theoretical framework, we found that controlling for the magnitude of change, frequency strengthens expectations about future price changes. Consumers hold stronger expectations that prices will decrease further in the future (F(1,598) = 46.84, p<.001), and are more likely to defer purchase when the frequency of price decreases is high versus low. Conversely, consumers hold stronger expectations that prices will increase further in the future, and are less likely to defer purchase when the frequency of price increases is high versus low F(1,598) = 31.12, p<.001, (interaction F(1,598) = 77.16, p<.001). Further, a conditional process analysis showed that expectations mediated the effect of frequency on deferral both when price decreased and increased (index of moderated mediation = -2.77, SE=.42, $99\%LLCI$=-3.94, $ULCI$=-1.82).

Subsequent studies test potential moderators. Studies 3a and 3b document the role of monotonicity. The presence of an inconsistent change—a change that goes in the opposite direction, compared to previous changes—attenuated the impact of frequency on purchase deferral. In these studies, we had low frequency, high frequency monotonic, and high frequency nonmonotonic conditions. In Study 3a, when prices were decreasing, participants in the high frequency monotonic condition were less likely to defer the purchase (29.6%) compared to their counterparts in the low frequency condition (60%), Waldχ^2 = 36.48, p<.001. Importantly, this result was eliminated when changes were not monotonic (high nonmonotonic = 64.2%, Waldχ^2 = .74, p=.389). We replicated these findings for price increases (Study 3b).

Study 4 showed that the impact of frequency on purchase deferral is stronger when the magnitude of the change in price is relatively larger. We added a new factor, magnitude of change (small vs. large) to our usual 2x2 design. The three-way interaction (direction, frequency, and magnitude) on deferral was marginally significant (Waldχ2 = 2.77, p=.096). Importantly, the interaction between our direction and frequency factors was stronger when the magnitude of the change was large (Waldχ^2 = 46.10, p<.001) versus small (Waldχ^2 = 16.22, p<.001).

Study 5 adds to the existing body of evidence for our effect by replicating our findings (interaction: Waldχ^2 = 6.01, p=.014) in a setting where decisions are incentivized and consequential for participants.

Lastly, to complement the previous studies which were conducted in controlled experimental settings, Studies 6a-c document our basic effects using data from online cryptocurrency, housing market, and automobile transactions.

In sum, we found that in the case of price decreases, participants were more likely to defer purchase upon observing a relatively higher frequency of changes. On the contrary, in the context of price increases, participants were less likely to defer purchase upon observing a relatively higher frequency of changes. These effects are explained by variations in consumers' expectations about future prices.

The Negative and Positive Consequences of Placing Products Next to Promoted Products

EXTENDED ABSTRACT

Consumers often select from a variety of competing products in multi-product displays. Some products might be discounted while others are regular price, and products are positioned at various locations within the display. Do price deals differentially impact demand for other products depending on their location within a display?

We find evidence for a deal proximity effect that differs depending on product substitutability. When the proximal and distal items are *strong substitutes* for the promoted item, a price promotion *decreases* the sales of proximal products relative to distal products: *a negative proximity effect*. We surmise that this occurs because the promoted product attracts attention that then spills over to the proximal product. Because both products are strong substitutes, they enter the same consideration set. The reduced price on the promoted product results in the promoted product being more attractive, leading to sales losses for the proximal product.

However, when the proximal and distal items are *weak substitutes* for the promoted item, the promoted product *increases* the sales of proximal products relative to distal products: *a positive proximity effect*. Because the proximal product is a weak substitute for the promoted product, it is unlikely to enter the same consideration set as the promoted product and thus, the reduced price on the promoted item is not a relevant referent for the proximal product. However, the proximal product still benefits from the increased attention, which positively impacts its sales.

Our first study explored whether grocery store managers would intuit the proposed pattern of effects. Grocery store managers were recruited by Qualtrics to participate in this study. They were shown a planogram from a yogurt shelf and told that a product was being promoted at a price discount. They were first asked to estimate the impact of this promotion on the percentage change in sales of four other products on the shelf in a 2 (Proximity to discounted product: proximal v. distal) x 2 (Substitutability: strong substitute v. weak substitute) design. Results indicate managers predict that a price promotion has a significantly stronger impact on stronger substitutes than weaker substitutes, but do not anticipate that price promotion effects differ by proximity or the interaction of proximity by substitutability.

Study 2 analyzes a secondary dataset of yogurt sales obtained from a retail grocer. The dataset provided information on each yogurt's sales, regular price and whether it was being promoted at a discounted price. We use the grocer's planogram to determine how far apart each yogurt is located from one another. We also ran a pretest on mTurk to determine perceived substitutability between yogurts based on various product attributes. A fixed effects analysis reveals that cross price promotion effects differ significantly depending on substitutability, distance within the planogram and their interaction. For highly substitutable products, a sales promotion had a negative cross price promotion effect that diminished as the distance between the two products increased. For weakly substitutable products, a sales promotion had a positive cross price promotion effect that diminished as the distance between the two products increased.

Studies 3a and 3b were designed to address limitations due to the correlational nature of the study 2 dataset. We ran two field studies at a campus bookstore in which we manipulated the proximity of products to a discounted product within a display. In study 3a, we used two different product categories to serve as weak substitutes for one another; plush toy keychains and car decals. We observe a positive deal proximity effect: when a plush toy keychain (car emblem)

is promoted at a discounted price, the proximally located car emblem (plush toy keychain) sells significantly more than the distally located car emblem (plush toy keychain). In study 3b, we used five product category replicates (energy drinks, keychains, lanyards, socks, and trail mix), each with its own display, to test for a negative proximity effect. For each product category, one product was chosen to be the discounted product, and two products were chosen to be strong substitutes for the discounted product. Collapsing across product replicates, a test of proportions showed that the choice share of the proximal product was significantly lower than the choice share of the distal product.

Our next study used two different operationalizations of product substitutability to provide further evidence that the effects result because of differences in perceived substitutability. We used a simulated internet shopping experience with participants on mTurk (n = 559). The two substitutability operationalizations were goal-based substitutability and product attribute-based substitutability. These conditions were run across eight product category replicates (cookies, chocolate covered snacks, savory snacks, candies, jams, chocolate bars, sodas and soaps) in a repeated measures latin-square design. We find evidence for a negative deal proximity effect when substitutability is highest, a null effect when substitutability is medium and a positive deal proximity effect when substitutability is low.

Across five studies, we observe evidence for a negative deal proximity effect when substitutability is high and a positive deal proximity effect when substitutability is low. This pattern of effects is novel to marketing practitioners and can offer actionable insights; retailers can use product proximity to actively manage the consideration sets and purchases of consumers.

These results contribute to literature on 1) price promotions (e.g., Blattberg and Wisniewski 1989, Rooderkerk, Van Heerde, and Bijmolt 2013) by offering shelf proximity as an important moderator of cross price promotion effects, 2) consideration sets (e.g., Nedungadi 1990, Shocker et al., 1991) by providing a proximity-based explanation for influences on brand co-occurrence in the same versus different consideration sets, and hence contexts in which brands are more/less likely to directly compete, and 3) retail shelf optimization (e.g., Corstjens and Doyle 1981, Eisend 2014) by offering insight into how to organize shelves so that multiple brands (e.g., promoted brand, weak substitute proximal brand) might benefit most from the promotional activity of a single brand.

An Examination of Consumers' Long-term Social Preferences Under Elective Pricing

EXTENDED ABSTRACT

Standard economic models assume that people maximize material self-interests, ignoring any concern for others. Accordingly, consumers want to pay as little as possible and tend to seek for deals and discounts to exploit in marketplaces. Yet, people also give money to charities or volunteer their time to help others. People care about fairness and reciprocity even at the expense of their own material self-interests (Andreoni and Miller 2002, Charness and Rabin 2005, Rabin 1993).

Consumer elective pricing applies in any transaction in which buyers can decide their own prices for the goods and services that sellers offer. Consumer elective pricing has been shown to be a valuable tool for studying social preferences in real market contexts. It has been well documented that even when consumers are allowed to be maximally selfish, most of them choose not to be (Kim et al. 2009, Mak et al. 2010, Gneezy et al. 2010, Jung et al. 2014, 2017).

The extant research offered important insights into how consumers determined how much to pay under elective pricing, but much less known about the stability of consumers' social preferences. Most studies that document consumers' decisions under elective pricing used the data that typically involved either single purchases or on aggregated data across time. This limitation is notable because it leaves open the possibility that apparently strong social preferences might actually be fleeting. A few studies looked at consumers' repeated purchases under elective pricing but showed mixed results on their long-term behavior. Some found that consumers' payments increased over time (Kim et al. 2010), whereas the others documented a decreasing pattern of payments over time (Levitt 2006; Riener and Traxler 2012). Although these papers provided new insights into the long-term dynamics of consumers' social preferences, their data lacked a critical feature-they could not observe individual-level social preferences over time. A few studies that recorded individual-level payments considered behavior in relatively short duration. Our goal is to examine the stability of consumers' long-term social preferences in a market exchange environment by addressing the key weaknesses of the previous research.

We analyze panel data from an online media retailer that sells bundles of electronic books (eBooks) written by independent authors. The data set includes 163,551 transactions from 57,196 customers, from the company's launch on August, 6th, 2012 to June, 26th, 2017. Our data contains the individual-level transactions for the sales of 114 bundles of eBooks, which contain a total of 1,147 books, written by 748 independent authors.

Given the firm's pricing features, we use consumer elective contribution as a proxy measure of customers' social preferences. We define consumer elective contribution to be how much more consumers pay than the minimum or bonus price for a specific bundle that they purchase. The notion is that the entirety of this marginal contribution is offered without any additional direct benefit to the customer.

Consumers' elective contribution decreases with each subsequent purchase; falling from an average initial elective contribution of over $2.50 to about $1.00 by the 25th purchase. More important, however, is that even by the 25th purchase, customers are still meaningfully contributing well beyond the bonus or minimum price. The pattern is similar when we look at consumers' elective contribution as percentage of the price paid. We looked at the sub-sample of 2,634 customers who purchased more than 10 bundles and find that customers decrease their elective contribution with each subsequent purchase. The results are consistent when we control for the bonus price and multiple product quality factors variations across the bundles.

We observe that frequent buyers indeed contribute less than infrequent buyers over time. Customers who only bought one bundle contributed an average elective contribution of $2.66, whereas consumers who bought two bundles contributed an average elective contribution of $2.29. When a consumer buys more than 30 bundles, the average elective contribution decreases to $1.26, less than half of the level of elective contribution of those who bought only once. The average level of elective contribution and purchase frequency are negatively correlated such that frequent buyers contribute less than infrequent buyers.

Consumers with increasing elective contribution exit significantly earlier than those with decreasing elective contribution. Therefore, the declining pattern of customers' elective contribution seems to be due to attrition of a certain segment. Customer exit is consequential for the firm. As we previously reported, frequent buyers start with a smaller elective contribution and their contributions

decrease over time, but they also stay with the company for a longer duration. Although customers who contribute increasingly pay more per bundle, because they leave the company earlier, they contribute only an average cumulative elective contribution of $6.55. Alternatively, the customers who contribute decreasingly pay less per bundle, but offer substantially more cumulative elective contribution to the company.

In sum, most customers voluntarily contribute a positive amount with their first purchases and continue to do so over subsequent purchases. Furthermore, although on average, customers always pay more than they have to, their voluntary payments slowly decline with each subsequent purchases. Lastly, we further identify customer heterogeneity in the stability of their elective contributions over time. We observe that generous customers are less likely to be loyal to the firm and therefore make fewer purchases over time. For a firm that leverages customers' social preferences for its revenue, customers who pay relatively less, yet loyal, contribute more to the firm in the long run than customers with larger initial contributions but less stable.

SESSION OVERVIEW

Extraordinary experiences as consumption phenomena remain a fascinating area of academic research (Beverland, Lindgreen, and Vanhamme 2012; Caru & Cova, 2006; Lanier Jr., Clinton, & Rader, 2015; Turner and Bruner 1986). Within marketing, multiple perspectives have been adopted to look at extraordinary experiences (Arnould & Price, 1993; Belk & Costa, 1998; Kozinets, 2002; Tumbat and Belk 2011). Even as extraordinary experiences have been explored in diverse contexts (Tumbat and Belk 2011), these studies have been largely restricted to the consumption sphere in the United States and other developed markets (Arnould & Price, 1993; Belk & Costa, 1998, Kozinets, 2002). Even as this stream of research has provided seminal insights about consumer behavior in the consumption of extraordinary experiences, it has left open the opportunity to explore this phenomenon using differing consumer cultural perspectives. In this special session, we aim to explore diverse facets of extraordinary experiences from hitherto under-explored cultural perspectives, with the broad aim of theoretically and empirically extending consumer research on extraordinary experiences. In doing so, we consider diverse empirical contexts, different methodological approaches to studying extraordinary experiences, and disparate *types* of extraordinary experiences.

In paper 1, we consider the context of a single temple festival in India, and examine how socio-historical institutions shape consumption. The study takes a naturalistic ethnographic approach to explore the *Nemmara-Vallangi vela*, a temple festival in Kerala, India. In paper 2, we consider a specific Buddhist ritual that occurs at the intersection of spirituality and consumption- the Thai Theravada Buddhist Death Ritual for the Living. The theorization seeks to extend Victor Turner's idea of liminoid consumption into the spiritual sphere. Paper 3 entails a multi-sited sensory ethnography of four different pilgrimages in Europe (Lourdes – France, Camino de Santiago – Spain) and Latin America (Juazeiro do Norte and Belém do Pará

– Brazil). The study investigates how the extraordinary experience of pilgrimage is experienced as a transformative sensory phenomenon. Finally, paper 4 takes a Turnerian approach to the theorization of solo travelling. Sixteen solo travelers are interviewed in order to generate insight into the personally transformative extraordinary experiences they sought and gained in the anti-structural realm of adventurous solo travel.

The papers have in common a focus on consumer experiences that can be deemed extraordinary in the dual sense that they are a) far from quotidian or routine and b) there is an expectation that undertaking these experiences will yield benefits of a spiritual and/or transformative character. Each paper discusses extraordinary experiences that go beyond the realm of everyday life (Bhattacharjee and Mogilner, 2014) and hold the potentiality of a personal change and renewal, even bringing joy (Arnould and Price, 1993, p. 25) and magic (Schouten and McAlexander, 1995).

In this session we explore three main research questions:

1. In what ways can extraordinary consumer experiences be empirically and theoretically extended/re-framed, particularly in the area of personally transformative experiences?
2. What is the role of socio-historical institutions and rituals in creating extraordinary experiences?
3. How does consumer participation affect extraordinary experiences?

Dissecting Consumption: The Temple Festival as an Extraordinary Experience

EXTENDED ABSTRACT

The consumption of extraordinary experiences has been studied as service encounters (Arnould and Price 1993), as a contrast to the consumption of ordinary experiences (Bhattacharjee and Mogilner 2014), as a means of consumer emancipation (Kozinets 2002), and as socially constructed fabrications (Tumbat and Belk 2011). This is representative of the different lenses through which extraordinary experiences have been conceptualized and examined in consumer research. However, a unifying thread connecting these research endeavors is an assumption of experiences being consumed by an *archetypal* consumer, unshackled by the social context. Even as research in the consumer domain has looked at consumer motivations, the role of social institutions in shaping consumption experiences has been overlooked. This is in line with Askegaard & Linnet's (2011, p. 381) contention that what is missing in Consumer Culture Theory (CCT) research is the lack of a 'context of context'.

In this paper, we investigate the impact of social institutions in the consumption of an extraordinary experience. In doing so, we attempt to answer the following broad research question

1. How is consumption of an extraordinary experience shaped by the social institutions of gender, social class, and caste?

To investigate this, we conducted a naturalistic inquiry of the *Nemmara-Vallangi vela*, a temple festival in Kerala, India. Planned as a multi-year participant observation of the week-long temple festival, we have completed the first round of data collection and analysis. A total of 25 ethnographic interviews of festival participants have been conducted. We have complemented this with still photographs

and videos of the festival. In keeping with the tenets of constant comparison (Glaser and Strauss 1967), data collection, analysis and informant selection were done iteratively.

We have chosen the Nemmara-Vallanghy *vela* (temple festival) primarily for the information richness that it offers. This annual festival is ostensibly fashioned as a competition between two adjacent villages (Nenmara and Vallanghy, in Palakkad district, Kerala state, India) that share a common temple. Aspects of ritual rivalry as discussed by Tarabout (1993) is prevalent in Nenmara-Vallanghy *vela.* Held annually, seemingly for the residents of the two villages, the temple festival is a major tourist attraction, bringing in thousands of visitors. Complexity in the context is evidenced in the disparity in consumption experiences, which we focus on.

Our findings suggest that the impact of diverse socio-historical forces at play in shaping consumption experiences is clearly visible in the Nemmara-Vallanghy *vela*. Visitors to the *vela* travel long distances to attend and consume the festival. People of Nenmara and Vallangy travel home in a process somewhat similar to Thanksgiving in the USA or Christmas in some other countries. They bring their families (spouse/children) so that they can share the history of the festival and can initiate them into the different activities. A mosaic of different castes takes up specific roles, performing mandated rituals during the festival. One dominant caste (The Nair community) monopolizes the organization of festivities for one of the competing villages (Nemmara) while a loose federation of members from different castes takes up organizing activities for the other competing village (Vallanghy). Consumption of the festival is also gendered, with women taking up traditional household roles, and also occupying 'safe space' vantage points while consuming the festivities. Men, on the other hand, 'perform' the festivities, and consume them, by taking center-stage. Though ostensibly egalitarian in consumption, economic status hierarchies also play a role in festival consumption. The best elephants and the best music ensembles are bid for, and perform for the village with the higher financial capability. Festival rituals are also broken down and chunks are sold to the highest bidders. For example, the house from which the main festival procession begins is decided based on a bidding process. It is therefore, the consumption of the overall festival or specific events in the festival that we investigate in this study in the context of the role played by social institutions including gender, social class, and caste.

Askegaard & Linnet (2011) argue that consumer research is largely characterized by a focus on the lived experiences of consumers (Thompson, Locander, & Pollio, 1989) without adequate focus on "macro-social explanatory frameworks." In this paper, we heed the call by Askegaard & Linnet (2011) and investigate consumption within the context of experiencing a temple festival in Kerala. We study this context through the different social institutional lenses of gender, caste, and social class. We find evidence for consumption shaped by the contextual socio-historical development of these social institutions, and for intersectionality at the individual consumer level. Our findings point to the fallacy of considering an *archetypal* consumer of extraordinary experiences and motivate us to look at differing consumption experiences of the same extraordinary experience, driven by larger socio-historical forces.

The Extraordinary Experience of Death and Rebirth in a Thai Temple Ritual

EXTENDED ABSTRACT

The ritual is visually striking, within the dramatic and beautiful setting of the temple with its giant golden Buddha statues, the huge ceremonial gong and the robed monks. The researchers are observ-

ing from within the temple, taking occasional photographs, the lead researcher translating and reflexively understanding the observed events in the light of her own personal life experience of being a Thai Buddhist since birth. The devotees gathered in the temple are invited by the monks to lie down in a row of neatly arranged coffins. Their palms are pressed together holding flowers, a candle and three incense sticks. The monks' mesmeric chanting of the funeral ritual chant *Ānisong Sīa Sop: "The Blessings of Disposing of Corpses"* interspersed with the striking of the resonant ceremonial gong adds to the sense of religious gravitas of the occasion. In spite of the similarities between this ritual and genuine death rituals in the temple, the death in this ritual, is symbolic. The coffins and their occupants are covered with a shroud. When the chanting is finished, the shroud is removed and the devotee rises from the coffin. The literal translation of *Norn-Loeng-Sa-Dor-Cro* is 'laying down in a coffin you can get rid of bad luck'. Devotees believe that the ritual will cleanse their soul by tricking bad spirits into thinking they have died, and hence the bad spirit will leave them alone. Through the symbolic rebirth, the devotee can start afresh with a new identity shorn of the negative karma of their old identity. As a consequence, their fortune in this life will improve.

In Thai Theravada Buddhism, religious doctrine and practice is interwoven with folk beliefs and practices, and the realm of death is interwoven with that of the living. Spirits, ghosts and ancestors are a vivid presence in material life, for good or for ill. Monks are often asked to intercede between the spirit world and the material world to help devotees, in exchange for gifts of goods, food or money that are donated to the temple. For example, monks might convey propitious lottery numbers for those devotees hoping for a lottery win to improve their circumstance in life, or the monks might be asked to intercede for an ancestor to improve the ancestor's lot in the next life. This, in turn, would bring merit to the devotee who commissioned the intervention, which could benefit them both spiritually, and materially.

The Thai Death Ritual for the Living requires some translation for Western audiences. Firstly, the notion of death in the East differs from the Western notion of death as a finality and end point (Tumbat and Belk, 2011: Bonsu and Belk, 2003). In Buddhism, there is a vivid sense of the continuity of life and death. Life on earth itself, then, is a liminal state (Turner, 1969) in the sense that it is but one of the Wheels of Life. In the Death Ritual for the Living, the liminality of this state, the sense of life being an unfolding state of potentiality, is rendered especially vivid through the intercession of the monks who mediate between this life and the next. Whilst the continuity of life and death is a reality in many practices of Thai Buddhist daily life, such as the belief in ghosts and the presence of a spirit house in most dwellings and business premises, there is still a need for frequent formal ritual intercessions mediated by monks in order to connect with the spiritual world for particular reasons and on significant occasions. Some rituals, such as this one, are exceptional in that they fall outside the usual rites of passage or calendrical rites in the religious life of Thai Buddhists and, instead, fall broadly within the realm of commissioned intercessions. That is, they are consumer experiences that are paid for by the devotees and undertaken for specific reasons of advancement or benefit in the material world.

In this project we extend Turner's (1969) ideas on the liminal phase of ritual process to a death ritual in order to draw out new theorizations of extraordinary consumer experiences (Arnould and Price, 2003). For Turner (1969), liminal experience was confined to compulsory rites, while he characterized consumer experiences as liminoid (Turner, 1974: 1982) rather than liminal. Liminoid experiences are freely entered into in a spirit of playfulness- they are not

trivial, but neither are they permanent. Just as consumer experiences can be disposed and repeated, so too can devotees of the Death Ritual for the Living repeat the experience many times if they choose. "The liminoid is more like a commodity- indeed, often is a commodity, which one selects and pays for, than the liminal" (Turner, 1982 p.55). Hence, Turner (1982) explicitly linked liminoid experience to consumer experience. The simulation of death and rebirth in this case also offers opportunities for cross-cultural insights into the profoundly different understanding of spirituality, death and eschatology that obtains in the Judeao-Islamic-Christian West, and in the Buddhist and Hindu influenced East. In their moments in the coffin, the devotees subsist in a state between life and death, and it is the liminal character of this state that opens up the potentiality of a new life, a new spiritual identity and new possible futures both as a human being, and subsequently as a being on a different Wheel of Life.

We frame this ritual as an extraordinary consumption experience because it is consumed as a commercial transaction and transports the consumer into the realm of the extraordinary. The case illustrates a liminal dimension that we suggest is latent in many extraordinary consumer experiences but foregrounded in spiritual consumer experiences. The theorization also challenges the use of Turner's ideas in consumer research.

Bodily Experiences and Self-transformation

EXTENDED ABSTRACT

Many people come to Lourdes facing difficulties. They are going through very difficult situations in life. However, in Lourdes they learn their lesson. They return home transformed. (Michael, Lourdes)

Consumer's senses have been investigated from the provider's view in consumer research and psychology, such as in the concept of sensory marketing, defined as marketing that engages the consumers' senses and affects their behaviors (Hultén, 2011; Krishna, 2011; 2012). In consumer culture, incipient line of research has also been dedicated to understanding the role of body and senses in experiences (Scott & Uncles, 2018), such as through the connection with nature (Canniford & Shankar, 2013), dancing (Hewer & Hamilton, 2010), impacted by time (Woermann & Rokka, 2015), or submitted to pain (Scott, Cayla, & Cova, 2017; Cova & Cova, 2019). Yet there is still space to understand how consumers live extraordinary experiences and how they enable consumer transformations and well-being. We believe that it can be better explained when showing that the body sensoriality (Kirmayer, 2003; Roux & Belk, 2018; Vom Lehn, 2006) is shaped by the place (Castilhos, Dolbec, & Veresiu, 2017) and other materials (Miller, 2005), especially during pilgrimage experiences.

How do consumers live pilgrimage experiences seeking self-transformation? This question guided the design of a multi-sited sensory ethnography approach (Pink, 2015) conducted in four different pilgrimages in Europe (Lourdes – France, Camino de Santiago – Spain) and Latin America (Juazeiro do Norte and Belém do Pará – Brazil). Sensory ethnography is an emplaced ethnography devoted to understanding an experience by addressing the relationships between bodies, minds, and the materiality and sensoriality of the environment (Pink, 2015). We employed three main techniques of data collection, which were (i) interviews, (ii) participant observations, and (iii) visual data. We carried out data analysis by coding each interview, looking for cultural categories and individual and collective interpretations mainly related to the concepts of embodiment, place and materiality (Spiggle, 1994).

Our findings demonstrate the recurrent mentions to self-transformations in participants' speech and practices not only in Lourdes, but at the four pilgrimage contexts. Pilgrims reported different types of transformations they've been through. They can address their transformations to religious and non-religious causes, such as:

To achieve their aimed transformations, pilgrims engage themselves in bodily enactments mainly related to (i) the *place,* and (ii) using *the materials* around. People going to these experiences feel a connection with the very ground of the pilgrimage site and the consuming interactions between their bodies and the place enables well-being and self-transformations as expressed in the following quote:

I think that the very ground of the pilgrimage site reveals a power that can help people to find their healing. And that is the reason people come to these religious sites. (Fatima, Lourdes)

Individuals engage their bodies in enactments involving materials, such as in the words of Lara explaining how the doing of the Camino de Santiago and the difficulties involved at carrying a 11 kg backpack paradoxically helps her to leave behind the emotional weight that she was carrying so far.

"I had around 11kg in my backpack. When you're walking with this material weight you are letting behind the emotional weight you were carrying with you before arriving here" (Lara, Camino de Santiago)

Religious sites mobilize about 380 million people per year around the world, which represents a market of around 400 USD million (UNWTO, 2018). These results are interesting for the comprehension of the patterns of consumption of such religions and experiences and how they are connected to well-being and self-transformation.

Personal Transformation Through Extraordinary Experiences

EXTENDED ABSTRACT

Extraordinary experiences are characterized as uncommon, infrequent, emotionally intense (Tumbat and Belk 2011; Arnould and Price 1993; Scott, Cayla, and Cova 2017), providing a sense of community (Arnould and Price 1993; Celsi, Rose and Leigh 1993), with identity manifestation being the result of belonging (Arnould and Price 1993). Extraordinary experiences go beyond the realm of everyday life (Bhattacharjee and Mogilner 2014), bringing a sense of newness, originality, and freshness, often changing the individual through "…personal integration, personal control, awareness of power, joy and valuing…" (Arnould and Price 1993, p. 25), sometimes even entering into the realm of the spiritual, the magical and supernatural (Fernandes and Lastovicka 2011; Schouten and McAlexander 1995).

Extraordinary experiences allow participants to create a new identity facet (Celsi et al. 1993), to "escape from the rationality, rules, and stresses of everyday life" (Tumbat and Belk 2011, p. 44), to temporarily invert one's social order by engaging in new social groups with a certain degree of homogeneity (Schouten and McAlexander 1995; Kozinets 2002).

Often, the kind of impact and transformation that extraordinary experiences provide is portrayed by researchers in a specific time-space, located within the experience per se. As illustrated by one of Tumbat and Belk's (2011) alpinists "I think it [the money] would only be worth it if I get to the top. I've had a really good time, but [reaching the summit is] the only reason I'm actually here" (p. 53).

Also, we know that it is through post-fact narratives that individuals make sense of their experience, for instance for those that are physically intensive and immersive (Scott et al., 2017). Traveling to off-track places often leads to self-accomplishment and personal development (Zinelabidine et al. 2018).

While some researchers have provided some extended effects of extraordinary experiences, such as learning new skills (Arnould and Price 1993; Celsi et al. 1993), personal growth and renewal (Arnould and Price 1993), personal development (Zinelabidine et al. 2018), and identity expansion (Arnould and Price 1993; Celsi et al. 1993), there is still a lack of studies that investigate the process that leads to the enduring consequences of engaging with extraordinary experiences. In this research, we expand the literature on the extraordinary experience by investigating its transformational effects, specifically by theorizing how it can act as a rite of passage (Rook 1985; Schouten 1991), and as symbolic marks of a permanent status change (Rook 1985). The research question we ask here is how can extraordinary experiences transform individuals?

Methodologically, we investigated the solo travel extraordinary experience, which we define here as traveling alone for some time (although the meaning of the experience is more important than its temporal length) and engaging with meaningful situations that transform the individual in significant ways. Travel has long been considered in the tourism literature as a rite of passage with transformative capacities (Grabowski et al. 2017; Decrop et al. 2018). The first author conducted in-depth interviews (Kvale 2008) with sixteen informants who have passed through meaningful experiences while traveling alone outside of their original country (Brazil), so they could describe their motivations, the most significant situations, their feelings, reflections, meanings and the outcomes of the solo travel experience. Data analysis was first conducted in an inductive manner (Spiggle 1994), coding for the situations, reflections, learnings, and transformations while and after the solo travel. After that, we used conceptual elements of rites of passage (Rook 1985; Schouten 1991) to consolidate our theoretical analysis of the transformational aspects of the solo travel experience.

Our findings indicate that the main motivation to engage in a solo travel experience is the desire to temporarily depart from the social structure in which one is immersed and to live functional and extraordinary experiences in a new place. The lived experience of solo travel is marked by performance experiences and stochastic experiences (Lanier and Rader 2015), which constitute an important source of reflection and transformation. Our informants learned and reflected upon ordinary functional instances of the solo travel, such as taking care of one's clothes, housing matters, transport, money, without any support, and getting immersed in new cultures, and upon stochastic (non-functional) experiences. The condition of being solo frequently contributed to the reflexive element of the experience, as it allowed time and space to think and reflect, even when establishing new and occasional social ties. Traveling solo is an experience rich in stochastic situations, such as walking in the city, seeing something interesting on the streets, getting to know someone new and forming unplanned ties, which leads to unplanned situations, visiting extraordinary nature places, and learning about rituals and practices of other cultures. The condition of having no previous social ties and space knowledge in the new places also contributes to a constant state of situation-awareness, immersion, and self-reflection.

In short, solo travel allows the experience of learning - acquiring knowledge and skills, playing with possible selves, questioning one's former values and practices, developing new goals and life models, planning how one wants to be and to live. We contribute to the literature by theorizing the process of personal transformation through extraordinary experiences using the lenses of rites of passage, with separation from social roles and status, transition into new roles, and incorporation of new selves, roles and status (Schouten 1991) marking the lives of our informants.

SESSION OVERVIEW

As we meet this year in Paris, a center of the Enlightenment and birthplace of new paradigms to thinking and knowing about the world, the setting seems particularly appropriate for discussing consumer knowledge. Consumer research has extensively studied how knowledge affects decision processes. However, little research has examined how knowledge shapes experiences. The current papers contribute to a nascent area of research addressing this important gap. These papers provide insight into the question of, "How can differences in consumer knowledge — in terms of both knowledge itself and the way in which knowledge is acquired — influence evaluations and enjoyment of consumption experiences?" The research in this session is relevant not just to academics, but also to marketers seeking to enhance consumer experiences by delivering the right information, in the right format.

First, **O'Brien** draws attention to the consequences of learning about the development of an upgraded version of a product. He finds that knowing that an improved version of the product will be available in the future affects consumers' subjective experience with the product in the present. The key finding is that merely knowing this fact has a negative effect on the enjoyment of the experience with the current product.

Fulmer and Reich also explore how perceptions of the same stimulus change as function of what consumers know about it. However, instead of examining the effect of knowledge about the future of the product, they look at the effect of knowledge about its inception. In the context of arts consumption, they find that the perceived quality of the same artistic product improves when consumers learn that its creation was an unintentional (as opposed to intentional) effort.

The third paper starts exploring the notion that cognitive influences on experiences arise not only from what consumers know, but also from how they obtain information. **Grillo, Pizzutti, and Ward** test the idea that accessing information about a product category through Google search (compared to the same information without online search) can subjectively enhance subsequent experiences with products of that category. This effect stems from decision confidence boosts induced by Google-based access to information.

The fourth paper shifts focus from a currently prevalent source of product-related knowledge (Google), to explore an emerging option — virtual reality (VR). **Chun, Baek, and MacInnis** look at a context where knowledge acquisition and consumption experience merge into a single event: product sampling. VR-based sampling experiences facilitate the mental simulation and conjuring of stories about the consumption of sensory-rich experiential products (e.g., luxury hotels), thus increasing behavioral intentions toward them.

This session demonstrates how complementary facets of cognition – content (i.e., what individuals know) and formation (i.e., how they obtain knowledge) – influence consumers' experiences. Moreover, the session takes a timely perspective on the topic. It takes into account that product information (e.g., their history [Fulmer and Reich] and their future [O'Brien]) is increasingly accessible, how consumers tend to access it (Grillo, Pizzutti, and Ward), and the tendency of evolving technologies to provide yet new forms of product knowledge acquisition (Chun, Baek, MacInnis).

The "Next" Effect

EXTENDED ABSTRACT

Imagine you are toying with a fun new gadget for the first time. Assuming things work as intended, experiencing a fun stimulus you have never experienced before should be highly enjoyable. Yet, consider one small tweak: You learn beforehand that an even *better* version is in the works. Despite still proceeding to play with the same gadget, and despite nothing objectively changing within it, the current research explores whether mere expectations of a more enjoyable future (e.g., upcoming versions of a technology) might *undermine* one's experience of an enjoyable present (e.g., a current version)—despite that present experience being brand new for you.

Why? Existing research might suggest the opposite: Better future versions of a good should, if anything, foster more *positive* impressions of targets subordinately associated with that good (e.g., assimilation effects: Bless & Schwarz, 2010). This idea is echoed by broader research on positive expectancies (e.g., studies highlighting benefits of dispositional optimism: Carver & Scheier, 2014). However, the current research advances these literatures by considering the additional possibility of inference-based effects. Indeed, assessing novel goods can be difficult. People reduce ambiguity by drawing inferences from other available cues, which can shape their consumption experience (Lee, Frederick, & Ariely, 2006). Put in current terms, one salient inference people likely draw from learning of future improvement is that there must have been something to improve *upon* (Grice, 1975)—but this need not be true, particularly in today's world of strategic change (e.g., planned obsolescence: Gershoff, Kivetz, & Keinan, 2011). Thus, despite being able to draw on one's bottom-up experience to inform one's judgment, bottom-up experiences may be tainted: Mere knowledge of a better future may prompt people to shift their attention to present problems warranting the change. Improvement may be self-fulfilling: Merely knowing a better future is coming may make the present worse (e.g., by prompting people to search for, and alas find, more "bugs").

Three preregistered experiments tested this hypothesis. In Experiment 1, 806 participants played "Art Time," a novel art-making game. All participants played the same game, dated from the same time, but we manipulated knowledge of upcoming versions: Some

participants first viewed a flyer for "Art Time: October 2016 release," then played "Art Time: October 2016 release" (control); others viewed a visually-identical flyer for "Art Time 2" announcing updates to the original, then played "Art Time: October 2016 release" (better-future); still others viewed a visually-identical flyer for "Paint Wars 2" announcing updates to an unrelated stimulus, then played "Art Time: October 2016 release" (unrelated-future). This latter condition isolates inference-based mechanisms (rather than *any* positive future spoiling the present, the future and present may need to be linked). After, all participants rated their enjoyment (dependent variable) and bugs noticed (proposed mechanism). The same game was less enjoyable ($p < .001$), and buggier ($p < .001$), when participants were merely aware of a better future (indirect effect via buggyness: $b = 0.42$, 95% $CI = [0.28, 0.56]$). Unrelated improvement, however, affected neither enjoyment nor buggyness (contrasts vs. control: $ps \geq .273$).

Experiment 2 replicated these effects using a different stimulus. 309 participants played the same novel virtual-reality "blaster" game. Better-future participants enjoyed the game less, and found it buggier, compared to control ($ps \leq .011$; mediation, $b = 0.32$, 95% $CI = [0.18, 0.52]$). We also tested boundaries: Other participants were informed of a better future version, but additionally evaluated a "Blast From The Past!" booklet reminding them of older blaster-game technology. The effect was attenuated with converse reminders of the past, by reducing perceived bugs (contrast versus control: $p = .206$, $d = 0.18$).

Experiment 3 replicated these effects using a third stimulus, and tested consequences. 487 participants tested the same novel 360-degree technology by which viewers can rotate the camera at any angle while a video plays. Better-future participants again reported a less enjoyable, and buggier, experience ($ps \leq .005$; mediation, $b = 0.25$, 95% $CI = [0.17, 0.36]$). Moreover, all participants were informed they had to re-experience the same technology, but could buy out of this task. Better-future participants wagered double to opt out ($p = .014$). Their "tainted" experience—for which they were willing to pay a real cost to avoid repeating—was purely a product of their beliefs.

These experiments reveal a perverse effect of positive future expectations: The same stimulus is less enjoyable merely when participants believe a better future version is in the works. This occurs because knowledge of better future is, in effect, self-fulfilling: It spurs people to discover more problems in the present that must have needed fixing.

These findings highlight the need for more research on how future circumstances serve as a standard for present circumstances (for a review, see Strahan & Wilson, 2006). We bridge these ideas with yet-disconnected literatures on expectancy effects, suggesting new insights into when and why, exactly, positive expectations can backfire. As reviewed by Lee et al. (2006), labels affect experiences: Drinking a "vinegar" beer makes the same beer taste worse; eating a "fatty" dessert makes the same dessert taste more decadent; and so on. However, past findings typically stop at the moment of choice. As Lee et al. (2006) note: "A third question concerns how specific perceptual, attentional, and cognitive mechanisms mediate the effect of expectations on experience" (p. 1057). To this point, we provide finer-grained evidence for *why* expectations change preferences: Mere awareness of a better future changes attention and prompts people to actively search for flaws.

Finally, future research should extend beyond technology. People with positive views of their future *self* may make wiser plans (Hershfield, 2011), but also discover more flaws in their present self and thus feel less happy at any one moment. Surrounded by so much

improvement across so many domains (Pinker, 2018), our findings hint at a vicious cycle: Ever-newer offerings are not necessarily ever-better, yet people may fail to learn from experience if their experience is psychologically tainted at each fresh start. Mere awareness of a better future often may risk spoiling an otherwise satisfying present.

Unintentional Inception: Why Unintentionality Increases Quality Perceptions of Artistic Products

EXTENDED ABSTRACT

Artistic product creation can be fundamentally intended or unintended from its outset. Presumably, this should not influence how the products are evaluated by consumers since their objective qualities are identical. However, research has documented a powerful influence of intentionality behind actions in shaping consumer preference and perceptions. The current research explores how quality perceptions of artistic products can be influenced by the intentionality involved in their inception; in other words, whether the product was originally intended by the creator. We suggest that because knowledge of unintentional product creation elicits heightened counterfactual thought about how the product may have never been created at all, consumers place a quality premium on unintentionally created artistic products.

Prior literature largely indicates that intention in creation can heighten quality perceptions of a finished product. Intention and perceptions of effort are psychologically linked (Caruso, Waytz, and Epley 2010; Heider 1958; Malle 2010; Malle and Knobe 1997), and perceptions of effort have been shown to heighten quality perceptions of artistic products such as effortfully created paintings and poems (Cho and Schwarz 2008; Kruger et al. 2004). This influence of perceived effort in product creation on perceptions of quality, and the association between intention and effort (Caruso et al. 2010; Heider 1958; Malle 2010; Malle and Knobe 1997), suggests that consumers may place a quality premium on intentionally created artistic products over unintentionally created artistic products.

Despite work showcasing such positive influences of intentionality and effort on quality perceptions, unintentionality has been shown to heighten consumer preference for products in certain contexts. Newman and Bloom (2012) demonstrated that near duplicates of paintings were considered more valuable when they resembled an original piece of artwork by mere coincidence compared to an intentional attempt to copy. Furthermore, when consumers perceive a company as intentionally creating an environmentally friendly product, they are less interested in purchasing it due to a belief that the company devoted resources away from other product attributes to make it environmentally friendly (Newman, Gorlin, and Dhar 2014). Especially relevant to the current research, Reich, Kupor, and Smith (2017) demonstrate that consumers prefer hedonic products resulting from a mistake in the creation process to otherwise identical products made intentionally. We build upon these lines of research by demonstrating that mere unintentionality in an artistic product's inception heightens quality perceptions of the final product.

We base our theorizing on the well-documented "intentionality bias", according to which people have a tendency to assume that actions are intentional (Bègue et al. 2010; Rosset 2008; Rosset and Rottman 2014; Spunt, Meyer, and Lieberman 2015). Because unintentional actions diverge from this assumption, and events considered unusual have been shown to inspire counterfactual thought (Kahneman and Miller 1986), we propose that unintentional creation inspires greater counterfactual thought than intentional creation. Research has demonstrated a variety of ways in which counterfactual

thinking can benefit perception (Kray et al. 2010; Teigen and Glad 2011). For example, Kray et al. (2010) demonstrate that counterfactual thinking can actually increase the perceived meaningfulness of one's own life experiences by leading to greater recognition of positive life events and perceptions that these events were fated. Further, research by Medvec, Madey, and Gilovich (1995) indicates that counterfactuals can change the perception of objective qualities of an outcome. Medvec et al. (1995) found that bronze medalists in the Olympics were judged as looking happier than silver medalists because the counterfactual of not having won a medal at all was more salient to bronze medalists, heightening perceptions of their outcome above those of the objectively superior silver medalists'. Similarly, we predict consumers will perceive an unintentionally created artistic product as higher quality than an otherwise identical intentionally created product because the counterfactual of an unintentionally created product never having been created should be especially salient to them.

Four studies examined the quality premium offered to unintentionally created artistic products in contexts in which consumers actually experienced the products. Our first study demonstrated that consumers perceive an unintentionally created poem's quality as superior to that of an otherwise identical intentionally created poem. Our second study demonstrated the robustness of the effect of unintentional artistic creation on heightened quality perceptions, extending it to the domain of visual art. Our third study identified that heightened quality perceptions of unintentionally created artistic products are mediated by increased counterfactual thinking about how a product's creation might never have occurred at all. Further, it ruled out an alternative explanation that this phenomenon is driven by a magical belief in divine intervention playing a role in unintentionally created artistic products. Through a process by moderation design in which participants evaluated a marketing slogan, our fourth study showed that quality perceptions of intentionally created artistic products rise to the level of quality perceptions of unintentionally created artistic products when consumers are encouraged to consider how an intentionally created product might never have been created at all.

This research is the first to reveal a quality premium given to unintentionally created artistic products, identifying greater counterfactual thought about how such products might never have been created at all as a hereto unrecognized antecedent of consumer quality perceptions. Consequently, it builds on previous work on benefits of unintentionality in product creation (Newman and Bloom 2012; Newman et al. 2014; Reich et al. 2017) by illustrating in multiple artistic domains that mere unintentionality in the inception of an artistic product's creation colors how the quality of the product is perceived.

These results could benefit artists by making them aware of what information they should include and emphasize about the creation of their artwork in advertisements in order to heighten perceptions of their artwork's quality. Additionally, organizations based around the appreciation of artwork such as museums could benefit from emphasizing unintentionality in the inception of their artworks' creation wherever possible. By positively coloring customers' perceptions of artistic products, museums and marketing managers could heighten foot traffic and increase purchases of artistic products.

The Effect of Google-Induced Confidence on Consumption Experiences

EXTENDED ABSTRACT

People increasingly turn to the Internet for information on virtually every topic. In consumer research, scholars have primarily focused on how the unparalleled access to information provided by the Internet carries consequences for decision processes or decisions themselves (e.g., Bhargave, Mantonakis, & White, 2016; Lynch & Ariely, 2015). The current research shifts this focus to explore consequences to consumption *experiences*. Specifically, we propose that confidence stemming from online search exerts a positive top-down influence on chosen consumption experiences, thereby enhancing subjective evaluations of objectively identical stimuli.

Our hypothesis builds on and contributes to two distinct streams of prior research: one examining the metacognitive errors induced by online search, and a second investigating the impact of expectations on experiences. A growing body of research finds that people misattribute online search results to their own memories; as a consequence, search tools like Google may inflate people's confidence in their own cognitive skills (Ward, 2013; Wegner & Ward, 2013). We extend this research by suggesting that when online search is used to access information related to a product category (such as when consumers prepare for upcoming decisions or experiences), this phenomenon causes consumers to be more confident in their own decision-making abilities. We further suggest that Google-induced confidence can exert a positive top-down influence on evaluations of chosen options. Prior research on top-down effects shows that expectation-inducing factors can cause subjective experiences with the same objective stimuli to conform to the expectation (e.g., Lee, Frederick, & Ariely, 2006). This type of effect is typically observed in response to information from an external source (e.g., telling someone that movie will be funny, or that a beer has been spiked with a weird ingredient). We extend this line of research by arguing that confidence in one's own decision skills functions as an internal source of positive expectations. Thus, factors that affect confidence — including Google-induced metacognitive errors — may improve subjective experiences by creating self-fulfilling expectations regarding the quality of chosen options.

Briefly, we propose that Internet search improves subjective experiences through a process mediated by confidence in decision skills. Study 1 (N = 465, MTurk) tested the first part of this process. Participants were randomly assigned to complete a cinema-related trivia challenge (sample question, "What was the first fully computer-animated movie ever?") using Google vs. not using Google. In the Google condition, they verified their answers using Google; in the no Google condition, they received the same answers their counterparts would find on Google but without engaging in online search. Following this manipulation, we measured participants' confidence in their abilities to choose movies using a validated scale of confidence in consideration-set formation skills (Bearden, Hardesty, & Rose, 2001 – sample item: "I am confident about my ability to recognize options worth considering when deciding to watch a movie"). We found that online search increased confidence in decision abilities, M = 5.59 vs. M = 5.29, $t(461) = 3.17$, $p = .002$.

Study 2 (N = 306, MTurk) tested the overarching hypothesis that online search enhances subjective experiences. After completing the same Google manipulation used in Study 1, participants chose a short film to watch as part of the study. Three options were provided, all of which were pretested to match on perceived quality. Film-choice was not different across conditions, $\chi^2(2) = 1.53$, $p = .466$, indicating that choices were not influenced by the manipula-

tion. After watching the film of their choice, participants were asked how much they enjoyed the film they watched. Despite the fact that participants in both conditions watched the same films, those who used Google reported greater film enjoyment, M = 5.22 vs. M = 4.83, $t(304) = 2.17$, $p = .031$.

Study 3 (N = 329, MTurk) connects the results of studies 1 and 2. After completing the trivia challenge (same as in the previous studies) and before choosing the film, we measured participants' confidence in decision skills by asking them "how confident are you that you will be able to identify and choose the best film available among the options provided?" (0 = *Not confident at all*, 100 = *100% confident*). They then watched the film of their choice and reported film enjoyment. Confidence in decision skills mediated the Google effect on enjoyment, $b = 0.17$, 95% bootstrap (10,000 simulations) CI = [0.05, 0.36].

In Study 4 (N = 499, MTurk), we further examined the role of confidence in decision skills using moderation. Theoretically, confidence in one's ability to choose should only enhance experiences that one chooses. We therefore added a "choice" manipulation to our study design. For participants in the *choice* condition, the study design replicated that of Study 2. Participants in the *no-choice* condition, however, were randomly assigned to a short film (instead of choosing one). If the increased enjoyment in studies 2 and 3 stemmed from self-fulfilling expectations regarding one's ability to choose the best option, the subjective experience of participants in the *no-choice* condition — who do not have a chance to employ their decision-making abilities — should not be affected by online search. We found a significant Google × Choice interaction, $b = 0.51$, $t(494) = 1.97$, $p = .049$ (controlling for participants' general liking of short films). When participants chose the film, Google increased film enjoyment M = 5.26 vs. M = 4.82, $t(494) = 2.41$, $p = .016$. However, when participants watched a random film, Google did not predict enjoyment, M = 4.91 vs. M = 4.97, $t(494) = 0.35$, $p = .723$.

The current studies illuminate a process where Internet search boosts decision-making confidence and, thus, ignites a self-fulfilling prophecy that results in improved subjective experiences. Marketers may benefit from this phenomenon by developing marketing communication that encourages consumers to learn about products through Internet search. However, we acknowledge that to better understand how Google-induced confidence can be explored in marketing practice and how it affects consumers' lives, future research should study the interplay of this boosted confidence with other "real world" factors – e.g., distractions, stress – that might inhibit/intensify its effects.

Glimpse into the Future Experience: When is Virtual Reality Sampling Beneficial?

EXTENDED ABSTRACT

Rapid adoption of virtual technologies is opening up new opportunities, enabling consumers to experience products and destinations and acquire information in an immersive manner. Although an increasing number of companies are designing immersive VR contents to engage consumers across various touchpoints of customer journey, they do so without clear understanding of when and how VR technology would actually benefit consumer experience and exert its intended positive effect. Given the technological investment and financial costs required for creating and distributing the immersive marketing content, companies need to be better informed about both the theoretical underpinnings of VR technology from the consumer psychology perspective and its practical implications.

Building on prior research on dynamic presentations inducing greater mental involvement (Roggeveen et al. 2015) and this, in turn, further increasing elaboration (e.g., Keller and McGill 1994), we propose that sampling a future experience through VR (vs. static images) enhances consumers' involvement with the mediated environment and the extent to which consumers conjure up stories about the future experiences. These imagined stories are likely to entail conscious representations of the self-experiencing future consumption situations (Walter et al. 2007), positively influencing behavioral intentions toward them. Importantly, we further propose a more nuanced view of the effect of VR—the extent to which the effect of VR is maximized vs. undermined (i.e., boundary conditions of VR effectiveness) depends on sensory richness of the target experience, individual differences in imagery vividness, and the perspective-taking prompted during the sampling process. We conducted four empirical studies across various experiential contexts (retail, hotel stay, tour) to test these ideas.

A pilot study (N = 108) utilizing a retail content (NYC Nike flagship store in New York City) found that, compared to 360-degree tour and static photo images, VR significantly increased mental involvement (but no difference between 360-degree tour and static photo images), subsequently enhancing future store visit intentions. Building on the initial pilot results, Study 1 (N = 188) investigated the role of sensory richness embedded in the experience by utilizing the content marketing materials posted on Youtube by actual hotel companies. With a 2 (sensory richness: luxury vs. economy-plus hotel experience) x 2 (medium: VR vs. photo images) between-subject design, we found that compared to photo images, sampling an experience through VR heightened mental involvement only for the sensory rich experience (i.e., luxury hotel tour). No difference was found between the two medium conditions when the target experience lacked high sensory richness (i.e., economy-plus hotel tour), rendering no advantage of VR over a more traditional medium of browsing static photo images. We further found support for an indirect serial mediation whereby mental involvement and the ability to imagine future consumption stories sequentially mediated the effect of VR on behavioral intentions only when the experience was high on (vs. lacked) sensory richness.

Study 2 (N = 188) further demonstrates that the extent to which VR enhances consumers' mental involvement and the ability to conjure up stories about the future consumption experience depends on individual differences in imagery vividness (VVIQ; Marks 1973). If VR boosts consumers' mental involvement of the experience and elaboration on future consumption events, this facilitative effect of VR should be more pronounced for individuals with low imagery vividness. By providing a sampling experience of a gondola ride in Venice, Italy, we found that the enhancing effect of VR occurred for those who are low on imagery vividness, but not for those who are high on imagery vividness. Those who are high on imagery vividness demonstrated a high level of mental involvement and the ability to imagine consumption stories on their own even with static photos.

Study 3 (N = 225) demonstrates that the perspective-taking adopted during the experience also matters in maximizing the effect of VR. We worked with a media content production company to create the content that took predominantly a first-person vs. third-person perspective, filming a zipline local activity in Maui, Hawaii for the study stimuli. We found that the immersive content that took more of a first-person perspective (i.e., experiencer), as opposed to a third-person perspective (i.e., observer), facilitates the mental involvement and conjuring up of future consumption stories, influencing behavioral intentions.

Across all three main studies, we find support for an indirect effect whereby mental involvement and the ability to evoke future consumption stories sequentially mediate the effect of VR on behavioral intentions. Taken together, VR's facilitating effect is limited when the target experience lacks sensory richness, when consumers taking a virtual tour are high in imagery vividness, and when the third-person perspective is promoted in the sampled experience. These findings not only provide insights into the mechanism through which the facilitative effect of VR manifests but also provides practical implications for designing marketing content for the maximal effect.

SESSION OVERVIEW

Consumers often prefer to acquire life experiences over material goods, because they derive greater happiness from such purchases (Van Boven and Gilovich 2003). Much of the follow-up work on this notion of experiential consumption has focused on demonstrating that experiential consumption contributes to better post-consumption outcomes and consumer preferences (Van Boven and Gilovich 2003). However, less is known about the mechanisms that drive consumers to perceive experiential and material purchases differently and how such differences affect consumer behavior. In this session, we address this gap in the literature, by examining the following questions: what are the antecedents and drivers of previously identified "experiential advantage?" And how do consumers seek and express information related to experiential vs. material goods? As we demonstrate, the questions investigated are important for many marketing stakeholders, including consumers and managers.

The first two papers of the session explore the antecedence of the "experiential advantage." In the first paper, Oh, Goodman, and Choi demonstrate that the causal direction of the experiential advantage can be reversed by manipulating consumers' happiness: happier consumers perceive their purchases as experiential. Further, they find that the effect of happiness on experiential perception is eliminated when consumers evaluate the purchase with a concrete mindset. In the second paper, Chu and Shu identify uniqueness of purchase as one of the driving forces of the "experiential advantage." They show that consumers find experiential purchase to be more self-defining and promote a greater sense of personal uniqueness.

The next two papers turn to how the differences in perceiving experiential and material purchases affect consumer behavior. In the third paper, Gallo and Gilovich investigate which information sources consumers are more likely to rely on depending on whether the purchase is material or experiential. They find that when evaluating experiential purchases, consumers rely more on reviews from those who have a closer social connection, but for material purchases, consumers are more likely to rely on reviews from aggregate online reviews. In the fourth paper, Kim, Ghosh, and Reimann examine how consumers express their consumption stories for experiential and material goods. The authors demonstrate that consumers adopt a more confident tone and use more emotional words when writing online reviews about experiential purchases.

The four papers in this special session extend our knowledge of the drivers of "experiential advantage" and the consequences of the differences between experiential and material goods for consumer behavior, such as acquiring and writing online reviews. Considering the increasing consumer demand in acquiring life experiences, we expect that this session will be of interest to a wide range of consumer researchers, particularly those examining experiential consumption, word of mouth, and consumer well-being.

The Bidirectionality of Experiences and Happiness: Happiness Leads People to Perceive Purchases as More Experiential than Material

EXTENDED ABSTRACT

How consumers perceive the nature of purchases has significant impact on how they react to product appeals, and ultimately their purchase decisions. One dimensions of purchases that prior research has identified is material versus experiential (Gilovich, Kumar, and Jampol 2015). In particular, prior research has demonstrated that consumers derive more satisfaction and happiness when they consume experiences compared to material goods (Nicolao, Irwin, and Goodman 2009; Van Boven and Gilovich 2003), suggesting that consumers should be spending more of their discretionary income on experiences instead of material goods to increase happiness (Dunn, Gilbert, and Wilson 2011). In this research, we investigate whether part of this puzzle may be backwards: Instead of experiences leading to more happiness, could happiness lead to more experiences? In other words, do happy consumers view their purchases as more experiential and less material?

Many relationships in psychology are bidirectional (e.g., power, choice, and control, Inesi et al. 2011) and related research hints at the possibility that happy people may view their purchases more experientially. Positive affect facilitates cognitive flexibility (Isen 1987) and broadens thought-action repertoires (Fredrickson 1998; Fredrickson and Branigan 2005) such that it broadens the range of potential actions people are prepared to do. Given that experiences are "doing" and thinking about what to do rather than to have (Van Boven and Gilovich 2003) and that there is the association between positive affect and broadened thoughts toward action, we expect that happy participants (both measured and manipulated) will perceive their purchases as more experiential than material compared to those less happy. Further, to examine our process, we test whether manipulating one's mental representation would moderate the effect of happiness on experiential perceptions. Specifically, we expect that the effect of happiness will be attenuated when a concrete mental representation is induced.

Studies 1 and 2 test our main hypothesis with chronic happiness, examining whether consumers high on subjective well-being (SWB) perceive purchases as more experiential (vs. material) than those low on SWB. Study 1 examined consumers' own purchases using the experience sampling (Csikszentmihalyi and Larson 1987). We measured SWB by creating an index based on satisfaction with

life and PANAS and messaging participants five times a day by a smartphone notification for 7 days. Participants also identified their most important purchase for the day and rated how experiential or material they perceived their purchase (sliding scale 0 =*definitely material* to 100 = *definitely experiential*). An HLM model (controlling for demographics and the purchase category), found a positive relationship between SWB and experiential-material perceptions (γ = 0.23, t(206) = 1.99, p = .048). In other words, the happier the respondent was, the more experiential he or she perceived their purchases.

Study 2 examined purchases made by others. Participants rated 37 different purchase items [varying from more tangible (e.g., wallet), less tangible (e.g., a movie ticket), and were ambiguous (e.g., television)] in terms of the extent to which each purchase was experiential or material on a 9-point scale (1=*definitely material*, 5=*equally material and experiential*, 9=*definitely experiential*; counterbalanced). Consistent with study 1, there was a positive relationship between SWB and material-experiential rating (r = .24, p = .001). In other words, the happier participants were, the more experiential they thought a purchase was in general.

Study 3 provides causal evidence by manipulating positive (happy), negative (sad), and neutral (control) affect. Participants first wrote about three recent events (either happy, sad, or neutral, depending on condition) in their life in a very detailed manner. Then participants rated 14 purchases as more experiential or more material. As expected, happy participants perceived purchases as more experiential (M = 4.87) compared to those in the sad (M = 4.56; t(356) = 2.31, p = .022) and control conditions (M = 4.58; t(356) = 2.15, p = .032). No difference was found between the control and sad conditions (p = .87).

Study 4a tested our mechanism by manipulating mental representation in a 2(affect: happy vs. neutral) × 2(representation: concrete vs. abstract) between subjects design. In the first part, 287 participants listed three ways of spending with the goal of advancing their happiness and enjoyment in life ($10-$1,000). In the second part, participants wrote about either a happy event or an event from yesterday (depending on condition). The concrete condition focused on the 'how' aspect of the event, whereas those in the abstract condition focused on the 'why' aspect (Vallacher and Wegner 1987). Results showed the predicted affect by mindset interaction F(1,283) = 5.67, p = .018). In the abstract condition, happy participants still rated their purchase more experientially (M = 5.89) than control (M = 4.91; t(283) = 3.02, p = .003). In the concrete condition, however, the impact of happiness on experiential perceptions was eliminated. There was no difference in experiential perception between the happy (M = 4.95) and control condition (M = 5.05; t(283) = 0.31, p = .75). Study 4b measured subjective well-being (instead of manipulating happiness) and replicated this interaction, providing further evidence of this process.

In sum, these results suggest that happy consumers view their purchases as more experiential than their less happy counterparts. By examining the other side of experiential advantage, the current findings help consumer researchers better understand the potential bidirectionality between happiness and experiential purchases. While this research does not rule out an experiential advantage (i.e., that experiential purchases can lead consumers to feel more happiness), it does show that the reverse is true too: Happiness can lead consumers to feel that their purchases are more experiential. Further, the results have important implications for how marketers may need to adjust their appeals based on consumers' perceptions of a purchase.

Happiness from Unique Purchases

EXTENDED ABSTRACT

Consumer research to date in the area of subjective well-being has focused on the experiential advantage, the finding that people derive greater enduring happiness from discretionary spending on experiences than material purchases (Nicolao, Irwin, and Goodman 2009; Van Boven and Gilovich 2003). While a number of reasons underlying the experiential advantage have been proposed and examined, little work has been done on how the uniqueness of experiential purchases may be contributing to this sense of happiness.

According to (Maslow, 1954), uniqueness is foundational to and even definitional of self-actualization, the highest level of human need fulfillment at which individuals realize their full potential. Recent research further suggests that believing oneself to be unique is positively associated with subjective well-being. Individuals with a higher sense of personal uniqueness demonstrate higher levels of optimism, hope, and resilience, as well as greater life satisfaction (Şimşek and Yalınçetin 2010). As possessions and experiences come to be incorporated into our extended self (Belk 1988), our purchases may also contribute to our sense of uniqueness and therefore enhance our subjective well-being. Despite the richness in the marketing literature documenting the pursuit of uniqueness through consumption, there is little on the subject directly examining the link between unique consumption and happiness.

In this research, we directly examine the role of uniqueness in the experiential advantage. In a series of five studies, we show that more unique purchases lead to greater happiness. Situating our investigation within the existing literature on the experiential advantage, we directly examine whether experiential purchases are thought of as more unique than material purchases and whether the greater uniqueness of experiential purchases compared to material purchases contributes to the experiential advantage. An exploration into potential explanations for why people derive greater happiness from unique purchases reveals that more unique purchases are also more self-defining and contribute to a greater sense of personal uniqueness.

Study 1 confirmed that experiences are generally regarded as more unique than material purchases; 50 participants in MTurk were given brief definitions of material and experiential purchases, described as in Van Boven and Gilovich (2003). They were then asked to briefly describe a recent purchase of $100 or more and made with the intention of advancing happiness and enjoyment, a prompt also adapted from the initial study. Compared to material purchases, experiential purchases were rated as significantly more unique (M=5.26 vs. M=3.83, t=2.751, p=.008), but not significantly more important (M=5.68 vs. M=4.83, t=1.892, p=.065) or more expensive (M=$426.53 vs. M=$451.54, t=.117, p=.907).

Studies 2 and 3 replicate and extend the original investigation by Van Boven and Gilovich (2003) on the experiential advantage, and demonstrate that the greater uniqueness of experiences mediates greater happiness from spending on experiences compared to material goods. In Study 2 (n=100), we survey individuals about either experiential or material purchases and find a significant indirect effect for the mediating role of uniqueness on experiential goods' perceived contribution to happiness (indirect effect=.1803, standard error=.1076, 95% CI [.0161, .4441]). Study 3 (n=500) further tests the mechanism by examining the role of uniqueness in driving self-definition; we find in a serial mediation that the indirect effect of purchase type on happiness in life is significant through uniqueness increasing self-definition (indirect effect=.1288, SE=.0396, 95% CI [.0609, .2147]).

Finally, in Studies 4 and 5, we look at how this relationship between uniqueness and self-definition helps to explain why spending on experiences affords greater happiness than spending on material objects. In study 4, we explicitly manipulate the uniqueness of the purchase reported by participants to further examine whether purchase uniqueness drives purchase happiness. A sample of 424 MTurkers were instructed to describe a recent material or experiential purchase that was unique or similar to other purchases. We find that experiential purchases produce greater happiness in life compared to material purchases when the purchases are not unique (M=7.25 vs. M=6.64; t=2.510, p=.013), but that this experiential advantage disappears when purchases are unique (M=7.41 vs. M=7.19, t=.967, p=.335). Replicating Study 3, self-definition mediates the effect of purchase uniqueness on happiness in life. Study 5 (n=215) uses a different study design in which participants described any recent purchase, and we find that the indirect effect of experiential purchase type on happiness in life is significant through personal uniqueness increasing self-definition (indirect effect=.0272, SE=.0119, 95% CI [.0074, .0538]).

Taken together, our results show that the benefits of experiential purchases on happiness come primarily through the fact that experiential purchases are regarded as more unique than material purchases, and this uniqueness increases self-definition, which in turn leads to higher happiness. These findings connect previously disparate streams of research on happiness and subjective well-being in psychology and consumer research and provide new insights into the role of uniqueness in consumer behavior.

Distance Matters: What Information do People Want When Making Experiential and Material Purchases?

EXTENDED ABSTRACT

When consumers consider making an experiential purchase, do they resort to more or less word of mouth, compared to when they consider making a material purchase? There is previous research in support for both. On the one hand, the evaluation of experiential purchases (EP) – such as trips, restaurants, and gym memberships – is more uncertain than the evaluation of material purchases (MP)– such as computers, clothes, and jewelry – and this uncertainty is frequently solved by turning to other consumers who have already undergone that experience (Nelson 1970). Nevertheless, there is also evidence that people rely *less* on consumer reviews when making EP than when making material purchases (Dai et al. 2020), because they believe that assessments of experiences are based less on the purchase's objective quality, which makes other consumers' reviews less helpful. This apparent contradiction is important to resolve given the ever-increasing volume of experiential consumption in consumers' lives, and the increasing use of customer reviews in consumers' decision-making.

We distinguish two different types of customer reviews. One type, accessible online (e.g., Amazon, Yelp, TripAdvisor), offers the assessments of a large number of unknown others. The other involves WOM assessments from a smaller number of well-known others (friends, family members). The former is likely to be seen as especially informative about what a potential purchase is like "objectively" because it is thought to reflect the wisdom of crowds. In contrast, WOM recommendations from close others are likely to be seen as more informative about how a potential purchase would be evaluated by us subjectively—what we're likely to think of it. We predict that when evaluating EP, consumers will rely more on reviews from sources that are closer to the self, such as WOM from friends and family members. Past research has shown that people consider their

EP to be more of a reflection of their true self than their MP (Carter & Gilovich, 2012), and so they should be more interested in consulting information sources that can take into account their idiosyncratic preferences. In contrast, when evaluating MP, consumers will rely more on information sources that are seen as more objective, such as aggregate online reviews or the opinions of experts.

In Study 1, participants considered the 26 Amazon categories from Dai et al. 2020. Half of them rated how useful they would find Amazon reviews when making a decision about a purchase in that category; the other half rated how useful they would find the opinions of close others in making such a decision. As expected, we replicate Dai et al.'s result for the Amazon reviews (i.e., they are rated as less helpful for more experiential categories) but find the opposite pattern for information from close friends and family (i.e., such information is seen as more helpful for more experiential categories).

In Study 2, participants read a scenario in which they were encouraged to imagine they were considering making a number of purchases (12 in total, half material and half experiential) and that they were looking for advice. They had access to two sources of information: (a) standard on-line summary reviews by previous customers, and (b) a new smartphone app that solicits input from people in your own social network who have had experience with the purchase in question. For each of the purchases, participants were asked to choose which of the two sources of information they would like to consult. As expected, participants chose to access input from people in their social network significantly more frequently when considering the six EP than when considering the six MP.

In Study 3, participants read the same scenario from Study 2. They were asked to imagine that, before making a decision, they could get advice from someone experienced with the item: "Suppose there are 12 people you can consult. Six of these people are not people who are close to you, but everyone would agree that they are very similar to you. The other six people are the opposite: They are people who are close to you, but you wouldn't say that you and they are very similar." To encourage participants to consider each purchase and source of advice individually, we limited to six the number of times they could use either source. In line with our theory, participants preferred to receive input from close others (as opposed to similar others) significantly more often when considering the six EP than when considering the six MP.

In study 4, participants were reminded that "before making any kind of purchase, we frequently access one or several sources of information." They were asked to rate the extent to which they would use each of four sources for 12 possible purchases: WOM from close others, online summary reviews by previous customers, expert reviews, and purchase description provided by the seller. As expected, participants claimed to use WOM coming from close others more often for EP than for MP. On the other hand, participants claimed the opposite regarding the use of the other three information sources: they claimed to use online reviews, information from experts, and product description coming from the seller more often for MP than for EP.

In Study 5, participants were asked to consider the purchase of each of four goods (two material, two experiential). Either a friend or an expert (varying between subjects) randomly endorsed each product. Consistent with our hypothesis, participants had better attitudes towards experiential goods endorsed by a friend (versus those endorsed by an expert), and towards MP endorsed by an expert (versus those endorsed by a friend). Study 6 confirmed this same result at the attribute level. One same purchase (smartphone) was described through its two most important attributes, one experiential, one material (established at a pretest): user friendliness, and the

ratio of screen size versus phone weight. We had four conditions, depending on whether each attribute was endorsed by an expert or a friend. The phone that was rated higher was the one for which an expert endorsed the material attribute, and a friend endorsed the experiential attribute.

Why Are Reviews of Experiential Purchases Less Credible?

EXTENDED ABSTRACT

Consumers derive more happiness from spending money on acquiring experiences than material purchases (Van Boven and Gilovich 2003). Greater happiness with experiences is often attributed to additional utility from memories of the experiences and ability talk to others about them (Kumar and Gilovich 2015; Zauberman, Ratner, and Kim 2009). Indeed, experiences have a greater conversational value as compared to material purchases (Bastos and Brucks 2017). We examine how consumers write about their consumption experiences on online review platforms.

When consumers write reviews, their goal is to share their consumption experience online to persuade others by providing helpful information (Berger 2014). However, recent research demonstrate that consumer reviews are often discounted, especially the reviews that might appear more extreme in tone and emotions because they are unexpected and considered relatively unhelpful due to subjectivity (Dai et al. 2020; Rocklage and Fazio 2020). Thus, if the review writers are aware of readers' discounting, they should be using less emotional words and extreme tone. Instead, we predict that for experiential purchases, review writers do exactly the opposite. This happens because consumers tend to view their experience more positively (Van Boven and Gilovich 2003), and they tend to use more positive emotional words as the valence of the experience increases (Rocklage and Fazio 2020). Further, when consumers focus on emotion in justifying their choice, they believe their choice reflects their true selves (Carter and Gilovich 2012) and are more confident about their choice (Maglio and Reich 2019).

Study 1 established initial evidence that consumers write online reviews for material and experiential purchases differently. Two hundred most recent online reviews for dining experience from ten most popular local restaurants for Yelp and ten more popular utilitarian products for Amazon were collected. These reviews served a proxy for experiential and material purchases, respectfully. They were analyzed with Linguistic Inquiry and Word Count (LIWC, Pennebaker et al. 2015) and Evaluative Lexicon (EL, Rocklage and Fazio 2015). Clout variable (degree of confidence) from LIWC and Extremity variable (extent of positive emotion) from EL were selected to assess differences in writing style. We found that compared to reviews on Amazon, consumers adopt a more confident tone for reviews on Yelp ($M_{material} = 41.15$ vs. $M_{experience} = 60.39$; $F(1, 199) = 19.89$, $p < .001$), controlling for actual review valence (number of stars) and length of review. There was no difference in use of positive emotional words, when controlling for length and valence of review ($p = .274$).

In the next set of studies, we replicate the effect and further attempt to change consumers' writing style by either drawing attention to discounting of reviews by readers (studies 2-3) or by incentivizing them to write more convincing reviews (studies 4-5). Study 2 used a 2 (purchase: experiential vs. material) x 2 (discounting message: present vs. none) between-subjects design. Participants were asked to write a short review about their latest dining (material) purchase. In the discount condition, participants were reminded that reviews are often discounted. Replicating Study 1, participants used a more confident tone when writing about their dining experiences vs. utili-

tarian purchase ($M_{material} = 29.08$ vs. $M_{experience} = 59.05$; $F(1, 220) = 94.50$, $p < .001$) and used more positive emotional words ($M_{material} = 2.80$ vs. $M_{experience} = 2.98$; $F(1, 213) = 10.70$, $p = .001$). We found no significant effect of discounting or interactions on either of the variables.

Study 3 used a 2 (purchase: experiential vs. material) x 2 (think about the readers: before vs. after) between-subjects design. Participants were instructed to write the review about their recent dining experience (vs. kitchen appliance purchase) of the same price, either before or after answering questions about how other consumers would evaluate their reviews. Again, participants wrote about their dining experience in a more confident tone ($M_{material} = 29.92$ vs. $M_{experience} = 54.44$; $F(1, 299) = 74.97$, $p < .001$) and used more positive emotional words ($M_{experience} = 2.92$ vs. $M_{material} = 2.64$; $F(1, 299) = 22.28$, $p < .001$) compared to kitchen appliances. Out of three measures of how others would evaluate their reviews (usefulness, reliance, and objective quality), participants in the experiential condition expected objective quality to be perceived lower, when participants answered questions before as compared to after writing the review ($M_{before} = 6.86$ vs. $M_{after} = 7.28$; $F(1, 299) = 4.44$, $p = .036$).

Incentives are often employed to encourage consumers to take a more professional approach to write more helpful online reviews (Stephen et al. 2012). Thus, studies 4 and 5 tested monetary and status incentives, respectively, as a moderator, to see if incentives could influence consumers to change their writing style. Both studies had a 2 (purchase: experiential vs. material) x 2 (incentives: yes vs. no) between-subjects design. Participants in the incentive condition were told that they would receive a $50 gift card and an Elite (Vine) status for monetary and status incentives, respectively. For monetary incentives, we replicate the effect of purchase type on confidence in tone ($M_{material} = 33.05$ vs. $M_{experience} = 51.13$; $F(1, 274) = 43.15$, $p < .001$) and positive emotions ($M_{material} = 2.80$ vs. $M_{experience} = 2.97$; $F(1, 273) = 10.47$, $p = .001$), but we found no effect of incentives on these variables or the interaction ($ps > .2$). The results were the same for status incentive (confidence in tone: $M_{material} = 29.18$ vs. $M_{experience} = 51.83$; $F(1, 167) = 46.27$, $p < .001$; positive emotions: $M_{material} = 2.78$ vs. $M_{experience} = 2.99$; $F(1, 160) = 8.14$, $p = .005$). Again, there was no effect of incentives on these variables or the interaction ($ps > .14$).

Our findings contribute to the literature in two ways. First, we add to the literature on how differences in consumers' processing of the experiential and material consumption manifest in consequential behavior, such as writing reviews. Second, our findings give insights to the marketers on developing strategies to guide consumers to write reviews that are less likely to be discounted by the readers.

SESSION OVERVIEW

Marketing, with its deep understanding of consumers, has the unique ability to improve their lives and make this world a better place. How can we, as consumer researchers, encourage people to *make a difference*? Tied together by this unifying theme, the four papers in this session showcase novel theoretical insights to promote an array of pro-social and pro-environmental behaviors such as conserving energy and recycling, reducing food waste, advocating for social and environmental causes, and helping strangers in need. Consistent with the conference theme *"Rendezvous,"* this session is a melting pot of diverse theories, approaches, and methods (including field and/or behavioral data across all papers) to illuminate how consumer research can contribute to the greater good of the society. The session features insights that are of strong interest to a broad set of stakeholders — including policy makers, businesses, not for profit organizations, communities, and consumers.

The first two papers present novel theoretical insights to increase pro-social/environmental behaviors and advocacy. Park, Huang, and Kupor set the stage by leveraging consumers' subjective age to encourage donations of time and money to charitable and environmental causes, across lab and field studies. They find that increasing people's subjective age, i.e., feeling older, enhances voluntary behavior by heightening felt responsibility for others. Su and Labroo uncover a novel antecedent for consumer activism, i.e., advocacy for critical social issues such as discriminatory gender, race, or environmental policies. Drawing from goal theory, they suggest that personal goal failures undermine consumers' agency, leading them to engage in activist behaviors by affiliating with likeminded others thereby restoring personal agency.

While the first two papers tackle broad social and environmental issues from a consumer perspective, the next two papers focus on specific pro-environmental actions of "reduce, [reuse] and recycle" by focusing on product characteristics. Madan, Savani, and Johar take a novel approach to understand consumers' aversion to ugly produce —their lay theories about physiognomy, i.e., the idea that people's appearance can reveal their character. Building on person-

perception and over-generalization literatures, they suggest theoretically rich and practically useful interventions to persuade consumers to buy ugly produce, thereby reducing food waste. Wu, Malter, and Johar suggest that product anthropomorphism may be a low-cost way to encourage consumers to recycle their possessions. They suggest increased empathy for human like products as the underlying mechanism while identifying important boundary conditions under which anthropomorphism backfires as an effective way to encourage recycling.

As social, environmental, political, and demographic changes transform and disrupt the way consumers think about and live their lives, these insights aspire to promote actions that enhance the long-term well-being of humankind and the environment. In this session, we aspire to encourage a lively discussion on the ways in which the field of consumer research can come together to provide theory driven, practically sound solutions for the most pressing concerns of the twenty first century.

Subjective Age and the Greater Good

EXTENDED ABSTRACT

Charitable organizations often struggle to solicit sufficient contributions to aid people in need. Substantial research reveals that increasing people's felt responsibility towards others can boost their prosocial contributions (e.g., Michel 2007; Wilson and Musick, 1997). We uncover a new driver that can increase consumers' felt responsibility towards others in need and increase their prosocial contributions as a result.

The perception that older (vs. younger) adults have greater responsibility for aiding society at large originates from a rich array of sources, including cultural narratives, public communications (Gheaus 2016), and normative pressures (e.g., Browning 1975; McAdams and Aubin, 1992). Drawing from this perception, we hypothesize that when consumers encounter cues that make them feel subjectively older, their felt responsibility for contributing to the greater good of society increases, which in turn heightens their contributions.

Studies 1A-1C found that objectively younger reference points increased consumers' subjective age. Participants in Study 1A were randomly assigned to a *Younger Cue* condition (imagined interacting with a younger individual), an *Older Cue* condition (imagined interacting with an older individual), or a *Baseline* condition (did not complete this interaction task). Participants then indicated how old they felt on a 100-point scale (1: *extremely young*; 100: *extremely old*). Analysis revealed that participants in the *Younger Cue* condition felt older ($M = 49.74$, $SD = 22.98$) than participants in both the *Older Cue* condition ($M = 38.90$, $SD = 24.44$; $p = .001$) and the *Baseline* condition ($M = 39.19$, $SD = 18.94$; $p = .001$), the latter of which did not differ ($p = .93$). Studies 1B-1C replicated this phenomenon across two additional interventions of subjective age: considering one's younger or older self (Study 1B) and viewing the ages of younger or older others (Study 1C).

Study 2 found that increasing consumers' subjective age increased their aid to strangers in need. Participants were randomly assigned to a *Younger Cue* (i.e., *Feel Older*) condition, an *Older Cue* condition, or a *Baseline* condition; these conditions were manipulated as in Study 1A. Then, all participants viewed an advertisement soliciting donations to aid the blind and indicated their willingness to

contribute to this cause on a 1-7 scale. Analysis revealed that condition impacted prosocial intentions ($F(2, 297) = 7.22$, $p = .001$): Participants in the *Younger Cue* (i.e., *Feel Older*) condition were more willing to support the cause ($M = 6.04$, $SD = 2.04$) than were participants in the *Older Cue* condition ($M = 4.98$, $SD = 2.31$; $p = .001$) and the *Baseline* condition ($M = 5.05$, $SD = 2.24$; $p = .002$); the latter two conditions did not differ ($p = .83$). This effect persisted when controlling for participants' chronological age, and participants' chronological age did not predict their prosocial behavior.

Studies 3-4 tested our prediction that feeling older increases contributions by heightening felt responsibility for others and ruled out an alternative account of perception of time left. Participants were randomly assigned to one of the three conditions described in Study 2 and indicated their willingness to volunteer their time for a pro-environmental cause on a 1-7 scale. Then, they completed a six-item scale assessing their felt responsibility for others' welfare (e.g., "I feel responsible for future generations"; Morselli and Passini, 2015; $\alpha = .90$) and a ten-item scale capturing their perception of the amount of time remaining (e.g., "I have the sense time is running out"; Carstensen and Lang, 1997; $\alpha = .71$). Participants in the *Younger Cue* (i.e., *Feel Older*) condition were more willing to contribute to the prosocial cause ($M = 4.56$, $SD = 1.77$) than those in the *Older Cue* condition ($M = 3.76$, $SD = 1.73$; $p = .001$) and the *Baseline* condition ($M = 3.83$, $SD = 1.72$; $p = .003$); the latter two conditions did not differ ($p = .78$). This result persisted when controlling for participants' chronological age ($b = .80$, $SE = .25$, $t(294) = 3.25$, $p = .001$), which did not predict prosocial behavior ($b = .03$, $SE = .03$, $t(294) = 1.24$, $p = .22$). Importantly, a mediation analysis revealed that felt responsibility mediated the effect of subjective age on prosocial behavior (95% CI: .1022 to .4149); a separate mediation analysis showed that time perception mediated the effect of chronological age on prosocial behavior (95% CI: -.0105 to -.0002). In other words, feeling *subjectively* older increased intentions to act for the greater good by heightening felt responsibility for others; in contrast, being *chronologically* older was associated with reduced perceived time remaining, which in turn was associated with reduced prosocial behavior. Using a similar design, Study 4 found that this phenomenon persisted regardless of whether subjective age was shifted through an *inter*personal or *intra*personal age cue.

Studies 5-6 examined that—because older subjective age increases prosocial behavior by increasing felt responsibility for distant others—older subjective age increases giving to *distant* others but not to *close* others. Specifically, Study 6 tested this phenomenon in the field. We organized a thank-you card event on campus and invited campus visitors to give thanks to their family members (i.e., close others) and/or university staff (i.e., distant others) by writing thank-you cards. Participants' subjective age was manipulated by varying the average age information about prior participants. As expected, and consistent with Study 5, subjective age condition did not impact the number of cards written to *close* others ($M_{Younger\ Cue} = .73$, $SD_{Younger\ Cue} = .97$; $M_{Older\ Cue} = .82$, $SD_{Older\ Cue} = .96$; $p = .58$), but participants wrote more cards to *distant* others when they felt older ($M_{Younger\ Cue} = 1.08$, $SD_{Younger\ Cue} = 1.30$; $M_{Older\ Cue} = .62$, $SD_{Older\ Cue} = .87$; $p = .01$). These results persisted when controlling for participants' chronological age.

In sum, we find that increasing people's subjective age heightens their prosocial contributions through increased felt responsibility for others. Our findings provide a novel insight into how a classic demographic variable (i.e., chronological age) can become a malleable construct (i.e., subjective age), which can be leveraged to nudge people toward actions that aid others in need.

Finding "I" in Activism: Seeking Agency after Personal Goal Failures

EXTENDED ABSTRACT

Activism is on the rise—and firms increasingly are not immune to activist action, as evidenced by a multitude of protests against brands including Chick Fil A, Uber, McDonalds, Starbucks, etc. for discriminatory gender, wage, or religious/racial policies. Activism typically arises in response to societal failures and injustice, and as a way for people to join likeminded others to bring about changes for the communal good. Activists are often seen as not directly benefitting from the change they bring about, and when they do benefit from the change, the change is assumed to benefit the greater good and community at large more. Indeed, engaging in activism is considered risky. To overcome these personal costs, activists are assumed to have a high degree of communal orientation and a concern for social justice (Hoffman 1989; Omoto, Snyder, and Hackett 2010). Research shows consumers are driven by their prosocial motivations to engage in activism, address social-political failures, and advance the welfare of disadvantaged groups in society (Horberg, Oveis, and Keltner 2011; Johnson 2009). While there is no doubt that prosocial orientations influence people's willingness to engage in activism, we shed light on a novel antecedent that is not prosocial, but instead potentially selfish, in nature: we demonstrate that perceived personal goal failures can also increase activism.

Consumers who face personal goal failures typically look to understand the causes of their failures. The causes could pertain to internal factors, things the consumer did or did not do, or to external factors that contributed to the failure (Heider 1958). Consumers are known to spontaneously make external attributions for their failures to protect their sense of self (Jellison and Green 1981; Jones and Harris 1967). For instance, drivers causing an accident are more likely to report a light suddenly turned than to admit they were driving too fast; students performing poorly are more likely to say the professor was a tough grader or the course was too difficult than to admit they did not try enough or seek assistance in time. We posit that making external attributions could make consumers infer a lack of external support, and they therefore have less personal agency—the ability to take action, be effective, influence their own life—because of others. As a result, they may seek to affiliate with like-minded others, as a way to reestablish their personal agency. Activism, by offering the opportunity to affiliate with like-minded others, could be seen by consumers as a way to garner personal agency. As a result, consumers who consider their personal failures may experience heightened need to affiliate with likeminded others to reestablish personal agency, which will increase engagement in activism, especially activism that could offer a higher boost to personal agency.

Across six studies, we show support for our hypotheses that failure to progress on one's goal leads to an increase in activism. In study 1, we examined the relationship between perceived failure on career goals and political activism using real-world data from a large cross-national survey (23 countries; N = 44,387). We show that expectations of unemployment in the next 12 months correlate positively with participation in public demonstrations ($b = .05$, SE = .02, $z = 2.00$, $p = .046$) and online political activism ($b = .08$, SE = .02, $z = 5.11$, $p < .001$), controlling for income, and for communal reasons for engaging in activism, including mistrust in the system, political orientation, etc. Study 2 (N = 182) established the causal link between personal goal failure and political activism using experimental methods, providing evidence that regardless of goal type, consumers who considered chronic or situational goal failures ($M = 2.31$, SD = .76) showed higher intentions of engaging in political activism ($M =$

2.03, SD = .87; *p* = .030) . Directing their thoughts to goal success reduced this tendency. In study 3, we replicated these findings in a field study run at an Auto Expo and at an upmarket cafeteria (N = 205). Consumers who considered failures to own a preferred car (*M* = .060, SD = .072) were more willing to engage in animal rights activism (*M* = - .15, SD = .073; *p* = .047). Notably, animal rights activism cannot address their lack of a preferred vehicle but engaging in such activism can afford affiliation with likeminded others and therefore a perception of reestablishing personal agency. Study 4 then demonstrated, as we predicted, that this effect only arises when people make external attributions for their goal failure, thus establishing external (vs. internal) attribution as an important boundary condition for our effect (N = 302, *p* = .017). In study 5, we examined our full process model: the mediating role of need for affiliation with like-minded others and a resulting need to reestablish one's agency through activism after the experience of personal goal failures, but only when activism can reestablish their agency (N = 299, *p* < .001). Lastly, study 6 explored the consequences of engaging in activism (N = 400).

Using multiple methods—observational data, experimental study, field settings—different personal goals (career, any listed spontaneously, affording luxury cars)—different causes (political activism, environmental activism, animal rights, free college for all)—across different populations (low-income MTurkers, middle/high-income executives, European respondents from 23 countries)—we showed a robust link between perceived failures to progress on personal goals and activism. Importantly, our hypotheses held even when controlling for a variety of factors that prior literatures suggest having an influence on activist intent—communal motives, political ideology, objective income, highest level of education, subjective experience of frustration, and general trust in the political system. Thus, while prosocial motivations and concerns for a just society certainly matter, as previously shown, we show that the desire to advance one's personal goals is also an important pathway to activism independent of prosocial influences. We therefore contribute to the current literature on activism by providing new insights into the importance of perceived personal goal failures in prompting people to engage in activism as a way to enhance their personal agency. Reducing Food Waste: Lay Theories of Physiognomy Shape Willingness to Buy Imperfect Produce

EXTENDED ABSTRACT

The global population is projected to touch 9 billion by 2050 making minimizing food waste critical to preventing large scale food insecurity. Food that gets rejected due to atypical or imperfect appearance contributes up to 40% of total food waste. In this research, we identify a novel lay theory that influences consumers' willingness to buy imperfect produce. We find that the more consumers believe in the idea of *physiognomy*, or that people's outer appearance reveals their inner character, the less likely they are to buy imperfect produce.

Across cultures, people have believed that a person's face is the window to their soul, a reflection of what lies beneath the surface. People unfailingly infer others' personality, intelligence, social skills, and mental health from their appearances in split seconds (Berry and Brownlow 1989; Willis and Todorov 2006). These judgments, such as inferring personality traits from appearance, are surprisingly robust and reliable (Berry and Wero 1993). The lay belief that people's outer appearance reveals their inner character suggests that what is on the outside is an accurate indicator of what lies on the inside. We argue that consumers tend to overgeneralize and apply this lay belief regarding people to judging produce with atypical appearance.

Six studies provide evidence for this idea, rule out several alternative explanations, test boundary conditions, and propose multiple interventions for retailers to persuade consumers to buy imperfect produce.

Study 1 manipulated the appearance reveals character lay theory and found that reading an article explaining that people's appearance can reveal their character lowered consumers' willingness to pay for imperfect produce ($WTP_{AppearanceRevealsCharacter}$=3.51, SD = 1.43, $WTP_{AppearanceDoesNOTRevealCharacter}$=3.96, SD=1.66, *t*(211)=2.08, *p*=.038). The inference of lower quality (poor taste, texture, and nutrition) mediated the effect (*B*=-.19, *SE*=.091, *95%CI* [-.38, -.026]. This inference of poor quality was the only significant mediator even after including several other explanations such as poor self-perception, self-esteem, disgust, and difficulty to use as competing mediators in the mediation model.

Study 2 replicated the above effect by measuring consumers' appearance reveals character lay theory and adding a typical produce control condition. We found a significant indirect effect of the lay theory on willingness to buy imperfect produce through the perception that imperfect produce might be poor in taste, texture, and nutrition (*B*=-.18, *SE*=.09, *95% CI* [-.37, -.02]) while ruling out additional concerns that imperfect produce is not natural or is genetically modified.

Given our hypothesis that over-generalization from people to produce drives this effect, Study 3 tested the idea that if consumers were made aware that over-generalizing from people to produce is illogical and irrational behavior, they would be less likely to use this lay theory to judge imperfect produce. We measured the lay theory as in Study 2 and randomly assigned participants either to an intervention condition (where they read a short paragraph about how illogical it is to perceive human like attributes in objects) or the control condition (where they read a short paragraph about memory). The interaction between lay theory and condition was significant (*B*=-1.084, *SE*=.51, *t*(143)=2.13,*p*=.035). In the control condition, the more participants believed that individuals' appearance reveals their character, the less willing they were to buy imperfect produce (*B*=-.95, *SE* = .42, *t*(71)=2.28, *p*=.026). More importantly, in the intervention condition, their lay theory was not related to their willingness to buy imperfect produce (*B*=.13, *SE*=.301, *t*(72)=.2, *p*=.66).

Studies 4 and 5 tested if explicit anthropomorphization (a communication strategy used by ugly produce startups), improves or reduces consumers' willingness to purchase ugly produce. We found that in this context, anthropomorphization backfires. Specifically, consumers who believed that appearance reveals character (+1 SD) were not swayed by anthropomorphized depictions of imperfect fruits and vegetables. However, consumers who believe that appearance does not reveal character became less likely to buy imperfect produce when it was anthropomorphized indicating that although these consumers did not infer poor quality from atypical looks, anthropomorphization shifted these participants' attention to the produce's weird looks and reduced willingness to buy (Wen Wan et al. 2017).

Finally, two field studies on Facebook™ tested another actionable intervention to persuade consumers to consider imperfect produce—by decoupling appearance from taste, texture, and nutrition by creating an appealing and healthy-looking soup from imperfect produce. In discussion with an ugly produce start-up, we sought to test if the intervention was effective at both increasing engagement (likes, comments, and shares) and link clicks (to go to an external website to learn more about imperfect produce). Studies 7 and 8

(*N*=34,602) found that the intervention ad was significantly more effective in generating active engagement among the target audience (152.9% more engagement) and also more persuasive in leading them to go to the website to learn more (38.2% more clicks) at a significantly lower cost.

The findings identify a novel lay belief that influences consumers' willingness to buy imperfect produce and multiple strategies for mitigating this bias. This research leverages a unique theoretical perspective, at the intersection of lay theories, over-generalization, and anthropomorphism, to create interventions that contribute to the emerging, and critically important stream of work on food waste.

When Products are People: The Impact of Anthropomorphism on Recycling

EXTENDED ABSTRACT

US consumers discard most materials (76%) after using them only once (White, MacDonnell and Dahl, 2011); thus, recycling behavior is a critical step to creating a sustainable environment. This research investigates a specific type of product characteristic, anthropomorphism, and its effect on recycling. Anthropomorphism is guided by the same social cognitive mechanisms that enable people to think about the minds of other people (Epley, 2018). We argue that when it comes to disposal decisions (trashing vs. recycling), people feel like they are discarding a person when they have to dispose a humanlike product. Because they feel empathy for this human-like product, they will be more likely to recycle it in order to avoid hurting it. However, if recycling requires consumers to disassemble the product into different parts (e.g., plastic, paper, metal), it feels like dismembering "a person" and thus consumers will be more likely to trash the product as a whole to avoid hurting it.

Anthropomorphism can be operationalized by making a product look humanlike (*perceptual*) or by giving the product a first-person humanlike voice (*conceptual*). We believe that consumers will only perceive the product to *feel* humanlike (not just *look* humanlike) for conceptual anthropomorphism thus inducing empathy toward the product. Therefore, only conceptual anthropomorphism should increase recycling.

To test our hypotheses, we conducted four studies. A pretest examined various types of manipulations of anthropomorphism to identify which manipulations consistently increase recycling. Experiment 1 tested our proposed main effect in a lab study with a real behavioral dependent measure of recycling. Experiments 2 and 3 explored our proposed interaction effect between anthropomorphism and disassembling on recycling.

Pretest. We designed 22 pairs of product pictures, with one option anthropomorphized and the other non-anthropomorphized. We manipulated perceptual and conceptual anthropomorphism - the perceptual-anthropomorphism condition displayed products with visual humanlike features (face or body shape), whereas the conceptual-anthropomorphism condition displayed products with the same humanlike physical features accompanied by a first-person perspective description. Participants were randomly provided with one of the pictures in each pair. Then participants were asked to drag and drop each object into one of the two bins – trash or recycling. Results showed that conceptual anthropomorphism consistently increased recycling behavior more than perceptual anthropomorphism (). Since conceptual anthropomorphism worked better in the pretest, we used it in the following experiments.

Experiment 1. We tested the hypothesis that anthropomorphism increases recycling. Participants were told that a newly opened local bakery wanted customers to evaluate their cookies. Upon arriving

in the lab, participants were randomly assigned to two conditions – anthropomorphism condition or the control condition. In both conditions, participants were given the same cookie to taste. Anthropomorphism was manipulated through an instruction sheet. In the anthropomorphism (vs. control) condition, participants read the instruction using first-person (vs. third-person) voice. After reading the instructions and tasting the cookie, participants answered several questions including the aesthetic feature, the sweetness, and their liking of the cookie. Before they left the lab, participants were told that since the bakery is new, everything should be kept confidential, so they needed to discard the experimental materials before leaving the lab. There were two bins by the door, trash and recycling. Participants disposed of the instruction sheet, any remaining cookie into the bins before leaving the lab. We found that in the anthropomorphism condition, 96.8% of the participants recycled the information sheet compared with 89.40% did in the control condition (). Moreover, we found that six participants tore the instruction sheet into pieces in the control condition, whereas no participant did the same thing in the anthropomorphism condition, indicating that people wanted to minimize potentially hurting the humanlike object when they disposed of it.

Experiment 2 aimed to a) replicate the findings in experiment 1 and b) examine when anthropomorphism backfires. In this experiment, we used a smoothie-maker as our stimulus and manipulated anthropomorphism by describing the smoothie-maker from a first-person perspective. We manipulated disassembling instruction by telling half of the participants that "*Since the smoothie maker consists of several parts, you must carefully disassemble it into different parts before disposing these parts into different recycling bins*." They then answered our dependent variable measures – "How likely are you to trash the smoothie maker?" and "How likely are you to recycle the smoothie maker?" on a seven-point scale. The other half of the participants received no disassembly instructions and just answered the dependent measures. We used the difference between the two measures as our dependent variable. Results showed a significant interaction effect between anthropomorphism and disassembling (). When there was no disassembling instruction, participants recycled more when the product was humanlike (); whereas when the disassembling instruction was present, participants recycled less when the product was humanlike (). The effect could not be explained by effort because in the control condition, disassembling instruction made participants recycle more ().

Experiment 3 replicated the effect that when people had to disassemble a product, anthropomorphism backfires. We used the same stimuli as Experiment 2 and all participants read the instruction that if they wanted to recycle the smoothie maker, they must disassemble it into different parts. Results showed a significant decreasing effect of anthropomorphism on recycling (). When the disassembling instruction was present, participants recycled less when the product was humanlike () than when the product was not humanlike ().

In sum, we find that people prefer to minimize hurting the anthropomorphized product – either by recycling it (and possibly giving it the potential to be resurrected) or by trashing it as a whole rather than dismembering it. Our findings suggest that this effect occurs because consumers have empathy for the humanlike product, but further research is required to test this theory.

Caleb Warren, University of Arizona, USA

SESSION OVERVIEW

Consumers want to be cool because coolness brings them admiration and esteem (Belk et al. 2010; Heath and Potter 2004; Warren 2010). Merely being in the presence of a cool product is enough to make consumers feel better about themselves (Quartz and Asp 2013). Recognizing this, marketing professionals spend a lot of time and money trying to figure out how to create cool products and brands (Gladwell 1997; Kerner and Pressman 2007; Southgate 2003) and marketing researchers attempt to understand what may distinguish cool product designs from designs that seem either funny or normal (Warren and Reimann 2019). And for good reason. Just as becoming a cool person can help consumers feel better about themselves (Quartz and Asp 2013), offering a cool product or brand can help firms feel better about their bottom line (Im, Bhat, and Lee 2015; Kim, Shin, and Park 2015; Shin and Biocca 2018).

Thus, upon closer inspection, it seems wise for consumers, firms, and especially consumer researchers to better understand how to become cool. All of the papers in this special session attempt to answer this question, each using a different approach to address a different aspect of how to become cool. Pol, Yin, and Tellis investigate how coolness varies across cultures by gathering data in the US, UK, Germany, and China, but shift their focus to how products, rather than people, become cool. Pol et al. also identify two interpretations of coolness, one relatively personal and the other more social, develop a set of measures to assess these two interpretations, and identify cross-cultural commonalities and variations in these interpretations. Biraglia and Brakus shift the focus from products to brands, by investigating why and when it is cool to for a brand to be autonomous. They find that autonomy is only cool under certain conditions, including when a brand comes from a disadvantaged background, the audience is relatively independent, and the product is self-expressive. Pezzuti and Warren investigate the characteristics that make people cool using a new methodology that distinguishes cool traits from traits that seem socially desirable or good. They additionally explore how the characteristics associated with cool people vary across a variety of cultural variables.

By taking different approaches to a similar question, the three papers advance our wisdom and understanding of how people, products, brands, and designs become cool. Collectively, they dispel some of the ineffability that has long characterized the concept of coolness, and help researchers, marketers, and designers alike become wiser about how to capture and create coolness.

Consumer Interpretations of Product Coolness Across Three Cultures

EXTENDED ABSTRACT

Deeply rooted in U.S. history and culture, the term and notion of 'coolness' have gained popularity in many other cultures (Belk et al. 2010; Van den Berg and Behrer 2011), with marketers around the world often willing to go to great lengths to figure out what appeals to consumers, and how to design and sell "the next cool thing" (Belk et al. 2010; Kerner and Pressman 2007). Yet despite the global importance of the coolness construct, prior research on coolness has been surprisingly scant, particularly in a cross-cultural context. This lack of research can be partially attributed to coolness being a socially constructed characteristic, which is somewhat elusive (Nancarrow et al, 2002; Tapp and Bird 2008) and highly subjective (MacAdams 2001; O'Donnell and Wardlow 2000). In the present paper, we set out to understand the different ways in which U.S.-based—or, more broadly, English-speaking—consumers intuitively interpret the meaning of product coolness, and to what extent these interpretations replicate to other cultures. We collect data from a survey in three major cultures that employ the term 'cool' in everyday language—the U.S. (along with a pilot study in the U.K.), Germany and China. Our research focuses on coolness in the context of a product (as opposed to a brand or person).

Study 1 is a pilot examination of how consumers interpret the meaning of product coolness. We use student samples from two English-speaking cultures: 207 respondents from the U.S. and 177 respondents from the U.K. Using open-ended questions—which we then code into categories—participants indicated how they define product coolness, and what they believe determines whether a product is cool. The results reveal a remarkably robust pattern across the two samples. Consistent with previous findings from coolness research (e.g., Warren 2010), respondents largely fail to articulate a clear definition of coolness, but consistently resort to using specific product attributes (such as usefulness, aesthetic design, uniqueness, etc.) as a basis for defining coolness. When it comes to the more general determinants of coolness, consumers interpret a product's coolness as emerging when the product provides some form of intrinsic, social, subjective, and/or marketing-driven value. Because our investigation appears to have good ecological validity, we decide to continue examining both the coolness-driving product attributes and the more general interpretations of coolness in tandem.

Using the insights generated in Study 1, in Study 2 we develop and validate a series of scale measures meant to capture the interpretations of product coolness, and the coolness-driving product attributes. Given the very strong similarity between the U.S. and U.K. samples, this study focuses solely on the U.S. as a representative of English-speaking cultures. We include 136 undergraduate students from a large US university, and a more demographically representative sample of 248 participants recruited via Amazon Mturk. For both the *coolness-driving product attributes* and the *interpretations of coolness*, we generate a pool of scale items derived from the exact words provided by participants in Study 1. Respondents are asked to indicate, on a scale from 1 to 7, the extent to which they believe each item describes cool products.

For the *coolness-driving product attributes,* we use EFA to arrive at a three-factor solution that is stable across the two samples,

and which includes functional attributes (i.e., usefulness and ease-of-use), symbolic attributes (i.e., exclusivity and aesthetics), and creativity. For the interpretations of product coolness, a two-factor solution emerges. Specifically, respondents view a product as cool (a) if it closely meets their needs and preferences (i.e., a *personal interpretation* that represents a combination of the subjective and intrinsic value identified in Study 1, and contains items such as "it possesses outstanding attributes" and "it makes me happy when I use it."), or (b) if it receives the social approval of others (i.e., a *social interpretation*, which represents a broad combination of the social and the marketing-driven value identified in Study 1, and contains items such as "it starts a popular trend," "it is perceived as cool by most people," and "it is associated with a cool brand").

Study 3 examines to what extent U.S. consumers' interpretations of product coolness replicates to Germany and China. We construct an integrative predictive framework that links the coolness-driving product attributes to the two interpretations of coolness, and to consumers' desirability perceptions vis-à-vis cool products. Using Structural Equation Modeling, we find that the framework provides a satisfactory fit to the data across all cultures (χ^2/df= 2.33, CFI = .89, GFI = .82, RMSEA = .05). The two coolness interpretations replicate cross-culturally in terms of both factorial structure and importance, with consumers across cultures agreeing more strongly with the personal interpretation of coolness–and hence rejecting the notion that they see coolness purely as a socially-determined characteristic. Nevertheless, while U.S. consumers view the two interpretations as fully independent facets of coolness (r = -.04, p > .05), Chinese consumers perceive them as strongly inter-related (r = .65, p < .001). The coolness-driving product attributes also vary cross-culturally, with symbolic attributes being the "cooler" ones in China ($M_{symbolic}$ = 5.56, $M_{functional}$ = 5.25, $F(1, 140)$ = 9.33, p < .05), functional ones being the "cooler" ones in Germany ($M_{functional}$ = 5.22, $M_{symbolic}$ = 4.85, $F(1, 135)$ = 7.65, p < .05), and neither of them dominating in the U.S. These findings suggest that Chinese consumers view coolness more strongly related to social and symbolic factors than do U.S. and German consumers, which may also explain why Chinese consumers perceive cool products as particularly high in desirability (M_{China} = 5.59, $M_{Germany}$ = 4.94, M_{US} = 4.75, $F(1, 522)$ = 17.04, p < .001).

Together, these findings support the notion that, despite gravitating towards a rather personal interpretation of coolness, different cultures perceive this interpretation, as well as the product attributes that ultimately factor into it, in a manner that is subject to cultural influences. We use several perspectives on cross-cultural differences to shed light on how the general replicability of our model across cultures can be reconciled with cultural variations.

Why Are Autonomous Brands Cool? The Role of Value Authenticity and Brand Biography

EXTENDED ABSTRACT

Coolness has attracted the interest of scholars from different disciplines: semiotics (Danesi, 1994), psychology (Dar Nimrod et al., 2012), and cultural studies (Hebdige and Potter, 2008). Consumer researchers have linked coolness to autonomous brands (i.e. brands that diverge from the norm; Warren and Campbell, 2014) or to the extent by which an endorser expresses or conceals emotions (Warren et al., 2018). In this paper we extend this research by addressing an overarching research question: when and why is high autonomy cool?

We contribute to the literature on coolness by linking highly autonomous behaviors to the disadvantaged financial and social backgrounds a brand can present in its biography. Such backgrounds are often offered in the companies' narratives about the background of their founders (e.g., Steve Jobs "home brewing" computers in a garage). These narratives are persuasive because of the *underdog effect* -- individuals root for and prefer a disadvantaged entity over an advantaged one (Paharia et al., 2011). We claim that consumers perceive a highly autonomous brand as cooler when the company highlights a disadvantaged rather than an advantaged biography. We argue that value authenticity (i.e. the capacity of sticking with and remaining true to inner values and beliefs; Newman and Smith, 2016) mediates this relationship. In other words, if a brand acts in congruence with its proclaimed values at all stages—production, promotion, or customer care—, then consumers perceive the brand as authentic and consequently as cool. We believe that this is the case because acting autonomously to succeed is more aligned with an underdog rather than with a topdog biography.

We further demonstrate how this mediating effect is stronger for individuals with an independent rather than with an interdependent self-construal (Markus and Kitayama, 1989). Moreover, we show how the link between high autonomy and being an underdog matters especially for the coolness in self-expressive than in functional product categories. Finally, we extend our findings to political marketing by demonstrating how the effect holds also when a politician is a highly autonomous underdog.

We conducted four experiments to test the hypotheses. In Experiment 1 (n = 215) we presented respondents in a laboratory setting with a scenario about a fictitious coffee company. We manipulated the background (disadvantaged vs. advantaged) and the positioning of the company (high autonomy vs. low autonomy). We found that the interaction between a disadvantaged background and a highly autonomous positioning significantly affects the perception of coolness ($M_{Disadvantaged\_high\_autonomy}$ = 5.38, $M_{Advantaged\_high\_autonomy}$ = 3.81; $M_{Disadvantaged\_low\_autonomy}$ = 4.41, $M_{Advantaged\_low\_autonomy}$ = 4.05; $F(1, 214)$ = 12.01, p < .001). We also found that the interaction was fully mediated by value authenticity (B =.0631, SE = .0862, t = .73, NS, LLCI = −.1069, ULCI = .2330; bias-corrected confidence interval = 95%; number of bootstrapping resamples = 10,000).

In Experiment 2 (N= 317 on MTurk) participants rated the coolness of a fictitious apparel brand in a 2 (autonomy: high vs. low) x 3 (background: disadvantaged vs. advantaged vs. control) between-subjects design. The results confirmed a significant interaction effect of the high autonomy with the disadvantaged background $F(2, 316)$ = 8.09, p < .001. Next, we tested a moderated mediation (Model 8; Hayes, 2013) using the interaction term as the IV, value authenticity as the mediator, coolness as the DV, and independent self-construal as the moderating factor. Results showed that value authenticity fully mediated the direct effect of the interaction effect on coolness and that consumers' level of independence moderated the relationship between high autonomy, disadvantaged biography, and coolness. In Experiment 3 (N = 442) we examined the relationship between the disadvantaged company background and the perception of coolness in different product categories (i.e. self-expressive vs. functional). We designed a 2 (autonomy: high vs. low) x 2 (background disadvantaged vs. advantaged) x 2 (category: functional vs. self-expressive) between subject design. As predicted, the a high autonomous underdog is perceived as cool especially when the company operates in a self-expressive category ($M_{Underdog\_High\_Autonomy\_Self-expressive}$ = 5.49, $M_{Topdog\_High\_Autonomy\_Self-expressive}$ = 3.26, $M_{Underdog\_High\_Autonomy\_Functional}$ = 4.48, $M_{Topdog\_High\_Autonomy\_Functional}$ = 3.89, $M_{Underdog\_Low\_Autonomy\_Self-expressive}$ = 4.28, $M_{Topdog\_Low\_Autonomy\_Self-expressive}$ = 3.28, $M_{Underdog\_LowAutonomy\_Functional}$ = 4.37, $M_{Topdog\_Low\_Autonomy\_Functional}$ = 3.88, $F(1, 441)$ = 4.32, p <.05). Finally, in Experiment 4 we show how the link between disadvantaged background and high autonomy works also in a political marketing

context. MTurk participants (N = 207) rated a politician with a disadvantaged background and a highly autonomous slogan as more cool than his advantaged counterpart ($M_{Disadvantaged\_high\_autonomy}$ = 4.57, $M_{Advantaged\_high\_autonomy}$ = 3.42, $M_{Disadvantaged\_low\_autonomy}$ = 3.51, $M_{Advantaged\_low\_autonomy}$ = 3.77; $F(1, 206)$ = 17.06, $p < .001$).

This research extends the literature on coolness, demonstrating how consumers' evaluation of advertising clues (such as a highly autonomous positioning) can be considered cooler under certain conditions (i.e disadvantaged company background; a high level of consumer independence; for self-expressive more than functional categories) due to the mediating role of value authenticity. On a managerial level, this research demonstrates that the use of a disadvantaged brand biography in presenting the company enhances the level of coolness in different contexts (groceries, apparel, and politics).

What Makes People Cool?

EXTENDED ABSTRACT

People want to be cool because being cool brings them the admiration of others and makes them feel better about themselves (Heath and Potter 2004; Quartz and Asp 2015). In turn, people emulate and imitate the behaviors of cool people in an attempt to be seen as cool (Runyan, Noh, and Mosier 2012; Warren and Campbell 2014). Recognizing the power of coolness in the marketplace, marketers pour money into consultants, such as cool hunters and trend spotters, who can ostensibly help them identify and develop cool products (Gladwell 1997; Southgate 2003). Consequently, identifying the characteristics and traits that distinguish cool people from uncool people is an important task for marketers and consumer researchers.

Initial research finds that cool people possess a variety of desirable characteristics (Dar-Nimrod et al. 2012; Horton et al. 2012; Warren, Pezzuti, and Koley 2018). However, if coolness is a distinct trait, rather than merely another way of saying that someone is desirable or good, then there should be a set of characteristics that distinguish cool people both from people perceived to be not cool and from people perceived to be good.

Our research had three objectives. One, to identify the personality traits and characteristics that differentiate cool people from uncool people. Two, to determine whether these characteristics are merely desirable (i.e., they also differentiate good people from bad people) or whether they distinctly apply to cool people. Three, examine whether the characteristics that are perceived to be cool vary across cultures.

To distinguish the characteristics that are perceived to be cool from characteristics perceived to be good, we designed three studies in which we asked participants from the USA and Chile to nominate a non-famous person who they know and like but who they also either consider good, not good, cool, or not cool using a 2 (characteristic type: cool or good) by 2 (characteristic level: present vs. absent) between-subjects design. Participants evaluated this person on 15 characteristics from the Portrait Values Questionnaire (autonomy, hedonism, excitement seeking, power, achievement, conformity, warmth [caring for friends and family], benevolence [appreciation, tolerance, and protection for the welfare of all people and nature], concern for security, and traditionalism [respect, commitment and acceptance of cultural traditions; Schwartz et al. 2001) and the Big Five personality traits (openness, conscientiousness, extroversion, agreeableness, and neuroticism; Gosling, Rentfrow and Swann 2003).

Our first study recruited USA participants (N = 287) on MTurk. To determine which characteristics are most useful for differentiating people that are cool from people that are uncool, we estimated 2 (characteristic type: cool vs. good) x 2 (characteristic level: present vs. absent) ANOVAS with each of the 15 characteristics as dependent variables. These analyses tested whether a characteristic was associated with both coolness and goodness (indicated by a main effect of "characteristic level") or more (or less) associated with coolness than goodness (indicated by an interaction).

Consistent with the literature (Dar Nimrod et al. 2012; Horton et al. 2012), most of the characteristics associated with coolness were also associated with goodness. Participants rated both cool people and good people as being more adventurous, capable, benevolent, warm, conscientious, agreeable, and open, and less neurotic than not-cool and not-good people, respectively. Interestingly, however, significant interactions revealed that the following characteristics were more strongly associated with coolness than goodness: adventurous, open, and (less) neurotic. In contrast, being benevolent warm, conscientious, and agreeable, were more strongly associated with goodness than coolness. Additionally, we identified several characteristics that were associated with cool people but not good people, including being autonomous, hedonistic, powerful, and extroverted.

Interestingly, most of the characteristics that American participants more strongly associated with coolness than goodness, including being autonomous, adventurous, open, hedonistic, powerful, and non-neurotic, signal that the person has the ability or motivation to do what they want rather than follow the expectations or desires of others (Warren and Campbell 2014). The other characteristic that is perceived to be cool but not good was extroversion, which suggests that cool people not only have the freedom to do what they want, they are not loners. They remain highly interactive and connected with others, despite having the ability to do their own thing.

Our second study (N = 335, USA, MTurk) examined whether measured cultural differences, including Hofstede's dimensions (collectivism, uncertainty avoidance, power distance, and masculinity; Yoo et al. 2011), materialism (Richins and Dawson 1992), and tightness-looseness (at the state level; Harrington and Gelfand 2014), influence which characteristics participants associate with cool and good people. The study replicated the findings from study 1. Interestingly, it also showed that the characteristics that distinguish cool people from not-cool people remained fairly stable across the measured cultural differences. For example, even though participants from relatively tight states (e.g., Mississippi, Oklahoma) perceived autonomy as being less good than participants from loose states (e.g., Oregon, California), all participants perceived autonomy as being cool. Similarly, even though participants who scored higher on uncertainty avoidance perceived conformity as being more good than participants who scored lower on uncertainty avoidance, participants did not associate coolness with conformity, regardless of their score on this measure.

Our third study, which recruited undergraduate students from Chile (N = 241; survey in Spanish) and the USA (N = 178, survey in English), replicated the results in a cross-cultural sample. To examine whether the results are similar in Eastern cultures, we are in the process of recruiting participants from India for a fourth study.

In sum, the results of three studies provided consistent evidence that the characteristics that make people seem cool are not the same as the characteristics that make people seem good. In three studies in two culturally distinct countries, autonomy, adventurousness, openness, hedonism, power, a lack of neuroticism, and extroversion differentiated cool people from uncool people more than they differentiated good people from not-good people. Moreover, although the characteristics that are seen as good vary depending on cultural differences like tightness-looseness and uncertainty avoidance, the

characteristics that make people seem cool appear to be relatively stable across cultures.

SESSION OVERVIEW

Advances in artificial intelligence (AI) and robotics enable firms to replace humans with modern technology, leading to a radical transformation in the production and consumption of goods and services. In the service domain, robots are used to communicate and interact with consumers in a wide variety of contexts, including stores, restaurants, and hotels. By 2025, it is predicted that 95% of all customer interactions will be powered by some form of AI or robotics. While research has started to shed light on this transformation (Castelo, Bos, and Lehmann 2019; de Bellis and Johar 2020; Granulo, Fuchs, and Puntoni 2019; Mende et al. 2019; Schmitt 2019), we are only beginning to understand its multifaceted consequences for consumers. The four papers in this session aim to improve this understanding by answering the following key question: What are the psychological consequences of robotic replacement for consumers?

The first paper by **Puntoni, Granulo, and Fuchs** examines for which products consumers prefer robotic versus human labor. It shows that consumers value human (vs. robotic) labor more for products with higher symbolic value, as it lends products unique qualities in the eyes of consumers. The second paper by **Van Doorn and Holthoewer** examines for which products consumers prefer robotic versus human service providers. It shows that consumers are more accepting of a robotic service provider when acquiring embarrassing products because they feel less judged by a robot than by a human. The third paper by **Castelo et al.** examines the downstream consequences of robotic versus human service providers for firms. It shows that consumers perceive firms that use robotic service providers as less customer-centric, which in turn decreases service satisfaction and willingness to recommend the firm to others. Whereas the first three papers contrast robots with humans, the fourth paper by **Clegg et al.** examines different types of algorithms that are the backbone of robotic technologies. It shows that technologies based

on adaptive algorithms are perceived as more creative whereas those based on pre-programmed algorithms are perceived as more predictable, showing that also the "inner values" of robotic technologies influence their adoption by consumers.

Taken together, this session is intended to deepen our knowledge on the psychological consequences of robotic replacement from a consumer perspective. The papers utilize multi-method approaches, combining data from online, lab, and field studies to explore the robustness and generalizability of the proposed effects. This session speaks to ACR's call for special sessions on the impact of technology on consumption by highlighting the diverse consequences of replacing humans by robotic technologies. This session should not only be of interest to scholars working on new technologies, AI, and robotics but also to anybody interested in symbolic consumption, emotion, and creativity.

Consumer Preferences for Human Versus Robotic Labor: The Role of Symbolic Consumption

EXTENDED ABSTRACT

Advances in robotics, automation, and artificial intelligence increasingly enable firms to replace human labor with modern technology, fundamentally transforming how goods and services are produced. The consequences of these developments for the demand for human labor are hotly debated in both academia and popular press. Within the social sciences, the debate has been most intense within economics with a focus on when, that is, for which tasks, human labor can potentially be replaced by robotic labor (e.g., Autor, Levy, and Murnane 2003). Despite the relevance of these developments to consumers—robots and algorithms are transforming consumer-firm interactions in many industries—consumer researchers have so far provided little insight into how consumers react to today's robotic revolution (cf. Granulo, Fuchs, and Puntoni 2019).

In this research, we examine consumer acceptance of human versus robotic labor—and how this acceptance depends on product characteristics. Specifically, this research investigates for which specific products, services, and product features consumers are more likely to favor human over robotic labor. In seven studies using different products, designs, and samples, we predict and demonstrate that consumers value human (vs. robotic) labor more for products with higher symbolic value (i.e., where expressing something about one's beliefs and personality is of central importance; e.g., Belk 1988; Reed et al. 2012). We theorize that human (vs. robotic) labor creates value by lending products unique qualities in the eyes of consumers. Consumers should value these unique qualities (e.g., Brock 1968; Tian and McKenzie 2001) more for products with higher symbolic value, resulting in greater preferences for human (vs. robotic) labor in the case of products with higher symbolic value. We provide support for this theoretical framework by documenting (i) greater consumer preference for human (vs. robotic) labor in more symbolic consumption contexts, (ii) that this effect is mediated by product uniqueness, controlling for various other alternative accounts (e.g., love, product importance, and product quality), (iii) that the effect is moderated by consumers' need for uniqueness, and (iv) that it can be observed even when there is no direct (physical) contact in the production process (differentiating the effect from work on handmade products; Fuchs et al. 2015).

To test our main prediction that consumers favor human (vs. robotic) labor more in symbolic consumption contexts, we conducted five studies focusing on the symbolic value of different products, services, consumption contexts, and product components. In study 1 ($N = 72$, students), we asked participants to rate a series of products on symbolic value or on relative preference for human labor. Preference for human (vs. robotic) production was highest for product categories whose symbolic value was in the upper third (e.g., jewelry or suits), and lowest for products whose symbolic value was in the lower third (e.g., toolsets or car brakes; 20 product categories in total). In study 2A ($N = 144$, students), we find that consumers prefer human (vs. robotic) labor more when the symbolic value of a service is high (i.e., getting a tattoo) than when the symbolic value of a service is low (i.e., getting a tattoo removed; $M_{high} = 5.03$ vs. $M_{low} = 4.03$, $t(142) = 3.65$, $p < .0001$).[1] In study 3A ($N = 322$, MTurk), we document that consumers are more likely to purchase products designed by a human (vs. algorithm)—but produced by a machine—when they have more symbolic consumption goals (i.e., purchasing a printed poster to decorate; $M_{human} = 4.39$ vs. $M_{algorithm} = 2.30$) than when they have less symbolic consumption goals (i.e., purchasing a printed poster to educate; $M_{human} = 4.30$ vs. $M_{algorithm} = 3.25$; $F(1, 318) = 5.20$, $p < .05$). And in study 4A ($N = 124$, MTurk), we document that consumers choose human (vs. robotic) production for more symbolic product components (i.e., the frame of eyeglasses; 59% vs. 41%, $Z = 2.00$, $p < .05$) but not for less symbolic product components (i.e., the lenses of eyeglasses; 23% vs. 77%, $Z = 6.01$, $p < .0001$, $= 35.2$, $p < .0001$).

To test our prediction that uniqueness can explain why consumers prefer human (vs. robotic) labor more in symbolic consumption contexts, we conducted two additional studies. Specifically, we tested whether this relative preference is moderated by individuals' need for uniqueness, and whether it is mediated by product uniqueness. In study 3B ($N = 402$, MTurk), we find that consumers value human (vs. robotic) labor more strongly for products with higher symbolic value when they have a higher need for uniqueness ($b = 0.724$, $(394) = 2.08$, $p < .05$; 95% CI: [0.04, 1.41]). Specifically, the interaction between production mode and symbolic value was non-significant for individuals low in need for uniqueness ($F(1, 133) = 0.57$, $p = .451$) and highly significant for respondents high in need for uniqueness ($F(1, 123) = 8.78$, $p < .01$). In study 4B ($N = 201$, Prolific), we find that consumers value human (vs. robotic) more for products with higher symbolic value because they want more unique products (indirect effect: $b = 0.222$, $SE = 0.09$, $Z = 2.42$, $p < .05$; 95% CI: [0.08, 0.45]).

In summary, our research demonstrates that human labor creates additional economic value in consumption contexts where symbolism plays a central role. By doing so, we complement the supply-side perspective in the economics literature (e.g., for which tasks human labor can and cannot be replaced by firms) with a demand-side perspective (e.g., for which products human labor can and cannot create value for consumers). Moreover, we demonstrate that one important driver behind our findings is that human (vs. robotic) labor lends products unique qualities in the eyes of consumers. Our findings suggest that the extent to which human labor will continue playing a role in production processes in the years to come should not only depend on cost and efficiency, but also on the inherent characteristics of products.

---

[1]   In study 2B (N = 192, MTurk), we replicate this effect in a 2(symbolic: high vs. low) × 2(labor: human vs. robotic labor) between-participants design (F(1, 188) = 6.40, p < .05).

This Robot Doesn't Judge Me – Service Robots and the Choice of Embarrassing Products

EXTENDED ABSTRACT

During the last years, there has been significant progress in service automation, robots, and artificial intelligence (AI; Kahn et al. 2013). Service robots have started to communicate and interact with customers in a frontline service setting. With a 61% sales increase of service robots for professional use from 2017 to 2018 (Industrial Federation of Robotics 2019), it is estimated that 95% of all customer interactions will be powered by AI by 2025 (Servion Global Solutions 2018). Service robots distinguish themselves from previous generations of technology and automation because they often go beyond a merely functional role and engage their users on a social level. The degree to which technology makes consumers feel the presence of another social entity is known as automated social presence (Van Doorn et al. 2017). Yet, previous literature shows that service robots are not always easily accepted. On the contrary, they can trigger negative feelings and compensatory behaviors (Mende et al. 2019), and cause more discomfort than dealing with a human employee (Čaić et al. 2019). Given that service robots are on the rise, it is imperative to identify circumstances where the negative effects documented in previous literature are attenuated, or can even be avoided altogether. In this paper, we investigate whether service robots can help overcome consumer reluctance to acquire embarrassing products.

Social identity theory posits that unwanted negative evaluations from audiences can cause a threat to one's social identity (Edelmann 1987; Miller and Leary 1992) and influence patronage decisions (Moore et al. 2006; Grace 2009). In embarrassing service situations, consumers endanger their health, engage in risky behavior, and avoid seeking medical care in order to avoid social judgment (Helweg-Larsen and Collins 1994; Lund-Nielsen et al. 2011; Kiefe et al. 1998). We argue that robots may reduce this feeling and thus make it easier for consumers to, for example, collect medication that they experience as embarrassing. Hence, we extend the concept of social presence, that has shown to influence embarrassment in purchase situations (Argo et al. 2005; Dahl et al. 2001), to automated social presence, therewith taking into account novel ways of purchase interactions that come with the development of new technology.

We furthermore explore the role of anthropomorphism in shaping how consumers react to service robots. Anthropomorphization means imbuing the "behavior of nonhuman agents with human-like characteristics, motivations, intentions, or emotions" (Epley, Waytz, and Cacioppo 2007, p. 864). Although humanizing robots is the ultimate goal in robotics (Rubin 2003), there is a certain risk that consumers feel uncomfortable in dealing with very human-like robots. This phenomenon is known as the "uncanny valley" (Mori, MacDorman, and Kageki 2012). We argue that very human-like robots might increase consumers' apprehension of judgments by anthropomorphizing this attribute to the robot, leading to a less positive consumer evaluation (Miller 1995). Thus, consumers may prefer less anthropomorphic robotic service providers in an embarrassing situation.

In three studies, we find that consumers are indeed more accepting of robotic service providers in embarrassing situations. In study 1 ($N=136$, 47 males) involving real choice behavior participants watched a video featuring a human vs. robotic ambassador promoting a new health initiative and offering a free giveaway. The giveaway was either a pack of condoms (high embarrassment) or hand sanitizer (low embarrassment). The percentage of participants taking the pack of condoms rather than refusing it rose from 38% for the

human ambassador to 61% for the robotic ambassador ((1)=3.353, p=.067).

Study 2 is a 2 (service provider: human vs. robot) × 2 (embarrassment product: low vs. high) between-subjects Prolific study. Respondents (N=395, 174 males) imagine buying antibiotics for an ear infection (low embarrassment) or a sexually transmitted disease (high embarrassment) from a human vs. robot at their local pharmacy. The results reveal a main effect of service provider (F(1,394)=27.209, p<.001) and a two-way interaction between service provider and product embarrassment (F(1,394)=5.066, p=.025). Participants acquiring non-embarrassing products had higher loyalty intentions when there was a human (M=5.04) rather than a robotic service provider (M=3.93; F(1,391)=27.943, p<.001). Yet, the preference for a human service provider was less pronounced when buying embarrassing products (M_{human}=4.65, M_{robot}=4.21; F(1,391)=4.387, p=.037). This indicates that product embarrassment attenuates the negative effect of a robot. As expected, social judgment acts as a mediator in that consumers feel less judged by a robot when acquiring embarrassing products, which again drives their loyalty intentions (M_{robot}=3.81, M_{human}=4.38; F(1,391)=8.684, p=.003, 95%CI: [0.020, 0.206]).

Study 3 (N=795, 376 males) extends the previous study and explores the impact of the level of anthropomorphism of the robot (machine-like, human-like, very human-like). When acquiring non-embarrassing products, participants express higher loyalty intentions when served by a human (M=5.10) than by any robot ($M_{machine-like}$=4.24, $M_{human-like}$=4.37, $M_{veryhuman-like}$=3.93; F(3,787)=10,733, p<.001). Buying embarrassing products attenuates this consistent preference for the human service provider. Particularly, participants are equally likely to be loyal to the pharmacy when served by a human service provider (M_{human}=4.60) or a more anthropomorphic robot ($M_{human-like}$=4.45, p=.490; $M_{veryhuman-like}$=4.37, p=.297). Countering our expectations, lowest loyalty is expressed towards the least anthropomorphic robot ($M_{machine-like}$=4.14; p=.034), although a moderated mediation analysis reveals that consumers feel less socially judged by it (M=3.75; 95%CI: [0.003, 0.130]) compared to a human (M=4.54) when acquiring embarrassing products. Consumers feel also less judged by a human-like robot (M=3.76; 95%CI: [0.003, 0.126]), yet the very human-like robot is perceived as equally judging as the human (M=4.03; 95%CI: [-0.001, 0.093]).

This paper contributes to literature by showing an important boundary condition to earlier work cautioning that consumers are reluctant to accept robotic service providers (Čaić et al. 2019; Mende et al. 2019). Importantly, we find that consumers are more accepting of robotic service providers when acquiring embarrassing products. As expected, social judgment mediates the relationship in that consumers feel less judged by a robot than by a human. Given that consumers feel less judged by a moderately anthropomorphic robot compared to a human, yet express equally high loyalty intentions when acquiring an embarrassing product, a moderately anthropomorphic robot seems a better choice when selling embarrassing products than a machine-like or very human-like robot.

How Robotic Customer Service Impacts Consumers' Evaluation of the Firm

EXTENDED ABSTRACT

Robots are being used to provide customer service online and in stores. However, only 15% of firms that currently use the market-leading Pepper service robot plan to renew their contracts (Whitton 2018). We use real customer-machine interactions to shed light on the challenges facing the use of service robots.

We propose that encountering service robots activates a lay theory that automation is motivated by profit maximization at the expense of the customer experience. Since firms have finite resources, consumers rely on a "zero-sum heuristic" (Chernev 2007), such that investments into service robots may be perceived as coming at the expense of a worse customer experience.

Firms using service robots should therefore be seen as less customer-centric than firms that do not, which should in turn decrease consumers' service satisfaction and willingness to recommend the firm to others.

These effects should be attenuated when the firm's perceived motivation for using the automation is to overcome current shortcomings in customer service.

Study 1: In a field study over four days, we varied whether 109 customers in a café placed their order with a Pepper robot or with a human. After ordering, customers rated their agreement with the statements "I would recommend this coffee bar to a friend or colleague" and "I am satisfied with my service experience today" (α = .92). These firm outcomes were worse in the robot condition (M = 5.34) than in the human condition (M = 5.81, F(1,107) = 4.89, p = .029). The difference remained significant controlling for technology affinity, age, gender, and frequency of visiting the café.

Study 2: 238 Prolific participants engaged in an online chat with a chatbot but were told that they were interacting either with a bot or with a human. This keeps the interaction identical across conditions. were told that we were testing new customer service platforms for a telecommunications company and that they would interact with one of the company's representatives. After the interaction, we measured service satisfaction and recommendation willingness as in Study 1. We also measured perceived customer centricity of the firm (Habel et al. 2019).

The firm seemed less customer-centric when participants believed they were chatting with a bot than with a human ($M_{Chatbot}$ = 4.75, M_{Human} = 5.28; t(236) = 2.66, p = .008), and consumers had lower satisfaction and willingness to recommend the firm ($M_{Chatbot}$ = 4.87, M_{Human} = 5.38; t(236) = 2.47, p = .014). A mediation model with bootstrapped estimates (5000 iterations) confirmed the positive effect of customer centricity on firm outcomes (β = .79, p < .001), switching off the main effect of condition (β = -.09, p = .49), and an indirect effect excluding zero (-.42, 95% CI = -.71, -.11), indicating full mediation.

Study 3: We used a platform called Chatplat, which allows researchers to connect participants to engage with text-based chat with each other. We recruited 1076 participants from Prolific and assigned them to either the "employee" role or the "customer" role. All participants were told we were working with a telecommunications company to test new customer service platforms and were given a script to follow, which involved the customer asking about changing a mobile phone plan and the employee asking for their customer ID and providing the requested information.

Customers were further divided into three conditions. In the *human* condition, they were told they would chat with a customer service employee from the company. In the *chatbot* condition, they were told they would chat with a chatbot. In the *customer-centric chatbot* condition, they were told that they would chat with a chatbot and that the company's goal in using chatbots was to "reduce wait times and improve service for customers." This condition also stated that since introducing the chatbot, "the average wait time for customer to connect with an agent has decreased from over 5 minutes to less than 10 seconds."

In reality, the "employee" with whom the "customers" chatted was always another Prolific participant. Our interest was in com-

paring participants' experience across the three customer conditions. After the interaction, participants again reported service satisfaction and recommendation likelihood.

We first cleaned the data by conducting several exclusions. We excluded the 541 participants in the "employee" role given our interest in the "customers'" experiences. We excluded 141 participants who reported having technical difficulties during the chat; these were inevitable since participants matched with each other in real time to conduct the chat and thus some participants had to wait too long for their chat partner and could not complete the chat in a timely manner. Finally, we excluded 72 participants who did not correctly remember whether they had chatted with a human employee or a chatbot and 111 participants who did not believe that they had chatted with a human or chatbot despite what they had been told. Final sample sizes per condition were 55 in the human condition, 86 in the regular chatbot condition, and 83 in the customer-centric chatbot condition.

Firm outcomes were best in the human condition ($M = 8.47$), worse in the regular chatbot condition ($M = 6.99$, $t(139) = 3.96$, $p < .001$), and also worse in the customer-centric chatbot condition but to a lesser degree ($M = 7.56$, $t(135) = 2.41$, $p = .016$). The difference between the two chatbot conditions was marginally significant ($t(167) = 1.75$, $p = .087$).

Taken together, these results show that firms using service robots to automate customer service are perceived as less customer-centric and that consumers are less satisfied with and less likely to recommend such firms to others, relative to firms using humans. Furthermore, we show that firms can reduce these negative consequences by highlighting a customer-centric motivation for using robots. Additional completed studies show that using service robots for less customer-centric tasks (i.e., food delivery vs. waiter) can also reduce these effects.

Our findings help explain why initial rollouts of service robots have been lackluster and have clear implications for how firms can improve outcomes while continuing to pursue the use of this technology.

Inner Values Also Count: Algorithm Types Drive Consumer Adoption of Robotic Technologies

EXTENDED ABSTRACT

Algorithms are implemented in all robotic technologies. These technologies take care of our elderly (Bemelmans et al. 2012), serve us food (Mende et al. 2019), and undertake domestic work (Rijsdijk and Hultink 2009). One major obstacle to accept robotic technologies (e.g., as co-workers or employees) is lacking transparency and informedness about their true technological underpinnings (Moreau, Lehmann, and Markman 2001; Rai 2020), since their "inner values" oftentimes remain opaque for consumers. Therefore, firms increasingly start to communicate details about algorithms of technologies to their consumers (e.g., the app FitnessAI or Samsung's smart fridge; FitnessAI 2019; Samsung 2018). However, no research so far has addressed the question of how this information can influence consumer behavior.

This research examines whether and how information about the details of implemented algorithms can shape consumers' technology adoption. It therewith complements former research that presumably takes a materialistic perspective focusing either on the outer appearance (Kim, Schmitt, and Thalmann 2019; Mende et al. 2019), or the observable output or attributes of a technology (Mukherjee and Hoyer 2001). It further extends research on algorithm acceptance that mainly measured lay perceptions of algorithms and AI as generic concepts (Castelo, Bos, and Lehmann 2019; Longoni, Bonezzi, and

Morewedge 2019) while highlighting additional barriers to consumer adoption of autonomous technologies (de Bellis and Johar 2020).

Based on computer science literature we distinguish two fundamentally different types of algorithms: adaptive (whose parameters can be changed by using external data) and pre-programmed (whose parameters are fixed in-advance by a programmer). We predict that adaptive (vs. pre-programmed) algorithms increase the intention to use a technology (usage intention) because they are perceived as more creative (H1A, H1B). We further predict that this effect reverses when the tasks of a technology require only a low degree of creativity and specific outcomes are valued (H2). In such cases, a pre-programmed algorithm increases usage intention, because it is perceived as more predictable (H2-H3).

The pilot study applied a Turing test paradigm (Turing 1950/2009) to test whether algorithm type influences consumer perceptions independently from a technology's output. According to the Turing test, a machine is considered intelligent if its communication behavior is indistinguishable from human behavior. In our version, we let participants (US-MTurkers, $N=192$, $M_{age}=34.14$, 46% female) chat with an advanced chat bot. Though all participants chatted with the same bot (thus holding output constant), we experimentally manipulated information about the bot's implemented algorithm (pre-programmed vs. adaptive). We found that participants rated the bot as more intelligent ($M_{adaptive}=4.10$, $M_{pre-programmed}=3.49$, $F(1, 190)=5.25$, $p=.04$) and more human-like ($M_{adaptive}=3.73$, $M_{pre-programmed}=2.80$, $F(1, 190)=16.34$, $p<.001$) if they were told it used an adaptive (vs. pre-programmed) algorithm. This indicates that not only the output but also the implemented algorithm matters for consumers.

Study 1 formally tests how algorithm type shapes consumers' perception of and intention to use a technology (H1-H2). In a lab study conducted at a large Northeastern university, participants ($N=207$, $M_{age}=24.55$, 57% female) were informed about the algorithm implemented in a voice assistant (adaptive vs. pre-programmed, 2-cell between subjects), before indicating their intention to use it. A one-way ANOVA revealed that usage intention was significantly increased if participants were informed that the voice assistant applies an adaptive (vs. pre-programmed) algorithm ($M_{adaptive}=4.70$, $M_{pre-programmed}=4.05$, $F(1, 205)=6.50$, $p=.01$). This effect is mediated by perceived creativity of the algorithm ($b=.61$, 95%CI=[.34; .94]). Note that we did not find a mediation via predictability ($b=-.02$, 95%CI=[-.20; .14]) because a voice assistant is considered a creative technology.

Study 2 tests whether task creativity (i.e., the creativity required by the tasks of a technology) moderates the effect of algorithm type on usage intention (H1-H3). We conducted an online study with US-MTurkers ($N=395$, $M_{age}=35.71$, 48% female) and employed a 2×2 between-subjects design. Participants were informed about the algorithm implemented in a cooking app (adaptive vs. pre-programmed), before indicating their intention to use it. We additionally manipulated the task for which the app should be used (high creativity: baking a completely novel cake vs. low creativity: baking a cake exactly by recipe). A two-way ANOVA revealed a significant interaction between both factors ($F(1, 391)=14.61$, $p<.001$). Follow-up contrasts confirmed that usage intention is significantly higher for the adaptive (pre-programmed) algorithm when task creativity is high (low). Parallel moderated mediation analysis supported H2 and H3: The mediation via perceived algorithm creativity on usage intention is significantly higher when task creativity is high (index of moderated mediation: $b=.40$, 95%CI=[.17; .67]), while a mediation via perceived predictability is significant only when task creativity is low (index of moderated mediation: $b=.59$, 95%CI=[.30; .93]).

Studies 3A and 3B generalize the findings to a broader range of products (H1-H3). In study 3A, we let US-MTurkers (*N*=181, M_{age}=35.46, 52% female) evaluate either task creativity or predictability of 54 robotic products. A separate MTurk sample (*N*=131, M_{age}=34.32, 48% female) received information about both algorithm types and indicated in a binary choice which they preferred for each of the 54 products. Analyses revealed a positive correlation between products' task creativity and the ratio of participants voting for an adaptive algorithm in the binary choice (*r*=.83, *p*<.001). Predictability ratings correlate much less with the ratio of adaptive choices (*r*=.23, *p*=.084). Corroborating these findings, we calculated the sentiment of over 11,000 Twitter posts that discussed the 54 products in the context of AI (with AI being colloquially used for adaptive algorithms; Arel, Rose, and Karnowski 2010). Sentiment positively correlated with products' creativity ratings (*r*=.29, *p*=.09), suggesting that consumers perceive AI in creative products more positively.

In sum, we find that also the inner values of technologies influence consumers' technology adoption. Interestingly, our findings imply that consumers assign a degree of creativity to technologies if they are appropriately informed about their capabilities (i.e., their adaptivity). This contradicts typical lay assumptions that creativity is a human-like trait which algorithms are incapable of due to their mechanical and analytical thinking (Huang and Rust 2018). Our findings imply that, aside from increasing the human-like appearance of technologies, informing about their inner values can boost their adoption.

SESSION OVERVIEW

Technological advancements and new societal trends have affected the way in which consumers engage with companies and with each other, as well as who consumers turn to when seeking information about products and services. These changes have posed new challenges for marketers who need to adapt to novel means of reaching, engaging, and ultimately persuading consumers—oftentimes foregoing direct communication in favor of enlisting social media influencers or leveraging online WOM communication. This special session addresses important theoretical and substantive questions surrounding the effectiveness of modern influencers and persuasion agents. In particular, this session addresses *how* the effectiveness of a persuasion agent is conditional on the language used (paper 1) and the use of expertise cues (paper 2), *who* the most effective agents of persuasion are (paper 3), and *what* happens if these agents fail to be persuasive (paper 4).

Rizvi, **Moore**, and **Messinger** study the persuasive effectiveness of using slang in digitally-mediated WOM exchanges. Across four studies, they find the use of mainstream slang (but not subcultural or unknown slang) improves a persuasion agent's effectiveness. In particular, relative to non-slang equivalents (e.g., great), the cultural value carried by slang terms (e.g., lit) elicits more favorable consumer responses in terms of how they evaluate WOM messages and the products promoted in these messages.

D'Angelo and **Valsesia** identify a novel cue persuasion agents can use to increase their perceptions of expertise and ultimately their persuasiveness. Across four studies, they find individuals who use combinatory mentions (talk of how products go well together) are perceived as domain experts. For this reason, consumers form a more positive attitude toward the products endorsed by these individuals.

Watson, **Grewal**, and **Segal** investigate why social media influencers are effective and compare the effectiveness of influencer- vs. brand-communicated messages. Across three studies, they identify the entertainment-value of influencers to be of utmost importance to consumers. Moreover, they find the effectiveness of influencer-communicated (vs. brand-) messages is reduced when the persuasive intent of the message is made salient and consumers' persuasion knowledge is activated.

Finally, **Hall**, **Hyodo**, and **Kristofferson** explore the consequences of persuasion agents' failed persuasion attempts. Across five studies, they demonstrate that recommenders reduce future choice away from their recommended product if their advice is not followed (unfulfilled recommendation). This switching occurs when persuasion agents make a recommendation with less-than-full confidence, leading them to use others' choices to make inferences about the product they recommended.

All papers are at an advanced stage of completion with multiple studies completed. Taken together, they shed light on the effectiveness of persuasion agents and on novel tactics that leverage the changing landscape in communication and technology. We expect this session to be of interest to researchers studying persuasion and social influence, as well as those interested in the impact of new technology on consumer behavior.

Slanguage & Cultural Value: It's Lit to Say It - How Mainstream Slang Affect Online WOM

EXTENDED ABSTRACT

In digitally-mediated exchanges, language is the sole basis of communication (Danet & Herring, 2007). Accordingly, prior research has studied how consumers are influenced by nuances in word choice in online word-of-mouth (WOM; e.g., Moore 2015). Despite their ubiquity (Zazulak 2016), slang terms have received little attention in this context. Yet up to 25% of tweets contain slang (Kundi, Ahmad, Khan, and Asghar 2014), and slang is common on other social media platforms (Facebook, Instagram) and online settings (Yelp), where consumers engage in WOM by recommending, evaluating, and discussing products and brands: "This got an #epic feel to it. #lit #EminemKamikaze"; "These new Jordans are lit af!"

Slang is an informal type of speech that is ephemeral and dynamic (Gleason 1961), and it can infuse all parts of speech with rich connotations: nouns (beast), adjectives (on fleek), verbs (trending), acronyms (yolo), and abbreviations (bae; Ayto and Simpson 2010). While most extant research examines group dynamics related to slang use (Eble 2012), we focus on broadly popular slang terms that are not restricted to specific groups. Specifically, we explore slang terms that emerge, gain mainstream popularity, and are used over the internet (Kundi et al. 2014). We propose that using mainstream slang improves the effectiveness of online WOM.

Specifically, we argue that slang terms have a unique ability to influence consumers through the cultural value imbued in them. We introduce the *cultural value* model to explain how slang affects consumers. Building on McCracken's (1986) model of meaning transfer, we theorize that slang terms are specialized words that users have encoded with value and meaning. Thus, internet users' collective (and tacit) agreement to regard certain informal words as valuable results in the social construction of culturally valuable verbal artifacts, in the form of slang terms. These slang words are similar to other cultural artifacts which hold special value in the marketplace, due to broad

agreement about their status (e.g., fashion, brands; Bikhchandani, Hirshleifer, and Welch 1992; Tsai 2005). Because of this cultural value, we predict that, relative to equivalent non-slang terms, slang terms used in online WOM will elicit more favorable responses from consumers in terms of how they evaluate the WOM message and the product. Furthermore, we expect that these effects will be mediated by perceived cultural value. Below, we report four experiments that test these hypotheses.

Study 1 examined the basic effect of slang on consumers. We recruited 158 North American undergraduates to participate in a single factor, 2-level (Slang: present vs. control) between-subjects design. The study introduced participants to a fictional brand of sneakers. They then read an online review which described the sneakers using either a slang word (fire) or a control word (trendy). Next, participants rated the review (was it well written, clearly understood), and the product (willingness to buy, product performance).One-way ANOVAs revealed significant effects of slang versus control for the review (M_{fire} = 5.58, M_{trendy} = 4.87; p = .02) and the product (M_{fire} = 5.72, M_{trendy} = 4.99; p = .006), providing preliminary evidence for the proposed effect.

Study 2 (N = 125 undergraduates) replicated and extended study 1 by examining various slang words that we hypothesized would vary in cultural value. We tested five words in descending order of cultural value: a currently popular slang term (lit), an equivalent non-slang adjective (great), a generic older slang term (cool), an emerging unknown slang term (blinding), and a made-up slang term (antipel). The procedure and measures were similar to study 1. The results revealed that the popular slang term outperformed the other conditions in review (M_{lit} = 5.04, M_{great} = 4.32, M_{cool} = 3.97, $M_{blinding}$ = 3.30, $M_{antipel}$ = 3.04; p < .001) and product evaluations (M_{lit} = 4.12, M_{great} = 3.80, M_{cool} = 3.60, $M_{blinding}$ = 3.92, $M_{antipel}$ = 3.60; p = .037).

Prior work has established that slang terms often originate in groups, and are intimately linked with group language (Eble 2012). We argue that slang can transcend its group status and attain mainstream appeal in the form of cultural value. However, since the identity of the review writer was not specified in previous studies, our effects may have been due to inferences of shared group membership (i.e., similarity) between the reader and the writer (Naylor, Lamberton, and Norton 2011). To address this issue, we manipulated sender identity in study 3 (N = 243 undergraduates), using a 2 (Slang: current [lit] vs. unknown [blinding]) x 2 (Sender: in-group vs. out-group) between-subjects design. Participants read a product review about a sweater and then completed measures similar to those in previous studies. The results revealed only a positive main effect of slang (M_{lit} = 3.78, $M_{blinding}$ = 3.18; p < .001). The main effect of sender identity and the interaction were insignificant, ruling out group membership as an alternative explanation.

Study 4 (N = 80 undergraduates) examined the proposed underlying process by measuring perceived cultural value. The study compared popular slang with outdated slang (i.e., previously cherished words that are no longer afforded cultural value). It was a single factor, 2-level (Slang: popular [dope] vs. outdated [gnarly]) between-subjects design, and used similar procedures and measures as before. Additionally, prior to measuring evaluations, we measured cultural value (2 items, e.g., "Would you consider the choice of words as culturally valued [cool]?"). The results showed that popular slang performed better than outdated slang (M_{dope} = 3.84, M_{gnarly} = 2.97; p < .001) and that cultural value mediated this effect ($CI_{95\%}$: -0.65, -0.03).

This research contributes to the literatures on slang and WOM. It extends our understanding of how mainstream slang affects consumers' product perceptions via cultural value; this renders slang a more effective communication tool than common vernacular. Fur-

thermore, this research speaks to theories of group membership and slang by demonstrating that mainstream slang functions differently from group/subcultural slang. Mainstream slang terms do not rely on shared group identity; rather, they benefit from their culturally-valued, popular appeal. Practically, this work suggests that employing culturally valued slang can enhance message effectiveness, a finding applicable to both consumers and firms.

You Should Try It With This: Recommending Compatible Items Increases Perceptions of Expertise and Persuasiveness

EXTENDED ABSTRACT

Decades of research on social influence suggest that some individuals can disproportionally sway the preferences and actions of others (Katz and Lazarsfeld 1955; Merton 1968). Generally, individuals who are perceived as experts tend to be more influential, as consumers are more likely to be persuaded by experts' recommendations (Alba and Hutchinson 1987; Gershoff, Broniarczyk, and West 2001).

In recent years, retailers, particularly those based online, have made significant investments in hiring individuals (e.g., stylists, designers, nutritionists) to consult consumers in what to purchase across a breadth of product domains (Bobb 2019; Gorin 2018; Howland 2018). To what extent do consumers perceive these individuals as experts? Perceived expertise can depend on many factors, including the individual's appearance and choices (Bellezza, Gino, and Keinan 2014; Sela et al. 2019). We suggest another signal of expertise is through the offering of opinions about compatibility among products (*combinatory mentions*).

Why might combinatory mentions signal expertise? Typically, complementary products are paired together *by the company* (Tellis 1986; Karataş and Gürhan-Canli 2020), alluding to the notion that lay consumers may lack knowledge of which products are compatible. Indeed, consumers often experience difficulty assessing the outcome of products that are combined or used together (Petre, Sharp, and Johnson 2006). A more nuanced understanding of product attributes and how they are related develops as expertise in a domain grows (Alba and Hutchinson 1987). Hence, if an individual not only understands the attributes of individual products, but also whether these attributes are compatible, consumers might view this individual as having expertise in the product domain. In sum, we suggest that an individual's mere mention of two or more products as compatible (i.e., go well together) can bolster perceptions that the individual is an expert within a product domain, subsequently increasing consumers' attitudes toward the products recommended by that individual. Four studies test our predictions, address an alternative explanation, and provide external validity for our findings.

Study 1 tests whether *combinatory mentions* improve attitudes toward recommended products. Undergraduate participants (N=257) were randomly assigned to one of two combinatory mention conditions (explicit vs. non-explicit). Participants received a subscription box modeled after the real company SpiceBar. A note from SpiceBar's chef detailed the contents of the box: one focal "spice of the month" and three other spices. The chef recommended the same spices across conditions, but in the high (vs. low) condition, the chef highlighted the compatibility among the spices. Participants then rated 1) their attitude toward the focal spice and 2) their collective attitude toward the other three spices (1=not at all positive; 9=very positive).

The focal spice was rated more positively in the explicit (vs. non-explicit) condition ($M_{explicit}$=6.47 vs. $M_{non-explicit}$=5.66; $F_{(1, 255)}$=15.21, p<.001), as were the other three spices ($M_{explicit}$=6.02

vs. $M_{non-explicit}$=5.23; F(1, 255)=13.27, p<.001). Participants then entered to actually win a subscription to either SpiceBar or another box. More participants in the explicit (vs. non-explicit) condition entered to win the SpiceBar subscription (42% vs. 29%; Wald χ2=4.67, p<.04).

Study 2 tests whether consumers' improved attitudes are driven by increased perceptions of expertise. MTurk participants (N=266) imagined shopping at a furniture store and overhearing an individual (i.e., the recommender) discuss dining chairs with a friend. In the *combinatory* [substitutable] condition, the recommender said the Logan chairs would *go really well mixed in with* [be a really good alternative to] the Bacci chairs. Participants then rated their attitude toward the Bacci chair (1=not at all positive; 9=very positive) and perceived interior design expertise of the recommender (1=not at all, 9=very much).

In the combinatory (vs. substitutable) condition, the Bacci chair was rated more positively ($M_{combinatory}$=6.90 vs. $M_{substitutable}$=6.42; $F(1, 264)$=5.36, p<.03) and the recommender was perceived as having greater expertise ($M_{combinatory}$=7.06 vs. $M_{substitutable}$=6.68; $F(1, 264)$=3.58, p=.06). Mediation analysis revealed the effect of the recommenders' mention on attitudes was driven by perceived expertise ($b_{indirect}$=.18, SE=.10, CI$_{95\%}$: .0058, .3947).

An alternative explanation for our findings may be that mentioning products are compatible implies versatility (i.e., the product could have many uses). Study 3 addresses this alternative explanation. If consumers' attitudes are driven by versatility, a recommender who established expertise by providing a combinatory mention should *not* improve consumers' attitudes toward *other* subsequently recommended products where compatibility is not mentioned. MTurk participants (N=500) read three Instagram posts from a food influencer. In each post, the influencer in the *combinatory* [control] combinatory mention condition recommended a food item *and mentioned* [but did not mention] a compatible food item. Participants rated the influencer's food expertise (1=not at all, 9=very much). Next, all participants viewed the influencer's fourth post which recommended a food product with no mention of a combatable item. Participants then rated their attitude toward this product (1=not at all positive; 9=very positive).

In the combinatory (vs. control) condition, the influencer was perceived as more expert ($M_{combinatory}$=7.26 vs. $M_{control}$=6.01; $F(1, 498)$=65.15, p<.001); the food product was also rated more positively ($M_{combinatory}$=6.37 vs. $M_{control}$=5.96; $F(1, 498)$=7.42, p<.007). Importantly, the effect of combinatory mention on attitudes toward the food product was driven by perceived expertise of the influencer ($b_{indirect}$=.73, SE=.10, CI$_{95\%}$[.5399, .9383]).

Study 4 provides external validity for our findings using a Facebook split-ad field study. We ran advertisements for a skincare website where website users provide skincare advice. In the explicit combinatory mention ad, the ad quoted and depicted a skincare advice giver's recommendation for which products go well together in a skincare routine. In the non-explicit condition, the ad quoted and depicted the same product recommendations from a skincare advice giver without explicitly stating that the products went well together. A logistic regression predicting click-through rate revealed that the explicit combinatory ad lead to significantly more clicks (1.52%) than the non-explicit ad (CTR=1.26%; Wald χ²=9.92, p<.002). Among those who clicked on the ad to visit the skincare website, membership sign-up rates were greater among those who arrived via the explicit combinatory ad (7.12%) relative to the non-explicit ad (4.51%; Wald χ2=3.24, p=.07).

Influencer Effectiveness: Contexts and Boundaries

EXTENDED ABSTRACT

With the proliferation of social media, influencers are more important than ever. Brands now spend over one billion dollars annually on influencer marketing, where micro-influencers are thought to be 6.7 times more cost efficient in generating engagement relative to their celebrity counterparts (Pierucci 2018). While brands have traditionally employed a broadcasting strategy (e.g., national commercials or print ads), they can now employ easily employ a narrowcasting strategy by selecting specific influencers to reach more homogenous populations. This begs the following questions: "why do consumers listen to social media influencers?" and "when should brands outsource their messaging vs. sending the message directly to consumers?"

While the effectiveness of celebrity endorsers has been widely researched (for a review, see: Erdogan 1999), this literature can't fully explain the effectiveness of social media influencers today. In addition to credibility and liking (Friedman and Friedman 1979), we posit that the desire for a parasocial relationship (Rubin and McHugh 1987) plays a role with consumers today. Whereas influencers may have traditionally existed through standard advertisements, consumers now seek out and "follow" influencers, whose marketing may seem more like an authentic message between friends than an advertisement. Thus, a consumer's persuasion knowledge (Friestad and Wright 1994) might not be activated in the same fashion that it is with traditional advertisements. Promoting too many brands can decrease an influencer's effectiveness (Mowen and Brown 1981; Tripp, Jensen, and Carlson 1994), but there are likely to be many other ways by which influencer effectiveness is moderated.

In this research, our goal is first to understand the attributes that characterize effective influencers. Then, we aim to determine the boundaries of said influencer effectiveness. In doing so, we aim to contribute to both theory and practice regarding this emerging marketing trend. In study 1, we survey participants to identify the manifest attributes of effective influencers, in general. Study 2 then asks participants to identify an influencer they follow and evaluate the influencer on the same attributes. Finally, in study 3, we investigate the relative effectiveness of a marketing message when it comes from the brand vs. an influencer to determine the relative value of employing an influencer. Due to space constraints, we will only highlight select findings.

Study 1 asked participants "what characteristics of influencers are important to you" then featured a battery of 14 items on a 5-point scale. A factor analysis yielded a 3-factor solution with the measures of *message value* (8 items; α = .907; e.g., "inspiring" or "helpful"), *entertainment value* (2 items; r = .622; i.e., "entertaining" and "funny"), and *physical value* (4 items; α = .741; e.g., "attractive" or "similar"). Relative to physical value (M = 2.45), paired t-tests indicated that consumers placed more importance on message value (M = 3.49; t(106) = 11.453; p < .001) and entertainment value (M = 3.59; t(106) = 10.602; p < .001). There was no difference in the perceived importance of message value and entertainment value (t(106) = -.944; p = .347).

Study 2 followed the same paradigm as study 1 with a few exceptions. We used fewer items (six) and elicited responses on a 7-point scale. And importantly, in this study, we first asked participants to indicate an influencer that they currently follow on Instagram, and thus, asked them to what extent each attribute described their influencer rather than the importance of that attribute. In doing so, we wanted to assess whether the responses in study 1 were reflective of perceptions of influencers that consumers already follow.

Paired samples t-test indicated that this was not the case. Relative to physical value (M = 5.04), paired t-tests indicated that consumers placed less importance on message value (M = 4.12; t(79) = -3.386; p = .001), while there was no difference with entertainment value (M = 5.25; t(79) = .946; p = .347). Naturally, entertainment value was also more descriptive of their recalled influencer relative to message value (t(79) = -5.163; p < .001). Taken together, these studies suggest that entertainment value seems to be of utmost importance while consumers might oversell the importance of message value and undersell the importance of physical value.

Having established why consumers might follow influencers. We now seek to understand the context-dependent value of influencers relative to brands. Study 3 adopts a 2x2 design in which frame the social media post as coming from the brand or an influencer, and whether a promotion code is absent or present. Our theorizing would suggest that consumers generally prefer marketing messages from influencers vs. brands due to the activated persuasion knowledge in the presence of a brand's marketing attempt, but the presence of a promotion code leads consumers to identify the influencer's message as a marketing message, activating persuasion knowledge, and lowering their effectiveness. After viewing the post, we measured Blue Apron purchase intentions (3 items; α = .867). A 2x2 ANOVA on purchase intentions yielded a significant interaction (F(1,403) = 10.757; p = .039). Neither main effect was significant (p's > .10). Planned contrasts demonstrate that in the absence of a promotion, whether the brand or an influencer posts the content does not significant impact intentions (M_{brand} = 4.09; $M_{influencer}$ = 4.30; F(1,403) = .869; p > .35). However, the presence of a promotion led to a significant decline for influencers (M_{brand} = 4.32; $M_{influencer}$ = 3.88; F(1,403) = 4.025; p = .045), suggesting the promotion made salient an ulterior motive and undermined the influencer's credibility.

Taken together, these studies begin to address the questions of "why do we follow influencers" and "what are the boundaries of their influence?" In subsequent studies, we plan to investigate the discrepancies between studies 1 and 2 by further exploring the role of an existing parasocial relationship with an influencer and creating a taxonomy of message characteristics (e.g., promo codes, behind-the-scenes content, etc.) that are better suited to come from the brand or the influencer.

You Didn't Take My (Uncertain) Advice? Examining the Effects of Confidence and Recommendation Outcomes on Recommender Preferences

EXTENDED ABSTRACT

Although limited, research considering how providing word-of-mouth influences the *sharer* often assumes that, i) those who recommend do so with initially-high confidence, ii) others will (and do) take the recommender's advice, and iii) recommending entrenches product-related attitudes. However, by incorporating the bidirectional nature of the recommendation environment, we challenge these assumptions and demonstrate that consumers who recommend a product can and do *reduce* future preference for that product when their recommendation is not followed (unfulfilled recommendation).

Research shows that confidence indeed predicts WOM engagement (Brown 2005). However, because recommendations are frequently solicited and provided in social settings, consumers often recommend with less-than-full confidence to fulfill perceived social obligations (Lui and Gal 2011) or avoid appearing unknowledgeable (Berger 2014). Confirming this assumption, a pilot study revealed that 77.9% of participants (n=103) had made a recommendation when they were unsure whether the other consumer would like their recommended product.

Given recommendations are being provided with less-than-full confidence, low-confidence recommenders may be prone to preference- or choice-influence based on recommendation feedback. The rise of social media as a recommendation platform, along with increased sharing of consumption choices, increases the likelihood recommenders will discover whether their recommendations are fulfilled/unfulfilled (Duan and Dholokia 2017). We propose those recommending with less-than-full confidence, despite publicly committing to the recommended product, will shift future product choice *away* from their recommended option when their recommendation is not fulfilled. We propose this will occur because low-confidence consumers perceive others' divergent choices as indicative of differing objective quality (Spiller and Belogolova 2013), thus inferring the unpurchased (recommended) product is of lower quality. Thus, we predict the interaction between recommendation fulfillment and confidence will be mediated by perceived product quality.

In Study 1a, undergraduates (n=91) tested three pens and selected their favorite. Next, they individually interacted with a trained confederate who had information about the pens but did not test them. During the scripted interaction, the confederate solicited a recommendation on which pen to select, and the participant provided his/her recommendation. After the recommendation, the confederate indicated she planned to select the recommended pen (fulfilled) or an alternative (unfulfilled). Participants returned to the lab and selected a pen to keep. Participants were more likely to shift preference when their recommendation was unfulfilled (36.5%), relative to fulfilled (5.9%; χ^2_{Wald}=9.88, p=.002).

In Study 1b, participants (n=301) read a scenario about recommending a bottle of wine to a wine-savvy friend, who either did or did not fulfill the recommendation. We also included a control condition in which participants did not learn the recommendation outcome. Again, those whose recommendations were unfulfilled reported lower intentions to repurchase the recommended wine (M=4.93; 7-point scale), relative to those in the fulfilled (M=5.57; F(1,286)=13.47, p<.001) and control (M=5.46;F(1,286)=9.26, p=.003) conditions.

In Study 2a, participants (n=326) completed a 2(fulfilled/unfulfilled recommendation) x 2(high/low confidence) study in which they read about recommending a bottle of wine to a friend. Confidence was manipulated via recommendee wine knowledge (Constant et al. 1994). A 2x2 ANOVA with product intentions as the dependent variable revealed the predicted interaction (F(1,322)=3.94, p=.048). Unfulfilled recommendations negatively affected future purchase intentions when confidence was low ($M_{Fulfilled}$=5.78, $M_{Unfulfilled}$=5.08;F(1,322)=8.23, p=.004), but not high ($M_{Fulfilled}$=5.40, $M_{Unfulfilled}$=5.39;F(1,322)=.005, p=.942). Perceived product quality mediated the interaction (CI_{95}:[.089,.680]).

Study 2b tested the moderating role of the presence of third parties' divergent/convergent recommendations. We propose recommendation confidence will be *enhanced* when supporting recommendations from others are present, thus attenuating our effect. Undergraduates (n=127) were assigned to one of three conditions (recommendation context: alone/converging/diverging) in which they recommended a restaurant to a friend on Facebook (stimuli presented as mock Facebook *Recommendation* posts). In the alone condition, the participant provided the only recommendation. In the diverging condition, another friend also responded, but recommended a different restaurant. In the supporting condition, one friend recommended the same restaurant as the participant, while two others recommended an alternative. All participant recommendations were unfulfilled. An ANOVA revealed a significant effect of recom-

mendation context on product intentions ($F(1,124)=3.71$, $p=.027$). Consistent with our framework, unfulfilled recommendations reduced future support of participants' recommended product in the lone/divergent conditions ($M=5.23$) compared to when a convergent recommendation was present ($M=5.65$; $F(1,124)=6.23$, $p=.014$). No differences emerged between the lone and divergent conditions ($M_{Lone}=5.13$, $M_{Divergent}=5.33$, $p=.275$). Importantly, the focal contrast was again mediated by perceived product quality ($CI_{95}=[.049,.446]$).

Others' choices are seen as more diagnostic when product quality is perceived to be objective (vertical differentiation; Spiller and Belogolova 2016). Alternatively, when products are differentiated on more taste-based dimensions (horizontal differentiation), divergent choices can be attributed to idiosyncratic preferences. Thus, we predict our focal effect will be attenuated when the product is perceived as horizontally (vs. vertically) differentiated. Study 3 employed the same design as Study 1a (confederate interaction) with one difference—manipulation of differentiation prior to participants' initial choice. The vertical condition stated the pens were made with materials of varying quality, resulting in some pens being objectively better than others—participants were asked to select the *best* pen. The horizontal condition stated the pens were made with materials of similar quality, meaning observed differences resulted from differing preferences—they were asked to select their *preferred* pen (Spiller and Belogolova 2013). Undergraduates (n=163) tested the pens and recommended their choice to a confederate, who then did/did not fulfill the recommendation. We planned to conduct a logistic regression, but low switching rates in three conditions rendered this inappropriate (Cox 1970). As such, to directly test our predictions, we used simple contrasts to compare mean switching rates in the vertical/unfulfilled condition versus the three other cells (Buckless and Ravenscroft 1990). As expected, those in the unfulfilled/vertical condition changed their choice *away* from their recommended option more often (10 of 40; $M=25.00\%$) than participants in the other three conditions (6 of 123; $M=4.88\%$; $F(1,161)=14.89$, $p<.001$). All simple effect comparisons were also significant.

By integrating the bidirectional nature of solicited recommendations and focusing on the consumption consequences of WOM sharers, this research challenges prior assumptions of WOM research to demonstrate possible deleterious effects of recommendation outcomes on subsequent recommender choice. We further demonstrate the crucial role that confidence and product differentiation play in this understudied aspect of WOM behavior.

SESSION OVERVIEW

Millions of consumers are struggling financially. According to the Consumer Financial Protection Bureau, 43% of Americans are unable to make ends meet (2017), and nearly 40% cannot cover an unexpected $400 expense (Federal Reserve Board, 2018). Thus, it is of great theoretical and societal importance to understand how consumers make financial decisions. In this session, we take a holistic approach and focus on understanding unique and underexplored factors that impact how consumers use the resources they already have (e.g., spending and saving) and factors that impact how consumers acquire more financial resources (e.g., intertemporal choices and debt collection).

The first two papers focus on factors that impact how consumers use financial resources that they already have: payment frequency and saving frames. In the first paper, De La Rosa and Tully examine the impact of payment frequency on consumers' spending decisions. The authors demonstrate that higher payment frequency increases consumers' perceptions of wealth, which in turn increases their discretionary spending. In the second paper, Shu et al. demonstrate how differing savings frames (save a penny of every dollar of salary vs. save 1% of your salary) impact consumers' perceptions of the affordability of saving. Through a series of experiments, the authors show that pennies framing increases savings rates by making saving seem more affordable.

The last two papers focus on factors that impact how consumers obtain financial resources: budget periods and social ties. In the third paper, Urminsky and Jang demonstrate that consumers' perceptions of their budgeting periods significantly impacts their intertemporal decisions. Consumers choose the smaller, sooner option less often (e.g., become more patient) when the larger, later option is still within (vs. outside of) their perceived budgeting period, which explains

present bias. Finally, in the fourth paper, Park, Cryder, and Gershon demonstrate the impact of relationship closeness on how consumers decide to request debt repayment. Across a series of studies, the authors show that consumers' are more likely to request the payment in person (vs. using a bank enabled app like Venmo) when they perceive the borrower to be a close friend.

Together, these papers enhance our understanding of how consumers decide to use and obtain financial resources. This topical and novel session sheds light on how unique interventions can help impact consumers' financial well-being.

The Impact of Payment Frequency on Subjective Wealth Perceptions and Discretionary Spending

EXTENDED ABSTRACT

An increasingly popular trend is for consumers to get paid more often, resulting in more frequent, yet smaller paychecks. For example, beyond day laborers and tipped employees, Uber drivers, and even Wal-Mart cashiers can now get paid on a daily basis. However, surprisingly little is known about whether and how payment frequency impacts consumer behavior. Higher payment frequency has been shown to help consumers spread out their consumption throughout a period (e.g., Parsons and Van Wesep 2013; Stephens and Unayama 2011). However, in the current work, we explore other potential consequences of payment frequency: consumers' wealth perceptions and their discretionary spending.

If consumers focused only on the smaller number on their paycheck, it could lead consumers to have lower wealth perceptions (Morewedge, Holtzman, and Epley 2007). However, we suggest that payment frequency is more likely to be experienced as a series of segregated gains. Past research demonstrates that smaller, more frequent segregated gains lead to higher hedonic assessments than a larger, less frequent, aggregated gain because hedonic assessments exhibit diminishing marginal returns (Thaler, 1985). We build on this work and posit that subjective wealth perceptions, like but distinct from hedonic assessments, also exhibit diminishing marginal returns. Thus, more frequent (albeit smaller) paychecks should increase consumers' wealth perceptions. In short, consumers' wealth perceptions are formed not just from consumers' objective wealth (or their objective wealth relative to a benchmark), but also from the timing of their payments. Moreover, we suggest that these increased wealth perceptions also increase consumers' willingness to spend on discretionary purchases.

In Study 1, we analyze the real-world spending behaviors of 27,000 consumers who were customers of a large US banking platform. This data included consumers' income and spending for each day. Using a linear mixed-effects model, our analysis revealed a positive and significant relationship between payment frequency and discretionary spending. Thus, higher payment frequency was associated with more discretionary expenditures ($\beta = 1.35$, $p < .001$), even after controlling for consumers' income (log-transformed).

In Study 2 (N = 405), we created a life simulation where participants earned income, incurred expenses (e.g., rent, utilities, phone bill), and made discretionary spending decisions (e.g., whether to eat out, whether to go to a concert, etc.) to examine the causal impact of payment frequency. We manipulated participants' payment frequency while holding constant the total amount earned. Participants

paid daily (vs. weekly) made more high-cost expenditures (Mdaily=9.47 vs. Mweekly= 8.48, *p*<.001) than those in the weekly condition. Moreover, those in the daily pay condition reported had higher wealth perceptions than those in the weekly pay condition (Mdaily=2.86 vs. Mweekly= 2.24, *p*<.001). These wealth perceptions mediated changes in spending decisions (*ab*=0.27, 95% CI[0.12, 0.46]).

Study 3 was designed to disentangle differences in objective wealth from subjective wealth perceptions. In Study 2, daily pay led to a higher average daily balance than the weekly condition. Hence, in Study 3, we designed the life simulation such that participants in the bi-weekly pay condition had a higher average daily balance than those in the daily pay condition (while maintaining the total amount of income earned the same across conditions). Again, higher payment frequency led to more high-cost decisions than weekly pay (Mdaily=8.01 vs. Mbi-weekly=6.94, *p*<.001; Moreover, this effect was again mediated by participants' wealth perceptions (*ab*=.12, 95% CI[0.01, 0.27]).

We next examined the introduction of a daily pay option by a sizable gig-economy platform. We received earnings and spending data for 752 people working for this platform three months before and three months after the introduction of daily pay through a third-party app, accounting for over 427,000 transactions. Using a linear mixed-effects model, we find that after the introduction of a daily pay option, workers made more discretionary expenditures (β=4.02, *p*=.035) as compared to before the introduction of daily pay.

We demonstrate that consumers' form their wealth perceptions based not just on their objective wealth (or their objective wealth relative to some benchmark) but also from the timing of their pay. Across several pre-registered, controlled lab studies, and two analyses of real consumer spending behavior, the current research demonstrated that higher payment frequency consumers' wealth perceptions and thus, their discretionary spending. Our research suggests that payment frequency impacts not just when consumers spend, but also how much, and calls for future research to understand how other aspects of consumer spending that may be impacted by payment frequency.

Pennies Reframing of Savings Rates

EXTENDED ABSTRACT

The savings crisis in the United States affects a broad swath of workers, and this disproportionately affects those with lower incomes, who may also have lower education levels, numeracy, and financial literacy. For example, one of the most pervasive ways of choosing a savings rate is to identify a percent of salary that one wants to contribute to their retirement account. However, the broader literature indicates that how numerical and financial information is presented affects people's judgments and decisions. Examples include the miles per gallon illusion versus gallons per mile (Larrick & Soll, 2008) where people underestimate the financial benefits of replacing certain cars, and the temporal reframing of recurring savings decisions (Hershfield et al., 2020 forthcoming) where more people participate in recurring savings programs when decisions are framed as saving $5 per day versus $150 per month, despite being essentially the same choice from an economic perspective. In other words, metrics matter. In our stream of research on pennies reframing of savings rates, we hypothesize that eliciting savings rates using percentages may lead to less desirable outcomes for some subpopulations. In a laboratory setting, we explore a novel, savings choice architecture that is essentially not available in the market today by framing savings decisions using pennies per dollar of salary, which avoids uses of percentages. This research stream currently includes three survey-based, experimental studies which focuses on savings decisions which include the joint choice of an initial savings rate and an escalator rate. For example, if a person elects an initial, economically equivalent savings rate of 3% and an escalator rate of 2%, then they will save 3% of their salary this year, 5% of their salary next year, 7% of their salary two years from now, and so forth.

Study 1 (N=200) covers a low, introductory savings choice and may effectively be viewed as a practical boundary case where companies would likely not implement initial savings rates and escalator rates any lower than 1% and 1%. We assess the difference in participants' selections in a between-subject design when faced with 1) an opportunity to either save 1% of salary, increasing by 1% every year thereafter or not save versus 2) an opportunity to either save 1 penny per dollar of salary increasing by 1 penny per dollar of salary every year thereafter or not save. We find evidence that setting rates this low, even for those among the lowest salaries, may be too low as evidenced by ceiling effects in participation rates (β=0.02, p=0.709) and insignificant main effects in perceived affordability (β=0.15, p=0.427), although a spotlight analysis indicates marginally significant simple effects of subjective numeracy on perceived affordability.

Study 2 (N=200) broadens the scope of inquiry by allowing participants to select higher savings rates within a range that effectively spans the range of default rates of a large majority of defined contribution plans. Participants first make a choice to save at an initial savings rate (limited to between 0% to 6% of salary) followed by an escalator rate (limited to between 0% to 3%) in a between-subject design with some seeing pennies versus percent framing. In this study, no differences were detected in the initial savings rate selected (β=0.11, p=0.648), although participants selected significantly higher escalator rates in the pennies condition (β=0.55, p=0.000). Note that a 55-basis point increase, if it were to be realized in the field, would be quite substantial given the benefits of money compounding and that the most common escalator rate in plans with auto-escalation is 1%. Spotlight analysis indicates that subjective numeracy moderates both choice of higher escalator rates and perceptions of affordability. Additionally, both structural equation modeling and Preacher-Hayes mediation analyses indicate perceptions of affordability partially mediating initial savings rates and escalator rate choices.

Study 3 (N=401) broadens the scope of inquiry to include both self-reported and objective psychological measures, the latter using methodologies from Query Theory (Johnson et al., 2007). Furthermore, a limitation of Study 2 was also relaxed in that instead of requiring people to choose an initial savings rate and then an escalator rate (i.e., restricted process flow), participants could freely choose to select and change either rate in any order. In Study 3, we find that people both save at both higher initial savings rates (β=0.50, p=0.004) and escalator rates (β=0.37, p<.001) in the pennies framing. We also find that people subjectively report higher affordability (β=0.41, p<.001) and understandability (β=0.21, p=0.043) with pennies framing. Spotlight analyses indicate that financial literacy moderates savings choices, especially for those with lower financial literacy. Financial literacy also moderates self-reported affordability and understandability. Structural equation modeling also shows evidence for people choosing higher initial savings rates and higher escalators with objective thoughts about affordability mediating choice.

The studies above offer evidence that a small change of eliciting savings choices using pennies versus percent framing can impact people's perceptions of affordability and thus lead people to select higher savings and savings escalator rates. Treatment effects seem to improve the outcomes for those with the lowest numeracy and financial literacy the most. In Study 3, those with the lowest financial

literacy selected initial rates that were more than 2 percentage points higher in the pennies frame (relative to a sample mean of 2.9%), and they also selected escalator rates that were more than 64 basis points higher (relative to a sample mean of 0.82%). Research on the pennies reframing of savings rates is continuing with a survey-based study (N=270) covering a higher income participant pool within a corporation and a field study (N = target of 1,000) covering the real retirement choices of eligible employees across a number of retirement plans (study launched in the field in November 2019 with data expected in June 2020).

How Soon is Now? Present Bias and the Mental Accounting of Time

EXTENDED ABSTRACT

Consumers often face situations where they have to choose between a smaller but immediate outcome and a larger but delayed outcome. Research on intertemporal choice has found that people are often more impatient for temporally proximate decisions (e.g., $40 today vs. $50 in 1 month) than for future decisions (e.g., $40 in 12 months vs. $50 in 13 months), contradicting the standard economic model that dictates constant degree of patience over time (for a review, see Urminsky & Zauberman, 2016). Present bias explains this inconsistency by suggesting that rewards lose more value when delayed from "now" or the present (Loewenstein & Prelec, 1992). However, prior literature has not clearly established what counts as the present.

Some research has shown that people often perceive time as discrete, which can impact their task initiation (Hennecke & Converse, 2017; Tu & Soman, 2014). Relating to financial decisions, how people divide time differently was shown to affect their estimate of future budget (Ülkümen, Thomas, & Morwitz, 2008) and their mental tracking of costs (Soster, Monga, & Bearden, 2010).

In the current research, we build on the notion of discrete perception of time as budget periods to fill in the gap in the literature on intertemporal choice regarding present bias. In seven studies, we demonstrate that people's choices are not consistent with treating now as the current day, and that how people subjectively categorize time into binary periods, as either current or future financial period, can provide a better explanation of preference reversals in intertemporal choice.

In studies 1A and 1B (total N=917), we first tested when present-biased preference reversals emerge. One possible heuristic is to define the current day to be the present and simply any time later to be the future. Under such an assumption, present bias would predict people to demonstrate relatively drastic preference shift toward the larger-later option between a choice "today" (e.g., $30 today or $50 in 1 month) and the same choice any time in the future (e.g., $30 in 1 month or $50 in 2 months), but less so between choices already in the future. Contrary to this prediction, delaying choice by either two weeks or one month by adding a relatively short "front-end delay" (i.e., how much the same choice is delayed into the future), did not result in a significant increase in choices of the larger-later option (ps>.05). Statistically significant differences only emerged when the front-end delay was three months or longer (ps<.01), which suggests people are not simply "today-biased." In an additional study (N=615), we found that the hyperbolic discounting model also cannot fully account for how preferences change with front-end delays.

In study 2 (N=262), we tested if how people think of budget periods can better explain present bias. After making a series of intertemporal choices, participants were asked to categorize different future times as being part of the current or future financial period when thinking about budgeting. This measure allowed us to estimate when the "current" budget period ends and when the "future" period begins for each participant, relative to the date of the survey. First, we observed substantial heterogeneity in the duration of the current budget period, with the modal response (two weeks from today) taking up less than 20% of total responses, consistent with prior research suggesting heterogeneity in people's planning horizons for finances (e.g., Lynch, Netemeyer, Spiller, & Zammit, 2009).

Importantly, our analysis on intertemporal choices showed that people were significantly less likely to choose the larger-later option when the options occurred in different subjective periods, i.e., the smaller-sooner option in their current budget period and the larger-later option in the future period (β=-0.235, p<.001). Whether the sooner option is promised today did not explain present-bias and was a weaker predictor of choice (β=0.02, p=.07), which is further confirmed by model comparison analyses. While participants with more savings had longer current periods, our results did not change after controlling for demographics, including the reported amount of savings. In an additional study, we replicated the same finding using longer delays (N=289).

Next, we further replicated our findings in more specific budgeting and consumption contexts. In study 3 (N =234), we asked participants to make a series of intertemporal choices with outcomes earmarked to specific consumer budget categories (i.e., credits for grocery shopping or credits for utility payment). We then again asked participants about their budget period specifically for the corresponding spending categories. On average, those who answered about utility payments reported having longer current budget periods than those who answered about grocery shopping (p<.001). Replicating the prior results again, we found that people were more impatient when the smaller-sooner and larger-later credits were promised in different budgeting periods for the given spending category (β=-0.07, p<.001), and relatively insensitive to whether one of the options can be received "today" or not (β=0.009, p>.05). We found no significant differences in these effects between the contexts.

Finally, in study 4 (N=532), we tested for a causal effect by providing participants with hypothetical budget periods—either two weeks or six weeks. For choices in which the smaller-sooner option was within two weeks and the larger-later option was after two weeks (but before six), participants given the two-week current period were more impatient on average (p<.001), but vice versa when the options spanned across current and future periods only in the six-week current period condition (p=.002). This did not hold for other choices in which period-spanning did not differ by condition (ps>.05).

Our results suggest that budget periods can explain present-biased preference: people are more willing to accept delays that occur in the same period but are reluctant to delay rewards from the current to future financial period.

Fighting Fiscal Awkwardness: The (Dis)Advantages of Digital Payment Methods on Peer-Debt Dynamics

EXTENDED ABSTRACT

People often lend and borrow money from peers. Although such financial transactions may appear superficially mundane, debt repayment among acquainted individuals is socially complex. The discussion of money among peers can be uncomfortable (Krueger, 1986; Trachtman, 1999; Rose & Orr, 2007), and accordingly, requesting and repaying money can evoke awkwardness. Because of this discomfort, consumers may turn to digital payment methods such as Venmo to avoid fiscal confrontations. However, the use of digital payment methods for peer-debt requests may also increase percep-

tions of impersonality (Walther, 1995; Schroeder et al., 2017). Thus, the use of digital payment methods may act as a double-edged sword for peer debt requests, where it can potentially reduce fiscal confrontation, but also make the interaction feel less personal.

In four studies, we investigate how consumers adjust the way that they request money from peers based on their relationship with the requestee. Specifically, we examine how the strength of social ties affects the choice of peer debt repayment methods. We find that consumers are *less* likely to request money via digital payment methods with their stronger social ties (i.e., close friends) compared to their weaker social ties (i.e., acquaintances). Mediation results indicate that, with close friends, *fewer* consumers choose to request via Venmo because digital payment methods seem impersonal. For weaker social ties, however, people attempt to avoid fiscal confrontation, thus, *more* people choose to request money via Venmo. In sum, consumers selectively use digital payment methods to match relationship priorities.

In Study 1 ($N = 300$), participants recalled a real instance where they requested money from someone they know. They described the situation, indicated how they requested the money (i.e., in-person, phone call, text message, electronic payment method, email, other), rated how they felt requesting the money, and rated their social ties with the requestee. Results showed that people who requested the money via electronic methods felt more impersonal than those who requested in person ($ps < .05$). Moreover, correlational results showed that the weaker the social ties with the requestee, the greater the discomfort people felt when requesting the money in person ($p < .01$). In short, we find that different request methods (e.g., in-person versus electronic payment methods) elicit different socio-emotional consequences depending on the social distance with the requestee.

In Study 2, a between-subjects experiment ($N = 300$), participants imagined requesting money that was owed from either a *close-friend* or an *acquaintance*. Participants indicated if they would request the money either (1) in-person, (2) via Venmo, or (3) they would choose not to ask. For *close-friends*, participants were *less* likely to request money using Venmo relative to requesting from an *acquaintance* (31% vs. 54%; $p < .01$). However, people were directionally *more* likely to request the money in person with a *close-friend* versus an *acquaintance* (52% vs. 41%, $p = .09$). That is, people were *less* likely to use digital payment methods with stronger (vs. weaker) social ties, while *more* likely to request in person with stronger (vs. weaker) social ties.

Study 3 ($N = 503$) replicated this basic effect and added a *Vendor* condition to test how a strictly transactional relationship with the requestee affects the choice of request method. In addition, we added a new method of request, a standard bank app, to see how a purely transactional, yet still digital, payment method differs from Venmo and in-person requests. All participants read a scenario where a *close-friend*, *acquaintance*, or *vendor* owed them money (randomly assigned). Participants were asked whether they would request the money either (1) in person, (2) via Venmo, (3) via a Bank app, or (4) they would not ask. Replicating Study 2, people were *less* likely to request the money that was owed via Venmo when requesting from a *close-friend* (19%) versus an *acquaintance* (35%; $p < .01$) or a *vendor* (30%; $p < .05$). However, people were directionally more likely to request the money in person with a *close-friend* (53%) versus an *acquaintance* (43%) or a *vendor* (43%). Moreover, people were substantially *more* likely to request the money using a standard bank app with a *vendor* (25%) versus a *close-friend* (5%; $p < .001$) and an *acquaintance* (5%; $p < .001$). That is, people were more likely to use a purely transactional payment app to request money from a strictly transactional relationship (i.e., with the vendor).

Study 4 (N = 503) addressed the mechanisms underlying the relationship between social distance and choice of request method. We investigated whether anticipated discomfort and impersonality between social distances are associated with Venmo versus in-person requests. Participants imagined requesting money from either a *close-friend*, *distant-acquaintance*, or *extremely distant-acquaintance* and chose to request the money in person or using Venmo. Then, participants rated how uncomfortable and impersonal it would feel to request the money. Consistent with previous studies, *fewer* people chose to request via Venmo with a *close-friend* (25%) compared to *distant-acquaintances* (42%; $p < .001$) or *extremely distant-acquaintance* (45%; $p < .001$). Conversely, more people chose to request in person with a *close-friend* (75%) than with a *distant-acquaintance* (58%) or an *extremely-distant-acquaintance* (55%; $p < .001$). Mediation results showed that anticipated discomfort from requesting in-person (indirect effect: 95% CI [-.07, .00]) and perceptions of impersonality using Venmo (indirect effect: 95% CI [.07, .00]) mediated the relationship between the strength of social distance and choice of request method.

Our findings suggest that people request money differently depending on the strength of their social ties with the requestee. With close friends, people are *less* likely to use digital payment methods because that makes the transaction feel less personal; instead, people request in person with those with whom they share close social bonds. At the same time, with weaker social ties (i.e., acquaintances), people are *more* likely to use digital payment methods to avoid fiscal confrontation and discomfort. Taken together, we see that consumers adjust their approach to peer financial interactions based on the needs of the social relationship at hand.

SESSION OVERVIEW

In this session, we present four empirical papers that, in addition to sharing text analysis as a methodological tool, explore the power of narratives. The contexts studied range from market perceptions of debt to brand backstories, and from the diffusion of surfing to rap lyrics. Each of these four papers utilizes a longitudinal dataset to study evolving market stories, as told by firms, news media, rap artists or surfers. The researchers in this session share the conviction that discourses in the market represent and construct reality. To study them, we engage in diverse forms of text analysis, widely considered a next frontier in marketing research (Berger et al. 2020), that include theme-coding, content analysis, and automated text analysis. Beyond a shared focus on textual data and analysis, these projects use a variety of data sources and theoretical lenses to contribute to our understanding of how narratives represent and drive the market. The presentations will dive deep into the everyday conversations of each topic to uncover the subtext behind everyday language and how it reflects deeper realities in the market.

The first presentation examines how brand managers strategically construct brand backstories from a curated set of facts, signs, symbols, that provide the firm's official narrative of the brand's origins. The authors reveal how practitioners design the backstory, curating brand materials to offer the 'real', 'authentic' story and the ultimate 'truth' about the brand. The next presentation focuses on the important topic of wealth disparities and the non-linear narratives of poverty and wealth. Rap music has had a fascination with these narratives, and their lyrics negotiate and link both ends. Though spending rituals are prominent in hip-hop lyrics, the authors explore how hip-hop lyrics also may encourage engagement in wealth creation rituals. The third presentation explores the timely topic of personal debt, attempting to uncover how the media constructs the perception of debt and what it does for/to people in society. Employing a variety of automated textual analysis on a large news database, the authors study in particular the role of metaphors framing issues in public discourse. The final presentation explores the dispersion of an indigenous practice, surfing, revealing that practice diffusion occurs through practice codification, transposition, and adaptation.

We structure the session as a series of four empirical presentations tied to the theme of market narratives and linked by a methodological focus on text. Each presentation will be 12 minutes leaving 20-25 minutes for discussion and debate. While all the presentations have implications for market creation, public policy, and branding, they borrow from a range of theories including narratology, conceptual metaphor theory, rituals and identity projects, or diffusion theory. This session will facilitate scholarly discussion of the complex interplay between markets and discourses. A big theme in it guiding the session and discussion with the audience will be the performative aspect of discourses or, in other words, how industries, firms, consumers "fake it till they make it", slowly creating a reality (a backstory, public consensus, wealth, a practice) by telling it. Jointly, we anticipate sparking conversation around questions such as: 1) how does a historical view of a specific market discourse (i.e. longitudinal, etymological, heritage or origin stories) inform understanding of current discourses? 2) how can industries, firms and consumers utilize these frameworks to strategically tell their stories? We expect lively audience participation and involvement based around the timeliness and relevance of the contexts and methods, as well as the eclectic theoretical perspectives.

Analyzing Brand Backstories: Combining Textual and Multi-sensory Data

EXTENDED ABSTRACT

Brand managers strategically construct brand backstories from a curated set of facts, signs, symbols, with accompanying evidentiary support that, when knitted together, provide the firm's official narrative of the brand's origins, including novel insights and revelations regarding the early days of the brand. Our research question is: How can analysis of multi-sensory archival data reveal how practitioners design the backstory, curating brand materials to offer the 'real', 'authentic' story and the ultimate 'truth' about the brand?

This multi-year, multi-country project focuses on the growing practice of the brand backstory, whereby firms grant consumers access to facts about the brand origins, 'private' backstage information. Often brand backstories unfold in the home of the brand (its headquarters or factory) or an authoritative institution, such as a museum. These sites (headquarters, factory, museum) frame the backstory, imbuing it with an aura of authenticity that bolsters the firm's authorial voice.

We draw on graphic narrative theory, a narratology theory grounded in the study of graphic novels and comics (bandes dessinées) and which allows a fuller understanding of storytelling via words and images. In particular, Thierry Groensteen's work on the System of Comics provides a novel lens through which we can integrate visual, verbal, spatial, and chronological expressions in narrative analysis. We share the insights gained from our ongoing analysis of four brand backstories. Our experience unearthed the challenges of incorporating visual and other sensory data in primarily text-centered consumer research and signals the need for narrative theories and rhetorical tools to supplement automated text analyses.

Our data consist of brand materials across four brand backstories (an entertainment brand, two fast moving consumer good brands and a nonprofit organization) that varied in the type of spatial brand backstory on offer (museum exhibit, factory tour and corporate headquarter exhibit), in the duration (one time event and ongoing) and location of the backstory (offsite museum and brand headquarters) as well as in the number and type of creators involved in the design of the backstory (multiple creators all not members of the brand-owning firm vs. a sole creator employed by the brand-owning firm). Practitioners approached for this project shared not only their views

and insights on their involvement with the brand backstory but also access to historical documents and curatorial practices such as backstory creation manifestos or documentation describing the project scope of the brand backstories.

Our data consist of in-depth qualitative with practitioners responsible for crafting and promoting brand backstories for the entertainment brand Outrageous Fortune (OF), the sole creator for the factory tour of Herr's Snacks, four practitioners for the headquarters of Girl Scouts USA, five for the Calissons du Roy Rene, a specialty almond delicacy. Interviews were conducted at the backstory site to enable the researchers to gain firsthand observations and an applied experience as a simulated consumer of the multisensorial backstory environments discussed in the interviews. First-hand observations were recorded as data through handwritten notes and supplemented the interviews carried out. The researchers visited each site on multiple occasions for lengthy periods of time. Follow up interviews were conducted with three OF backstory practitioners in a group interview, one GSUSA backstory practitioner, and two members of the Tourism Office in charge of industrial tourism and the Calissons tours. Interviews centered on the processes involved in the creation and maintenance of the brand curation, the motivations of the producers for the genesis of the brand backstory, the type of information included, the narrative structure and spatial organization of the exhibit, the goals and aims of the backstory during and after creation, and general opinions on consumer reactions to the backstory.

We supplemented interview data with analysis of the curation materials: all the OF materials from the Arts Department were provided digitally as well as the Official 'behind the Scenes' DVD, the tour guide manuals and instructions for the guided visits at Herr's, GSUSA, and the Calissons (in as many iterations as were available), as well as archival documents, when available, outlining the processes for selecting and organization curation materials into the backstory space . We also relied on the hundreds of photos and videos of the exhibits provided by the organizations as well as our own.

Our analysis of interview transcript data and the curated materials were analyzed hermeneutically, noting the relationships between codes and then nomothetically across interviews and data sources (Glaser & Strauss 1967; Mick & Buhl 1992; Thompson, Locander & Pollio 1989). A refinement of ideas and themes was achieved by way of the constant comparative method whereby data were compared to other sections that contained similar incidents and themes, as well as contrasted with other sections of data with differing themes (Goulding 2002).

We highlight the challenges of analyzing multi-sensory data. The brand backstories in our sample were multi-lingual, multi-cultural and multi-industry. The data collection and analysis followed the procedure and protocols of multiple traditions: textual media data, textual interview data, visual brand collateral (brand advertising and promotional material), and experiential data (factories, headquarters and museums). Complicating matters, the practitioner curated materials represent different punctuated moments with temporal notions of brand attributes and market perceptions. Our data represent a process theoretic approach (Giesler and Thompson 2016) centering on the brand backstories, consisting of the process of brand becoming, or the ways in which brands enter the market and minds of market constituents.

Rituals in Rap: Remaking the Road to Riches

EXTENDED ABSTRACT

Wealth disparities have long garnered attention in lyrics of rap music, and continues to do so with more recent lyrics focusing on overcoming such differences. Art serves a functional purpose within the African American community (French 2017; Karenga [1972] 1997). Rap, a musical art form embedded in hip-hop culture, was once a marginal influence and has emerged as a prominent global socialization force (French 2017; Lena 2006; Motley and Henderson 2008). Motley and Henderson (2008; p. 243) note "Hip-hop culture influences styles of behavior…"

Prior research identifies hip-hop influences on brand consumption (Burkhalter and Thornton 2014; Ferguson and Burkhalter 2015; North and Hargreaves 2007). While spending is integral to consumption, so is saving (Bradford 2015). Studies of hip-hop lyrics suggest listeners are socialized to rituals in support of spending (Leung and Kier 2010). Though spending rituals are prominent in hip-hop lyrics, we explore how hip-hop lyrics also may encourage engagement in wealth creation rituals.

Hip-hop lyrics often include implicit endorsements of specific forms of consumption (Motley and Henderson 2008; Rehn and Sköld 2005). Consider Petey Pablo's song featuring Seagram's gin (Burkhalter and Thornton 2014) or Run-DMC and the "My Adidas" campaign (Ferguson and Burkhalter 2015). Hip-hop music emerged from urban and ethnic enclaves providing an outlet of expression for those in marginalized communities, and is now found globally across other marginalized communities (French 2017; Motley and Henderson 2008). Hip-hop lyrics focus on current issues, where one such issue is the need for wealth creation (vs. spending). The primary emphasis in hip-hop lyrics are on those spending rituals related to brand acquisition. However, there is evidence that hip-hop lyrics also may encourage performance of wealth creation rituals.

The study explored lyrics of one of the wealthiest hip-hop artists, Shawn Carter—"Jay-Z", who amassed wealth through a diversified portfolio music, real estate, sports management (Akhatar 2018). Jay-Z shares his rags-to-riches story outlining his transition from poverty to drug-dealing "in the crucible of Brooklyn's Marcy projects." (Simmons 2005). Data were collected from studio albums released between 1996 and 2017 (212 songs). Lyrics were analyzed individually, within its album, and across albums. The data were coded using codes associated with wealth accumulation from the literature and the lyrics. Three themes emerged from that analysis related to wealth creation rituals.

Prior research on savings explores how individuals employ earmarks and social comparison in support of wealth creation and identity projects (Bradford 2009, 2015). Missing is an explanation of how wealth creation rituals may be introduced through music. This research finds such rituals may be introduced through three key mechanisms: social comparison, nostalgia, and aspiration. Studies of social comparison finds people seek salient others as points of reference (Festinger 1954). Research on wealth creation finds African Americans employ social comparisons with whites (Bradford 2009). The lyrics serve as a metaphorical device that provides a wealth creation ritual model, and an alternative social referent for listeners who are not likely to achieve acclaim.

Ritual performance provides a link between the past and the future. Where nostalgia is employed by marketers to sustain brand vitality (Brown, Kozinets, and Sherry 2003), these lyrics employ nostalgia to elevate notions of simplicity found in poverty as noble and worthy of retention amidst the complexity of wealth. Where prior research on voluntary simplicity focuses on reductions in consumption (Craig-Lees and Hill 2002), we find that the notion of simplicity is not segregated from material possession. Rather, an orientation toward simplicity is emphasized with respect to consumption to support performances of wealth creation rituals. Thus, nostalgia is em-

ployed to facilitate balance between drives for material possessions and security.

Continuity of rituals also inspires a future focus which may include aspirations. Aspiration in consumption may be found in notions of a future self (Bonsu and Belk 2003). We find these lyrics inspire aspiration not only related to identity but also through an adoption of wealth creation rituals. Early research purports a relationship between social class and savings patterns (Martineau 1958), yet our findings expand Bradford (2009) that illustrates that the impact of social class may be mitigated by adoption of rituals.

This study contributes to the literature on how behaviors are influenced through hip-hop lyrics (Motley and Henderson 2008). More specifically, we identify how wealth creation rituals within hip-hop lyrics challenge notions of spending rituals, and also may inspire wealth creation rituals for all individuals. Wealth creation rituals proposed in these lyrics include a broader set of ritual participants, and encourage performance continuity through social comparison, nostalgia and aspiration.

Metaphorical Framings in Market Discourse

EXTENDED ABSTRACT

We communicate using borrowed tools. When businesses, academics, or consumers quote, reference, meme, we are deliberately recontextualizing past words to make them do our biding. But all words are borrowed. As Bakhtin (1981) puts it, "language has been taken over, shot through with intentions", each word acquiring the taste of a collective, a generation, an ideology. In this intertextual game, market actors can unquestioningly replicate the linguistic conventions of communications on a topic, or they can strategically design their "borrowings" to fit their agenda. These latter, discourse-driving market actors shape public opinion by framing reality through a specific lens.

Metaphors are one such lens that influences perception of a topic and drive behavior. Beyond being stylistic devices to attract attention and spice conversation, metaphors work as frames, affecting how we see the world or our definition of an issue. In this article, we explore how metaphors structure discourses in the context of debt. No other product of the market economy carries the emotional and moral baggage of debt. According to market narratives (Peñaloza and Barnhart 2011), debt empowers as much as it constrains borrowers. With innovations in conversational AI such as Bank of America's virtual assistant Erica (Legters 2019), the Consumer Financial Protection Bureau increasingly shifting the discourse to one of responsibility put on ordinary citizens (Hayashi 2019), and presidential candidates making debt cancellation a cornerstone of their campaigns, few dialectical battles are more current than the framing of consumer-firm responsibility regarding debt.

Whether debt is framed as a tool, a burden, or a prison, the power of the words describing it is compounded in the age of social media sharing and content aggregators. Largely repackaging facts from elsewhere, news outlets engage in a constant parroting of each other, much like social media users retweeting, reposting and sharing. The language used to speak of an issue, with its frame and ideology, is echoed by numerous sources and cements in public opinion. Persuasive influencers like savvy politicians and firms design their scripts carefully to guide perception, opinion and action.

We develop a framework to judge the aptness of metaphors to frame marketing-relevant issues such as personal debt to lead public opinion in a given direction. The implications of this work extend from the design of persuasive marketing communications to the promotion of public policy or nudging behavior towards consumer well-being. To this end, we build on the established literature on discursive frames (Barsalou 1992, Shoemaker and Reese 1996, Gamson et al.1992; Humphreys and Latour 2013) and we strengthen the known association in academic research between metaphors and frames, or metaphorical frames (Boeynaems et al. 2017, Lee & Schwarz 2014, Lakoff 1993, Lakoff and Johnson 2008). By spelling out an issue in relation to one particular schema and not another, frames become shared understandings not only on what to think about the topic but on how to think about it. In contrast to the immense potential to harnessing metaphors, the alternative, unquestioningly echoing the metaphors used by others can backfire or result in the implicit endorsement of ideologies embedded in the language.

Acknowledging its established role influencing and reflecting public discourse (Deephouse 1996, Humphreys 2010, Humphreys and Latour 2013, Warren and Sorescu 2017), we turn to mass news media for an investigation of the metaphors and frames in the topic of debt. We conduct a large-scale text analysis on a comprehensive database of ten years of news media articles. Employing textual methods at the forefront of market research innovation (Berger et al. 2020), we approach the research question: how do metaphors frame market-oriented discourse to guide action? Although we build on literature investigating discourse in market activism (Humphreys 2010; Karababa and Ger 2010; Kurzer and Cooper 2007; Sandlin and Callahan 2009; Woodly 2015), we align more closely with a rarer and more recent body of research (Giesler and Veresiu 2014; Humphreys and Thompson 2014) concerned with the already established institutional discourses against which activists sometimes compete. Our data is analyzed through a three-fold approach of interpretive deep reading, computer-assisted discourse analysis, and a deep learning Natural Language Processing (NLP) model of debt conversation.

Consistent with research on framing, we find metaphors to be of central importance not only defining a problem, but also suggesting a solution. Far from being neutral, metaphors form frames regarding the topic in terms of valence, responsibility assignment, and action. These metaphors tend to cluster around topics, ideologies and language that support their definition of the frame. We argue that metaphors associated with social issues form entrenched framings that shape perceptions of the topic and our lived experience. While these framings reflect and perpetuate ideologies, we foreground an effect that can be insidious rather than overt: an endorsement that is often-times tacit rather than explicit. Strategic marketing action requires carefully choosing the metaphorical frames that advance the firms goals. Conversely, acts of resistance against the dominant discourses can be forced to articulate their criticisms through the same frames that work against them, or consciously break the mirage of figurative language that traps them.

Written in the Sand: Tracing Practice Diffusion Across Time and Space

EXTENDED ABSTRACT

Prior consumer research underscores the importance of practices in shaping market-mediated experiences and social structures. Little is known, however, about how practices diffuse across various social and cultural contexts over time and the consequences of diffusion on consumption.

This research involved 10 years of data collection, 2009-2018, and multiple rounds of analysis, in which we iterated between data and theories to interpret our findings. We include a variety of market-related actors' narratives that capture different practices and perspectives; the sample of interviewees was purposive. We interviewed a number of surfing historians and historical figures (e.g., contest

organizers, surfboard shapers, and entrepreneurs) in the evolution of surfing to verify our archival data and to better understand and capture specific first-person accounts of particular events. Differences in occupation and gender provided a variety of viewpoints and perspectives of surfing as well as the history of surfing. We used a variety of archival sources, including newspapers, magazines, photos, websites, movies, and Observations include participation in the practice of surfing, engaging in surfing related events or activities, spending time in surf-related retail environments, writing for a surfing magazine, and volunteering at a surfing competition. In addition, two of the authors spent considerable amounts of time as members of local surfing communities and cultures prior to the initiation of this study.music, which served as surrogate data when first-person accounts were unavailable Karababa and Ger (2011). With each source of data, we examined each artifact as an individual representation of surfing and then considered its meaning within the wider scope of the surfing subculture. This approach enabled us to oscillate across micro- to meso- to macro-levels of social phenomena (Karababa and Ger 2011) within the surfing ecosystem (Akaka et al., 2013; Chandler and Vargo 2011).

We approach these data from an ecosystems perspective (e.g., Giesler 2008; Vargo and Lusch 2016) that allows us to consider how particular events and practices fit into a broader socio-historic narrative. We are particularly interested in understanding how micro-level social phenomena (e.g., practices) construct broader social structures (c.f. Giddens 1984) enabling the spread of practices. We utilize a longitudinal and historical data set (Karababa and Ger 2011), through a process theorization approach (Giesler and Thompson 2016).

Chronological accessibility of the emergence and re-emergence of specific practices requires the ability to track the spread of a particular local artifact across time and space (Giesler and Thompson 2016). While the complete pollination of surfing around the globe is beyond the scope of this particular study, we aim to understand how practices diffuse across regions and cultures.

Our historical research is guided by the work of Karababa and Ger (2011) and a process theorization approach that focuses analytical attention on change occurring in social collectives (Giesler and Thompson 2016). Change is made manifest in actions, ergo we utilize event-based data and analytical bracketing to organize the events (Giesler and Thompson 2016: 502) that, in our context (surfing) and with our interpretive lens (diffusion) reveal the manner in which surfing spread across multiple locales. Specifically, we examine what Giesler and Thompson (2016: 500) call topological change, or the "shifts in patterns of power relationships." These shifts from one reality to the next disrupt the status quo relations causing topological displacements (Giesler and Thompson 2016: 503). Based on the precipitating tensions arising from power struggles regarding respectability and reputation, we identify power shifts, manifested through events, which enable the spread and perpetuation of surfing (Giesler and Thompson 2016: 499).

Part of the challenge of understanding the practice diffusion is that in studying practices and local culture, there is a tendency to focus on understanding particular micro-social processes and contexts. Askegaard and Linnet (2011: 381) argue "there is a need for bridging the analytical terrain between the anthropological search for thick description and deep immersion in the field, and the sociological inclination towards broad social theories and movements that are often quite remote from the emic illustrations of everyday life experiences." To investigate communities of practice (Wenger 1998) that underpin surfing's consumer culture, we draw on the work by Schau and colleagues (2009) to identify specific micro-level practices that contribute to the emergence of common structure, and frame these

practices with a broader classification of value co-creation practices and their relationship to practice diffusion. This provides a framework for studying value co-creation and practice diffusion among micro- and higher (meso- or macro-) levels of social phenomena (Akaka et al., 2013).

This exploration of the dispersion of an indigenous practice, surfing, reveals that practice diffusion occurs through practice codification, transposition, and adaptation. Our data reveal that practice diffusion is not the wholesale adoption of a practice. We show that practice diffusion is influenced by the origins of a practice and the social and cultural contexts in which its diffusion occurs. Practice adaptation is a process that integrates varying perspectives of a practice into the broader nexus of understandings, doings and sayings associated with that particular practice. We find that the as a practice diffuses across contexts it has the potential to lead to social change and the emergence new social structures (subcultures of consumption).

SESSION OVERVIEW

Personal experiences using hand movements and gestures have been shown to influence attitudes by activating heuristics, visual fluency, and emotional attachment (Labroo & Nielsen, 2010; Hadi & Valenzuela, 2014; Streicher & Estes, 2016). This is particularly true since, unlike visual or auditory cues, tactile exchanges require direct contact with a stimulus (Peck, 2010). Touch is considered the most "proximal" sense (Montagu & Matson, 1979) and has an idiosyncratic capacity to evoke a sense of psychological closeness (Trope & Liberman, 2010). A sense of movement can also be delivered through a device itself. In fact, computer science research suggests that "mediated touch" is possible, where haptic feedback from devices symbolizes the experience of the movement delivered by other (Gallace & Spence, 2010; Haans et al., 2006).

This session combines four papers that shed light on dimensions, which drive how movement actions on objects, received from objects or embodied on the trajectory of objects may have downstream consequences for advertising effectiveness, product preferences, and choice.

The first paper investigates how speed of observed hand-motor actions affect consumer judgments – driven by schematic associations between speed of hand-motor actions and femininity-masculinity. Specifically, Malik and Sayin propose that observing slow (vs. fast) hand-motor actions evokes feminine (vs. masculine) schematic associations, which leads to perceiving that the product itself is more feminine and transfers onto higher product evaluations among female (vs. male) consumers.

The second paper by Ostinelli, Luna, Ringberg and Suurmets reconciles disparate findings in the semantic association connected with vertical movements by introducing the conceptual distinction between static embodied experiences (i.e., being up/down in a stationary fashion) and dynamic embodied experiences (i.e., moving up/down). They suggest that static experiences lead to assimilative behavior and dynamic experiences lead to complementary behavior when they involve aversive situations.

Next, Hampton and Hildebrand demonstrate that certain movement delivered by devices, such as mobile vibrations, is consistently perceived as rewarding and can influence shopping decisions. They also provide evidence that conditioning drives this vibration-reward association.

Finally, Hadi, Valenzuela, Sridhar and Du develop a novel framework to predict consumer responses to synchronic integration of haptic effects into audiovisual mobile content, particularly movement. They demonstrate that, while haptic augmentation may indeed improve consumer responses to advertising, the positive effect is moderated by dimensions of brand personality.

This session should be of interest to a broad audience of researchers with substantive interests in the consequences of consumer associations with object-directed actions and the experience of movement within human-technology communication, as well as a theoretical interest in embodied cognition, associative processes, and information processing. The consequential nature of the dependent variables provides insights for practitioners.

Is Fast Feminine? The Effect of Speed of Observed Hand Movement on Consumer Judgment and Behaviors

EXTENDED ABSTRACT

Hand movements, gestures, and actions have been shown to influence consumer attitudes and behavior (Labroo & Nielsen, 2010; Hadi & Valenzuela, 2014; Streicher & Estes, 2016). Extending this literature, we investigate how speed of observed hand interaction with an advertised product affects consumer judgments.

We argue that consumers cognitively relate speedy or fast (than gentle or slow) movements with masculinity (than femininity). They may develop the associations about what it is feminine (vs. masculine) through social learning and repeated exposure to stimuli in their environment (Becker, Kenrick, Neuberg, Blackwell, & Smith, 2007). For example, in advertisements, consumers oftentimes observe a female protagonist performing a gentle hand interaction with a product (e.g., applying L'Oréal face cream, spreading Nutella on a pancake etc.) and male character doing a rather speedier hand movement (e.g., twisting the handle of Harley Davidson bike, spraying the AXE body deodorizer etc.) We propose that recurrent exposure to such sensorimotor experiences in advertisements, dance-forms, films, etc. can lead the consumers to develop distinct associations of slow (vs. fast) hand movements with a more feminine (vs. masculine) behavior (H#1). These associations may even be taken as an input to form product judgments. We hypothesize that slow (vs. fast) hand movement with a product will alter the attribute perception of the product – such that the touched product will be perceived more feminine (vs. masculine; H#2). Finally, drawing upon the social identity theory, we expect that observing a slow (vs. fast) hand movement with a product will evince a higher product evaluation among female (vs. male) consumers (H#3). This is because individuals are motivated to process information and make product choices that match their social identity (Berger & Heath, 2007).

In Study 1A, MTurk workers (N = 158) completed the computer-based Implicit Association Test (IAT; Greenwald, McGhee, & Schwartz, 1998). The findings revealed a positive and significant association for fast (vs. slow) movement with masculinity relative to femininity [D-score=.67, t(157)=20.40, p<.01, 95% CI =(.60, .73), Cohen's d=1.62]. The association of speed held across the participant genders.

In Study 1B, MTurk participants (N= 259) were assigned to either slow or fast speed between-subject conditions. Each participant watched three randomly-presented videos depicting commonly-encountered hand movements (i.e., ironing, vacuuming, and spray-cleaning) that varied on speed of action. They, then, shared their attribute associations for the action-doer i.e., feminine (gentle, nurturing, and caring) and masculine (forceful, aggressive, and dominant; Hoffman & Borders, 2001), perceived speed, video characteristics (manipulation checks), age, and gender (control variables). A repeated-measures ANCOVA with speed as between-subjects factor and the three contexts as within-subjects factor on the feminine-attributes index (average of feminine attributes) showed a significant effect of speed (M_{slow}=4.91 vs. M_{fast}=4.35, p<.01; ηp2=.06) suggesting that slow speed evinced a feminine schematic association. Likewise, the analysis on masculine-attributes index found that fast speed triggered a masculine schema (M_{slow}=3.30 vs. M_{fas}t=4.06, p<.01; ηp2=.07). These effects retained significance without the covariates (p<.01) as well.

Study 2 demonstrates the use of distinct associations from slow (vs. fast) speed as an input to form attribute perceptions of a product (i.e., shaving foam; H#2). In a pre-test of 5 shaving foam cans (fig.1), MTurk participants (N=103) identified "Ultra-Sensitive" labelled foam as significantly lower on perceived masculinity ($M_{Ultra-Sensitive}$=4.66) compared to "Bold" labelled foam (M_{Bold}=5.87, p<.01).

In main Study 2, MTurk participants (N=254) were assigned to either slow or fast between-subject conditions. The stimuli video showed a male applying shaving foam (fig.2). Participants were asked to choose the foam product they believed that the protagonist is applying ("Ultra-Sensitive" or "Bold"). They, then, rated the individual on the schematic attribute associations, video characteristics, manipulation checks, and control variables as study 1.

We conducted a logistic regression to test whether slow (vs. fast) hand movement led the featured product to be perceived as low/ "Ultra-Sensitive" (vs. high/ "Bold") on masculinity. The main effect of speed was significant (χ2(6)=3.71, p=.05; H#2) with no significant covariates (p>.35). Specifically, participants chose less of the high masculine product ("Bold") upon observing a slow (P_{slow}=48.81%) vs. fast (P_{fast}=60.62%) hand movement (χ2(1)=3.56, p=.06). We then ran a MANCOVA on schematic associations [DVs: femininity and masculinity index]. The analysis showed that slow (vs. fast) speed activated a significant feminine schema (M_{slow}=4.53, M_{fast}=3.79; p<.01) but did not alter the masculine associations (M_{slow}=3.59, M_{fast}=3.54; p=.79) for the protagonist. Gender and video characteristics had a significant effect (p<.01) but did not interact with speed to influence the associations. Subsequently, we ran a mediation analysis that showed that slow (vs. fast) observed hand movement elicits a higher feminine (vs. masculine) schematic association, which mediates the effect on choice of shaving foam product.

In Study 3, we investigate whether female (vs. male) consumers use speed of observed hand movement to form their purchase intention. We expect female (vs. male) consumers to evince higher evaluations upon observing a slow (vs. fast) hand interaction with a product. This is because consumers are influenced by gender-identity maintenance motives and choose products that match their own social identity.

Study 3 had a 2(speed: slow vs. fast) x 2(participants' gender: male vs. female) between-subjects design. Postgraduate students (N=89) watched the stimuli video depicting a lateral hand-movement, which varied on speed (slow: 2.5 cm./sec. vs. fast: 5 cm./sec) over a duvet cover (i.e., target product; fig.3). Participants, then, shared their purchase intention. An ANCOVA on purchase intention revealed no significant main effect of speed (F(1,82)=.41, p =.52) and participant's gender (F(1,82)=.08, p=.77) but a significant interaction effect (F(1,82)=3.75, p=.05; H#3). The effect-size improved upon excluding the covariates (F(1,85)= 5.09, p=.03).

To summarize, across four studies, we demonstrate that observing hand movements, varying on speed, can affect the consumer responses. We demonstrate that consumers evince higher evaluations for not only products but also hand movement speed that matches their distinct social identity – such that female (vs. male) consumers evoke higher evaluations for a product depicted with slow (vs. fast) hand movement. These findings have direct implications for product management, advertising, and online marketing.

Assimilative Versus Complementary Effects of Embodied Verticality: Neural and Behavioral Evidence

EXTENDED ABSTRACT

The embodied cognition literature presents, at times, contradictory effects of verticality. Most of the literature draws on the semantic association between power, general valence, and verticality to show *assimilative effects*, where "up" is generally associated with greater power and with positivity, and "down" is associated with less power and with negativity (Esteky, Wineman, & Wooten, 2018; Guido, Pichierri, Nataraajan, & Pino, 2016; Sundar & Noseworthy, 2014).

At the same time, other research has shown *complementary effects* of verticality. Complementary responses occur when sensory-motor experiences lead to effects that are inconsistent with, and even opposite of, the underlying conceptual metaphor of "up is good." These effects result from goal-oriented behaviors aimed at reducing the gap between a current and a desired state (Zhang and Risen 2014). For example, Ostinelli, Luna and Ringberg (2014), show that moving down leads individuals to experience lower self-worth, which motivates individuals to obtain better results in cognitive tasks.

We reconcile those seemingly disparate findings in the domain of verticality by introducing the conceptual distinction between *static* embodied experiences (i.e., being up/down in a stationary fashion) versus *dynamic* embodied experiences (i.e., moving up/down). We suggest that static experiences lead to assimilative behavior and dynamic experiences lead to complementary behavior when they involve aversive situations (e.g., moving down).

Study 1

Study 1 is an EEG study that measures the brain states that result from the manipulation of static versus dynamic verticality. Previous research suggests that the simulation of movement can activate the brain areas responsible for processing goals to prepare individuals to cope with changes in the environment (Barsalou 2009; Borghi 2012; Gallese 2009; Hamilton 2013; Hickok and Hauser 2010; Pezzulo and Castelfranchi 2009; Semin and Cacioppo 2009; Sartori, Bucchioni, and Castiello 2013). From that basis, we predict that the simulation of downward movement activates the brain areas responsible for compensatory goals aimed at reacting to unpleasant changes in self-worth. This leads to complementary effects such as a preference for products with positive associations (Sivanathan and Pettit 2010).

We found that, compared to static scenarios, theta synchronization in dynamic scenarios was higher in the parietal lobe. Syn-

cronization of theta power in the parietal lobe has previously been described as reflective of redirecting attention to goal-relevant semantic information (Atienza, Crespo-Garcia, & Cantero, 2011). This finding suggests that dynamic scenarios activate goal-directed behavior, which may drive the desire to compensate for an aversive state in the moving-down scenario. In addition, alpha synchronization was higher for dynamic imagery in the frontal, central and parietal regions. This implies that dynamic scenarios do trigger an increased internally focused attention. Synchronization of alpha oscillations in parietal regions may also reflect increased processing of motor, semantic and perceptual aspects of an imagined scene (Bartsch et al., 2015).

Study 2

Study 2 shows that down conditions activate more negative associations than the up conditions, both in dynamic and static simulations. The results show a main effect of direction such that respondents in the up condition had a higher self-worth than respondents in the down condition (M_{up} = 3.23, SD_{up} = 1.79; M_{down} = 2.66, SD_{down} = 1.45, F(1,234) = 8.60, p < .01), controlling for task enjoyment. Similarly, we analyzed the top three words that came to respondents' minds while imagining the vertical scenario. The results again show a main effect of direction such that the up condition led to typing more positive words than the down condition (M_{up} = .14, SD_{up} = 1.88; M_{down} = -.36, SD_{down} = 1.70, F(1,234) = 4.54, p = .03).

Study 3

Study 3 investigates whether dynamic verticality leads to complementary effects and static verticality leads to assimilative effects. The study was a 2 (direction: up vs. down) x 2 (movement: dynamic vs. static) between-subjects design. A significant interaction emerged ($F(1, 212) = 13.94$, $p < .001$). In the dynamic condition, participants who imagined moving downward were willing to pay a greater price premium for the high-status product relative to the low-status product than those who imagine moving upward ($M_{moving\ down}$ = 18.68%, $SD_{moving\ down}$ = 34.42%; $M_{moving\ up}$ = 4.23%, $SD_{moving\ up}$ = 28.79%, $t(212)$ = -2.19, p = .03). This is consistent with a *complementary effect* of vertical position. In the static condition, however participants in the "being down condition" reported a lower price premium for the high status iPad relative to the low status Klu tablet ($M_{being\ down}$ = 4.82%, $SD_{being\ down}$ = 31.04%; $M_{being\ up}$ = 24.73%, $SD_{being\ up}$ = 39.71%; $t(212)$ = 3.10, p < .01). This pattern of results is consistent with *assimilative effects* of vertical position (Zhang and Risen 2014).

Study 4

Study 4 provides support for a motivational goal priming explanation of complementary effects, including the mediating role of goal activation, through a moderation-of-process approach (Spencer, Zanna, and Fong 2005). We introduced a goal satiation condition, in which respondents had to write about their own success, and a control condition in which responents had to write about a trip to the grocery store. We found that in the dynamic down condition, writing about one's success led to lower willingness to pay for status products than writing about a trip to the grocery store ($M_{goal\ satiation}$ = 21.11%, $SD_{goal\ satiation}$ = 20.54% vs. $M_{no\ goal\ satiation}$ = 36.9%, $SD_{no\ goal\ satiation}$ = 27.6% vs; t(202) = -2.09, p = .04).

Our work provides two main theoretical contributions: First, we introduce a goal systems framework to the study of verticality, resolving discrepancies in the existing research. Second, we introduce and explain the difference between static and dynamic simulations in embodied cognition. Methodologically, we add to the incipient body of work that integrates neural and behavioral empirical studies

through the use of EEG and behavioral evidence. The implications of our findings extend beyond the domain of verticality, as our framework can help explain potential discrepancies in other embodied cognition areas such as the experiences of weight and/or approach behavior.

Good Buzz, Bad Buzz: Using Vibrotactile Feedback to Shape Consumer Choice

EXTENDED ABSTRACT

Although smartphones have been vibration-capable for over a decade, mobile vibration features have been relatively unutilized by firms. Within the last two years, however, large e-commerce platforms such as Amazon have quietly begun to pair mobile vibration with certain consumer behaviors such as shopping cart adds. Anecdotally, people tend to report that a vibration from their mobile evokes an approach response, hinting at its potential as rewarding stimulus, yet scholarly research examining the subjective perceptions of mobile vibration is lacking. The current research integrates and builds upon existing haptic and reward perception research to examine three fundamental research questions relating to mobile vibrations: (1) how they are subjectively perceived, (2) whether they influence consumer choice, and (3) by what mechanism they exert influence, focusing on the role of classical conditioning.

Almost every modern consumer now carries a vibrating mobile device that they interact with for up to 10 hours per day (Roberts, Yaya, & Manolis, 2014). This massive uptick in mobile usage has been accompanied by increasing reports of mobile dependency (Salehan & Negahban, 2013), heightened impulsivity (Wilmer, Hampton, Olino, Olson, & Chein, 2019), as well as experiences of "phantom vibrations," i.e. imaginary vibrations (Drouin, Kaiser, & Miller, 2012). Academic research of mobile vibration has focused primarily on its use as an alerting or communicative stimuli (Sahami, Holleis, Schmidt, & Häkkilä, 2008; Saket, Prasojo, Huang, & Zhao, 2013), though one recent marketing study does suggest that mobile vibrations can boost the persuasiveness of certain text messages (Hadi & Valenzuela, 2019). Nonetheless, it remains unclear how consumers perceive, and are affected by, mobile vibrations in consumptive contexts such as online shopping. We therefore conducted an initial pretest to establish a base understanding of consumer perception of different mobile vibrations and to guide our selection of vibrational stimuli.

In the pretest, online participants (n=150) reported their subjective perceptions mobile vibrations (ranging from 25ms to 3200ms; random presentation) along a variety of dimensions (reward, pleasantness, arousal, etc.). The findings of this pretest demonstrate that reward perception varies by vibration duration F(3,147)=6.52, p<.001, with reward perception peaking at 400ms.

Our pretest finding that 400ms mobile vibrations are rewarding, together with robust evidence that reward influences choice (Papies, Barsalou, & Press, 2015), led to our main Study 1 hypothesis: consumers will prefer an action that produces a rewarding vibration, compared to one that does not. Using a within-subjects design, we presented participants (n=150) with two visually-identical boxes (analogous to online shopping carts). Participants were instructed to add items to either box as many times as they liked during a fixed timeframe. As predicted, we find that participants added more items to the vibration-producing box (MVibrationClicks=14.69; MNonvibrationClicks=10.71; F(2,148)=4.08, p<.05). Interestingly, the extent to which participants found vibrations rewarding was significantly correlated with the positive-valence of their daily mobile notifications (r=.29, 95%-CI=[.11,.41], p<.01, suggesting that con-

ditioning may underlie mobile vibration reward perception (further examined in Study 3).

In Study 2, we extend our findings with a lab-controlled study (n=138, Swiss sample) examining the effect of rewarding vibro-tactile stimuli on consumer choice in a highly-ecological online shopping setting. Participants in this study used identical tablets to complete a custom-built online grocery shopping task. In the control condition, as in a typical online shopping interface, adding an item updated the shopping cart, but produced no other feedback. In the vibration condition however, clicking the add-to-cart button triggered a rewarding vibration. We find that consumers in the vibration condition had significantly higher basket totals compared to the control group (MVibrationBasketTotal=72.78CHF ; MControlBasketTotal=57.84CHF; F(1,138)=10.01, p<.001, and that this effect is moderated by impulsivity. This result establishes that mobile vibrations can be rewarding and influence consumer choice, but does not address the underlying mechanism.

In Study 3 we test the hypothesis that perception of mobile vibrations as rewards stems from classical conditioning (Gormezano & Moore, 1966). To test this hypothesis, we adapted a classic associative learning, Multi-armed Bandit (MAB) task (Gittins, Glazebrook, & Weber, 2011). In our incentive-compatible, two condition MAB task, we presented online participants (n=215, U.S. sample) with four visually-identical slot machines, and tasked them with finding the most rewarding slot machine (each with unknown win probability) to maximize their points across 4 blocks of 30 trials (120 total; probability assignment randomized between blocks). Participants were randomly assigned to either a (1) vibration-win condition in which wins were visually-salient and carried an approximately neutral mobile vibration (100ms), while losses were less visually-salient and carried no vibration or (2) a vibration-loss condition, in which the opposite was true: losses were salient and carried the vibration. In this way we conditioned participants to associate a previously-neutral vibration with either a positive stimulus (a win) or an aversive stimulus (a loss). Participants then completed a MAB task questionnaire, followed by the shopping task (Study 2, but with 100ms vibration for item-adds) and final questionnaire battery.

Study 3's findings support that consumers in the vibration-win condition had significantly higher basket totals compared to the control group (MVibrationWinBasketTotal=$158.13; MVibrationLossBasketTotal=$126.37; F(1,213)=9.62, p<.01) and, in line with our theorizing, the effect of vibration condition on shopping basket total was mediated by how rewarding participants found the MAB task.

The current study demonstrates that mobile vibration is parsed as a reward that can systematically influence consumer choice. Our findings show that even when the touch modality is kept constant, mobile vibrations evoke shifts in consumer preference toward stimuli that are paired with a vibration. We further provide evidence a classic conditioning mechanism likely underlies vibration reward perception and its influence on consumer decision making. Together, our findings have important implications for the effective design of haptic human-machine interfaces in marketing and the role of vibro-tactile stimuli as a novel form of reward.

Consumer Responses to Haptic Sensing of Movement in Mobile Advertising

EXTENDED ABSTRACT

While consumers' prolific smartphone usage provides a fruitful advertising avenue, small screen and limited ad visibility present a challenge to marketers (Bart et al., 2014). One way to circumvent this shortcomings and exploit the handheld nature of smartphones is to utilize haptic feedback technology, which takes advantage of the sense of touch by applying vibrations to the user in synch with displayed movement and content (Brewster et al., 2007). In the marketplace, some brands have begun to distribute such "haptified" experiencd (e.g., mobile ads for Stoli vodka, users feel their phone vibrate when a woman shakes a cocktail; Johnson, 2015).

Importantly, unlike visual or auditory cues, tactile exchanges require direct contact with a stimulus (Peck, 2010). Touch is considered the most "proximal" sense (Montagu & Matson, 1979) and has an idiosyncratic capacity to evoke a sense of psychological closeness (Trope & Liberman, 2010). Computer science research suggests that "mediated social touch" is possible, where haptic feedback from devices symbolizes the touch of another person (Gallace & Spence, 2010; Haans et al., 2006).

Drawing from this interdisciplinary literature, we propose that haptic sensations experienced in a mobile phone advertisement can be perceived as a form of touch from the sender (i.e., the brand). Further, because haptic sensations are so uniquely associated with immediate proximity and contact, haptic feedback in advertising may have the ability to make these consumer-brand exchanges feel more engaging and personal, ultimately augmenting mobile advertising effectiveness. However, any positive effect of haptics will likely depend on the brand's characteristics since the source of haptic sensations plays an important role in their interpretation (Martin, 2012).

IPG Media Labs recruited 1,136 Android mobile phone users in the U.S. from an online panel (MedianAge = 25-34 years; 51.67% female). Participants took a mobile survey, ostensibly about video content of their choosing. Before viewing the selected video content, all participants were served one of four pre-roll advertisements, which were either haptically augmented or not. Several other factors were manipulated, including: density of the haptics (high versus low), the presence/absence of a "bumper" notifying participants they were experiencing haptics, whether or not the "bumper" was branded, and the ability to skip the ad or not. We accessed this dataset and analyzed it to test whether the effect of haptic augmentation was universal or contingent on the brand being advertised. To do so, we employed a logit specification to investigate customer's purchase intentions (Top Box and Second Box of purchase intentions were assigned a value of 1, as we did not have access to the continuous variable) as a function of haptic augmentation at the category level while controlling for gender (due to the nature of the categories) and advertisement evaluation (see details in Exhibit 1). We were also able to control for other properties of advertisements: (i) the density of haptic effects (ii) whether the ad was skippable, and if so, whether it was watched to its completion and, (iii) whether there was a branded bumper/notification at the beginning of the advertisement. Overall, we found that while the overall impact of haptics on purchase intention was positive and significant, a closer look revealed the effect only manifested for certain brands. The model also confirms (as suggested by IPG itself) that high haptic density and the possibility to skip the advertisement has a negative impact on purchase intentions, but that adding a notification of haptics generates a positive effect instead.

Notably, brands can differ not only in how familiar they are to consumers (Kent & Allen, 1994) but also in personality dimensions (Aaker 1997; differences in perceived brand warmth are particularly robust; Kervyn et al., 2012). We expect that haptic feedback delivered from warm brands will exert a positive effect on downstream consumer responses, whereas the same feedback delivered from unfamiliar or cold brands will not. We conducted a series of experiments to explore these predictions. All haptic effects were professionally integrated by a developer of haptic feedback technology.

Study 2 held brand familiarity constant, varied product category as a within-subjects variable, and manipulated brand warmth and haptics between-subjects. Study 3 (N=174) was a 2(Haptics: absent versus present) x 2(Brand Warmth: low versus high) x 2(Product Category: Insurance versus Retail) mixed-model design. Within a video reel, participants viewed two advertisements: one for a retailer and one for an insurance provider. In the high brand warmth condition, participants viewed advertisements for Target and Geico, and in the low brand warmth condition, participants viewed advertisements for Walmart and Allstate (all brands were selected based on pretest results). Afterwards, participants indicated their brand attitudes and those in the haptics-present conditions described how the haptic effects felt to them. A repeated-measures ANOVA revealed no significant main effect of haptics on brand attitude, but a significant interactive effect of haptics and brand warmth on brand attitude (F(1,170)=5.91, p<.02). Planned contrasts revealed that as expected, haptics had a positive effect on attitudes towards high-warmth brands (F(1,170)=3.83, p<.06) but not towards low-warmth brands. Notably, this pattern did not differ across product categories (F(1,170)=.06, p>.80). In the haptics-present condition, independent coders coded participants' description of how the haptics felt. We also found a significant effect of brand warmth on affective reactions to the haptic effects (F(1,72)=8.80, p<.01).

Study 3 examined the effect of haptic advertising on a consequential downstream variable: product choice. Participants (N=85) viewed one of two 30-second advertisements on mobile phones according to a 2 level (Haptics: absent versus present) between-subjects experimental design. The advertisement was for the chocolate brand Cadbury, which pre-test results revealed to be high in both familiarity and warmth. Afterwards, participants were offered a snack as a gift (either a Cadbury chocolate bar or an equivalently-sized cereal bar). Binary logistic regression results revealed a main effect of haptics on choice ($\chi2$=3.80, p=.05). Participants in the haptics-present condition were more likely to choose the chocolate than those in the haptics-absent condition (80% versus 59%, respectively).

This is the first academic research to explore the effects of haptic advertising on consumer responses. We investigate an intersection between haptic feedback and source characteristics allowing us to differentiate between the nature of the haptic sensation and its evaluative implications.

Paper #4: Hands off My Brand: Strong Self-Brand Connection and Psychological Threat

Nari Yoon, Indiana University, USA
Mansur Khamitov, Nanyang Technological University, Singapore

SESSION OVERVIEW

Consumers live in a digitalized environment in which they experience brands both on- and offline. Extensive research has studied self-brand connection offline, the extent to which brands overlap with the self, arguing that brands can be part of the self (Belk 1988) and showing that brands help consumers enact their social identities (Escalas and Bettman 2003). Further research is needed, however, to investigate how self-brand connection can form, how it can affect consumers in powerful ways, and what prospects it can open in an increasingly technological world.

This session explores different facets of self-brand connection. How can self-brand connection be reflected in our self and in our actions? How can perceptions of self-brand connection arise? How is self-brand connection further shaped in our technological environment? The four papers provide insight into these questions and more. In particular, they should foster a discussion about the interplay between self-brand connection and different forms of technology, such as facial recognition, selfies, apps and electronic word-of-mouth.

First, at a time when facial recognition technologies are ever more precise and pervasive, Sellier and Linares investigate if brands that consumers are loyal to can manifest in their faces. They find support for a *face-brand matching effect*, whereby a social perceiver can accurately match a person's perfume brand to their face, above chance level. This means that we can look like our brands.

Next, Hofstetter, Funk, and John show how a benign act such as taking a selfie with a brand can trigger self-brand connection and in turn impact brand preference. Eight studies provide evidence that consumers' brand preference is increased after taking a selfie with it, even if the brand is of lower utility than the alternative. Consumers' self-inferences account for this effect.

In a field study, and using a new app transmitting relationship metaphors and tracking real-time behavior, Lopez, Reimann, and Castaño explore the role of self-brand connection in the influence of relationship metaphors (e.g., complete a puzzle and breaking something) on brand relationships. They show that in the presence (absence) of a brand transgression, a negative (positive) metaphor will decrease (increase) the strength of a consumer's brand relationship.

Finally, contributing to expanding research on online reviews and electronic word-of-mouth, Yoon and Khamitov share an unexpected finding regarding highly self-brand connected consumers. Although one might expect such consumers to generate positive word-of-mouth, they show that highly self-brand connected consumers feel psychologically threatened when the brand is used by others. In turn, psychological threat leads participants who do not want to share the brand to engage in negative word-of-mouth.

Overall, these papers demonstrate how self-brand connection can unfold in rapid and fundamental ways, and particularly resonates in this age of technology. We believe this session can create a rich discussion, hopefully renewing interest for research on this topic. This session is likely to attract researchers working on a broad array of topics, brands, identity, the self, but also technology, face perception, embodied cognition, metaphors or word-of-mouth.

We Can Look Like Our Brands: The Manifestation of Adopted Brands in Facial Appearance

EXTENDED ABSTRACT

Considerable branding research suggests that brands can evoke general brand user human age and/or body type stereotypes (e.g., a brand user is a grandfather, Belk, Bahn, and Mayer 1982; Absolut Vodka is a hip 25-year old, Aaker 1997) and that possessions actively contribute to our identities (e.g., Belk 1988; Berger and Heath 2007; Escalas and Bettman 2003). We ask the reverse question: can consumers' faces evoke the brands they are loyal to? If the bulk of research on facial appearance has focused on how it influences social perceptions (e.g., Ballew and Todorov 2007), recent research shows that social perceptions can shape facial appearance. In particular, Zwebner, Sellier, Rosenfeld, Goldenberg, and Mayo (2017) demonstrated that given names produce a face-name matching effect, the finding that both a social perceiver and a computer can accurately match a person's given name to their face, above chance level. Zwebner et al. (2017) pinpoint the existence of shared face-name stereotypes (e.g., Gordon and Tanaka 2011; Tanaka 2001) to explain the effect. They suggest that we live up to these stereotypes to meet the social expectations of how someone with our given name should look.

The present research examines whether brands that consumers are loyal to can similarly manifest physically in our faces. In three studies, we find support for a *face-brand matching effect*, whereby a social perceiver can accurately match a person's perfume brand to their face, above chance level. We propose that brands that consumers actively link to their identities may similarly manifest in their faces. Unlike given names, brands are social tags that individuals choose to embrace. Considerable research suggests that consumer identity (both actual and ideal) markedly influences the connection to brands (e.g., Escalas and Bettman 2003; Levy 1959; Malär et al. 2011; McCracken 1986) and that brands actively help consumers build their self-identities (e.g., McCracken 1989; Escalas and Bettman 2019). It is the resulting interdependence between consumers and their brands that leads to the development of a proper relationship (e.g., Fournier 1998). It may be, then, that after enough time in a brand relationship, consumers begin to look like a stereotype of the brand user, if only to signal to others around them that they "carry" the social identities enacted by the brand.

The repeated finding of a face-brand matching effect means that some evocation of the perfume brand we have been loyal to for a long time may get tattooed in our faces. This means that a social tag may show up in our face more rapidly than was known to date. A second possibility is that people choose brands because they look like the brand user stereotype ex ante and self-select into brands that they can more easily live up to.

This research focuses on the case of perfume brands, as perfume users symbolically identify with their fragrances (Aaker 1997; Belk 1988), particularly in France, where our data was collected (Statista 2017). In each study, female participants saw the headshots of 10 to 30 targets that they did not know prior to the study. For each headshot, participants chose, out of two perfume brands, the one they thought was the target's actual perfume: one brand was the target's true perfume, the other was a filler. We consistently found evidence of a face-brand matching effect: Across all headshots in each study, participants picked the targets' true perfumes above chance level (here, 50%). We extensively calibrated the stimuli to minimize confounds such as brand familiarity, the perfume brands' release dates, ethnicity, socioeconomic factors, target age and any difference between the target and filler brands that we used.

In study 1, we photographed the faces of 10 Caucasian women who had been loyally wearing a well-known perfume for at least four and up to 15 years. In this study, the photographs were framed to include the face, the shoulders and the beginning of the chest. We paired their true perfumes with fillers that were perceived as equivalently well-known. All the perfumes were from the high-end perfume market and were overall in an equivalent price range. Results from a *t* test and a logistic mixed-effect regression that accounts for the random selection of faces showed that participants found the targets' true perfumes significantly more than random chance (50%).

In study 2, we further controlled for differences related to the two perfume options and for age. Headshots were also more tightly framed on the oval of the face. We developed two sets of 10 headshots, such that each headshot in set A had a counterpart in set B for whom the true perfume was the filler option of set A. With this design, an intrinsic preference or any other difference between the true perfume and the filler that might have caused an accurate face-brand matching in set A is controlled for by having set B. In particular, pooling the accuracy rates of the two corresponding faces in sets A and B effectively controls for any bias linked to the perfume options themselves. Headshots were also paired to minimize the age difference. Across the two sets of headshots, participants guessed the true perfumes above chance, controlling for socioeconomic, age and preference factors, as well as familiarity and release dates of the perfumes.

Study 3 provided an identical and conceptual replication of study 2 on a total of 30 headshots. Participants first saw the 20 headshots of study 2 in two different orders. They then saw 10 extra headshots. Across the two orders, the face-brand matching effect held once again.

In summary, our studies repeatedly support the existence of a face-brand matching effect, whereby social perceivers can accurately match a person's actual perfume brand to a headshot of their face, above chance level. Critically for marketing, a contribution of this research is to show that our faces *alone* can evoke a brand user stereotype. On a practical level, facial recognition systems may be able to push certain brands as a result of an estimated good match with targeted consumers' faces in the not so distant future.

From Sweetheart to Scapegoat: Brand Selfie-taking Shapes Consumer Behavior

EXTENDED ABSTRACT

Increasingly, consumers are taking self-photos and marketers, eager to capitalize on this trend, routinely encourage consumers to take "brand-selfies"—self-photos with a brand logo or product from that brand in tow. Despite the pervasiveness of selfie-taking, and marketers' attempts to promote brand selfie-taking in particular, little is known about the effect of this behavior on the selfie-takers themselves.

We suggest that consumers' compliance with such requests sparks a self-inferential process that leads the consumer to feel connected to the brand (e.g., "If I took the brand selfie, I must feel connected to this brand"). We base this on self-perception theory which holds that people have a tendency to infer *who they are* by looking to their behavior (Bem 1967; Chaiken and Baldwin 1981; Fazio, Zanna, and Cooper 1977). The theory has already been useful in explaining many consumer behavioral and social phenomena (e.g., Grewal et al. 2019; Summers, Smith, and Reczek 2016; Xu, Shen, and Wyer 2012). Building on prior findings, we propose that taking a self-photo together with a brand can trigger self-inferences that increase self-brand connection. Prior work in consumer behavior indicates that, in turn, feeling connected or attached to a brand can foster positive behaviors toward the given brand, for example increased purchase intention (Whan Park et al. 2010). However, based on attribution theory (Festinger 1957; Heider 1958) we further suggest that when a consumer encounters a less-than-stellar image of herself in a brand selfie, instead of revising her impression of her own attractiveness (downward)—a threatening undertaking because it could be damaging for the ego—she may instead use the brand as a *scapegoat*, projecting her personal dissatisfaction onto the brand.

Eight studies support this account. In a dataset of 283,140 user reviews from Yelp, study 1 documented a positive association between a reviewer's propensity to take a brand selfie and the star rating he gives the restaurant.

Studies 2a to 2c establish causality. Study 2a tests brand selfie taking vs taking no photo whatsoever on purchase intention and studies 2b and 2c test whether it is specifically *brand* selfie-taking, and not simply taking a selfie (without the brand), that affects brand choice. In all three studies we find a positive and significant effect of brand selfie-taking over the control on brand preference.

Study 3 tests the specificity of the effect and rules out the possibility that the effect is driven by the higher exposure to the brand in the brand selfie-condition. Therefore, in study 3, we added an additional control condition, in which participants were instructed to simply take a photo of the brand (without the self). Participants were assigned to one of three photo-taking tasks: selfie with the brand (brand selfie), a selfie without the brand (selfie) or a photo of the brand in front of a neutral background (brand photo). We still find, that purchase intention is higher for the brand selfie-takers relative to the mere selfie-takers and to the mere brand photo-takers. And that the effect is fully mediated by self-brand connection (indirect effect = .35, SE = .13, 95% CI [.10, .62]).

Study 4 was preregistered and designed in order to provide process evidence via serial mediation. Participants were instructed to take either a brand selfie or a selfie, and to then report their intention to purchase that brand. Critically however, in addition to assessing self-brand connection as we did in studies 2a, 2c and 3, we also assessed participants' propensity to look to their selfie-taking behavior to make self-inferences. In line with our conceptual framework we find that self-inferences and self-brand connection serially mediated

the relationship between brand selfie-taking and purchase intention (indirect effect = .402, BootSE = .111, 95% CI = [.197, .634]).

In study 5, instead of measuring self-inferences as in study 4, we sought to manipulate them, by varying participants' facial expressions in their selfies. Specifically, participants were instructed to either have a negative expression on their face (e.g., frown), a positive expression (e.g., smile), or, in a control condition, were given no instruction on how to appear. This manipulation was crossed with our standard manipulation of selfie type (brand selfie vs. selfie). We predicted and found an interaction such that the facial expression manipulation affects purchase intention only among those in the brand selfie condition, and not among those assigned to simply take a selfie (without the brand). Particularly, self-brand connection mediates the effect of brand selfies on purchase intention for those in the positive expression condition (conditioned indirect effect = .550, BootSE = .131, 95%CI = [.296, .801]) and for those in the control condition (conditioned indirect effect = .191, BootSE = .075, 95% CI = [.045, .336]) but not for those in the negative expression condition (conditioned indirect effect = -.168, BootSE = .111, 95% CI = [-.385, .053]; index of moderated mediation = .359 BootSE = .096, 95% CI = [.170, .549]).

Finally, study 6 tests whether satisfaction with the selfie moderates its effect on self-brand connection. Participants again took a brand selfie or a selfie, and in addition to assessing self-brand connection and purchase intention we also assessed participants' satisfaction with the selfie. We find that the effect of brand selfies on self-brand connection is moderated by the level of selfie satisfaction, i.e., the positive effect of brand selfie-taking on brand preference is attenuated by dissatisfaction with one's selfie (index of moderated mediation = .16, BootSE =.075, 95% CI = [.011, .305]).

By testing how a new form of user-generated content affects self-brand connection formation we contribute to the literature on brand relationship formation and to the literature on consumer photo-taking experiences, and branded user-generated content.

With respect to practice, our investigation offers guidance to marketers on when and why encouraging consumers to take brand selfies may augment or detract from attempts to foster a consumer-brand connection. Our findings imply that marketers may be over-concerned with the appearance of the brand in the photo, and under-concerned with helping the consumer to feel satisfied with her own appearance.

When and Why Metaphors Affect Consumer–Brand Relationships

EXTENDED ABSTRACT

In the interaction between brands and consumers, metaphors with relationship-related meanings often appear (e.g., in slogans, brand names, logos). Moreover, metaphors seem to be increasingly used by consumers themselves (Reimann, Nuñez, and Castaño 2017).

However, despite their common usage, it is unclear how exactly relationship-related metaphors affect consumer–brand relationships. Indeed, the extant literatures in psychology, linguistics, and consumer research are inconclusive regarding whether metaphors affect consumer–brand relationships. Classic views insist that metaphors represent the one universal way in which both language (Hawkes 1972; MacCormac 1985) and marketing (Bremer and Moonkyu 1997; Fournier 1998) work. However, recent investigations imply that the effectiveness of metaphors is uncertain (Landau, Meier, and Keefer 2010). We focus on *positive metaphors* associated with starting/maintaining a romantic relationship (i.e., the behavioral act

of "putting something together") and *negative metaphors* associated with ending a romantic relationship (i.e., the behavioral act of "breaking something"). We hypothesize that relationship metaphors' effect on consumer–brand relationships is contingent on the (non-)occurrence of a brand transgression, in that positive (negative) relationship metaphors affect the relationship only in the absence (presence) of a transgression. Furthermore, we hypothesize that the inclusion of a brand in the self mediates the relationship.

Study 1

We relied on archival data by scraping 1,000 reviews from the best-selling products on Amazon.com. Of these reviews, 418 were classified as containing metaphorical speech, in which consumers frequently utilized positive metaphors such as "[this brand] and I make a better couple than me and my boyfriend" and "I could marry [this brand]," as well as negative metaphors such "I am breaking up with [this brand]." Our data show that consumers actively and extensively use metaphors when referring to their brand-relationships.

Study 2

Study 2 employed a 3 (metaphor: positive, negative, absent) × 2 (brand transgression: present, absent) experimental design, with metaphor and brand transgression as between-subjects independent variables and brand relationship strength as dependent variable. A new brand called snapholio, a virtual portfolio app, was developed. After giving informed consent, 196 participants were randomly assigned to one of the six conditions. Participants in the brand transgression present conditions had to endure brand-transgressive events involving severe failures of the app. Participants in the negative metaphor condition were shown images of broken things and asked to write about times when they had broken something. Participants in the positive condition were asked to complete a series of simple puzzle tasks. Participants in the control condition were shown a neutral image and asked to write about their day (Larson and Billetera 2013; Marin, Reimann, and Castaño 2014). To measure brand relationship strength, we employed an established scale (Aaker et al. 2004), which was measured five times (T1-T5). Inclusion of brand in self was measured employing an established brand inclusion Venn diagram (Reimann et al. 2012). Data were submitted to a two-way repeated-measures ANOVA. Results revealed a significant interaction effect between metaphor and brand transgression on brand relationship strength, $F(2, 185) = 7.27$, $p < .01$, $\eta p2 = .073$. Direct effects of metaphor, $F(2, 185) = 20.70$, $p < .001$, $\eta p2 = .18$, and brand transgression, $F(1, 185) = 572.98$, $p < .001$, $\eta p2 = .76$ were also significant. At T1, all conditions were the same (baseline). At T2-T4, it was systematically found that the effect of relationship metaphors on consumer–brand relationships is contingent on the (non-)occurrence of a brand transgression, in that positive (negative) relationship metaphors affect the relationship only in the absence (presence) of a transgression (all p's of contrasts < .05). To test whether our hypothesized effects were short-lived or long-lasting, we collected additional measures (T5) four days after having the app was no longer required, revealing that metaphors have a lasting effect on consumers' brand relationships. Furthermore, in the presence of a brand transgression, only 13% of participants in the negative metaphor condition chose to share the brand (vs. 41%) p < .05. In the absence of a brand transgression, 42% of participants in the positive metaphor condition shared the brand (vs. 31%), p < .05. We also assessed whether or not participants had kept the app on their phones. In the presence of a brand transgression, only 9% of participants in the negative metaphor condition kept it (vs. 31%) p < .05. In the absence of a brand transgression, 73% of participants in the positive

metaphor condition kept it (vs. 47%) p < .05. Following mediation-testing guidelines by Hayes and Preacher (2014), we constructed three regression models that support our hypothesis that the inclusion of brand in self mediates the relationship.

Study 3

The goal of Study 3 was to test the effect of metaphors when consumers actively write (vs. are merely exposed to) metaphorical reviews. We employed the same measures as in Study 2. We presented participants with a positive or negative hypothetical brand interaction (Park and John 2018). Participants in the negative (positive) metaphor condition were instructed to write a metaphorical review of the brand using words like *break*, *breaking*, and *broken* (*match*, *matching*, and *together*). Data were submitted to an analysis of variance. Results revealed an interaction effect between metaphor and brand transgression on brand relationship strength, $F(1, 178) = 2.36$, $p < .09$, $\eta_p^2 = .026$. The direct effects of both metaphor, $F(1, 178) = 6.59$, $p < .01$, $\eta_p^2 = .071$, and brand transgression, $F(1, 178) = 34.68$, $p < .001$, $\eta_p^2 = .17$, were significant. The results suggest that the effect of metaphors on consumer–brand relationships holds regardless of the mode of exposure.

General discussion

In summary, across different methods (i.e., lab, longitudinal field experiment, archival study) and different dependent variables (i.e., psychometric measures, actual behaviors, written accounts from online reviews), the present research not only demonstrates that relationship metaphors depend on the (non-)occurrence of brand transgression in order to influence consumer–brand relationships but also provides insight into the mechanism underlying this effect. Our empirical investigations illustrate that the inclusion of the brand in the consumers' self represents a key explanation for the role of metaphors in consumer–brand relationships.

Hands off My Brand: Strong Self-Brand Connection and Psychological Threat

EXTENDED ABSTRACT

The dominant paradigm in the consumer-brand relationships research stream suggests that when consumers love the brand, they will do everything in their power to influence others to consider or buy the brand and happily spread positive word-of-mouth (WOM) about it (Batra et al. 2012; Fournier 1998; Park et al. 2010). The current work proposes that this may not always be the case. Specifically, we pose that when some consumers exhibit elevated self-brand connection (SBC), they would instead be more likely to willingly engage in negative WOM and feel unhappy about others trying the brand. We theorize that this "brand for me and not for you" effect should be driven by perceived psychological threat generated by the prospect of other consumers using the 'coveted' brand. That is, building on the self-expansion theoretical account (Aron et al. 1992; Reimann and Aron 2009), we anticipate that when highly self-brand connected consumers engage in self-expansion of their self-concept, once they deeply incorporate the brand into the sense of self, the prospect of other consumers trying the brand should result in a sense of psychological threat. This should in turn make such consumers more willing to engage in negative WOM, make them feel less happy, and prefer to selfishly keep the brand for themselves.

Experiment 1 assessed consumers' reactions to others using the brand which they got primed to perceive high connection with. Online participants (N=206) were asked to imagine that they have been using Rondo, a diary notebook brand. In high SBC condition, Rondo was framed very special to them personally because they have been using it for a long time since they received it from their grandparents, and because it fits their personal values very well. In control condition, the scenario did not reference SBC but mentioned they like the brand very much. We measured participants' psychological threat when Rondo is used by others. As predicted, participants who have a high SBC (vs. control) felt their bond with the brand is threatened (M_{sbc}=2.71 vs. $M_{control}$=2.15, p=.042) and their sense of identity was endangered (M_{sbc}=2.79 vs. $M_{control}$=2.06, p=.008). Importantly, there was no effect of uniqueness seeking (p=.18), ruling out the alternative explanation that people feel threatened because usage by others may take away their uniqueness.

Experiment 2 extended experiment 1 to real brands and examined whether consumers' perceived psychological threat translates into negative behavioral intentions. Students (N=358) wrote either about a brand which they like so much that they do not want to share with others (not share) or a brand they like so much (control). In addition to perceived psychological threat items (4 items, α=.903), we measured consumers' intention to say something negative about the brand just to make sure others do not try it. Participants in the not share condition exhibited greater psychological threat (M=2.25) compared to the control condition respondents (M=1.56; p<.001). Additionally, participants showed greater intention to spread negative WOM when they recalled the brand they did not want to share ($M_{not\ share}$=1.82 vs. $M_{control}$=1.48, p=.008). Mediation results revealed participants experienced greater psychological threat from sharing the brand which they like so much that they do not want to share versus the brand they simply like, which in turn led to greater negative WOM intentions (B=.36; 95% CI: .22, .52).

Experiment 3 extended our findings beyond physical possessions and examined feelings of happiness associated with sharing. Online participants (N=204) read a scenario about a café named Janko's that they either perceive high connection with or they enjoy visiting. Strong SBC consumers were marginally less likely to feel happy if others visit their café (M=5.88) compared to participants in the "enjoy visiting the café" condition (M=6.22; p=.055). Interestingly, participants felt less happy if their acquaintances (M_{sbc}=5.66 vs. $M_{control}$=5.99, p=.074) or random strangers (M_{sbc}=4.95 vs. $M_{control}$=5.49, p=.020) started going to Janko's, but it did not bother them if their family (p=.83) or friends (p=.74) started going there. This suggests interpersonal proximity plays a potential role.

We contribute to the literature on consumer-brand relationships (Fournier 1998; Escalas 2004; Khamitov et al. 2019). While the predominant paradigm within this research stream suggests that consumers who have a strong brand relationship would go to great lengths to support their favored brands and thus should be encouraged to become public brand advocates, our findings imply that high SBC individuals are likely reluctant to spread positive WOM to the extent that the prospect of other consumers laying hands on their brand comes across as threatening. While the extant literature tends to view high SBC levels as an invaluable asset (Escalas 2004; Escalas and Bettman 2003, 2005), the present research underscores an instance where typical benefits of high SBC are unlikely to accrue and instead may reverse. Last but not the least, our work adds a nuance to the brand community research stream (McAlexander et al. 2002; Muniz and O'Guinn 2001) by providing a conceptual and empirical account of what can be construed as the opposite notion of brand community where instead of a shared brand-enabled bond consumers appear to harbor a rather selfish and egoistic SBC they want to keep for themselves.

Prior WOM research established that when consumers feel favorably toward a product or a service, a number of them exhibit a

tendency to leave positive reviews, encourage their friends and acquaintances to give it a try, and put in a good word (Berger 2014; Lovett et al. 2013; Moore and Lafreniere 2020). Mapping our results on this literature, the findings nuance some of the WOM work by providing a type of boundary condition wherein instead of engaging in increased WOM, consumers with strongly favorable product and service opinions are actually engaging in more negative WOM. Lastly, we contribute to the related consumer research on secrecy (Rodas and Roedder John 2020; Thomas and Jewell 2019) that has largely focused on the desire to maintain secrecy before, during, or after consumption. To this end, our findings reinforce the value and importance of studying phenomena wherein consumers would rather keep their consumption objects private and for themselves.

Paper #4: Support or Oppose? The Effects of Political Attitude Framing on Sharing Behavior

    Rhia Catapano, University of Toronto, Canada
    Zakary Tormala, Stanford University, USA

SESSION OVERVIEW

More and more, firms are taking public stances on political and social issues. In the past few years, Nike created an ad campaign centered around Colin Kaepernick, Dick's Sporting Goods and Delta publicly severed ties with the NRA, and dozens of CEOs from major companies made public statements opposing the 2017 immigration ban. Although firms have always been involved in politics, it has traditionally been behind the scenes (Lawton McGuire, and Rajwani 2013), rather than in public. Moreover, there is little precedent for firms taking stances on political and social issues that are not directly relevant to the firm's value proposition. For this reason, little is known about how taking a stance impacts consumer behavior. Do firms benefit from taking public political stances? What happens when firms do choose to take a stance? And, when they do choose to take a stance, how can they maximize the impact on consumers?

Our session sheds light on these questions. Paper 1 (Silver and Alex Shaw) explores why it may be beneficial for firms to take political stances, even at the risk of alienating some consumers. They find that despite its intuitive appeal, remaining neutral can harm trust, even relative to outright opposition. This effect occurs because consumers interpret neutrality as concealed opposition and therefore as a dishonest impression management tactic.

The next two papers explore what happens when companies do take a stance. Paper 2 (Boegershausen and Watson) focuses on what happens to reviews after a brand takes a political stance. They find that the resulting political review storms include reviews from supporters and opposers, leading to a set of reviews that provide very little information diagnostic of product quality. The authors investigate the downstream consequences for the brand involved, exploring the differential effects on liberals and conservatives. Paper 3 (Shepherd, Chartrand, Fitzsimons, and Kay) focuses on the impact of political ideology on how consumers respond to advertising that implicitly represents a political stance. Specifically, they find that conservative (liberal) ideology is associated with more negative (positive) attitudes and behavioral intentions when ads feature ethnic diversity/non-White actors. Symbolic threat (seeing the ethnic group as a threat to culture/values), product status, and actor-product fit mediate this effect.

Finally, Paper 4 (Catapano and Tormala) explores how companies should frame their stances in order to maximize impact. They find that consumers believe that expressing attitudes in terms of support, rather than opposition, is more expressive of their values, and will lead to more liking from others. Thus, when brands talk about the policies they support, rather than policies they oppose, consumers are more likely to propagate these messages through sharing.

Together, these papers provide multiple perspectives and enhance our understanding of when, why, and how, companies should weigh in on political issues in order to maximize benefits to their brand. Whereas limited research to date has explored the emerging trend of companies weighing in on political issues, the work presented in this session begins to address this gap, enhancing our understanding of consumers in a changing world.

Political Neutrality Aversion: When and Why 'Staying Out of It' Backfires

EXTENDED ABSTRACT

Business leaders, celebrities, and politicians wield significant influence over many facets of life, from the laws that pass to the products and ideas that spread. However, public figures derive much of their power from public opinion and consumer support. How do consumers decide whom to trust, buy from, or vote for?

One important consideration is a public figure's commitment to social causes. Indeed, consumers increasingly care where public figures and the organizations they represent stand on hot-button issues like abortion, climate change, and immigration, and they will boycott, condemn, and punish actors who take positions they deem unacceptable (Haidt 2012; Skikta 2010). Perhaps as a result, public figures frequently choose to remain neutral when asked to weigh in on such issues, citing the merits of each side or expressing a preference not to get involved at all (Shaw et al. 2017).

This paper explores how consumers react to political neutrality. We propose that despite its intuitive appeal, remaining neutral often resembles a 'false signal' (Jordan and Bloom 2017), which can undermine trust and erode support.

When public figures express political neutrality, consumers frequently have information about their intended audience (e.g., viewers of a particular media outlet, constituents from a particular political party). We hypothesize that this audience information can shift how neutrality is interpreted in predictable ways. Specifically, we predict that remaining neutral in front of a more liberal audience will signal underlying conservative convictions and vice versa.

Moreover, to the extent that expressing neutrality over a divisive issue seems like a form of strategic non-disclosure (John, Barasz, and Norton 2016), neutral public figures may seem insincere, dishonest, and untrustworthy. Indeed, remaining neutral (and signaling concealed opposition) may harm trust even relative to opposing a consumers' viewpoint directly, a phenomenon we term *political neutrality aversion*.

Study 1 (n=301) sought to demonstrate that audience information predictably shapes how expressions of neutrality are interpreted. Participants read one of three stimulus-sampled vignettes which each described a public figure expressing neutrality in a public forum. Between-subjects, we manipulated whether the actor was speaking to

a predominantly liberal or a predominantly conservative audience. Participants were then asked to make attributions about the neutral actor's personal beliefs on scales from -3 (holds strongly liberal beliefs) to +3 (holds strongly conservative beliefs). As predicted, we found a main effect of audience (F(1,295)=111.14, p<.001), such that participants believed an identical expression of neutrality to be concealing conservative beliefs when addressing a liberal audience, and liberal beliefs when addressing a conservative audience. This effect held separately in each vignette-condition (ps<.001).

Studies 2a-b (n=187, n=300) replicated the belief inference effects from Study 1 with real press video clips of public figures (A member of the Backstreet Boys, the owner of the Kansas City Chiefs) expressing neutrality in live answers to reporters' questions about divisive political issues (support for President Trump, NFL players kneeling during the national anthem). We again manipulated the actor's audience by describing the reporter in each clip as being from either a conservative or a liberal news outlet. Once again, participants saw neutrality as signaling conservative beliefs when addressing a liberal audience and vice versa (2a: t(185)=1.91, p=.058; 2b: t(298)=6.15, p<.001). Moreover, participants who agreed with the speaker's audience (and thus inferred that the neutral actor tacitly opposed their viewpoint) reported that they would find him *more* trustworthy if he had *explicitly* opposed their viewpoint instead of remaining neutral (3-item trust scale, αs>.75: -3: Much less trustworthy to +3: Much more trustworthy; 2a: t(96)=2.67, p=.009; 2b: t(146)=1.92, p=.057; vs. scale midpoint).

Study 3 (pre-registered, n=541) sought to demonstrate that neutrality harms trust, but only when it resembles strategic concealment, and not when it signals sincere middle-ground beliefs. Participants read a scenario in which a prominent businesswoman is asked to weigh in on immigration policy at a press conference. In all conditions, we described the businesswoman's audience as holding the same views on the issue as the participant. This time, we manipulated whether the businesswoman remains neutral (*public neutrality condition*) or sides against her audience (and the participant) outright (*opposition condition*). We also included a third condition in which the businesswoman remains neutral in public at the press conference, but later expresses a neutral viewpoint in private to her spouse (*private neutrality condition*). As predicted, public neutrality signaled concealed opposition, but private neutrality did not (F(2, 522)=114.44, p<.001). In turn, public neutrality was seen as less trustworthy than both outright opposition (t(347)=12.09, p<.001) and private neutrality (t(347)=10.61, p<.001).

Study 4 (pre-registered, n=600) aimed to examine neutrality's effects on trust in an incentive-compatible economic game. Participants first indicated their views about gun control in a forced binary choice and shared these beliefs with a partner. We manipulated whether the partner (a confederate) then signaled back agreement, opposition, or neutrality (a preference not to take sides). Finally, participants rated attitudinal trust (3-item scale, α>.9) and played an incentivized prisoner's dilemma game. Participants judged neutrality to be substantially less trustworthy than outright opposition (t(396)=6.98, p<.001). Additionally, although participants were significantly more likely to cooperate when their partner signaled ideological agreement (90% cooperation), they were no more likely to cooperate with a neutral partner (70%) than with one who opposed them outright (73%; Neutrality vs. Opposition: p>.5).

Finally, Study 5 (n=190) investigated whether participants would intuit neutrality's costs when asked to weigh in on a political issue themselves. They largely did not. Participants in a business school's behavioral lab were told to imagine that they were running for a leadership position in an organization and that they disagreed

with the majority of their peers on a divisive political issue. When asked which approach would effectively win trust and support from peers, the majority chose 'remain neutral' (66.8%), more than 'side-against' (24.2%) and 'side-with' combined (9.0%; p<.001).

Together, these studies illuminate the surprising costs of remaining neutral, and they reveal an attribution process which incentivizes side-taking and may ultimately instigate polarization. Furthermore, actors who do choose to remain neutral on important social issues may be inadvertently mismanaging their reputations.

Chasing Political Review Storms

EXTENDED ABSTRACT

Today, brands who take a political stance may receive reviews from supporters and opposers, resulting in a political review storm that provides the consumer very little information diagnostic of product quality. For example, a bakery in Colorado refused to bake a wedding cake for a same-sex couple resulting in a flood of 1-star reviews from liberals and 5-star reviews from conservatives (Gajanan 2018). Utilizing the accessibility-diagnosticity framework (Feldman and Lynch 1988) and moral foundations theory (Graham, Haidt, and Nosek 2009), we propose that liberals and conservatives will differentially respond to political review storms. While reviews are generally helpful in forming product quality inferences, like other attributes (Rao and Monroe 1989), we propose that product quality is not the only attribute that matters amidst a political review storm. Our theorizing suggests that liberals will attempt to utilize both product quality information and a brand's political ideology to form their decisions, whereas conservatives will rely on the brand's political ideology. To reconcile their need for ingroup loyalty, the review voice (i.e., is it written by a liberal or conservative) will lead conservatives to discount the credibility of reviews written by liberals. On the other hand, liberals will recognize the bias in both review voices as they sift through the reviews for diagnostic quality information. Across three studies, we begin by demonstrating the effect of political review storms on perceived review credibility, then ultimately the consequence of this on brand intentions.

Study 1 (N = 327) employed a 2(review voice: liberal, conservative) x 2(political ideology: liberal, conservative), between-subjects design. Participants were randomly assigned to the reviews factor and we measured their ideology with the item "with which political party do you most closely identify?". Participants were asked to view the information for a bakery on Yelp. The business was framed as being conservative and this was revealed through the voice manipulation. Review voice was manipulated with reviews that mentioned claims like "can't believe they support a conservative agenda [1-star]" (liberal voice) or "proud to have a local business fight back against corruptive liberal ideologies [5-star]" (conservative voice). When it came to the perceived review credibility, a 2x2 ANOVA yielded a significant interaction (F(1,323) = 28.709; p < .001), qualified by main effects of the review voice (F(1,323) = 11.518; p = .001) and political ideology (F(1,323) = 5.968; p = .015). For a conservative voice (e.g., 5-star reviews), conservatives found the reviews to be much more credible than liberals ($M_{conservatives}$ = 5.22, $M_{liberals}$ = 4.11; F(1,323) = 32.306; p < .001; partial η^2 = .162). Whereas for a liberal voice (e.g., 1-star reviews), liberals found the reviews to be more credible than conservatives ($M_{conservatives}$ = 3.97, $M_{liberals}$ = 4.39; F(1,323) = 4.016; p = .046; partial η^2 = .025). Importantly, we see a much smaller effect for liberal voices relative to conservative voices, suggesting that ideology impacts perceptions of credibility differentially.

In study 2 (N = 621), we sought to generalize our findings and determine downstream consequences of these political review storms. Study 1 positioned the brand as "promoting Conservative ideologies" or "opposing Liberal ideologies". However, we realize that these two positions are not equal (Catapano and Tormala, *working paper*). To avoid this potential confound, study 2's voice manipulation disclosed that the business refused to seat a member of the Republican [Democratic] congress. Thus, the political review voice was always negative (i.e., 1-star). We also included a control condition where none of the reviews had a political voice. Political ideology was assessed as in the prior study. We replicated the previous patterns on review credibility as we again found a significant interaction between voice and political ideology (F(2,616) = 6.60; p < .01), which qualified the main effect of voice (F(2,616) = 60.45; p < .001). The main effect of political ideology was not significant (F(1,616) = 2.47; p > .11). For conservative reviews, conservatives perceived the review significantly more credible ($M_{conservatives}$ = 4.65) than liberals ($M_{liberals}$ = 3.97; t(207) = 3.75; p < .001). In contrast, there were no significant difference between liberals and conservatives for liberal reviews ($M_{conservatives}$ = 4.23, $M_{liberals}$ = 4.33; t(206) = .50; p > .62) or non-politicized control reviews ($M_{conservatives}$ = 5.44, $M_{liberals}$ = 5.54; t(203) = .68; p > .49).

Lastly, study 3 employed a 2x2x2 design where we first measured political ideology (conservative or liberal), then manipulated overall quality (2- or 4-star average rating) and (review voice: conservative, liberal). We matched participants with a business that aligned with their ideology, then randomly assigned them to a review voice condition that supported their position (5-star) or opposed their position (1-star). A 2x2x2 ANOVA on brand intentions yielded a significant 3-way interaction (F(1,495) = 4.436; p = .036). Due to space constraints, we will not fully detail the patterns here, but we will summarize them by saying that when the rating was consistent with the reviews (e.g., 2-star business with 1-star reviews), liberals indicated directionally higher intentions than conservatives. However, when there was inconsistency (e.g., 2-star business with 5-star reviews), conservatives indicated greater intentions than liberals, suggesting that they will support a business with a Conservative agenda, regardless of brand quality.

Taken together, these studies demonstrate that liberals and conservatives are both influenced by their political identity; however, liberals will also use quality as diagnostic information when determining whether to engage with a brand. Conservatives, on the other hand, appear more concerned with ingroup loyalty than quality concerns, whereas Liberals place less concern on ingroup loyalty. More research is needed to determine if this stems from some relationship to perceived review credibility or reviewer intentions or if it arises from a tribe mentality given the perceptions of the political climate currently. This work is currently limited with its focus on the U.S. population, but we hope to expand the investigation to include other countries to disentangle these potential pathways.

The Changing Face of America: When Majority Group Consumers Prefer vs. Are Threatened By Ethnic Diversity in Advertising

EXTENDED ABSTRACT

By reflecting the diverse composition of American society, advertising has the potential to say something about society and culture (Pollay 1986). However, diversity in ads may take on political meanings given the recently stoked culture wars regarding ethnicity, immigration, and the call to "make America great again". At the same time, companies feel pressure to take a stance on social issues (Global Strategy Group 2012).

Drawing from work on ideology (Jost, Glaser, Kruglanski, and Sulloway 2003; Jost, Nosek, and Gosling 2008) and intergroup attitudes (Stephan and Stephan 2000), we posit that conservative ideology will be associated with more negative attitudes toward diversity in advertising, whereas liberals will actually prefer ads with (vs. without) ethnic diversity/non-White actors. We also test relevant moderators of this effect and offer process evidence, including the role of symbolic threat (i.e., seeing immigrants as a threat to one's culture), product status, and the product's cultural origins. We argue that our results are not explained by felt targetedness (Aaker, Brumbaugh, and Grier 2000; Grier and Brumbaugh 1999), or similarity to the target (Aaker et al. 2000).

In Study 1 (n = 170, White, US undergraduates), participants were asked to rate their attitudes toward a series of ads that either featured White or Non-White (Sikh or Muslim) actors. Participants completed a measure of symbolic threat (e.g., extent to which immigrants undermine or enhance core American values, American identity, etc.). After a delay, participants also completed a measure of support for the current sociopolitical status quo (system confidence; Kay and Jost 2003) as a measure of conservative ideology (Jost et al., 2003). The two-way interaction was significant; those higher in system confidence rated the non-White ads more negatively than the White ads, and the opposite was found for those low in system confidence. Higher system confidence scores were also associated with lower non-White ad evaluations. System confidence also predicted symbolic threat, and symbolic threat mediated the effect of system confidence on ad attitudes for the ads with non-White actors, but not when the ads had White actors (moderated mediation effect was significant).

Study 2 replicated the interactive effect of ad content and ideology on ad attitudes, but with ads for businesses and services ostensibly available around campus. Ads either featured all White actors or a diverse range of ethnicities (including White). Ideology was measured using the social dominance orientation (SDO) scale (Ho et al. 2015), which is a conservative ideology (Ho et al., 2015; Jost et al. 2003) where hierarchical differences and inequality between groups is seen as desirable. Those high (low) in SDO rated the diversity ads more negatively (positively) than the no-diversity ads. They also reported less likelihood of visiting the business.

To further test the role of symbolic threat in the relationship between ideology and attitudes toward diversity in ads, Study 3 (n = 395, White US residents) manipulated the description of an ostensibly real ethnic group (Camarians), such that their culture and values were described as either similar or dissimilar to American culture and values (adapted from Maio et al. 1994, Stephan et al. 2005). Participants viewed and rated three ads said to feature Camarians. The interaction between the symbolic threat manipulation and ideology (system confidence: low vs. high) was significant. Those high (vs. low) in system confidence reported more negative attitudes toward the ads when symbolic threat was high, but this effect was eliminated and ad attitude ratings were significantly higher when symbolic threat was low.

Conservative ideology is also associated with valuing vertical differentiation and status (Kim, Park, and Dubois 2018; Ordabayeva and Fernandes 2018). Given this, and given the relationship between conservative ideology and attitudes toward immigration and various ethnic groups (Esses, Jackson, and Armstrong 1998; Ho et al. 2015; Jost et al. 2003), we posited that conservatives would see the product in the non-White ad condition as lower status, which would then predict negative ad attitudes. Study 4 supported this. Partici-

pants (n = 243, White American residents) saw an ad for sweet tea that featured a White family or Sikh family. Participants rated ad attitudes, indicated their WTP ($0-$5), and rated the status of the product. Finally, they completed the SDO scale. The ad content X ideology interaction was significant. Those higher in SDO responded more negatively to the non-White ad (vs. White ad), whereas those low in SDO showed the reverse effect. Similar effects were observed on WTP and perceived status. Moderated mediation analysis found that those higher in SDO saw the product as lower in status in the non-White (vs. White) ad condition, which predicted more negative ad attitudes and decreased WTP.

Finally, we reasoned that if conservative ideology is associated with seeing various ethnic groups as a symbolic threat and maintaining boundaries between groups, then it follows that those higher in conservative ideology will particularly dislike ethnic diversity in ads for products that are associated with American culture compared to those that are not. Study 6 (n = 362 White American residents) tested this. Participants saw the same ad with a Sikh family from Study 4, except the ad was either for Southern Breeze sweet tea (American brand and product), or Southern Breeze bael fruit tea (American brand, Indian product). Actor-product fit (Pounders and Mabry-Flynn 2016) was also measured (e.g., "choosing this family for this product is appropriate"). High SDO was associated with seeing less actor-product fit particularly for the domestic product (vs. foreign product), and also liking the ad for the domestic product less (moderated mediation effect was significant). Thus, despite the foreign-origin product being unfamiliar to participants and not being targeted by the ad, the high SDO participants liked the ad for the foreign-origin product more. Although counterintuitive, this is consistent with conservative ideology as a hierarchy- and status quo-maintaining ideology.

Even though the US has long been a diverse society, ethnic diversity in ads is not ideologically neutral. We provide evidence for the role of ideology in shaping attitudes toward culturally diverse ads. Moreover, we find evidence for theoretically-relevant moderators and mediators that also have marketing implications.

Support or Oppose? The Effects of Attitude Framing on Sharing Behavior

EXTENDED ABSTRACT

What factors affect whether consumers share their views with others? We identify a novel determinant of whether consumers share—*attitude framing*, defined as whether consumers think of their own attitude in terms of what they support or what they oppose. Attitude framing is distinct from attitude valence, as the same attitude can be framed in terms of support (e.g., I support that this policy is bad) or opposition (e.g., I oppose that this policy is good).

Six preregistered experiments provide evidence for an attitude-framing effect, whereby consumers are more likely to share, or express, attitudes framed in terms of positions they support rather than positions they oppose. This effect occurs due to two interaction goals: value expression and impression management. In our final study, we show how brands can leverage this psychological tendency to encourage sharing on social media.

Study 1 examined the basic relationship between attitude framing and sharing across a variety of attitudes. We asked participants their attitudes toward seven statements regarding companies and company policies (e.g., "Facebook has had a negative effect on America), varying the valence of the statements in order to ensure that "support" was not consistently associated positive attitudes. For each statement, participants reported their attitudes towards the

statement (*Strongly Oppose* (0) and *Strongly Support* (100)), and their intentions to share their attitudes on a 3-item index (e.g., "How likely would you be to share your views on this topic with friends or family who disagree with you on this issue?"). This index was used across studies. Across topics, participants were more likely to share their views when they considered statements they supported rather than statements they opposed, $t(2172.02) = 17.00$, $p < .001$. This effect was consistent across statements, and we found no interaction between attitude framing and attitude valence ($p = .96$).

Study 2 aimed to provide causal evidence for the attitude-framing effect in a more controlled setting. Participants in the lab were assigned to either a support-framing or oppose-framing condition. We began by asking participants to select which statement best characterized their attitude towards gun control: "More gun control would be (helpful/harmful)." In the support-framing condition, participants were asked about the statement they supported (the one they selected), whereas in the oppose-framing condition, participants were asked about the statement they opposed (the one they did not select). Thus, in both conditions, participants were asked about an attitude position that was consistent with their own view. For example, a participant who indicated that more gun control would be beneficial would be randomly assigned to answer questions about either their support for the beneficial statement or their opposition to the harmful statement. Then, participants were then asked how likely they were to share their attitudes on the statement with another participant currently completing the study. Participants reported greater sharing intentions in the support-framing than in the oppose-framing condition, $t(206) = 2.13$, $p = .033$.

Study 3 aimed to provide evidence for the proposed value expression and impression management mechanisms. We manipulated attitude-framing as described in Study 2. After indicating their likelihood of sharing, participants were asked to imagine that they had decided to share their view, and reported their prediction for the message recipient's impression of them (2 items; e.g., "How positively do you think the message recipient would view you as a person") and how value expressive sharing this position would be (2 items, e.g., "How representative of your values is your attitude [in favor of/against] this statement?"). Participants reported greater sharing intentions when the issue was framed in terms that they supported relative to terms that they opposed, $t(823) = 4.68$, $p < .001$. In addition, support framing led to greater value expressiveness, $Z = 9.40$, $p < .001$, which in turn predicted greater sharing intentions, $Z = 4.69$, $p < .001$; *indirect effect* = .12, $Z = 4.28$, $p < .001$. Support framing also led to higher positive impression ratings, $Z = 2.53$, $p = .01$, which predicted greater sharing intentions, $Z = 7.64$, $p < .001$; indirect effect = .05, $Z = 2.35$, $p = .02$.

In Study 4, we replicated this effect, finding that the effect holds regardless of whether the target of sharing agrees or disagrees on a given topic. In Study 5, we replicated this effect with another topic, and showed that the effect is attenuated when individuals do not want to be liked.

How can companies leverage this knowledge? More and more, companies are weighing in on social issues through their advertising campaigns and social media, and consumers are deciding whether to share and propagate these messages. The current research suggests that if companies want consumers to share their messages on social media, it may be more beneficial to talk about what a company supports, rather than what they oppose – even when a tweet relays the same underlying message. To test this proposition, in Study 6 we asked participants their attitudes towards immigration ("Immigration policies should be implemented that decrease/increase the number of people coming into the US"), and used their answers to assign

participants to support- or oppose- framed messages, as in previous studies. Then participants saw a Tweet from Uber consistent with their own attitude, framed in terms of either what they supported (e.g., "We support policies that increase immigration") or what they opposed (e.g., "We oppose policies that decrease immigration."), modelled from corporate tweets after the 2017 immigration ban. We then asked participants how likely they would be to retweet, and asked them to give us their email address to contact them about retweeting tweets like this one. Support framing led to greater sharing intentions than oppose framing, $t(975) = 2.89$, p = .004. Participants who viewed support-framed attitudes were also more likely to agree to be contacted (27.5%) than participants who viewed oppose-framed attitudes (17.5%), $x2(2) = 13.92$, $p < .001$. Thus, the current research suggests that support-framing allows companies to best maximize their return on their investment for these sorts of decisions and tweets.

SESSION OVERVIEW

Consumers often make choices with a high degree of uncertainty regarding the outcomes. For example, the decision to purchase an unfamiliar product could ultimately increase or decrease utility, and consumers typically do not know beforehand what that outcome might be. Similarly, consumers spend trillions of dollars each year on stocks, bonds, gambles, and other bets, which suggests that predicting what might occur in the future is a common – and potentially lucrative – aspect of consumers' lives.

When it comes to understanding consumers' predictions in these various contexts, two key questions stand out: what predictions do they actually make, and how accurate is that choice? The four papers in this session explore how different aspects of the prediction environment play an important role in consumers' actual choices regarding future events and the accuracy of such predictions.

The first two papers examine what factors affect consumers' predictions, and specifically, their willingness to choose more "risky" options. The first paper explores when people are more likely to choose the "risky" (i.e., less likely) outcome relative to the "safe" (i.e., more likely) outcome across a sequence of predictions; for example, when predicting outcomes in a sports tournament, when might consumers pick the "underdog" to win over the "favorite?" Five studies show that people more often predict that unlikely outcomes will occur later (versus earlier) in the series of predictions of independent events because they believe that the unlikely outcome must occur at some point even within a small sample. The second paper investigates how the potential to make forecasting errors, like choosing the wrong team to win by X points, affects willingness to select riskier gambles. Four studies show that because people have a diminishing sensitivity to this type of error, they are more likely to choose the riskier gamble or outcome when the gamble involves prediction error in addition to monetary consequences.

The last two papers examine what factors affect consumers' accuracy when making predictions of uncertain events. The third paper investigates what conditions lead people to follow advice for predicting future events. Seven incentive-compatible studies show that people are (significantly or directionally) more likely to follow advice that includes a confidence interval around the specific best guess. Thus, assuming that advisors give good advice, including confidence intervals when giving advice can improve the accuracy of consumers' predictions. Finally, the fourth paper focuses on the accuracy of more personal, financial predictions, such as consumers' expectations of their future expenses and income. Nine studies featuring unique field data (e.g., budget forecasts made with a personal finance app, longitudinal spending reports from credit union members), find that people rely on their "most common" past experience when making predictions, leading them to under-predict the magnitude of their upcoming expenses, but over-predict the magnitude of their earnings.

Taken together, these papers shed light on how consumers make predictions, and when such predictions may be suboptimal. Given the pervasiveness of uncertainty about the future, understanding consumer predictions and their accuracy is critical for consumers and marketers alike.

How Order Affects People's Choices in Sequences of Independent Predictions

EXTENDED ABSTRACT

How does the order in which consumers make predictions about independent events (e.g., gambles) affect those predictions? We find in five studies (four pre-registered) that consumers more often choose that an unlikely outcome will occur *later* (vs. earlier) in a sequence of predictions; that is, consumers more often choose the "underdog" over the "favorite" for their second, third, and/or fourth prediction (versus first).

We propose that when consumers predict the outcomes of multiple events, they make their first prediction without necessarily considering the other events for which they will make predictions, and thus rationally tend to predict that the more likely outcome will occur. However, because people often falsely perceive independent events as related to each other (i.e., the belief in the law of small numbers: Tversky and Kahneman 1971), they believe that the unlikely outcome is bound to happen at some point. This belief disproportionately affects predictions later in the sequence, making consumers more likely to predict that the unlikely outcome will occur later (versus earlier).

By demonstrating that the (arbitrary) order in which consumers make predictions affects their choices, this research contributes to work on the representativeness heuristic (Kahneman and Tversky 1972), and specifically its effects on sequential bets (gambler's fallacy: Croson and Sundali 2005) and predictions of multiple outcomes made simultaneously (probability matching: Gal and Baron 1996). We are the first to show that the representativeness heuristic applies to multiple sequential predictions for which the outcomes are unknown (as opposed to a prediction following a known sequence of outcomes, such as predicting "heads" after seeing several coin flip outcomes). Additionally, our findings contribute to the broad literature on variety seeking. The fact that consumers in our studies vary

their *predictions* over time suggests that people seek variety even in contexts in which satiation, preference uncertainty, and social pressure (e.g., Kahn 1995) are unlikely to play a role.

In Study 1 (N = 402), we show the predicted effect "within subject:" consumers are more likely to choose the underdog later in a sequence of predictions (compared to their first prediction). Participants predicted the outcomes of three randomly ordered hypothetical basketball games in which one team slightly outranked the other (e.g., Team A ranked 12th vs. Team B ranked 15th). A repeated measures logit model revealed that more participants predicted that the underdog would win in the second (38%) and third games (40%) they made predictions about (vs. the first: 31%; $ps < .003$).

Study 2 (N = 601) replicated this effect in a different paradigm with real incentive-compatible choices (making predictions about upcoming Rugby World Cup games). Participants predicted the outcomes of one close game (Wales, 5th vs. Australia, 6th) and two other games with clear favorites (e.g., Ireland, 1st vs. Russia, 20th). We randomized the order such that participants predicted the outcome of the close game either first or last. We also manipulated whether participants were incentivized to make correct predictions or not: half of the participants knew they would receive a bonus if they made a correct prediction, and the other half did not receive any bonuses. A logit model revealed a main effect of order condition, such that more participants chose Australia (i.e., the underdog) when they predicted that game's outcome last (59%) versus first (39%; $p < .001$). Separate chi-square analyses showed that the effect held both with and without incentives ($ps < .01$; ANOVA interaction $p > .40$). An additional study using four real NCAA "March Madness" tournament basketball games replicated this order effect (Study 3, N = 199: *first* = 31% vs. *last* = 49%, $p = .010$).

In Study 4 (N = 178), we examined the effect of choice order in a more generalizable, non-sports context: predictions about what color ball (red or black) would be drawn from an urn. As in Studies 2 and 3, participants predicted the outcome of a draw from a focal "close" urn (with 27 red balls and 23 black balls) either before or after predicting the outcomes of two draws from urns with a large majority of red balls (e.g., 43 out of 50). Again, more participants chose the unlikely option (black) when they made the focal prediction last (43%) versus first (6%; $p < .001$). We also found evidence of the psychological process driving this effect: we asked participants how much they were thinking about their other predictions when making their prediction for the focal urn. Participants in the *last* condition reported considering their other predictions more ($M = 5.21$) than in the *first* condition ($M = 3.10$; $p < .001$), which mediated the effect of order on prediction (Indirect effect = -0.05, SE = 0.03, 95% CI = [-0.13, -0.01]).

Study 5 (N = 2000) tested our theory through moderation. We hypothesized that if participants' belief that the unlikely outcome must occur at some point in the sequence drives the effect, then it should be attenuated when participants learn that the events are in fact independent. As in Study 4, participants predicted what color ball would be drawn from three different urns, with the same focal urn appearing either first or last. We also manipulated if, in the instructions phase, participants completed a short tutorial on how separate sequential events (e.g., coin tosses) are statistically independent or not. The order effect replicated for participants who did not do the tutorial (*last* = 8% vs. *first* = 36%; $p < .001$) and was still present but smaller among participants who did the tutorial (*last* = 8% vs. *first* = 25%; $p < .001$, interaction $p = .048$). Importantly, among participants who made the focal prediction *last*, participants who completed the tutorial were less likely to choose the black ball ($p = .001$).

From placing bets to predicting the weather for a multi-day vacation, consumers often have to make predictions about multiple future events. Thus, our finding – that the order in which consumers make predictions has a systematic effect on their choices – is important for marketers and consumers alike.

Consumers are (Relatively) Risk Seeking in the Domain of Error

EXTENDED ABSTRACT

In most theories of choice under risk, preferences are elicited over prospects (outcomes and associated probabilities; see Starmer, 2000). When testing these theories, most researchers have used purely monetary gambles (e.g. 50% chance of $1,000 vs 100% chance of $450; Kahneman & Tversky, 1979). People's choices over these prospects are supposed to inform us about their choices in the real world. However, real world prospects usually have outcomes that are not purely monetary. Namely, they also produce an error – the difference between a prediction and the realized outcome. For example, betting that a die will land on "6" when it actually lands on "4" produces an error of two. Sports betters' realize an error when betting on a spread, manufacturers realize an error when deciding how much of a good to produce, and investors realize an error when selecting assets based on projections. If this context affects people's appetite for risk, then people's preferences in the abstract scenarios used in past research may not accurately represent consumer's preferences in the real world.

In this project, we find that consumers make fundamentally different choices when gambles produce an error in addition to a monetary outcome. Recent work has found evidence that people have diminishing sensitivity to forecasting error, which makes them risk seeking over forecasting error (Dietvorst, & Bharti, 2019). Following this work, we predict that people will be significantly more risk seeking when their choice in a gamble will produce an error in addition to a monetary gain or loss.

In Study 1, 755 participants chose between safe and risky options and we manipulated whether their choice produced an error. Participants in the "Gain" chose between a 50% chance of $0.30 and $0.12 for sure. They learned that the computer would flip a coin to determine the outcome, but they did not learn how this process would work. Thus, their choice did not produce an error because it was not clear what outcome they were betting on when they chose the risky option. Participants in the "Heads" chose between a gain of $0.30 if the coin landed on heads (50% chance), and $0.12 for sure. Participants in the "Choice" condition faced the same gamble, but could choose whether heads or tails resulted in the $0.30 gain. Thus, the risky option in the Choice and Heads conditions produced an error because participants knew what outcome they were betting on. We found that participants in the Gain condition were significantly more likely to pick the safe option (44%) than participants in the Heads (31%, $X^2(1, n=504)=9.34$, $p=.002$) and Choice (25%, $X^2(1, n=504)=20.43$, $p<.001$) conditions. We replicate this effect in Study 2, with a different coin flip gamble.

In Study 3, 401 participants bet on a gamble that would be resolved with a die roll. Participants in the Gain condition chose between three options without learning how the outcomes would be determined. The two riskier options each offered a 40% chance of $0.30, a 20% chance of $0.10, and a 40% chance of $0; the safer option offered a 20% chance of $0.30 and an 80% chance of $0.10. Participants in the Error condition learned how these gambles corresponded to the outcome of the die roll: 1) the die was 5-sided and displayed the numbers "1, 1, 2, 3, 3", 2) they could bet on "1", "2",

or "3", and 3) they would earn $0.30 for a perfect prediction, $0.10 for a prediction off by 1, and $0 for a prediction off by 2. Thus, the two riskier options corresponded to betting on "1" and "3", while the safer option corresponded betting on "2". We displayed the odds of each monetary outcome the same way to both groups to ensure that they had the same information about the monetary gamble. We found that participants were significantly more likely to pick the safer option in Gain condition (56%) than the Error condition (39%, $X^2(1, n=401)=11.89$, $p=.001$).

In Study 4, we explore this phenomenon in a completely different context. Participants saw two different forecasting options (Option E and Option S) make 20 trial forecasts in a prediction task, and then chose between those options for a final incentivized forecast. Participants earned $0.50 for a prefect forecast, and this bonus decreased by $0.10 for each unit of error in the forecast. Unlike the previous studies, participants only learned about the odds and outcomes associated with their options through experience. We configured the predictions so that Option E was always off by 1, and Option S was equally likely to be perfect or off by 2. Thus, Option E was a safe option that always produced $0.40, and Option S was a risky option that produced $0.50 and $0.30 with equal probability. We manipulated the instructions and feedback that participants got between conditions. Participants in the Gain condition never learned about the prediction component of the task – they only saw the gains that the two options generated in each of the 20 trials. Participants in the Error condition only learned about the prediction task; they saw the predictions, the gains, and the correct answers in each trial. We found that participants were significantly more likely to pick the safe option (Option E) in the Gain condition (53%) than the Error condition (40%, $X^2(1, n=401)=6.59$, $p=.010$).

These results suggest that consumers are more likely to make risky choices when their choices produce an error in addition to a monetary gain or loss. These results can help to explain how the same consumer can simultaneously buy insurance (a choice without a clear prediction component) and gamble on sports (choices with a clear prediction component) – two actions that suggest very different risk preferences. Further, they suggest that marketers can manipulate people's tolerance for risk by highlighting or hiding the prediction component of a risky choice. For example, consumers may value uncertain promotions (see Mazar, Shampanier, & Ariely, 2017) more when those promotions generate an error in addition to a monetary outcome.

Should Advisors Provide Confidence Intervals Around Their Estimates?

EXTENDED ABSTRACT

Many of a consumer's everyday decisions require them to make accurate predictions about inherently uncertain events. For example, consumers may need to forecast how likely it is that the price of a product will fall, that a new model for a product will be released, or that their investment will be profitable. To navigate such uncertainties, consumers often ask for and rely on advice. Despite the potential perils of following overly precise advice, advice is often given with too much certainty (Moore and Healy 2008; Moore, Tenney, and Haran 2016; Radzevick and Moore 2011; Soll and Klayman 2004).

Recent research suggests that consumers actually do not inherently dislike uncertain advice, as they do not judge advisors more negatively when these advisors include uncertainty into their advice (Gaertig and Simmons 2018). However, we do not yet know (1) whether people are more likely to *follow* uncertain advice, and (2) how advisees react to uncertain advice in the form of confidence intervals.

In the current project, we set out to test whether people are more or less likely to follow advice that is accompanied by a confidence interval. For example, the website Kayak.com may recommend to buy a flight ticket now because "prices will rise in the next two weeks" (certain advice) or because "there is a 90% chance that prices will rise between $20 and $30 in the next two weeks" (uncertain confidence-interval advice). We tested participants' reactions to these different types of advice in the domain of sports predictions, as this allowed us to incentivize participants for accurate predictions and to give them high-quality advice.

Across seven studies ($N = 9,471$), we found that participants are directionally *more* likely to follow advice that is accompanied by a confidence interval. The effect was significant in four of the seven studies, and non-significant in the other three studies. Our results suggest that advisors may be more persuasive if they provide confidence intervals around their estimates.

In Study 1 ($N = 399$), we asked participants to predict the outcomes of upcoming NBA basketball games. We presented participants with 9 different games, and, for each game, we asked them to predict how many points one of the teams would score in the game (e.g., "How many points will the Philadelphia 76ers score in this game?"). Participants first made a prediction for each of the games. Then, we asked them to choose whether they would want to submit their own prediction or a prediction made by an algorithm as their official, incentivized prediction. Before making their choice, participants saw how the algorithm had performed in the past. For each game, participants were then shown the algorithm's prediction alongside their own prediction, and were asked to choose which they would like to submit as their official, incentivized prediction.

We manipulated the certainty of the algorithm's advice by manipulating whether or not the advice was accompanied by a confidence interval. In the certain advice condition, participants only saw the algorithm's best guess (e.g., "The statistical model's best guess is that the Philadelphia 76ers will score 111 points."). In the uncertain advice condition, the best guess was accompanied by a confidence interval (e.g., "According to the statistical model, there is a 90% chance that the Philadelphia 76ers will score between 84 and 118 points. Its best guess is that the Philadelphia 76ers will score 111 points."). We found that participants were more likely to follow the algorithm's advice when it was accompanied by a confidence interval than when it was not accompanied by a confidence interval. Specifically, in Study 1, 25% of participants followed the algorithm's advice when it was accompanied by a confidence interval, but only 18.7% of participants followed the advice in the certain advice condition, $b = .063$, $SE = .026$, $p = .015$.

In six additional studies, we replicated this procedure using different incentives and different sports prediction tasks. In all of our studies, participants were directionally more likely to follow the algorithm's advice when it was accompanied by a confidence interval than when it was not accompanied by a confidence interval. This effect was significant in three of the additional six studies ($p = .032$, $p = .004$, and $p = .007$), and non-significant in the remaining three studies ($p = .112$, $p = .314$, and $p = .439$).

Taken together, our results suggest that presenting a confidence interval alongside advice may be appealing to customers. Our results have important practical implications and are relevant to any company or individual who seeks to effectively communicate their advice.

A Prototype Theory of Consumer Financial Misprediction

EXTENDED ABSTRACT

Consumers frequently make financial predictions (Peetz et al. 2016, Zhang and Sussman 2018), and the accuracy of these predictions can be consequential for their financial well-being. For example, *under*-predicting future *expenses* is associated with high-interest payday loan use (Pew 2012) and revolving credit card debt (Yang et al. 2007). Similarly, *over*-predicting future *income* may lead consumers to over-spend because expected income growth typically leads to increased spending (e.g., Berman et al. 2016; Carroll et al. 1994). However, relatively little is known about the prevalence and magnitude of expense and income prediction biases, why these biases occur, and how these biases can be neutralized.

In the present research we develop a prototype theory of consumer financial misprediction that helps explain: 1) why consumers display an *expense prediction bias* in which they *under*-predict their future spending, 2) why consumers who face variable income display an *income prediction bias* in which they *over*-predict their future income, and 3) how consumers' expense and income prediction accuracy can be improved. The logic of the prototype theory is that financial predictions are based on prototype attributes that come to mind easily when predictions are being constructed. These attributes represent a consumer's average spending or income, where "average" refers to the mode of the relevant distribution rather than the mean. This leads consumers to under-predict expenses because expenses are positively skewed with mode < mean, and over-predict income when it is negatively skewed with mode > mean. One important implication of this framework is that predictions will be more accurate when the relevant distribution is approximately normal (with mode = mean) than when it is skewed (H1). A second key implication is that when outcomes are naturally skewed prediction accuracy can be improved by prompting consumers to consider reasons why their expenses (income) might be *different* than usual because most values in a positively (negatively) skewed distribution that are different from the mode are also higher (lower) than the mode (H2).

In Studies 1–3 we test H1 in the context of expenses. In Study 1 we use longitudinal data from a popular personal finance app (+400 million transactions across +65,000 users from 2014 to 2018) to examine monthly prediction accuracy across expense categories that naturally vary in terms of skew. On average, consumers under-predict their monthly spending by 21.1% ($p < .001$). However, supporting H1, prediction accuracy is higher in expense categories characterized by more normally distributed spending (e.g., Fuel: Skew = .10, Mean under-prediction = .03%, n.s.) and lower in categories characterized by more positively skewed spending (e.g., Dining and Drinking: Skew = .38, Mean under-prediction = 34.22%, $p < .001$).

Study 2 extends the descriptive findings of Study 1 by examining the causal effect of skew on expense predictions. Participants viewed 52 weekly expense values in quick succession (Andre et al. 2017), then predicted their spending for the next week. The experimental manipulation was that the values were drawn in random order without replacement from either a positively skewed distribution with mode < mean (Mode = $180, Mean = $200, SD = 38.14, Skew = 3.13) or a normal distribution with mode = mean (Mode = $200, Mean = $200, SD = 28.14, Skew = 0.00). Supporting H1, and consistent with the descriptive results of Study 1, predictions in the normal distribution condition were remarkably close to the $200 mean of the underlying distribution ($M = $200.32, p = .83$), but predictions in the positive skew condition were significantly lower than $200 ($M = $195.14, p < .02$). Study 3 directly replicates Study 2 and also shows

that the effect of distribution condition on predictions is mediated by what participants perceive to be their "average" spending (indirect effect = 3.41, SE = 1.32, 95% CI = [1.05, 6.37]).

In Studies 4–5 we test H2 in the context of expenses. In Study 4 we partnered with Canada's largest credit union to run a five week longitudinal field study with 187 of its members. In weeks one through four participants were asked to predict their spending at the beginning of the week then report their actual spending at the end of the week. In the fifth week of the study participants were randomly assigned to predict their expenses in a control condition or an intervention condition that prompted them to consider three reasons why their spending for the next week would be *different* from a typical week before they made their prediction. During the first four weeks of the study participants under-predicted their weekly spending between 11% and 19% (p's $< .01$). During the fifth week of the study participants in the control condition once again under-predicted their weekly spending (mean bias = 18%, $p < .01$). However, supporting H2, under-prediction was virtually eliminated in the intervention condition (mean bias = -1.3%, $p = .85$). Study 5 (n = 1,048, nationally representative sample of US consumers) extends Study 4 by demonstrating that the intervention makes it easier to think of atypical expenses when predicting, and that the number of atypical expenses that come to mind mediates the effect of the intervention on predictions (indirect effect = .05, SE = .02 95% CI = [.02, .09]).

In Studies 6–9 we test H1 and H2 in the context of income predictions. Our primary expectations were that consumers who work in the gig economy tend to *over*-predict their future earnings because gig income is often negatively skewed with mode > mean (Hall and Krueger 2018), and that our "atypical" intervention would therefore make income predictions more accurate by making them lower. To briefly summarize the results of these studies: 1) Uber drivers (n = 57) and Mturkers (n = 200) over-predict their weekly gig income by as much as 61% (p's $< .001$), 2) Income predictions are more accurate when income is normally distributed than when it is negatively skewed, and 3) Prompting people to consider reasons why their gig income for the next week might be different than usual reduces over-prediction.

SESSION OVERVIEW

Doing good is generally beneficial in terms of reputation and status (Flynn 2003; Flynn et al. 2006; Hardy and Van Vugt 2006). Further, people not only have greater goodwill towards prosocial agents, but also evaluate these agents more positively in unrelated domains (i.e., a moral halo effect; Chernev and Blair 2015). However, when might consumers respond negatively to do-gooders? In this session, we focus on instances when beneficence backfires. Specifically, four papers identify cases in which people respond negatively towards those who do good (in terms of willingness-to-spend, consumer decisions, judgments, and monetary allocations). This novel experimental work highlights the importance of understanding responses to do-gooders and contributes to the literature on altruism, prosociality, CSR, and social and political causes.

The first two papers show how beneficence backfires when prosocial actors behave in a manner that is seemingly inconsistent with their mission. Despite generally positive perceptions of nonprofits relative to for-profits, Paper 1 shows that people are actually more resentful and less forgiving of a nonprofit than a for-profit that commits the same wrongdoing. These findings are particularly important as evident by the dramatic decrease in Red Cross donations following news that it mismanaged Haitian relief money. Consistent with past work, Paper 2 finds that actors who do good in exchange for certain rewards suffer negative consequences because they are judged as less purely motivated. However, interestingly, this paper finds that this effect is attenuated when rewards for doing good are uncertain; for example, consumers prefer to buy products from and write more positive reviews of companies whose prosocial initiatives face uncertain profit outlooks (i.e., they may earn no profit at all) versus certain profits of equivalent expected value.

The last two papers examine how identity plays a role in negative responses to those who do good in the context of social and political causes, an area particularly relevant in today's ideologically charged world. Paper 3 examines situations in which do-gooders are faced with a tradeoff between acting inconsistently with their past behavior versus acting inconsistently with their underlying values, and finds that in these situations actors are condemned to be judged as hypocrites regardless of what is chosen. Paper 4 demonstrates that

do-gooders themselves may act in a way that harms their side of a political cause (e.g., gun control). Counterintuitively, when faced with the choice between taking money from their side of a cause or allocating money to the opposing side, people take money from their own side. In fact, the more one cares about their cause, the more likely they are to harm their side rather than help the opposition, undermining their ability to do good for their cause.

Taken together these four projects highlight the importance of understanding the negative responses to actors who aim to do good. Counterintuitively, this session identifies that beneficence can backfire and reveals the potential negative consequences of doing good. In line with the conference theme, the impact and widespread applicability of these papers' findings could attract researchers, practitioners, and policy-makers.

Unable to Rebound: The Downside of Being a Nonprofit That Errs

EXTENDED ABSTRACT

Organizations often err. Understanding peoples' responses to organizational mistakes and apologies is of utmost managerial importance (Koehn 2013; Pace et al. 2010). Previous work examining these responses has focused on for-profits and not nonprofits (e.g., Grégoire and Fisher 2008; Joireman et al. 2013; Reimann et al. 2018). Yet, how do consumers respond to a *nonprofit* that errs and apologizes?

Nonprofits are generally perceived more positively than for-profits (Aaker et al. 2010). Indeed, Bhattacharjee, Dana, and Baron (2017) document that people hold anti-profit beliefs such that nonprofits are judged as doing less harm and more societal good than for-profits. Further, prosocial actors receive reputational benefits such as high status (Flynn 2003; Hardy and Van Vugt 2006), and a benevolent halo effect (Chernev and Blair 2015; Sen and Bhattacharya 2001). Given these findings, one would expect that people would be more forgiving towards a nonprofit than a for-profit that transgresses. Counter to this, we find that consumers are more resentful of an organization that transgresses when it is a nonprofit than when it is a *for-profit*. Further, consumers feel more exploited by a nonprofit that errs than when a for-profit errs. Therefore, even after apologizing, nonprofits still have a harder time rebounding than for-profits.

Study 1 (N=501, MTurk) was a 2(between: nonprofit vs. for-profit) x 3(within: wrongdoing) design. Participants evaluated 3 different organizations that had done wrong (released pollutants, published inaccurate information on its website, had misleading ads). The organizations were described identically except they were either nonprofits or for-profits. Across all 3 wrongdoings, participants who evaluated nonprofits were less likely to continue donating/spending and perceived the organization more negatively than those who evaluated for-profits ($ps<.01$). Thus, nonprofits that transgress are penalized more than for-profits for the same transgression.

Study 2 (N=200, Mturk) builds on Study 1 by examining responses towards an organization that has not only erred (misleading ads) but also apologized. We find that people are less forgiving of a nonprofit than a for-profit. Specifically, participants were still more likely to avoid donating/spending at a nonprofit (M=5.33) than at a for-profit (M=4.48) after the organization apologized for their mistake ($p<.001$).

Study 3 (N=167, lab) ensures that differences in baseline willingness to donate/spend cannot explain the effect. After reading a description about the organization (nonprofit or for-profit), participants were equally likely to give to/spend at the organizations (M=5.50 vs. 5.23, $p = .18$). However, after they learned about the wrongdoing and apology, participants were less willing to give to/spend at the nonprofit than the for-profit (M=3.25 vs. 4.42, $p<.001$; interaction: $p<.001$).

Next, we examined *why* consumers have more negative responses towards nonprofits who erred and apologized compared to for-profits who did the same. Consistent with Expectation-Disconfirmation Theory (Oliver 1977), we reason that consumers feel exploited by a nonprofit that errs because they expect the organization to do good in exchange for their money, while this expectation does not exist for for-profits. In Study 4 (N=404, lab), after reading about an organization that donates (vs. sells) warm clothing and had apologized for doing wrong (misleading ads), participants again indicated they were less likely to continue donating/spending at the nonprofit (M=3.57) compared to the for-profit (M=4.90; $p<.001$). Furthermore, participants also felt more exploited by the erring organization when it was a nonprofit (M=4.60) than when it was a for-profit (M=3.85; $p<.001$). Importantly, this reduced forgiveness towards the nonprofit (vs. the for-profit) was mediated by how exploited participants' felt (B=-.62; 95% CI [-.85, -.39]). Lastly, participants were asked whether they would prefer to transact with a different organization, as opposed to the erring organization, that has lower quality of clothing but has never erred. Consistent with our main finding, 56.9% of participants in the nonprofit condition preferred to switch to the organization that had never erred, while only 7.4% indicated they would switch in the for-profit condition ($p<.001$).

Finally, we rule out an alternative account. Specifically, if the unfavorable responses towards nonprofits that err are because people feel *personally* exploited by the organization, then we should not observe these unfavorable responses towards nonprofits when advising *someone else* on whether or not to continue transacting with the organization. Accordingly, in Study 5 (N=603, Mturk) we employed a 2(organization type: nonprofit vs. for-profit) x 2(self vs. other) between-subjects design. Similar to the previous studies, the organizations were described identically except they were either nonprofits or for-profits. Participants were asked whether they would (vs. advise their friend to) continue donating to/shopping at an organization. We found a main effect for organization type (nonprofit: M=4.05 vs. for-profit: M=4.74, $p<.001$), and no significant interaction ($p=.304$). Replicating the effect observed in the previous studies, participants who were asked about their own money, were less willing to keep donating at a nonprofit (M=4.20) than they were to keep spending at a for-profit (M=5.03) after the organization apologized for their mistake ($p<.001$). Furthermore, this effect was also observed in the *other* condition in which participants advised their friend (nonprofit: M=3.91 vs. for-profit: M=4.46; $p=.003$). Unexpectedly, we also observed a main effect for self vs. other (self: M=4.61 vs. other: M=4.18, $p=.001$) suggesting people in general are less willing to advise others to transact with an organization after it errs. Together, these results suggest that feeling exploited towards the nonprofit is not because of a deeper personal connection with an organization.

In sum, previous research has mostly focused on corporate reputations and consumers' reactions to for-profits who err; however, less is known about how people respond to nonprofits that err. Our findings suggest that, instead of giving nonprofits that transgressed slack the opposite is true: after erring, consumers are more resentful and less forgiving of nonprofits than for-profits. This has important social and financial implications. For instance, the Red Cross was vilified after it mismanaged and misrepresented the use of donation money intended to support the victims of the 2010 Haiti earthquake. Following news of the scandal, the Red Cross had the lowest amount of donations in over 15 years (*The Washington Post* 2015). Thus, paradoxically, those who do good have trouble rebounding after they transgress.

Doing Good for (Maybe) Nothing: How Reward Uncertainty Shapes Consumer Responses to Prosocial Behavior

EXTENDED ABSTRACT

Scholars have long studied decision-making under reward uncertainty (i.e., when there is an *ex ante* chance of no reward at all; Kahneman and Tversky 1979). Here, we examine how people evaluate the decisions of *others* in response to reward uncertainty. Specifically, we hypothesize that actions taken when rewards are uncertain seem more purely (i.e., intrinsically) motivated, whereas actions taken when rewards are certain seem more tainted by extrinsic benefits, holding reward value constant.

We investigate this effect in the domain of prosocial behavior, where inferences about motive purity powerfully guide judgment and evaluation (Critcher and Dunning 2011). Although prosocial behavior can lead to substantial reputational benefits for the actor, good deeds can backfire if they appear tainted by extrinsic benefit (Small and Cryder 2016). In extreme cases, doing good and turning a profit can provoke stronger backlash than doing no good at all (Newman and Cain 2014).

We theorize that when selfish rewards for doing good are uncertain *ex ante*, observers infer that prosocial actors *would have been willing* to do good for nothing. For example, an individual who volunteers in exchange for a raffle ticket with a large (but unlikely) payout seems like she *would have* volunteered for free (even if she wins); a volunteer receiving a smaller sure reward enjoys no such inference. Analogously, a brand that launches a sustainability initiative despite an uncertain profit outlook seems more praiseworthy than one that launches an identical initiative with a certain profit outlook.

Studies 1a-b (n=128, n=199) test our prediction in the context of product choices and customer reviews. In Study 1a, participants read about two chocolate brands which recently switched to fair-trade cacao beans. For one brand, the fair-trade program was sure to boost profits by $100,000 (certain reward). For the other, the program had a 25% chance of boosting profits by $400,000 (uncertain reward; equivalent in expectation). Participants subsequently evaluated the brand facing uncertain profits as more purely motivated ($p<.001$, $d=.87$), and 64% preferred to take home a chocolate from that brand (Z=3.18, $p<.01$). In Study 1b, participants read a press release about a new corporate philanthropy project from a major wireless provider. We manipulated, this time between-subjects, industry reports about the project's likely impact on the brand's bottom line (certain reward: 100% chance of $100,000 profit, uncertain reward: 10% chance of $1,000,000 profit). Participants again rated the brand facing uncertain rewards as more purely motivated ($p<.01$, $d=.43$), and this time they also wrote more positive customer reviews ($p=.001$, $d=.48$).

Studies 2a-b (n=150, n=301) replicate this effect of reward uncertainty on motive inference across different profit magnitudes and prosocial acts. These studies also find effects of reward uncertainty on downstream inferences about moral character, likeability, and predictions about future good behavior ($ds>.20$).

Study 3 (n=248) asks whether these effects can be explained by an alternative mechanism: differences in perceived value between

certain and uncertain rewards. We first asked participants to imagine receiving a raffle ticket with a 10% chance of winning a $250 gift card and to indicate how much sure compensation they would require to trade in the ticket. Two weeks later, we invited the same participants back for our main study. Returning participants read about a donor who gives blood either in exchange for the same raffle ticket (uncertain reward) or a gift card in the value the participant had previously indicated (certain reward). Although the rewards received were matched on participants' perceived value, the donor in the uncertain reward condition was still seen as more purely motivated ($p<.001$, $d=.56$) and likely to donate blood again in the future ($p<.001$, $d=.64$).

Study 4 (n=605) tests whether the impact of reward uncertainty on motive inference is robust to *ex post* reward outcomes. Participants were asked to evaluate a manufacturing company that launched a new recycled product with either a certain profit forecast (100% chance of $100,000) or an uncertain profit forecast (10% chance of $1 million). This time, participants also learned about profit outcomes, yielding a three-condition design (certain reward, realized uncertain reward, and unrealized uncertain reward). The brand was judged to be more purely motivated in both uncertain reward conditions relative to the certain reward condition ($ps<.001$, $ds>.70$). Here, even if a prosocial initiative turned a 10x profit *ex post*, it was still seen as more purely motivated.

Studies 5a-b (n=369, n=1,419) explore boundary conditions based on reward probability. Study 5a finds that the effect is specific to situations in which uncertain profits include a chance of earning nothing, and not present in broader cases of risk over multiple possible outcomes (i.e., a chance of either a smaller or larger profit). Study 5b tests the effect over seven profit probabilities, finding that motives begin to appear substantially less tainted when the chance of no reward reaches 50%.

Study 6 (n=1,007) finds that the effect is attenuated if we make salient that the actor needs the large possible reward in the uncertain condition. Participants read about a student who volunteers in exchange for a raffle ticket with a 5% chance at $400 (uncertain reward) or a sure payment of $20 (certain reward). As we found previously, participants judged the volunteer as having less tainted motives in the uncertain reward condition ($p<.001$, $d=.40$). However, this result actually reversed when we told participants that the student was $400 short on his rent ($p<.01$, $d=.27$; interaction $p<.001$). Presumably, this additional information attenuated the inference that the student would have been willing to volunteer if no reward were offered.

Finally, Study 7 (n=449) asks whether revealing a prosocial initiative's uncertain profit outlook can earn more credit than not mentioning profits at all. Here, participants rated a bank's decision to invest in urban revitalization as more purely motivated when it faced an uncertain profit forecast relative to both a certain profit forecast ($p<.001$, $d=.57$) and no mention of profits whatsoever ($p<.01$, $d=.38$).

Our findings challenge conventional wisdom that extrinsic benefits always lead to cynical motive inferences and deepen our understanding of how observers evaluate actions taken when rewards are uncertain.

Damned Either Way: Hypocrisy Judgments When Goals and Commitments Conflict

EXTENDED ABSTRACT

While those who behave ethically are often rewarded with reputational benefits (e.g., Flynn et. al. 2006), behaving ethically can be socially risky. For instance, individuals often denigrate the character of do-gooders if those prosocial others are seen as implicitly impugning the character of the self (Minson and Monin 2012). More generally, people tend to be suspicious that prosocial actors harbor self-interested motives (Berman, et al. 2015; Critcher and Dunning 2009; Miller 2001). Such suspicions can grow into perceptions that the actor is a hypocrite – someone who benefits from *appearing* virtuous without paying the price of actually *being* virtuous (e.g., Monin and Merritt 2012).

Hypocrisy often involves inconsistency but not all inconsistent behavior is labeled hypocrisy. To perceive hypocrisy, an audience must interpret inconsistency as signaling that a person appears or feels more virtuous than they deserve (Effron et al. 2018). However, the conditions under which inconsistency invites this interpretation are poorly understood.

We investigate how people perceive two types of inconsistency that a prosocial consumer could display: *commitment-based inconsistency*, whereby the consumer's present actions are inconsistent with past commitments made; and *goal-based inconsistency*, whereby the consumer's actions fail to maximize the stated ethical goal they are trying to achieve.

Consumers sometimes must choose between acting inconsistently with their past commitments or their stated goals. Consider someone who adopts vegetarianism to benefit the environment. Now imagine an invasive fish species is destroying local habitats, and environmentalists recommend sell the fish commercially for consumption in order to limit the damage. Suppose the consumer is offered the invasive fish for dinner. She must choose between acting inconsistently with her commitment to avoid meat versus acting inconsistently with her goals to help the environment.

Across four studies, we find evidence for a "Damned Either Way" effect such that consumers are labeled hypocrites for displaying either commitment- or goal-based inconsistency (Studies 1-4). Study 1 presents an initial demonstration of the effect and Study 2 assess its robustness. Study 3 shows that this effect occurs when evaluating consumers who provide a reason for their commitment, but not for those who believe that a given behavior represents a categorical imperative (Kant, 1781/1908). Finally, Study 4 finds that motivated reasoning determines which form of inconsistency that evaluators evoke when making hypocrisy judgments.

Study 1's participants (N = 301) read a scenario involving a consumer, Jeff, who became a vegetarian for environmental reasons. In the Control condition, the scenario simply ended. In the other two conditions, participants read that Jeff learns that environmentalists recommend the public eat a specific invasive fish species in order to protect local habitats. Shortly thereafter, Jeff finds himself at a restaurant that has this fish species on the menu. In the Commitment-based inconsistency condition, Jeff orders the fish, thereby acting in a manner inconsistent with his past commitment to vegetarianism. In contrast, in the Goal-based inconsistency condition, Jeff orders the vegetarian option, thereby failing to maximally help the environment. Consistent with a "Damned Either Way" effect, we find that, relative to the control condition (M = 1.96), participants judged Jeff to be more of a hypocrite regardless if he ordered the fish (M = 2.79, $p < .001$) or the vegetarian option (M = 2.76, $p < .001$).

In Study 2 (pre-registered: https://aspredicted.org/blind.php?x=m6ab5q, N = 311), we replicate these findings in a within-subjects design and utilizing three different scenarios to test the effect. In all three scenarios, we find a significant effect that behavioral-based inconsistency leads to judgments hypocrisy relative to control (ps < .001), while in two of the three scenarios we find a

significant effect of goal-based inconsistency leading to attributions of hypocrisy relative to control (ps < .001).

In Study 3 (pre-registered: http://aspredicted.org/blind.php?x=3uf789, N = 600), we ask whether the Damned Either Way effect depends on the stated goal. In particular, we compared reason-based goals (e.g., eating fish to reduce environmental harm) versus categorical imperatives (e.g., refusing to eat fish because it is inherently wrong to do so). Consistent with our pre-registered hypothesis, we replicate the DEW effect in the reason-based goal condition: relative to the control (M = 1.86), the actor was again judged to be a more of a hypocrite regardless if he ate the meat (M = 3.24, p < .001) or the vegetarian (*M* = 2.52, *p* < .001) option. However, we do not find a DEW effect when the actor's behavior is driven by a categorical imperative. In this case, relative to the control (M = 2.20), he was only considered a hypocrite when he chose to eat meat (M = 4.16, p < .001), but not when he ate the vegetarian option (M = 1.99, p = .30).

In Study 4 (pre-registered: http://aspredicted.org/blind.php?x=cp87p5, N = 806) we test the Damned Either Way effect in a new context, and further show that both commitment- and goal-based hypocrisy judgments are shaped by motivated reasoning. Participants first reported attitudes towards illegal immigrants. They then evaluated a scenario in which a man who commits to opposing immigration for economic reasons learns that immigrants in fact benefit the economy. A canvasser accepting donations in support of immigrant rights then approaches him. The individual either donates (commitment-based inconsistency) or does not donate (goal-based inconsistency). A control condition was also included to assess baseline ratings of hypocrisy. We additionally reversed the scenario such that the individual who supports immigrant rights for economic reasons learns that immigrants are harmful to the economy. A canvasser accepting donations in support of deporting illegal immigrants then approaches him.

Results show a Damned Either Way effect across both versions of the scenario (ps < .03). We further find that judgments of hypocrisy were moderated by participants' own attitudes about immigration. Specifically, participants were more likely to judge the actor as a hypocrite if his final actions contradicted their personal beliefs regardless of the nature of the inconsistency they judged (ps < .06).

In sum, we find evidence that both commitment-based and goal-based inconsistency leads ethical actors to be judged as hypocrites.

The Cost of Opposition: Preferring to Punish our Own Rather than Help our Opponent

EXTENDED ABSTRACT

Imagine that you are pro-choice and are given two options: add $5 to a donation going to a pro-life organization or subtract $5 from a donation going to a pro-choice organization. Would you choose to help the opposing group or harm your own? In three studies (and two supplementary studies), we find that when given two options – to help the opposition through greater funding or hurt one's own side through diminished funding – research participants consistently choose to harm their own cause. This replicates across polarized contexts: abortion access, gun control, and political affiliation. Moreover, we find that individuals prefer to harm their own interests despite the fact that they generally believe their own cause is more effective with funds.

We propose that that the preference to harm one's own group rather than help an opposing group stems from the belief that helping the opposition is a stronger violation of group norms. We find evidence that individuals act in accordance with their beliefs about group norms – those who chose to harm their own group rather than concede resources to the opposition believed others in their group would do the same. Changing individuals' beliefs about the norm changed their behavior.

In our primary study (preregistered: http://aspredicted.org/blind.php?x=sx6vb7, N = 800, MTurk), participants were asked to modify donation amounts for three important and polarizing causes: abortion access, gun control, and political parties. We first measured the degree to which participants identified with each side of the three issues. Participants in the counter-attitudinal condition were asked to choose between subtracting $1 from a donation to an organization on their side of the cause or adding $1 to a donation to an organization on the opposing side. Given these two unfavorable options, most participants (71%) chose to subtract $1 from the organization on their side. This choice to hurt one's own organization, rather than help an opposing organization, conflicts with a harm minimizing strategy, as individuals rate organizations on their side as more effective with funds (*p* < .001). The implication is that the participants' own cause suffers greater overall harm when their organization is deprived of funding than when the opposing organization is given that same funding.

Participants in the pro-attitudinal condition were given opposite choices: to add $1 to a donation to an organization on their side of the cause or to subtract $1 from a donation to the opposing side. The majority of participants (75%) chose to help their own side, indicating that choices do not stem from a preference to simply hinder the opposition above all else. The results from both conditions also hold at various levels of aggregation, including for each of the three causes individually, as well as for both sides of each cause. We find that the choice to help (vs. harm) is moderated by the strength of participants' attitudes toward the cause – those with stronger attitudes are more likely to choose to harm their side (vs. help the other) in the counter-attitudinal condition, and help their side (vs. harm the other) in the pro-attitudinal condition.

An additional study (N = 403, MTurk) elicited the amount of money participants would prefer to be subtracted from a donation to their side of a cause, in order to feel indifferent towards a $1 increase in a donation to the opposing side. After removing large outliers, we conservatively estimated the average amount to be $2.33 (compared to $1: *p* < .001), suggesting a preference to harm one's side to a greater magnitude than helping the opposition.

To investigate the role of group norms in counter-attitudinal choices, we ran a study (N = 653, MTurk) manipulating the norms towards helping the opposition. In the control condition, participants were informed that the experimenter would be making a donation to a pro-life and a pro-choice organization, and that they would have to choose how to alter the amount. In the norm-add condition, participants were also told that in a previous study, 70% of MTurkers on their side of the cause chose to add to the opposing group rather than subtract from their own. In the norm-subtract condition, participants were instead told that 70% of previous participants on their side of the cause had chosen to subtract from their own group rather then add to the opposing group. The proportion of participants choosing to add $1 was less than 50% in the control group (39.2%, *p* =.002), and was not significantly different from the proportion in the norm-subtract group (36.7%, *p* = .68), suggesting that subtracting is the norm. However, there was a significant increase in the proportion of participants choosing to add $1 in the norm-add group, relative to both the control and norm-subtract conditions (57.7%, *p*s < .001), suggesting that behavior in this context is guided by perceptions of group norms.

When making decisions in polarized contexts, individuals do not always make choices to minimize harm. Our findings add to a literature on the power of social influence and how psychological barriers can impede the advancement of a cause. In contexts in which accommodating two groups' desires is crucial for progress, how do we compromise when both sides would rather harm their own cause than make concessions in which the opposition benefits? Given our highly polarized political system, determining how to shift these norms is critical. Otherwise, paradoxically, the individuals who care the most may be most likely to forestall the other group's progress at the expense of their own cause.

SESSION OVERVIEW

Consumers have limited time and money that they can spend in an infinite number of ways. Deciding how to best spend one's resources involves tradeoffs between short-term desires and long-term investments. To help people make better choices, individuals and firms frequently impose constraints on how consumers spend their time and money (Cheema and Soman 2006; Gollwitzer and Sheeran 2006; Shefrin and Thaler 1988; Thaler and Bernartzi 2004). For example, people often self-impose deadlines to reduce procrastination or create budgets to encourage fiscal responsibility (e.g., Ariely and Wertenbroch 1999; Cheema and Soman 2006). This session seeks to better identify and understand the unanticipated consequences of constraining such behaviors. Four papers answer questions about how different types of constraints (i.e., time limits, schedules, budgets, and pre-commitment devices) can have unanticipated and even negative outcomes for how consumers spend their time and money.

The first two papers investigate how consumers seek and manage time spent on "leisure," exploring how constraining time spent through setting limits and scheduling can have surprising consequences. Paper 1 examines how a common time management tool—setting an alert after a pre-determined amount of time spent (akin to the option on most smartphones)—affects how much time people spend on the activity. Results show that setting such non-binding time limits on entertaining activities, like social media or games, counterintuitively increases the time spent on them. Paper 2 finds that, even though consumers desire more leisure time, when they actually gain time that could be spent on leisure activities, they show more interest in work. This is because gaining time (versus having free time) prompts individuals to question how to best allocate their time, leading them to consider – and address – their "to-do" list more.

The next two papers examine counterintuitive effects of constraining another important resource – money – by exploring how budgeting money and pre-committing to future savings can backfire, increasing spending and reducing savings. Paper 3 finds that mental budgeting, which is intended to inhibit spending, actually encourages it. Results show that consumers are more inclined to spend money

that has been budgeted for a specific purpose than money that has not been budgeted because the loss is psychologically realized when the money is initially mentally allocated. Finally, Paper 4 explores the effects of having the choice to pre-commit to a savings program. Specifically, a field experiment finds that allowing employees to choose between immediate or delayed enrollment (vs. immediate enrollment only) did not affect enrollment rates but led employees to delay enrollment, thus saving less overall.

Together, these four papers highlight the importance of understanding how consumers manage their time and money, documenting ironic psychological processes and unintended negative consequences of multiple popular resource management tools. In line with the conference theme, the differing experimental approaches and research questions addressed within this session would provide a "rendez-vous" for researchers, policy-makers, and practitioners who are interested in a wide variety of topics, including time management, mental accounting, savings, goals, and how new technologies impact wellbeing and decision-making.

When Limits Backfire: The Ironic Effect of Setting Limits on Entertainment Consumption

EXTENDED ABSTRACT

New technologies have made it easier than ever before to consume entertaining content. On average, people spend nearly 2.5 hours per day on social media alone—over half of which occurs during the workday. To help people better manage their time, many technological devices (e.g., iPhones; Nintendo Switch) and popular apps (e.g., Facebook, Instagram, YouTube) have introduced time-tracking tools, providing consumers with the option to set costless, non-binding time limit reminders on entertaining activities. These reminders alert consumers to having spent a pre-determined amount of time on an activity or platform each day (e.g., 45 minutes on Instagram).

Presumably, people set time limits on entertaining, but unproductive, activities in order to encourage themselves to spend less time on those activities (and more time on productive work). Contrary to this intended effect, we propose that such limits can backfire, increasing, rather than decreasing, time spent on the activities they are meant to constrain. We argue that this counterintuitive effect occurs because, much like when consumers set goals (e.g., Heath, Larrick and Wu 1999; Wallace and Etkin 2018), setting limits changes salient reference points. Without a time limit, consumers use their starting point (i.e., spending no time on the activity) as the reference point by which to judge their (dis)satisfaction with the time spent. Once a time limit has been set, however, the focal reference shifts to this limit amount (e.g., 45 minutes), making any time spent under the limit amount feel more acceptable (i.e., less like a loss or a waste of time) and overall discouraging restraint. Five pre-registered studies examining both external and self-set time limits on different entertaining activities (browsing social media, playing an online game) support these predictions.

In Study 1a (N = 208), participants imagined that they were regular users of a social media app and that they had spent 52 minutes on the app yesterday. Participants were randomized to either imagine that they had set a limit on their phones, such that they would see a reminder of their time spent at 60 minutes, or not. We then asked participants to rate on -10-to-10 scales their satisfaction with how they

had spent their time yesterday (4 items: how happy they felt about the time they spent on the app, how much they felt they had lost/gained time, how well they used their time, and how much they felt they had wasted their time [reverse-coded]). A one-way MANOVA found a main effect of condition across these four items (F(4, 203) = 6.27, $p < .001$). An independent t-test revealed that participants who set a limit reported felt significantly better about how they spent their time ($M = 0.01$) than participants who did not set a limit ($M = -1.60$; t(206) = 3.46, $p < .001$). Study 1b (N = 807) replicates this effect; participants felt better about the time they spent on smartphone games (either 18 or 52 minutes) when they imagined having set a daily limit of 60 minutes ($M = 2.97$) versus when they did not imagine setting a limit ($M = 0.91$; t(805) = 7.06, $p < .001$). Together, Studies 1a and 1b suggest that people do indeed shift their reference point regarding how much time they should spend on entertainment in response to setting a limit.

Our remaining studies directly test the effects of setting a limit (versus not) on real consumption behavior (i.e., actual time spent on an entertaining activity). In Study 2, participants (N = 199) were given a total of 5 minutes to spend on an entertaining activity (a bubble shooter game) and a paid work task (transcribing text strings). They could spend as much time as they wanted on the game before switching to the work task. Half of participants read that, to help them manage their time, a reminder would appear after spending three minutes on the game. Importantly, after seeing the reminder, they could continue to engage in the game for as long as they liked. The other half of participants did not read about or receive such a limit. As predicted, an independent t-test on log-transformed time spent revealed that participants in the limit condition spent more time on the game ($M = 117.21$ seconds) than those in the control ($M = 94.77$; t(197) = 2.59, $p = .010$).

Study 3 (N = 192) replicated Study 2 with a different entertaining activity (scrolling through Pinterest), again finding that setting a limit increased the time spent compared to the control ($M_{limit} = 24.48$ seconds vs. $M_{control} = 15.88$; t(190) = 2.63, $p = .009$).

Study 4 (N = 201) tested if self-set limits would have a similar effect on behavior. It used the same design as Study 3, but allowed participants to choose their own limit. In particular, participants were told that, to help them manage their time during the study, they could set a non-binding time limit, which would appear as a reminder during the Pinterest activity. The limit could be set in 15-second increments for up to the full 5 minutes (i.e., the equivalent of not setting a limit; $M_{self-set\ limit} = 83.96$ seconds, SD = 92.65, Median = 60). As predicted, participants in the limit condition spent significantly longer browsing Pinterest ($M = 23.52$ seconds) than those in the control ($M = 14.84$; t(199) = 2.03, $p = .044$). Importantly, this effect casts doubt on a potential alternative explanation based on externally imposed limits signaling how long people *should* spend on the task.

In sum, despite intending to reduce the time spent, setting limits can ironically increase time spent on unproductive entertaining activities (over paid work). This occurs because limits change consumers' salient reference point when evaluating their use of time. Our findings contribute to emerging research on the unintended consequences of tracking behavior (Etkin 2016; Soman and Cheema 2004) and how new technologies impact wellbeing and decision-making (e.g. Melumad and Pham 2020).

Spending Gained Time

EXTENDED ABSTRACT

Working hours have steadily declined over the last century (Huberman and Minns 2007), and consumers increasingly outsource

their unpaid work, buying services like childcare and housekeeping (Whillans et al. 2017). These trends imply an increase in leisure consumption. However, hours dedicated to socializing have decreased over the last decade (ATUS 2017), potentially because when feeling busy, leisure activities are often jettisoned (Southerton 2003). We study this paradox by examining how people consume gained time (due to a cancelation or plan change) and propose that despite a desire for more leisure, consumers may choose to work when they actually gain time.

Consumers desire free time, which often means time free from obligations or generally "leisure" (Unger and Kernan 1983). However, we argue that despite being objectively free of obligations, gained time is not automatically classified as "free." Instead, it is assigned to an "available" time account, which spurs consumers to question how to allocate that time. In doing so, consumers turn to their running list of tasks requiring their time (i.e., to-do list), which are usually work-oriented. As an outcome, the more salient work-like tasks take precedence and otherwise desired leisure activities are abandoned.

Study 1 demonstrates this paradox of desiring leisure, but choosing work during gained time. We compared chosen tasks during a gained time with those for an unspecified future date. Unlike the present or near future, the (unspecified) future is often decontextualized from our daily demands (Zauberman and Lynch 2005). As such, we expected participants to treat an unspecified future time as free (and meant for leisure), while treating a particular gained hour as simply unaccounted (prompting a need to account for it).

175 undergraduates imagined either gaining a few hours in the next couple of weeks or later in the same day and indicated how they would spend this time (1=definitely leisure; 9=definitely work). We also measured participants' perceived time famine and their desire for more work and leisure in their life. Unsurprisingly, participants reported experiencing time famine (M=4.79; $p<.01$ compared to the scale midpoint) and wished they had more leisure (M=5.06) than work (M=3.83, $p<.01$). Further, reported time famine was positively correlated with desire for more leisure ($r = .28$, $p < .01$), but uncorrelated with desire for more work ($r = -.03$, $p = .63$). Thus, it appears that participants crave more time to increase leisure consumption. However, we found that when participants considered gaining a particular period of time, they preferred work-like tasks (M=7.27) compared to those who considered gaining an unspecified future time (M=5.27, $p<.01$). Importantly, participants' desire for more leisure did not predict their intended behavior in either condition (both p's>.90).

In Study 2 we directly compared *having* 1.5 hours of free time to *gaining* 1.5 hours. 153 MTurkers reported how they would consume this time (1=fun and enjoyable task; 9=work-related task). As expected, we found that participants were more likely to choose work-like tasks during gained time (M=3.17) than free time (M=2.44, p<.05).

In Study 3, we examined whether differences in construal level (Trope and Liberman 2010) account for our results by manipulating temporal distance. 342 undergraduates imagined having/gaining 1.5 hours either that evening or the same evening in one week and indicated their task preference (1=catch up with friend/family/neighbor; 9=catch up on errands/housework/chores). We predicted that a particular period of time gained in distant future is similar to time gained sooner as they both define a specific time period and require its accounting. As expected, participants who gained time preferred a work-like task (M = 5.46) compared to those who had time free (M=4.71, $p<.01$). Importantly, there was no main effect nor interaction of temporal distance (both p's>.2).

The remaining studies test our proposed framework: gaining time prompts individuals to account for this time, leading them to reference their to-dos, and to choose work. First, in Study 4, we added a third condition in which participants were told that a unit of free time was "unaccounted." In line with the idea that free time is often equated with leisure, but that prompting consumers to think of how to account for time increases propensity to choose work, participants in both the gained time (M=3.68) and unaccounted time conditions (M=3.89) were more likely to choose work than the free time condition (M=2.82, ps<.05).

Importantly, if gaining time indeed increases prioritization of work, then the effect should be exaggerated for consumers who have a tendency to work first and save leisure for later. Testing this, in Study 5, 202 participants imagined having or gaining 3 hours and indicated their activity preference (1=fun and enjoyable task; 9=work-related task) and their desire to prioritize work (e.g., I'd rather get some work tasks out of the way). As before, participants who gained time were more likely to prefer a work-like task (M=2.83) than those who had time (M=2.17, p < .05). Importantly, this was moderated by participants' desire to prioritize work, where participants who prioritize work to a greater extent (-.27 standard deviations from the mean or higher) showed greater preference to work during gained (vs. free) time.

Finally, in Study 6, we tested the proposed role of to-do lists. In addition to indicating how they would spend gained versus free time (1=definitely leisure/fun; 7= definitely work/productive), participants (N=374) also provided their running to-do list for the day. Analyses revealed a main effect of gained time, whereby participants were more likely to choose work during gained (M=6.98) compared to free time (M=6.31, p=.004). There was also a significant interaction with the number of to-dos. Those with more tasks on their to-do list (-.40 standard deviations from the mean or higher) showed greater propensity to choose work during gained (vs. free) time.

In sum, despite their desire for more leisure, consumers may paradoxically prefer to work when they gain time. This is because while gaining time creates free time, gained time is categorically different from free time.

Loss Booking: Mental Budgeting Facilitates Consumer Spending

EXTENDED ABSTRACT

Budgeting is a common money management practice. Approximately 41% of Americans prepared a written or computerized budget every month (U.S. Bank Possibility Index, 2016). It has a mental analog, mental budgeting, whereby mental labels associated with money change how it is spent (Heath and Soll 1996; Thaler 1985). People create spending plans, for example, by earmarking funds into various mental accounts (e.g., groceries, clothing). Once money is budgeted into mental accounts, it is no longer perfectly fungible, or substitutable, with other money.

Mental budgeting is often characterized as a self-control device that inhibits consumer spending (Heath and Soll 1996; Thaler 1985). In this research, however, we propose a *loss booking theory* to reinterpret mental budgeting—that creating budgets for expenses facilitates rather than inhibits consumer spending. The intuition behind the concept of loss booking is that consumers psychologically realize or "book" the loss of the money when it is budgeted into a mental account. This implies that many fungibility violations occur because losses are realized for the expenses when the mental budget is "booked," and would be realized again if that money were spent outside the budget.

We posit loss booking an important case in which expectations serve as the reference point by which consumers evaluate outcomes (Kőszegi 2006). This suggests that the psychological loss associated with the expense occurs when the mental budget is created for anticipated expenses rather than at the time when the goods are purchased. Consequently, the psychological impact of the loss associated with the purchase of goods within the mental budget is mitigated or diminished. Specifically, loss booking theory predicts that losses are psychologically realized when consumers budget for certain expenses (H_1). Due to the prior realization of losses, consumers experience less pain of paying for expenses associated with existing mental budgets (H_2). Finally, the reduced pain of paying incurred when purchasing goods associated with an existing mental budget facilitates spending within that budget (H_3).

We report five experiments providing evidentiary support for our hypotheses. Experiment 1 illustrates the effect of mental budgeting on actual holiday spending. Experiments 2-5 used vignette designs. Experiment 2 provides evidence for "loss booking" (H_1). Experiment 3 supports the hypothesis that due to the loss realization, the subsequent consumption of that money elicits less pain of paying than would the expenditure of unbudgeted money or money budgeted towards other accounts (H_2). Experiment 4 shows that this hypothesis holds when the budgeting process is implicit. Finally, Experiment 5 shows that this reduced pain of paying facilitates the purchase of expenses associated with the mental budget, even when the purchase exceeds the budget limit (H_3).

Experiment 1 (*N*=328) was conducted in two phases on separate days. In phase 1, we manipulated the presence of a mental budget by assigning half of participants to explicitly make a holiday shopping budget for the upcoming Black Friday weekend. Six days later (i.e., in phase 2), participants reported how much money they actually spent. We found that participants in the budget condition spent significantly more money than did controls, who were not asked how much they planned to spend. Experiment 2 (*N*=244) manipulated whether participants made a clothing budget before they went shopping, and whether they purchased a t-shirt. We measured the extent to which participants perceived themselves to have lost or gained money during the shopping trip. We found that the purchase of a shirt without a budget was evaluated as a loss (i.e., loss framing), whereas the purchase of a shirt that did not exceed the budget was evaluated as a gain. In addition, whereas participants without a budget perceived themselves to have neither gained nor lost money, those with a budget perceived themselves to have gained money if they did not make a purchase

Experiment 3 (*N*=300) manipulated whether or not participants made a clothing budget (vs. food budget or no budget) before they purchased a pair of jeans. We measured the extent to which participants perceived the purchase of jeans as a monetary loss, and the pain of paying associated with their purchase. We found that participants were less likely to perceive purchasing the jeans as a loss in the clothing budget condition than in the control and food budget conditions. Moreover, the difference between the control and food budget conditions was not significant. A similar pattern of results was observed for the pain of paying. A mediation analysis revealed the mediating impact of loss framing on pain of paying.

Experiment 4 (*N*=100) manipulated whether participants withdrew cash at ATM (i.e., implicit budgeting) in advance of expenditures (controls imagined that they had the same amount of cash in their wallet). In addition to the two measures used in Experiment 3, we measured the extent to which participants expected to spend the cash that they had. We found that participants in the withdrawal condition (a) exhibited a higher expected propensity to spend, (b) were

less likely to perceive the expenditure as a loss, and (c) experienced less pain of paying than participants assigned to the control condition. We found the serial mediating impact of expected propensity to spend and loss framing on pain of paying.

Experiment 5 (*N*=309) manipulated whether participants budgeted money to buy sunglasses ($90) in advance of their purchase, and whether their price was under or over that budget (i.e., $69 vs. $110). We teased apart the budgeting and reference price accounts in explaining spending by including a reference price condition. Moreover, we measured purchase likelihood. We found that in both price conditions, participants in the budget condition (a) were less likely to perceive the purchase of sunglasses as a loss, (b) experienced less pain of paying associated with its purchase, and (c) more likely to buy the sunglasses than participants in the control and reference price conditions. A mediation analysis revealed the serial mediating impact of loss framing and pain of paying on purchase likelihood across prices.

Save More Later? The Roles of Present Bias and Perceived Urgency

EXTENDED ABSTRACT

Previous research has shown that choice architects can increase farsighted behavior by offering the option to pre-commit (e.g., Milkman, Rogers, and Bazerman 2009)we analyze the film rental and return patterns of a sample of online DVD rental customers over a period of four months. We predict and find that should DVDs (e.g., documentaries). People are more likely to save for retirement, for instance, when offered the option to start saving in the future, rather than today (Thaler and Benartzi 2004). We reexamine this idea and show when and why the strategy can backfire.

In a field experiment, 5,196 employees at four US universities were sent a mailing that encouraged them to join a savings plan. Employees were randomly assigned to receive either: (1) the *immediate commitment* mailing, which offered employees an opportunity to immediately enroll in a savings plan or (2) the *simultaneous pre-commitment* mailing, which gave employees the choice to either immediately enroll or pre-commit to enroll months later. Contrary to prior work, offering pre-commitment reduced the likelihood of *immediate* enrollment by 21.4% (p=0.015) with no effect on whether or not people enroll at any time (p=0.25), causing people to save 6% less on average over the eight-month study period (p=.007).

We theorize that offering a pre-commitment option along with an immediate enrollment option (1) reduces the anticipated costs of doing the farsighted behavior (consistent with prior research on present bias) but simultaneously (2) leads people to infer that the choice architect less urgently recommends the behavior. These opposing forces together can explain why pre-commitment can yield a null effect on people's willingness to engage in the farsighted behavior. Meanwhile, lack of perceived urgency may lead people to choose to delay the behavior; thus, offering pre-commitment may cause people to opt to do it later instead of now.

We tested this theory in a preregistered study where 1,161 MTurkers imagined that they just joined a company and had to choose whether to enroll in any of three employer-sponsored benefits programs. Participants were randomly assigned to either the *immediate commitment* condition where they chose which programs they would enroll in immediately or the *simultaneous pre-commitment* condition where they had the option to enroll in each program either immediately or in six months. Consistent with our theory, the results suggest that adding a pre-commitment option (vs. only offering immediate enrollment) made enrolling feel less painful, which increased the number of programs they would enroll in (95% CI of indirect effect=[.02,.07]) but led people to infer that the employer less urgently recommended these programs, which reduced the number of enrolled programs (95% CI=[-.09,-.04]). These competing forces could explain a null effect on program enrollment (*p*=0.40). Furthermore, lower perceived urgency reduced the number of programs that people chose to enroll in immediately (95% CI=[-.07,-.02]).

To reconcile our findings with the Save More Tomorrow (SMarT) intervention, we compared our choice sets with SMarT in a preregistered study (N = 1,499 MTurkers). Participants imagined receiving a mailing about their company's retirement savings plan. They were randomly assigned to one of three conditions. In the *immediate commitment condition,* participants only had the option to enroll immediately. In the *simultaneous pre-commitment* condition (mimicking the simultaneous pre-commitment condition in our field experiment), they had the option to either enroll immediately or enroll in four months. In the *sequential pre-commitment* condition (mirroring the classic design of SMarT), they were first given the option to enroll immediately, and then if they declined, they were offered the option to enroll in four months. Consistent with our theory, participants in the *immediate commitment* condition viewed their company as conveying a stronger recommendation to save (M=5.10, SD=1.42) than participants in the *simultaneous pre-commitment* condition (M=4.77, SD=1.58), p<0.001). Moreover, participants in the *sequential pre-commitment* condition inferred a marginally stronger recommendation to save than participants in the *immediate commitment condition* ($M_{sequential}$=5.27; $M_{immediate\ commitment}$=5.10; p=0.06), which may offer a potential explanation for why SMarT is able to capitalize on the power of pre-commitment without backfiring.

We tested our full theory in an incentive compatible experiment (N = 2,399). Following a filler task, participants were offered an optional, unpaid ten-minute financial well-being assessment. Participants were randomly assigned to either be offered (1) the option to take the assessment now (the *immediate commitment condition*), (2) the option to take the assessment either now or in 1 week (the *simultaneous pre-commitment* condition), or (3) the option to take the assessment now followed by the option to take it in 1 week if they declined (the *sequential pre-commitment* condition). Consistent with our theory, participants that were offered *sequential pre-commitment* were more likely to enroll (57%) compared to participants offered *simultaneous pre-commitment* (48%) or *immediate commitment* (32%). Participants offered *simultaneous pre-commitment* were marginally less likely to enroll immediately (28%) than participants offered *immediate commitment* (32%; *p* = .07). This may happen because, while both *sequential pre-commitment* and *simultaneous pre-commitment* made the farsighted behavior (taking a financial-well-being assessment) seem less costly ($M_{sequential}$=4.2 & $M_{simultaneous}$=4.2 VS. $M_{immediate\ commitment}$=4.5), *sequential pre-commitment* increased the perception that the action is urgently recommended and *simultaneous pre-commitment* decreased this perceived urgency ($M_{sequential}$=4.2 VS. $M_{immediate\ commitment}$=3.9 VS. $M_{simultaneous}$=3.6). Our mediation analyses confirmed that while anticipated costs always positively mediated the relationship between receiving a pre-commitment option and likelihood of enrolling in the assessment, perceived urgency negatively mediated this relationship when pre-commitment was offered simultaneously and positively mediated when it was offered sequentially.

In sum, we develop and test a new theory about how different forms of pre-commitment nudges impact whether and when people engage in farsighted behavior. While prior research suggests that pre-commitment nudges can increase farsighted behavior by reducing the anticipated costs of doing farsighted behavior, we document an

overlooked mechanism; people draw inferences about the urgency with which the choice architect recommends the behavior based on the sequence with which pre-commitment options are offered. More generally, the current research contributes to a growing literature about decision makers' inferences about the motives and implicit recommendations of choice architects (Krijnen, Tannenbaum, and Fox 2017). Researchers and practitioners can anticipate and leverage these inferences to better design choice architecture that works as intended rather than backfiring.

SESSION OVERVIEW

"It is a mistake to regard age as a downhill grade slide towards dissolution. The reverse is true. As one grows older, one climbs upwards with surprising strides." - **George Sand**

While a large amount of research on aging consumers has focused on the paradigm of the privation that accompanies aging (Mochis 2012), this special session focuses on how women transcend the stereotypes of aging and nurture their capacity to create and co-create alternative social imaginaries with respect to their feminine aging process. The special session draws from the consumer research literature, which investigates old age and new beginnings (Schau, Gilly & Wolfinbarger, 2009) as well as gender issues (Steinfield, Coleman, Tuncay Zayer, Ourahmoune and Hein 2019).

The four papers examine how women transcend aging and turn it into a creative force. The papers complement each other in examining various facets of feminine aging, focusing on popular culture, the decline of the body, collective experiences in the context of intergenerational transmission, and the Elderly Consumption Ensemble (Barnhart and Peñaloza 2013) in a span of women's life stages from middle life to old age.

Our aim in this session is to extend discussions on women, aging and consumption to counterbalance the traditional view of aging as a state of privation and decline, a moment of lost capacities (Szmigin and Carrigan 2001). This belief has been to the disadvantage of women in comparison to men who are more likely to benefit from positive associations attached to their aging process such as maturity and charisma (Steinfield et al. 2019).

The first paper focuses on cultural representations of the Crone as an empowering figure in popular culture. Their work contributes to this special session by showing how the emerging themes associated with the Crone invite us to reimagine old age and female power.

The second paper focuses on women's narratives reflecting their experience of going through the menopause in the UK. Their work offers a theoretical reflection on how women can transcend their 'unproductive' body.

The third paper explores how the aid of material and technology can enhance value co-creation for elderly women with family members/friends and service providers. It illustrates how women stimulate and leverage their interdependence in the context of the Elderly Consumption Ensemble.

The fourth paper explores intergenerational transmission though the theoretical lens of wisdom. Their paper raises issues about how grandmothers transcend aging thanks to the sharing of wisdom, and how this process helps them to build and maintain their relational identity.

This special session aims to stimulate discussion and further consumer research to shine light on the power of female aging. Together, the four papers raise two key questions: first, how can women enhance our power to transcend age by better understanding and utilizing aspects of consumer culture, the market, and family dynamics? And second, how and what can women's empowerment in aging contribute to a more enlightened society? By gaining more insights into and leverage over the creative aspects of female aging, consumer researchers, policymakers and marketers are able to enhance women's well-being, negotiate brand positioning, develop communication campaigns, and thus advance the discourse of female aging in order to provide more positive and fairer representations.

Reclaiming the Crone: Reimagining Old Age and Feminine Power

EXTENDED ABSTRACT

"The rhythmic phases of the moon waxing and waning, light and darkness, the crescent, sickle-shaped new moon, the full moon, and the waning, darkening moon – the maiden in the crescent, the mother in the full moon and, in the darkening moon, the wise old woman whose light was within her. The Divine Trinity of the Mother Goddess, as old as time itself, endlessly renewing itself – darkness, light, darkness - all aspects of the Mother Goddess to be embraced, expressing the unity of sky, earth, sea, and the rhythmic patterns of nature and all living things." (Baring and Cashford 1993: 63)

Associated with the final stage in the cycle of life, The Crone was the third aspect of the Triple Goddess in ancient culture. Being the wise old woman, the seer, the midwife, and the healer, she symbolised wisdom, knowledge and the underworld. In Irish mythology she was the Dark Morrigan, presiding over death in the battlefield, taking back the bodies of the fallen ones into her eternal, primordial embrace (Stevens and Maclaran 2007). In time the sacred associations of the Triple Goddess (Maiden, Mother, Crone) came to be de-sacralised and diabolized by male-centred religions. (Walker 1985). They supplanted matri-centred societies and replaced the worship of nature and the Mother Goddess with the worship of culture and a Male God and Son. The 'crone' came, in the Middle Ages, to be de-sacralised as an ugly, withered old woman, loathed and feared in

equal measure. She was witchlike, evil, cruel, cantankerous; a hag, an old bag, an old bat (Collins Thesaurus); she was an object 'usually of contempt' (Webster Dictionary).

The contempt expressed for the post-menopausal woman, often depicted as physically repulsive, argumentative and difficult, has echoed down through the centuries, and nowhere is this contempt more visible than in Western popular culture, where women's youth, beauty and fecundity is worshipped (acknowledging the Maiden and the Mother), but older women (the Crone) are viewed with horror, fear and revulsion.

This negative perception of the Crone, reflected historically in the Patriarchal suppression of Goddess Culture and in contemporary society by negative attitudes towards aging women, has always been challenged by feminists (Rountree 1997; Ronn and Daugaard 2005). This is aided by the flourishing of contemporary counter-cultural movements such as Neopaganism and Wicca (Griffin, 1995). The crone is now reinstated, re-imagined and reinvigorated in our 'collective consciousness' (Walker, 1985), as women grow increasingly tired of the negative associations that go with being beyond the menopause (Bay 2004; Pearsall 2018) and seek to reframe how we think about the Crone and the aging woman.

The crone, often a vilified and marginalised figure, is thus a positive archetype and force in contemporary women's culture, her fire fanned by the internet. She is celebrated as a source of wisdom, knowledge, freedom and feminine power, as evidenced by the proliferation of books, websites, forums, workshops, retreats, artworks, magazines and e-zines, performances, music, workbooks, and films, all of which reclaim the Crone for our times. Drawing on these popular culture sources, we reveal key themes associated with the crone that assist women in reclaiming her as an empowering figure, namely: freedom to choose; a disruptive cackle; and the censoring look. Then, using Butler's theory of gender performativity (Butler 1990; 1993), we discuss how these themes denote a range of resignifying practices that challenge existing ideals of femininity and disrupt norms that value a youthful - as opposed to aged - female body.

'The Foreigner within us': Catharsis amid Horror and Confusion in Menopause

EXTENDED ABSTRACT

"The worst symptom is never mentioned: there is a post-menopausal elephant in the bedroom and its name is Dry Vagina (...) A person can apply only so much lubrication. Even then, penetration is excruciating. (...) Finally, I developed a vaginal infection (...) So what are all those other post-menopausal, sexually active women doing (referring to celebrities)? Have they miraculously escaped?" (reader's testimonial, The Guardian, 2019_01_04).

"When biology no longer defines a body by its potential to reproduce, a woman will find further equality in her relationships." (journalist's testimonial, The Guardian, 2019_05_19)

"Insomnia gone, full of energy, no more night sweats, only very occasional flushes and a new confidence and stronger sense of self." (reader's testimonial, The Guardian 2019_08_25)

"I catch glimpses of the enthusiastic child I once was, and intimations of an older woman's wisdom, hard-won through a lifetime of experience. 'I feel like a snake, shedding its own skin,' I told a friend recently. On the surface I may look more or less the same. Inside, nothing is as it was." (female writer's testimonial, The Guardian, 2008_01_05)

One of the major assumptions of popular culture is that "a woman is her body", or more specifically, her body's reproductive capacity. "'In the hyper visible landscape of popular culture, the body is recognized as the object of women's labor: it is her asset, her product, her brand and her gateway to freedom and empowerment in a neoliberal market economy.' (Winch 2015, 233)." The centrality of woman's role as a mothering agent has resulted in less attention given to the development of women in midlife when reproductive capacities diminish and women start to become invisible in cultural representations (Segal 2014). Moreover, when attention focuses on women's middle life, the concern is often exclusively biological (Ballard, Elston, Gabe 2009, Gerguen 1990, p476), perpetuating the assumption that women are their body.

The hyper visibility of the reproductive body emphasizes the fact that the menopause is seen as a decline. Corus and Saatcioglu (2012) refer to the literature on the menopause as a loss, guided by medical discourse: "Although menopause is a natural hormonal transformation, it is sometimes treated as a 'process of breakdown, failure and decline'" (Martin 2001, p43, cited in Corus and Saatcioglu 2012). In this mainstream medical discourse, the menopause is described as a problem of hormone deficiency, a pathological state that needs to be treated. "Terms such as 'deterioration', 'wearing out', 'failing', 'no longer up to it' and 'getting slower' are traditionally used to describe the age-related physiological changes within the body" (Ballard et al. 2009, 279). Alternative stances, like the natural perspective, view the menopause as a natural physiological transformation that brings with it new roles and freedoms in women's lives (Corus and Saatcioglu 2012).

We tend to focus on women's biological aging and pay less attention to the cultural dimension of aging. This is what Susan Sontag (1972) called 'The double Standard of aging' (14): women are marginalized and diminished when youthful looks depart (Segal 2014), and are subject to growing gender inequality in aging (Steinfield, Coleman, Tuncay Zayer, Ourahmoune, and Hein 2019). However, feminist writers have highlighted some powerful aspects of female aging (Segal 2014, Pearsall 2018, Beauvoir 1970), referring to the real self versus the aging self. More recently, consumer researchers have called for further investigation into new understandings of the context of aging (Schau, Gilly, and Wolfinbarger 2009, Barnhart and Peñaloza 2013, Corus and Saatcioglu 2012). Our paper contributes to this call for alternative perceptions of aging by examining the context of women's experiences of the menopause.

In this study, we seek alternative discourses about the menopause experience. How do women live and make sense of their transformation in relation to the menopause? How can these women, at the intersectionality between age and gender, re-empower themselves? We collected 1000 articles referring to the menopause and published in the Guardian newspaper between 2005 and 2020. Among them, 150 articles included personal testimonials about the menopause experience written by regular readers and opinion leaders (female journalists, artists, managers).

We conducted our analysis based on these 150 testimonials. They reveal three main themes: 1. Confusion and taboo, 2. Menopause horrors as experienced by the writers, 3. Catharsis. The study expands on the philosophical ideas of Julia Kristeva (1991) about being *strangers to ourselves* to further explore the menopause as a lived experience. Kristeva suggests searching deep inside ourselves

for our more profound fears about those we call 'the foreigners'. In a similar way, old age is often approached with the same kind of fear that is felt with regard to foreigners. By welcoming the other within us, in other words, aging and the menopause, by facing the confusion and sometimes the horror it arouses in women and society at large, we may be able to get a better understanding of the strangeness of aging and its cathartic benefits. Our study goes beyond the dichotomy between medicalization and a more 'natural' approach to dealing with the menopause by representing women's experiences with the menopause as an embodied encounter with the strangeness of an 'unproductive' body.

One interesting finding of the study has to do with the distribution of voices among the different opinion pieces. Testimonials from regular readers frequently refer to confusion and horror with regard to the menopause, while its cathartic and empowering nature is defended to a greater degree by the testimonials of female opinion leaders rather than by regular readers.

This paper contributes to the discussion of female aging in middle life. It extends prior research that opposed the mainstream medical discourse on menopause with the feminist discourse (Corus and Saatcioglu 2012) by showing the capacity of women to transcend their unproductive and declining body and reveal themselves beyond their body. In this process, becoming "strangers to themselves" helps women to distance themselves from the patriarchal assumptions that associate them uniquely with their bodies. In this context, the paper raises the question of how the empowerment testimonials of women opinion leaders can support or clash with regular women in their journeys to discover the other within themselves.

What's Love Got to Do with It that Technology can't Handle? Opportunities and Challenges for Aging Women in CoCreating Value in the Elderly Consumption Ensemble

EXTENDED ABSTRACT

They need me. I mean, if they are capable to be alone, they will not need me. –Maria, paid caregiver, age 55

There really is…a need for a book, the Dr. Spock parenting book for doing this, cause there's just so much…You've been living your own life and now you're 55 years old, suddenly somebody has to inherit Mom… –Kevin, age 60

If my iPad were a woman, I'd marry her! Doris, age 76

Persons 65 years of age and over represent approximately 18% of the population in Europe, as compared to 9% in the U.S. (Population Reference Bureau 2019). In the U.S. persons over the age of 65 exhibit somewhat similar rates of home ownership (78%) and internet access (76%), although patterns of living alone, with family members, and with nonfamily members tend to vary with the loss of sight, hearing, mobility, cognitive ability, and self-care that many persons experience as they advance in age (Roberts, Ogunwole, Blakeslee and Rabe 2018). The opening quotes illustrate the importance of family, service providers, and technology, and previous research strongly and repeatedly shows that greater social contacts bring about higher and longer quality of life (Pettigrew and Moschis 2012; House, Landis, and Umbertson 1988). And yet, what is the impact of technology on value cocreation in the elderly consump-

tion ensemble (ECE hereafter, Barnhart et al. 2014; Barnhart and Peñaloza 2013)—how might it enhance these social and market ties?

This research builds on previous work on the ECE by developing theoretical and practical insights pertaining to the cocreation of value (Karababa and Kjeldgaard 2014; Kelleher et al. 2019; Storbacka et al. 2016) by examining the experiences and concerns of elderly women. Elderly women's value cocreation in consumption in the ECE is of particular importance for their quality of life and for the societies they inhabit. Notably, of the 49 million persons in the U.S. over the age of 65, 55% are women (Roberts et al. 2018), with an average life expectancy of 81 years compared to 76 years for the 45% who are men (Population Reference Bureau 2019). In addition to living longer on average, and having played particular roles in families and households for those who have/did not have children, aging women have distinct life situations and experiences that shape and impact their consumption (Drolet et al. 2010). According to a recent census report on the elderly in the U.S. (Roberts et al. 2019), elderly women have lower levels of education (approximately 1 in 5 women over the age of 65 have at least a bachelor's degree as compared to 1 in 3 men of the same age), income (their respective median incomes are $41,200 versus $56,850 for men), and poverty (11% of women live below the poverty level as compared to 7% of men in this same age cohort), and exhibit higher rates of employment (14% of women continue to work as compared to 22% of men).

The context of this study is the U.S., in drawing from empirically grounded analysis of interviews exploring the daily life of aging American women in relation to family members/friends and paid care providers in 10 ECEs, participant experience in researchers' families, and representations of elderly women in popular culture. Our findings detail the circumstances and patterns of relationships in the ECE, as aging women cocreate value with and against family members/friends and service providers, with the aid of material and technology. To explain the figure: in the circle at the top left, the figure illustrates an existing division of consumption 'labor' activities among the elderly person, E, family member/friend(s), F, and paid provider(s), P. While all persons within the ECE utilize technology, we focus on its use by the elderly person in this study, as designated by MT at the top, center of the diagram. Circumstances that alter this division of consumption labor activities include changes in the health, physical abilities, and living arrangements of the elderly person, their proclivities, and relations with others, as well as changes in the participation of other members of the ECE. In turn, these changes ripple through the ECE in altering patterns of collaboration (E and F begin to jointly pay bills, for example), alliances (E and P exclude F from an activity, for example), conflict (between E and F, or F and P, for example), deferral (E defers to F to enhance their relation, F defers to the expertise of P, for example), and dis/engagement (E fires P or F exits the ECE, as examples).

Discussion elaborates how the women empower themselves by leveraging technology in cocreating value with other agents in the ECE, by enhancing their capabilities to monitor health and living arrangements, handle finances, procure provisions, maintain social relationships with ECE and others, and remain active in their communities by keeping abreast of/participating in local events/interest groups. Implications concern women's autonomy and vulnerabilities in enhancing such value cocreation through the use of technology in dynamic, ongoing, and emergent experience and interaction with family members, friends, and service providers in the ECE and beyond, and in favorably comparing their life situations and experiences with those of others, both real life and mediated. The presentation closes with promising avenues for further research.

Wisdom Examined via a Qualitative Investigation of the Bathing Rituals of Aging Moroccan Women and their Granddaughters

EXTENDED ABSTRACT

This study investigates how aging women (Barnhart and Peñaloza 2013) exhibit consumer wisdom (Luchs and Mick 2018; Luchs, Mick and Haws under review) in their families. It specifically examines how wisdom is revealed during the public bathing practices and rituals of older Moroccan women with their granddaughters.

Wisdom in consumer behavior research refers to "the pursuit of wellbeing for oneself and for others through mindful management of consumption-related choices and behaviors as realized through the integrated application of intentionality, contemplation, emotional mastery, openness, and transcendence" (Luchs and Mick 2018, 371). The five facets of consumer wisdom refer to specific dimensions and traits – cognitive, affective, and behavioral characteristics and tendencies. Recently, Luchs, Mick and Haws (under review) extended their framework and depict six dimensions to consumer wisdom in the specific context of purchase decisions: lifestyle responsibility, purpose, flexibility, perspective, prudent reasoning, and transcendence. Lifestyle responsibility corresponds to how people resist temptation to achieve their lifestyle goals. Purpose relates to prioritizing experiences that help build relations with others. Flexibility is about sharing things with others. Perspective refers to the efforts made to grasp multiple perspectives. Prudent reasoning is about being cautious before making a decision. Transcendence refers to ethical, communal, and environmental values.

How consumer wisdom manifests and is understood heavily depends on contextual settings (Hall 2010). In the marketing and consumer behavior fields, research on wisdom has essentially focused on business managers (Mick, Bateman and Lutz 2009), shoppers (Mick, Spiller and Baglioni 2012), gatekeepers in local organizations (Luchs and Mick 2018), or innovative members of e-tribes (Kozinets, Hemetsberger and Schau 2008). However, little is known about how wisdom manifests in family settings and intergenerational exchanges, and particularly the intersection between consumer wisdom and aging women in intergenerational exchanges.

Grandmothers embrace various individual, relational and collective identities (Epp and Price 2008), which are embedded in intergenerational exchanges. Intergenerational exchanges were examined between adult children and their parents (Karanika and Hogg 2016) and between grandmothers and their young grandchildren (Godefroit-Winkel, Schill and Hogg 2019). However, little is known about how grandmothers' wisdom plays out in intergenerational exchanges particularly between grandmothers and their granddaughters.

This study aims to fill this gap by capturing Moroccan grandmothers' and granddaughters' narratives about bathing rituals and practices. In the Arab world, women traditionally go to the public bath, *hammam,* each week. While today many families have their own private bathroom in their homes, going to the public bath remains an important practice among both younger and older Moroccan women. This study captures how both Moroccan grandmothers and their teenage/adult granddaughters shape and ascribe meanings to a ritual that is steeped in history.

To grasp a deeper understanding of how wisdom works between grandmothers and granddaughters in the context of bathing rituals and practices, we conducted long interviews (McCracken 1988) with 12 Moroccan grandmothers in their homes, and with their granddaughters (age 16-24; varied socio-cultural backgrounds). We also used participant observation in public baths in Casablanca, Morocco. Interviews ranged from 45 minutes to 2 hours.

Data was analyzed following recommendations for qualitative data analysis (Moisander and Valtonen 2006). The authors analyzed the data first separately and then together (Sherry 2007). Iteration was used to form, revise, and develop understandings of the entire data set. The data analysis focused on informants' reflexive thoughts about bathing experiences and their relationships with their relatives. After considering several theoretical frameworks, we were able to identify how wisdom emerged in narratives.

Our findings first uncover how grandmothers use their wisdom in the building of their relational identities with their granddaughters. Specifically, it shows how grandmothers' wisdom is manifested - through sharing their views on lifestyle responsibility, purpose, flexibility, perspective, prudent reasoning and transcendence (Luchs, Mick and Haws under review) - as they build their relational identities with their granddaughters in the context of bathing practices.

Second, this study unveils how grandmothers' wisdom is informed by their granddaughters' consumption practices. In particular, grandmothers integrate contextual cues related to their bathing practices with their granddaughters to redefine their own sense of wisdom. This result complements existing work, which has essentially focused on how one's *personal* consumption is used to develop wisdom (Luchs, Mick and Haws under review).

Finally, this study highlights how granddaughters - younger women - build their own sense of wisdom when they interact with their grandmothers, and how they learn from their grandmothers' consumption experiences. This finding contributes to existing knowledge on wisdom, which has mainly conceived wisdom building as an individual process, which occurs in late adulthood (Hall 2010).

Our study contributes to existing literature about consumer wisdom and relational identity in old age as related to bathing and beauty rituals in consumption. It extends prior research on wisdom, and takes account of interpersonal relations (Luchs and Mick 2018) and contextual cues (Hall 2010). Grandmothers' wisdom refers to the collective pursuit of balanced relational identities and family members' wellbeing through shared consumption experiences. Grandmothers' wisdom is co-created in intergenerational exchanges.

SESSION OVERVIEW

The body is the primary conduit to consumers' sense and understanding of the world (Canniford et al 2019; Joy and Sherry 2003). The body is a site at which consumers enact self-identity (Roux and Belk 2019; Patterson and Schroeder 2010), reflexivity (Husemann and Eckhardt 2019; Thompson and Üstüner 2015), as well as pleasure and pain (Goulding et al. 2009; Scott, Cayla, Cova 2017). In all cases, however, the consumer's body is surrounded and augmented with forms of physical and discursive equipment. By equipment, we mean sets of devices used to achieve practical ends (Rabinow 2009). Equipment can span multiple scales, from the apparatus of the individual body (Zanette and Scaraboto 2019), through meso-level assemblages of body and consumption goods (Murphy et al 2018), to technologies that link consumers into large-scale dispositifs (Lupton 2015). In this special session, we extend current understandings of embodiment with new perspectives on the relationships between consumers' bodies and equipment. We explore material and non-material concepts of equipment to ask: What does the relationship between body and equipment reveal about consumption? And more particularly how does considering different facets of equipment enlighten an understanding of embodiment?

The first paper considers how consumers mobilize and shape their bodies in preparation for contingencies and imminent threats through the equipment common to the global phenomenon of CrossFit. Based on a two-year ethnography, this study analyses CrossFit's marketplace culture as a meso-level inflection of reflexive modernization. The study's findings offer an alternative to extant existential and neoliberal explanations of consumer's embodied risk-taking.

The second paper considers the equipment of time, and time as equipment. Through an analysis of diary data and depth interviews with mothers from deprived urban areas, this study illuminates the entangled practices and temporalities of mothering. The resulting configurations shape the (im)possibilities of physical activity and mothering. A body equipped with time is better off, but the equipment of time is both gendered and classed, raising considerations for rising levels of obesity.

In the third paper, the materials necessary for hobby motorcycle repair constitute the equipment for expressing embodied masculin-

ity. This study examines the embodiment of material culture to show how consumers assemble masculinity through an array of socio-material practices. Findings show how the dualistic categories of mind/body and subject/object dissolve in the intricacies of embodied socio-material relations.

The fourth paper considers skill and knowledge as equipment through which consumers effect body practices that have restorative benefits. In an ethnographic study of hobby fly fishing, we contribute an extended theory of flow to show how consumers bodies, the environment, and fishing equipment create restorative experiences.

We use various contexts, theoretical, and methodological approaches to body-equipment relationships to reveal new perspectives on the role of the body in consumer experience, consumer responsibilization, and gendered understandings of practices. This session embraces the suggested conference themes of technology (equipment) and obesity. The session is especially relevant for researchers interested in embodiment, temporality, and practice and assemblage theories.

Why Do Consumers Put Their Bodies at Risk? A Reflexive Modernist Analysis of CrossFit's Marketplace Culture

EXTENDED ABSTRACT

Consumer researchers and sports sociologists have taken an interest in understanding why consumers choose to literally put their bodies on the line, subjecting themselves to extreme physical stress and pain, and to risk injury (and even death) in the service of autotelic leisure activities (Atkinson 2011; Celsi, Rose, and Leigh 1993; Dawson 2017; Scott, Cayla, and Cova 2017; Saville 2008; Schneider, Butryn, Furst, and Masucci 2007). These studies have been framed by two distinct interpretive frameworks, which we refer to as the existential and neoliberal models, each highlighting a different set of explanatory socio-cultural conditions.

The existential model builds on the work of David Le Breton (2000) and argues that such risk-taking activities provide individuals opportunities for spiritual quests and authenticating experiences that they find lacking in the rationalized flow of modern life and its bureaucratic work orders (Celsi et al. 1993; Scott et al. 2017; also see Arnould and Price 2000; Caillois 2001). In comparison, the neoliberal model maintains that physically challenging activities are part and parcel of a new disciplinary regime of neoliberal governmentality (Foucault 2008) whereby individuals regard social life as a sphere of cutthroat competition in which only the fittest (and most self-disciplined) can attain success (Cederström and Spicer 2015; Datta and Chakraborty 2017).

Previous examinations of CrossFit's marketplace culture—which affords a communally shared experience of physical challenge, risk taking, and calculated endurance of pain—have rather expectedly followed an existential (Dawson 2017; Herz 2014; Pekkanen, Närvänen and Tuominen 2017) or neoliberal lens (Heywood 2016; James and Gill 2017; Nash 2017). While the narratives of the CrossFit enthusiasts we interviewed exhibit motifs that are compatible with both existential and neoliberal interpretive frames, we propose that there is more to the story than an enactment of neoliberal

responsibilization (Giesler and Veresiu 2014) or a quest to authenticate the self through transcendent experiences (Arnould and Price 1993, 2000).

Another important macro influence on these risk-taking consumption practices is the reflexive modernist orientation that has arisen from the structural imposition of global systemic risks (Beck 1999, 2006; Beck, Giddens, and Lash 1994). According to this framework, systemic, human-generated risks are the unintended and unanticipated consequences of the modernist project and its abiding goals of creating wealth and prosperity. Modern economies produce risks just as they produce economic gains, and these risks are difficult to manage and distribute through probability assessment—as exemplified by climate change, large-scale industrial accidents, terrorist attacks, and outbreaks of infectious diseases. As a cultural response to these conditions, the reflexive modernist ethos comprises of a reflexive awareness of systemic risks, a socially pervasive state of doubt about the ability of experts to accurately predict and control such risks, a profound uncertainty about which authorities to trust, and a paradoxical quest for being prepared for a wide range of imaginable contingencies in hopes that such preparations might prove useful to a certain degree in a time of crisis. When CrossFit practices are analyzed in relation to this reflexive modernist frame, we identify a set of socio-cultural motivations that are ideologically and experientially distinct from those highlighted by the existential and neoliberal models.

Founded in 2000 by former gymnast Greg Glassman, Cross-Fit hinges on the idea that constantly varied, high intensity, whole body workouts could induce a state of all-round functional fitness unattainable through conventional gyms. With this principle in mind, Glassman developed high-intensity workout routines that integrated movements from gymnastics, calisthenics, and Olympic weightlifting, all involving multiple repetitions in rapid-fire succession. Glassman's unorthodox approach to building functional fitness through maniacal physical exertion attracted an expanding clientele of former athletes seeking to recreate bygone experiences of competitive intensity and, importantly, first responders and military personnel who face a broad spectrum of physical challenges in the conduct of their occupations (Crockett and Butryn 2018). In press interviews, Glassman matter-of-factly discussed latent risks that CrossFitters knowingly take in order to garner the benefits of its hyperintense training regimen: ""It can kill you," he said. "I've always been completely honest about that"" (Quoted in Cooperman 2005).

Based on a two-year long ethnography of CrossFit's marketplace culture—consisting of participant observation, semi-structured interviews, and examinations of media discourses and branded content—, we analyze CrossFit as a meso-level articulation of reflexive modernization. We demonstrate that CrossFitters' understanding of embodied risk taking is shaped by the normative goal of preparing oneself for unexpected contingencies and imminent threats. In doing so, we bridge the analytical gap between studies addressing consumers' proactive risk taking and those focusing on the feelings of anxiety and uncertainty induced by the structural imposition of systemic risks. We highlight that such risk-taking challenges can themselves be market-mediated responses to the conditions of reflexive modernization, whereby consumers proactively take calculated bodily risks out of a desire to expand their capacities to effectively respond to the unpredictable manifestations of systemic risks. Finally, we show that the notion of personal responsibility—which has predominantly been studied as a defining feature of neoliberal governmentality by consumer researchers (Giesler and Veresiu 2014)— serves different ideological ends in a reflexive modernist frame. Rather than taking a neoliberal, entrepreneurial orientation as represented in previous

accounts, it manifests an always contingent endeavor for being prepared to effectively respond to challenges and contingencies amidst the radical uncertainty induced by systemic risks.

The Socio- and Material-temporal Routines of Mothering:
Why and How Physical Activity Often Fails to Fit

EXTENDED ABSTRACT

The transition to parenthood is a critical transformative experience and an inflection point for obesity (Saxbe et al., 2019). Becoming a parent often leads to reduced physical activity (PA) levels, but this effects mothers more than fathers, both in volume and type (Rhodes et al., 2014). Studies report that whereas some mothers adjust physical activity participation strategies to fit around children (McGannon et al., 2018), many attempt unsatisfactorily to integrate PA into family time (Hamilton and White, 2010). Lower socioeconomic-economic status mothers are the least likely to be active (Bellow-Riecken et al., 2008). Supporting mothers from deprived areas to become and maintain healthy levels of physical activity is therefore an important challenge for social marketers.

Qualitative health research tends to explain mothers' low PA levels as the product of social and cultural discourses which mothers draw on. 'Mother' is understood as women's 'true calling', with an emphasis on intensive presence and prioritising caring above all else (Molander and Hartmann, 2018). PA is therefore constantly subordinated through daily computations made in the shadow of socially prescribed expectations. Relatedly, mothers' low PA levels is explained by illuminating the limited leisure time afforded to mothers as they assume fuller caring roles than male partners (Hamilton and White, 2010), which compresses and fragments time for themselves. Mothers' 'free time' is noted to be highly dependent on the support of others (Wearing, 1990). Time is conceptualised as a resource that mothers have little of.

Existing studies tend to overemphasise the capacity and responsibility of individuals to realise change through resistance to societal expectations (McGannon and Schinke, 2012). Through a novel practice theory lens, this study shifts focus to the mundane experiences of mothering, examining everyday temporalities and mundane yet expertly operated materialities. The connecting theme of 'time' emerges as vital for understanding the 'demands' of the system of practices that dominates the organisation of mothers' everyday lives and often competes out physical activity.

We undertook and analysed 15 depth interviews with mothers in Bristol. Mothers in lower socio-economic positions were selected because they have less control over how their paid and non-paid time (Southerton, 2006). Half the mothers kept a diary for a week prior to the interviews. Interviews explored everyday household routines, use of material things and explored experiences and reflections of PA. Mothers ranged between 20 and 50 years and the sample included single, adoptive, married and cohabiting mothers and those whose children had special needs. Five participated in regular PA. Transcripts were analysed using thematic analysis and three key themes were identified.

Mothering can be understood as a multiple integrative practice inseparable from a larger household system of practices involving multiple practitioners: children and fathers but also schools, workplaces and childcare providers. Mothering is highly competitive, even predatory. As one respondent explained, "We don't really do anything [now we have kids]…" PA for all our respondents took a low priority, and the synchronisation of physical activity alongside

mothering practices was found to be highly unsatisfactory and "not really proper exercise", or impossible.

Three intersecting themes add theoretical power to our understanding of the predatory nature of mothering and how this implicates PA participation. Firstly, mothering practices have a dominant temporal rhythm through their entanglement with external interlocking space-time configurations. For example travel timetables, distances from work and childcare/school opening hours all shaped the rhythm of mothering. These space-time configurations demand skilful use of materials such as managing the weekly wash, which often happened in a prescribed 90 minute slot; or calculating how long a bus journey would take and if there was time for an errand or visit between school hours.

Secondly, cutting across the external space-timescapes are the temporal rhythms of everyday caring. These were dominated for our participants by the need for careful synchronisation of multiple activities and by temporal 'hot spots'. Mothers were required to orchestrate practices so they occurred in the right order, with the skilled use of particular equipment (like toothbrushes or cooking equipment), at the right time of day and with understood degrees of periodicity. Hot spots occur because many of these practices colonise (Shove, 2012) particular points of the day such as children's bedtime, and are also intersected by external, institutional spatial-temporal rhythms. PA needs to compete to recruit mothers. As Jane explains, her walk was delayed because "he poo-ed all over the carpet and that takes half an hour out of your day before you can go anywhere". Mothering practices must often be accomplished in a particular order.

Thirdly, infusing the household system of practice were collective expectations towards 'time spent' that shape PA participation. In line with others (Silva 2002), we found an accepted lack of 'time to yourself' for mothers and a low prioritisation of PA for mothers but not fathers. The way practices compete and intersect raises questions about value and authenticity. Carrie exemplifies her frustration at the elevated 'value' of her partner's PA in comparison with her own, explaining that "he just takes off and goes cycling". Later, she admits how difficult the household level expectations about her own PA are to change: "it's hard-wired as to how our daily structure works… we are just stuck in a daily routine I guess".

Only when there was compatibility between the external space-time configurations, everyday temporal rhythms of mothering practices and the temporal expectations that infuse the household system of practices did our respondents participate in regular PA. As such, our findings suggest that responsibilising mothers to participate in PA through 'sporty' identity creation or resistance is unlikely to succeed and is ethically problematic. Rather, social change relating to mothers' PA should acknowledge socio-cultural, material and above all temporal characteristics of the practices which both demand and shape the everyday organisation of mothering. Insodoing, our analysis contributes to the burgeoning critical social marketing agenda (Gordon, 2011; 2018) which draws on social practice theory to illuminate the socio-cultural shaping of everyday life (Gordon, 2018) as a basis for conceptualising intervention.

Assembling Embodiment: Body, Techniques and Things

EXTENDED ABSTRACT

By positioning embodiment to the forefront of enquiry, a nascent corpus of CCT research illuminates the sensuous and affective nature of transformative consumption experiences. Extending analysis beyond the focus on discourse and meaning which preoccupied the 'interpretive turn', these studies animate the lived experience of embodiment as it surfaces through intense sensory immersion (Goulding et al., 2009; Scott et al., 2017) and emotive bodily expressions (Hewer and Hamilton, 2010). Recent studies broaden the scope of multi-sensory enquiry, by establishing a basis for consumer research that attends to the olfactory (Canniford et al., 2018) and sonic (Patterson and Larsen, 2018). Notwithstanding these significant contributions, a deep understanding of embodiment cannot be reached through recourse to the senses alone. Embodiment also foregrounds body techniques, habituation, and the social, physical and mindful cultivation of skilful dispositions (Mauss, 1973; Crossley 2007; Murphy et al., 2019). Recent CCT studies illuminate the skilful nature of a host of consumption activities that range from freeskiing and paintballing (Woerman and Rokka, 2015), Cosplay (Seregina and Weijo, 2017), craft beer connoisseurship (Maciel and Wallendorf, 2017) and high-speed motorcycling (Murphy and Patterson, 2019). Although consumption objects are clearly central to the performance of these skilful activities, these studies do not foregrounded materiality conceptually, and as a consequence we know little about how things feature in the development of skills and the embodied dispositions that pertain to them. To this end, the present study extends Dant's (2004) assemblage theory to examine the intricacies of socio-material relations between motorcycle repairers and their motorcycles.

Re-theorizing Assemblage: An Embodied Perspective

Tim Dant's extensive work on materiality (1999; 2004a; 2004b) brings the issue of embodiment and its role in the formation of human non-human assemblages into critical light. Dant (2004) argues that the embodied experience of being-in-the-world only makes sense because we have a history of sensory experience. We know how it feels to be in the world, and we intuitively know how to interact in the world because of this experience. This embodied way of being-in-the-world is not something that we are born with, it perpetually develops over time through interaction. This process crystallises as bodily memory and because of this being-in-the-world becomes intelligible (Merleau-Ponty, 1962). Throughout our lives we engage further in the material world, embodying new skills and techniques, thereby bringing the material world more and more into our everyday lives (Dant 1999, 2004). By drawing attention to the intricate nature of socio-material relations, assemblage theory invites us to consider how things become active not only in shaping perceptual capacities but also the development of skilful embodied techniques. By examining the case of the repairer/motorcycle assemblage, this research aims to develop a theoretical understanding of how skilful embodied relations with things are formed and also how these relations become constitutive of embodiment.

A Brief Summary of Findings

The repairer's ability to relate to the material world of the motorcycle is acquired and strengthened in skill (Borgmann, 1987). As a central socio-material dynamic of assemblage formation, skill development closes the distance between the repairer and the motorcycle. Sharpened skills bring people and things together to the extent that they can assemble as one. This dynamic was exemplified in instances where the participants describe using tools with such ease and dexterity that they become like an extension of hand (Mellström, 2002). Being always takes place in the world, and because of this our capacities for skill development and habituation are inextricably relational (Dant 2004; Merleau-Ponty, 1962).

Crawford (2010) describes motorcycle repair as a *stochastic art*, which necessitates a disposition that is open and attentive to the machine. To embody this disposition, perception must be trained in relations with the motorcycle. This study illuminates how novices are taught to perceive the motorcycle's obscurities by developing

an aural appreciation of its rhythms. By mindfully listening to the sounds of engines, the capacity for acoustically informed diagnosis gradually accumulates. Similarly, through immersion in these activities, the body becomes attuned to diagnosing problems by identifying resonant sounds, smells and feels (Mellström, 2003). This pathway to skill development is illustrative of the recursivity of these socio-material relations. The motorcycle demands a finely attuned attentiveness that is receptive to its signals. But the repairer/motorcycle assemblage, also illuminates a recursivity to socio-material relations which complicates any notion of agentic subjects continuously acting upon inanimate objects.

By tuning into the socio-material dynamics of assemblage formation, we see that repairers are oftentimes drawn out of themselves and into an intimate relation with the motorcycle, whereby they are forced to question what it needs. In these instances, 'technology is no longer a means by which our mastery of the world is extended' but rather it becomes 'an affront to our usual self-absorption' (Crawford, 2010: 16). Skilled repairers must be able to see beyond the embodied techniques of their craft, to see how skills can be grounded in relations with the material demands of the situation. It is only with this outward orientation towards fixing things that the repairer can truly understand their nature. It is through these socio-material relations that the repairer incorporates the daily movements and actions of repair culture.

When we segment the world into imaginary categories and hierarchies in order to get things done, we in-effect produce dualisms (Canniford and Shankar, 2015). When we resist dualisms, by altering the ontological assumptions that guide our research, we open new up new pathways to see how previously overlooked elements constitute phenomena. Rather than slipping into the naturalised ontological stance which separates mind/body and subject/object, this paper illuminates the socio-material processes through which mind/body and subject/object assemble to co-constitute embodiment. In the routine, habitual practices of motorcycle repair sensory perceptions and gestural dexterity become mindfully honed to interact with the motorcycle and its world. By illuminating the bodies aptitude for knowledgeability and the material objects capacities to impose demands upon the would-be-subject, these socio-material relations blur the boundary that typically separates mind from body and subject from object. We see cogently that the motorcycle repairer could not come into being without this embodied emplacement in the material world.

Extending Flow: How Place, Materials, and Body Create Restorative Consumption in Nature

EXTENDED ABSTRACT

Consumer research documents a broad range of consumer experiences that offer restorative benefits. From extraordinary experiences in nature (Arnould and Price 1993; Canniford and Shankar 2013; Celsi, Rose, and Leigh 1993), to painful (Scott, Cayla, and Cova 2017), or conflict-laden experiences (Tumbat and Belk 2011), drug-induced nights out (Goulding et al. 2009), pilgrimages for the deeply devoted (Higgins and Hamilton 2019; Husemann and Eckhardt 2019), or through natural products (Thompson 2004), such experiences are understood to ameliorate the demands of today's society, the burdens of reflexivity, and the resulting "saturated self" (Husemann and Eckhardt 2019; Scott, Cayla, and Cova 2017, 24). We draw into question what many of these consumption experiences share in common: they take place in nature. A common trope in consumer research is that nature is imbued with healing qualities (Canniford and Shankar 2013). Consumers who seek out such experiences in nature, using limited leisure time and financial resources, are restored and rejuvenated, able to return 'healed' and better able to deal with life in a time-stricken and ever-connected world (Canniford and Shankar 2013; Husemann and Eckhardt 2019). While we may know why consumers seek out these experiences, and that they are restored and rejuvenated by them, how such experiences are restorative and rejuvenating remains less well understood.

To answer this question, we use Csikszentmihalyi's (1975) concept of flow as a guiding theory. Flow, characterized as a state of total absorption, diverts people's attention from the mundane to focus on the task at hand (Csikszentmihalyi 1975). As a guiding framework, it sensitizes our work to the experience of temporarily losing a sense of place and time. We also draw upon actor-network theory (Law 1992) to examine how these experiences come together as an assemblage of place, materials (equipment), and body (mind and skills). We engaged in an ethnographic study of fly fishing. Fly fishing offers a unique perspective of consumers who have a deep engagement with the activity—which includes the study of entomology, river conditions, equipment, the skills necessary to cast, and adapt to varying weather conditions. We collected data based on the ethnographic immersion of two authors of this project, participant observation, and phenomenological interviews with 21 fly fishers. In order to more closely capture the in-situ experience, we also engaged in video recording participants who then reflected upon their experiences further in interviews.

Our findings show that the restorative and rejuvenative nature of these experiences relies on a deep engagement with the context, sometimes spanning over a lifetime or decades. We show the process of restorative consumption occurs through an extended model of flow that includes: (1) preparing for flow, (2) flowing, (3) remembering flow. First, preparing for flow involves a ritualized material, embodied, and cognitive practice. Second, flowing is the phenomenological experience in which consumers enter a non-reflexive state where embodied practice prevails. Finally, Csikszentmihalyi (1990, 229) argues that flow happens in the "here and now"; however, we find that remembering flow is a highly ritualized and integral part of the flow experience. The act of remembering what flow feels like comes to shape consumers' understanding of flow and future experiences of flow.

Our research contributes an understanding of the process by which consumption environments and practices create rejuvenative experiences. First, we show that rejuvenative experiences are fleeting, and difficult to achieve and maintain. Beyond Csikszentmihalyi's (1975) descriptive need for an intersection between skill and challenge, our work captures the phenomenological experience of the entire process of flow. Second, consumer researchers broadly refer to flow as akin to a broad range of experiences—transportation experiences (Phillips and McQuarrie 2010; Wang and Calder 2006), edgework (Canniford and Shankar 2013), immersion (Phillips and McQuarrie 2010), transcendental (Schouten, McAlexander, and Koegin 2007). We bring clarity to distinguish flow from other flow-like experiences that, after Turner (1969), we call flowoid. Third, self-awareness is usually considered a virtue. Literature extols the benefits of the reflexive consumer agentically navigating social class (Thompson, Henry, Bardhi 2018), however, in our study, consumers are involved in a deep engagement to reflexively engage in non-reflexivity. In juxtaposition with extraordinary experiences literature that shows that consumers need an escape to achieve the restorative benefits of flow, we suggest that it is through a deep immersion that consumers reap these benefits. Lastly, we draw to attention the importance of the availability of a place to flow. Sustaining natural en-

vironments that facilitate such flow experiences, and making them readily available to populations is important.

SESSION OVERVIEW

Increasingly, scholars are interested in understanding the motivating factors and consequences of consumers engaging in pro-social consumer behavior. In fact, a recent special issue of the *Journal of the Association for Consumer Research* points to an 848% increase in such studies from 2000 – 2018 (White, Habib, and Dahl 2020). Pro-social behavior refers to behaviors that consumers engage in that may come at some cost to the self for the greater good or benefit for others (Small and Cryder 2016; White et al. 2020); and can include behaviors such as: charitable giving, volunteering, altruistic behaviors, ethical purchasing, engagement in cause-related activities, and advocacy or activism. For the most part, motivations for pro-social consumer behaviors have dealt with individual and situational factors mainly from a micro-level perspective. From an individual perspective, factors such as maintaining a positive image (Aaker and Akutsu 2009), self-concept (Grant and Dutton 2012), moral self-worth (Jordan, Mullen, and Murnighan 2011; Sachdeva, Iliev, and Medin 2009), or acting in one's self-interest through charitable giving may create positive feelings that encourage pro-social behaviors (Chang and Hung 2018). From a situational perspective, factors such as whether one may socially benefit from public displays of pro-social behavior (Ariely, Bracha, and Meier 2009; White and Peloza 2009), situational norms surrounding engagement in pro-social behavior (Frey and Meier 2004; Shang, Reed, and Croson 2008); and attempts to gain a sense of belonging (Lee and Shrum 2012; Twenge et al. 2007) all contribute to whether and how someone engages in pro-social behaviors.

While these studies provide insight into why individuals choose to engage in pro-social behaviors, there remains a limited understanding of the role of meso- and macro-level factors vis-à-vis these behaviors. Through a series of investigations of charitable giving, this special session seeks to fill this gap and addresses the following:

- What role(s) does the marketplace play in enacting pro-social behaviors?
- How does public discourse shape the types of pro-social causes we value and thus contribute to?
- How does pro-social and market logics shape meanings of pro-social behaviors and thus decisions to enact them?

According to Giving USA (2019), total charitable giving rose 0.7% over a total of $424.74 billion contributed in 2017. Interestingly, while giving by individuals decreased by 1.1% (for a total estimate of $292.09 billion), giving by foundations and corporations increased by 7.3% and 5.4% respectively, leaving giving by bequests flat. Though individual giving has decreased, individual giving remains the highest form of charitable giving, accounting for 68% of the total giving. Thus, charitable giving is an ideal context to examine pro-social behaviors across multiple levels, journeying from the micro-level: *A Divine Duty: Commercial Surrogacy in India and Kin Altruism* (individual). To the mezo-level: *Bodies as Gardens, Bodies as Machines: Charitable Giving as Coping* (family). And finally, to the macro-level: *The Influence of Public Discourse on Charitable Giving* (societal) and *When Pro-social and Market Logics Collide: the Sensemaking Journeys of Egg Donors in the American Infertility Field* (market).

This session will be of interest to pro-social, gift-giving, and healthcare marketing scholars.

The Influence of Public Discourse on Charitable Giving

EXTENDED ABSTRACT

This research investigates the influence of public discourse on charitable giving and how this evolves over time. The context of our study is the United States charitable marketplace, the largest philanthropic market in the world, between the years of 1991 to 2015. We contribute to a growing literature devoted to understanding how individuals, through monetary contributions to nonprofit organizations, address pressing societal issues, such as poverty, hunger, public health, animal welfare, and socioeconomic and environmental justice. The significance of these issues, alongside the rise in charitable giving to the nonprofit sector, makes the focus of this research important. To this point, in 2018 alone, the nonprofit sector hit a new record with $410 billion U.S. dollars in contributions distributed across approximately 10 million nonprofit organizations worldwide (Giving USA 2018; Salamon and Newhouse 2019).

By large, extant research encompasses two major influences on charitable giving. The first influence deals with individual donor characteristics such as altruistic identity, morality, and personal values of the donor (e.g., Boenigk and Helmig 2013; Nilsson, Erlandsson, and Västfjäll 2016; van Dijk, Van Herk, and Prins 2019). The second influence deals with the strategic action of and within nonprofit organizations and includes the effectiveness of rhetorical communication appeals, perceived characteristics of the organization, and the entrepreneurship of institutional actors (e.g., Botner, Mishra, and Mishra 2015; Gautier, Pache, and Chowdhury 2016; Sargeant, Ford, and West 2006). Surprisingly, little is known about

how macro factors, such as public discourse, which both reflect and influence historic, regulatory, socioeconomic, and political issues, impact charitable giving over long periods of time. In addressing this gap, we show how charitable behavior emerges and evolves as public discourse also changes. And, consequently we provide a more comprehensive understanding of the dynamism associated with charitable behavior.

Our research methods involved a multi-method approach. We collected charitable giving patterns of the top 400 charities in the US (1991-2015) and related fundraising expenses. This data served to operationalize actual historical charitable behavior and the ranking of organizations based on total contributions received in a given year. We also utilized three archival data sources of public discourse. First, we used a consumer opinion dataset that provide an aggregated picture of what issues or charitable causes consumers value. Second, we used archival data from popular news media including newspapers, magazines, TV, radio, podcasts, to identify, quantitatively and qualitatively, what issues and topics the U.S. society values. Third, we collected information about the top 400 charitable organizations, including advertisements in high-circulation news media to assess the strength of and/or interaction between public discourse and organizational strategic actions on charitable giving.

The quantitative analysis of datasets includes correlations, t-tests, and automated content analysis. The qualitative analysis of news media data and charitable data (e.g., textual like articles, textual/visual like advertisements) follows a hermeneutical approach (Thompson 1997) to interpret patterns of meanings in these data. We integrate both approaches by following Sanders' (1982) recommendation to identify and reflect on emerging patterns, and to derive key themes from the team's reflections. We use the program MaxQDA to transcribe analytical memos and analyze both qualitative and quantitative data.

Our preliminary results indicate that there is not a significant correlation between fundraising expenses and donations received by nonprofit organizations, from 1991 to 2015, across 18 categories of charities (e.g., social services, children & youth, health, public affairs, international, arts & culture, education, and environment & animal welfare). Rather, we find that three interrelated types of public discourse played a role in the rise of donations received by nonprofit organizations in the US: consumer opinions of pressing societal problems, earned media by nonprofit organizations, and advertisements by non-profit organizations in high-circulation news media outlets. For instance, we find a significant correlation between pressing societal problems in the mind of consumers and donations received by organizations focused on those issues in 1991-1999. In addition, over time we find that consistently nonprofits in the social services and college education categories have received combined the highest amounts of earned media and advertised across high-circulation news media.

Our research provides two key contributions. First, we expand the literatures on prosocial behavior and value by providing evidence of public discourse-driven charitable behavior and their resulting hierarchies of value (e.g., pressing societal issues, charitable causes, and non-profit organizations). In doing so, we extend the types of antecedents and consequences of prosocial behavior examined thus far in consumer research. Second, we contextualize patterns of individual charitable behavior and embed them in macro historical contexts, thus addressing calls for contextualization of micro consumer behavior (Askegaard and Linnet 2011).

Bodies as Gardens, Bodies as Machines: Charitable Giving as Coping

EXTENDED ABSTRACT

Individuals source solutions to problems in the marketplace. These problems range from basic provisioning and entertainment to broader issues such as managing significant life transitions (e.g., marriage, death) and addressing societal issues (e.g., homelessness, health crisis). We investigate charitable giving as a means of addressing societal issues, with a focus on the shortage of organ donation for transplantation.

Charitable giving is recognized as a means for individuals to provide help, hope, and life to others in need (Sherry 1983). The psychological literature examines roles for individual differences and empathy to inspire charitable behaviors (Lee and Bradford 2015), and sociocultural perspectives examine such gifts in relation to their impact on society (Bradford 2013; Strathern 2012; Titmuss 1997). While benefits of charitable giving accrue to those in need, donors may be motivated to participate to attain any number of benefits such as enhancing the well-being for others, or attaining benefits (e.g., tax, career advances) for themselves (Bendapudi, Singh, and Bendapudi 1996). The literature provides insights into how donors may partner with organizations to support those in need. Missing is an understanding of how donors may employ charitable giving as a means of coping in response to loss.

Consumer researchers examine various forms of loss and roles for consumption related to loss. Individuals experience loss in various forms throughout life—jobs, relationships with people or brands, or the transference of possessions from one owner to another. Prior research finds that voluntary losses may be managed as individuals prepare for disposition of their wealth or special possessions (Bradford 2009; Price, Arnould, and Curasi 2000; Winterich, Reczek, and Irwin 2017). And though less prevalent, there are some considerations in the literature of involuntary loss such as with homelessness (Hill and Stamey 1990), illness (Wong and King 2008), or death (Bonsu and Belk 2003). What is the relationship between loss and charitable giving? The present research examines the traumatic experiences of loved ones' sudden loss. More specifically, we examine the experience of deceased family (DDF) members who participate in charitable giving by donating their loved one's organs to others in need. More specifically, our research examines how experiences of charitable giving may serve as a means of coping when individuals are faced with loss.

The relationship between the marketplace and coping find that the market may be both a source of and a relief from stress. For example, scholars examine how consumers cope with stress in the marketplace, such as with unsatisfactory experiences (Duhachek 2005), brand termination (Russell and Schau 2015), difficult decisions (Luce, Bettman, and Payne 1997), or bias (Bone, Christensen, and Williams 2014). Further, scholars find consumers employ the marketplace as a means of coping to manage life transitions, such as divorce (Yap & Kapitan, 2017), or relieve temporary stress, as through retail therapy (Atalay & Meloy, 2011; Townsend & Sood 2012). It is evident the marketplace provides opportunities for consumers to cope with life stressors. While prior research considers common life stressors and roles for the marketplace in consumer coping, the present research examines sociocultural influences to explain how individuals employ the marketplace to cope with trauma.

We conduct an ethnographic study with deceased organ donor family members to interrogate experiences of involuntary loss. We find three themes: transforming loss into gifts of comfort; crafting

new futures from loss; and, the marketplace and the sacred. Deceased donor families contemplate the life of their loved one, and the potential of some part of the body living even as the essence of their loved one is dead. For those families, sacralization is evident as they recognize continuity of life through a loved one:

Good, really positive that something good comes out of something so tragic, it doesn't seem a waste. In some way it's better than if someone just dies, they're cremated or buried and that's it. He's still out there, part of him is still out there. When you've come from the family that we have, we've all worked helping other people in our lives, it's a natural thing to do to, go on a do it when you're dead. Totally unselfish. ~ Jade

Deceased donor family members begin to consider parts of the body and how body parts may provide life to others. In so doing, the body itself is recognized as sacred as a whole as well as each of its parts due to its life-giving forces. We extend prior understandings of consumer coping with an explanation of how charitable giving facilitates the transformation of loss from that of suffering into new futures.

A Divine Duty: Commercial Surrogacy in India and Kin Altruism

EXTENDED ABSTRACT

The emergence and global expansion of Assisted Reproductive Technologies (ART) continues to challenge deeply held values and beliefs regarding reproduction, parenthood and family across the world (Sobande, Mimoun, and Trujillo Torres 2019; Takhar and Rika Houston 2019). While certain types of ART such as in vitro fertilization have become more accepted(Fischer, Otnes, and Tuncay 2007), commercial surrogacy remains a highly controversial (Tadajewski 2016), and regulated practice characterized by perceptions of exploitative commodification and (dis)empowerment of gestational carriers (Fenton-Glynn 2019). This industry, now estimated at 6 billion dollars (USD), is subject to moral, ethical, legal, and political debates, especially in countries with large numbers of socioeconomically vulnerable women (Varman et al., 2016).

In public discourse surrounding international reproductive tourism, commercial surrogacy is often construed as dirty work (Pande 2010) and surrogates are derided and silenced for participating in this exchange process. Moreover, commercial surrogates operate as commodified consumers and stigmatized producers in a market system where the exchange boundaries between these two roles are blurred. That is, they consume conventional health services and act as value-producing actors within socio-cultural contexts that harbor negative attitudes towards surrogate's participation. Because commercial surrogacy, especially in an emerging market context like India, is conceived as a stigmatized exchange, market actors cannot rely on mainstream discourses to legitimize their participation in this exchange. Particularly, in the Indian context, the public discourse associated with gestational surrogacy is increasingly influenced by ongoing regulatory actions to ban surrogacy and curb the growth of this industry. Thus, our project investigates how surrogates, as consumers and co-producers, construct and justify their participation in an increasingly regulated and stigmatized exchange process.

To address our research question, we conducted an examination of gestational surrogate women in the heart of the international, commercial surrogacy industry in Gujarat, India. Data were collected primarily through nineteen in-depth interviews with commercial surrogates and their families over a period of eighteen months. To triangulate this initial dataset, we also interviewed eight local health

service providers and politicians, and systematically collected and analyzed articles on the topic published in four leading daily newspapers. We rely on prolonged engagement, purposive sampling, and thick description to address the issue of trustworthiness (Belk, Fischer, and Kozinets 2013).

Our initial findings suggest that surrogates construe their market participation as two forms of kin altruism (Ashton et al. 1998; Lee, Winterich, and Ross Jr 2014; Small and Simonsohn 2008) downplaying the pecuniary aspects related to it. Kin altruism refers to the "tendency to feel empathy and attachment toward others. This is based on the deduction that one is more likely to behave altruistically toward one's kin if one considers costs and benefits to those kin, and not only costs and benefits to oneself, when deciding among behavioral alternatives" (Ashton et al. 1998). On one hand, surrogates adopt a discourse that invokes existing and popular sociocultural and religious symbols, which aims to remove social-cultural differences between them and non-surrogates in India. For instance, several participants equate themselves with Yashoda, a foster mother of mythological Hindu God Lord Krishna. In doing so, they emphasize the responsibility put on them by their divinity to help the needy and deficient. On the other hand, surrogates create kin-like connections with the commissioning mothers, often with the aid of marketplace intermediaries such as health clinics and for-profit agencies. By adopting empathetic and deep sisterhood connections, surrogates aim to remedy the deficiencies (i.e., infertility) of commissioning mothers, which enable them to justify and manage their own bodily, social, and cultural sacrifices. Through these discursive constructions, commercial surrogates attempt to challenge and to rectify the increasingly disdainful societal attitudes toward gestational carriers and influence policymakers.

Our work contributes to understanding how constructions of altruism are used to justify the participation in a market exchange process in dramatically under-researched context (Belk 2016; Tadajewski 2016), which is characterized by vastly different sociocultural, economic, political, and legal values and systems than the typical free market contexts seen in the literature. Furthermore, our work addresses the justification of actors engaging in an increasingly regulated and stigmatized market exchange, while most of the prior literature considers market actors' practices in contexts which are destigmatizing (e.g., Sandikçi and Ger 2010; Scaraboto and Fischer, 2013). By doing so, our work highlights how market participation in stigmatized market exchange is emphasized as a prosocial behavior helping deficient consumers. This work also broadens the growing literature on assisted reproductive technologies markets by showing how constructions of charitable giving intersects with the emergence, growth, and eventual decline of an international biotechnology market.

When Pro-social and Market Logics Collide: the Sensemaking Journeys of Egg Donors in the American Infertility Field

EXTENDED ABSTRACT

In fields characterized by institutional complexity, where multiple and often contradictory logics are at play, the prescriptions and proscriptions of differing logics can lead to tensions in the marketplace (e.g., Ertimur and Coskuner-Balli 2015; Scaraboto and Fischer 2013) . These tensions are likely to be particularly acute in contexts characterized by both market and pro-social logics (e.g., Beverland and Luxton 2005; Hartman and Coslor 2019). While considerable research has studied how formal organizations such as social enterprises navigate competing market and prosocial logics (e.g., Jay

2013; McMullen and Bergman 2017) less research has examined how individual actors who are not members of formal organizations manage the multiple logics that confront them as they interact with other market actors and engage in exchanges.

In this study, we examine a particular category of actors who engage in exchanges in a context characterized by competing pro-social and market logics: we study women who sell their ova or eggs to buyers in the U.S. infertility industry. We do so to understand how they make sense of their role in the marketplace, and how their sensemaking influences their actions. This paper thus contributes to a better understanding of the implications of logic multiplicity in general, and of conflicting pro-social and market logics in particular.

Since the mid 1980's, the demand for donated human eggs has steadily increased as a solution to certain types of infertility diagnoses. Egg donors are usually young, college-aged women recruited by market intermediaries (donor egg agencies) or fertility clinics to be matched with potential recipients. Historically, donors would work directly with matched recipients to provide eggs through a fresh cycle and embryo transfer to the recipient. More recently, due to innovations in Assisted Reproduction Technologies (ART), donors can also provide eggs without a matched intended recipient, where eggs are retrieved for frozen egg banking to be used at a later time. While there is no data available on how many women have donated their eggs, nor how many cycles have been performed on donors, we do know that in 2016, 24,300 ART cycles were performed for recipients using donor eggs (CDC, 2018). The prosocial logic in this context is reflected in terminology that frames women who provide eggs as 'donors' and 'angels' who 'give the gift of life' (Almeling 2007). At the same time, the market logic in this context is everywhere in evidence, and is reflected in discourse regarding how egg donors can 'make $10,000' and 'pay off their bills/tuition' (Hartman and Coslor 2019).

Depth interviews were conducted with 11 women who had donated their eggs in the US medical marketplace and received compensation. Additionally, online observations were conducted in online forums where egg donors and potential recipients discuss salient issues such as compensation, motivation and matching. Data were analyzed in an iterative fashion, that involved both initial open coding and multiple stages of higher order coding, guided by the research goals of this paper and abetted by the enabling lens of institutional theory.

In the initial stages of considering egg donation, when participants were first engaging with recruitment advertising or egg donor agencies, many drew on both prosocial and market logics to make sense of the possibility of becoming a donor. While some participants stressed altruism as a primary rationale consistent with a pro-social logic and referred to financial compensation as "a nice bonus," others explained their initial motivation as primarily economic. Most informants invoked both logics to rationalize their initial involvement in the industry.

As the participants moved from considering egg donation to actually engaging in the practice, balanced sensemaking typically gave way to an a nearly exclusive focus on the market logic. At least partially in response to interactions with medical personnel that were experienced as highly depersonalizing, many described objectifying themselves, specifically as a provider of eggs responding to a market demand. While we know that some young women perceive their eggs as potential babies, (Rauscher et al. 2017), most of our participants sought to distance themselves from any emotional attachment to their the eggs. They tended to view their eggs as expendable "things" that they could monetize. For example, one participant recalled a conversation where she was asked: "'How could you have

done this? How could you have given your babies away?' But they weren't babies, you know. It wasn't like I was putting them up for adoption, these weren't mine. These were just things that we produce each month." Another stated. "It was like having an old piece of furniture in your house that you don't need and somebody said, 'Hey, I'll give you $8,000 for it.' I was planning on getting rid of it anyway." This market-logic influenced way of making sense of their own egg donation was compounded for those who became "known donors," a term used to describe those whose previously donated eggs had reliably resulted in the birth of healthy babies. These individuals could command higher compensation levels; choosing to do so would be difficult to reconcile with a pro-social logic.

Our data analysis suggests, however, that not all egg donors came to rely purely on market logics to rationalize their behaviors. In particular, those donors who exerted their agency to connect with the recipients who purchased their eggs, and particularly with their biological offspring, often tended to circle back to a reliance on both pro-social and market logics to make sense of their past behaviors and plan their future actions. As a tentative theoretical insight, we posit that when actors can engage in meaningful social relations in contexts of the type described here, they are more likely to find pro-social logics and market logics similarly salient. In contrast, those whose exchanges commence and remain anonymous are less likely to draw on pro-social logics to rationalize their actions and more apt to rely solely on market logics for sensemaking.

SESSION OVERVIEW

An increasing share of the population in industrialized countries is obese, with severe public health consequences. Although consumers generally have the goal to eat healthily, they often struggle to follow through (Hofmann et al. 2012). Helping consumers to make healthier food choices is thus an important avenue for marketing research to ultimately foster consumer well-being.

This special session examines how consumers navigate the social influence that other people exert on their food choices and what beliefs underlie their behavior. We use a multi-method approach to investigate which social situations aid versus hinder consumers' healthy choices, and how consumers think about social influence on their food choices. Thereby, we add to the understanding of consumption not only as need satisfaction, but also as a way to seek recognition and belonging (Berger and Rand 2008).

The first and second paper highlight that consumers use healthy food choices to manage the impression that others have of them. Specifically, the first paper shows that consumers make healthier food choices in the presence of outgroup (vs. ingroup) others. This effect holds across a variety of outgroups (e.g., racial, professional, or academic outgroups). Consumers anticipate that outgroups others judge them more negatively than ingroup others, and they use healthy food choices to counter these anticipated negative judgments, as healthy eating is believed to be a generally praiseworthy behavior (Stein and Nemeroff 1995). The second paper tests whether consumers believe that they can use healthy food choices as a means to signal social status to others. Because restraint is associated with many positive life outcomes, restraint itself might signal status. Consumers who chronically or situationally desire high social status make healthier food choices, due to the belief that high status entails exerting restraint.

The third and fourth paper look at consumers' active role in shaping the social environments of their food choices. In more detail, the third paper argues that consumers encourage others to match their consumption behavior when making indulgent (vs. healthy) choices to justify their own indulgence. Consumers feel worse about indulging when their social environment eats healthily. Therefore, consumers try to influence others to indulge so they can, too. The fourth paper investigates consumers' beliefs about being influenced by their social environment to make healthy choices. Consumers approve of others trying to influence their food choices by nudging, but only when the nudges are perceived to be effective at aiding healthier choices. Thus, consumers endorse social influence when they believe that it helps them to eat healthily.

Taken together, we show that consumers take an active role in influencing others' impression of them based on their food choices, influence others based on their desires, and approve of being influenced if it helps their healthy eating. These behaviors are based on consumers' beliefs about healthy choices being desirable but difficult to make without a little help from others. These findings have important theoretical implications for research on social influences and food choices, as well as practical implications for marketer and public policy makers.

Feeling Judged? The Presence of Outgroup Members Promotes Virtuous Choices

EXTENDED ABSTRACT

Consumers routinely choose between products of virtue (e.g., healthy food) and those of vice (e.g., indulgent food). These choices take place not in a social vacuum, but often in the presence of observers, for example in supermarkets or cafeterias. Whereas much research has shown that consumers choose virtue over vice in the presence of observers compared to when alone (e.g., Griskevicius, Tybur and van den Bergh 2010), what is not yet known is whether characteristics of the observers affect consumers' choices.

Social diversity is increasing in neighborhoods, schools, and workplaces (Putnam 2007). As a consequence, consumers regularly encounter outgroup others who belong to different social groups (e.g., ethnic, academic, or professional outgroups). In such instances, consumers might fear negative judgment, because they themselves judge outgroup members more negatively than ingroup members (Brewer 1979). As consumption not only fulfills personal needs for specific products, but also social needs for recognition and acceptance (Berger and Heath 2007), consumers might choose products to alleviate the negative judgments they expect from outgroup observers.

In this research, we investigate whether the presence of an ingroup vs. outgroup observer influences consumer choices of virtuous versus indulgent foods. We predict that consumers will make healthier choices in the presence of outgroup (vs. ingroup) others, mediated by the anticipation of being judged negatively by outgroup members. In seven studies, we showed the effect of observers' group-membership on choice virtuousness using various types of group memberships (race/ethnicity, school- and work-affiliation),

food choices, and participant populations (university-students and general-adult populations).

Study 1 tested the causal link between an observer's group membership and participants' food choices. Three hundred thirty-six participants were approached by a black or a white research assistant (RA) to complete a filler survey. Afterwards, participants chose between an indulgent KitKat bar and a healthier fruit snack (our dependent measure). We coded as ingroup (vs. outgroup) any responses for which the RA and the participant were of the same (vs. different) race. A greater proportion of participants in the outgroup condition chose the healthier raisins (44.16%) than in the ingroup condition (29.41%; $b = .64 (.33)$, $z = 1.94$, $p = .053$).

Studies 2 and 3 replicated the effect of observer group-membership on food choice for another type of group membership: university affiliation. In Study 2, 180 student participants were approached by an RA dressed either in their university's t-shirt and cap (ingroup condition) or in another local university's t-shirt and cap (outgroup condition) to complete a filler survey. Afterwards, participants chose between indulgent M&Ms and healthier raisins (our dependent measure). A greater proportion of participants in the outgroup condition chose the healthier raisins (31.25%) than in the ingroup condition (12.16%; $b = 1.19 (.45)$, $z = 2.66$, $p = .008$. In Study 3, 154 student participants completed an online study they believed originated from their own university (ingroup) or a foreign university (outgroup). For our dependent measure, participants chose between a health-minded vs. an indulgent restaurant gift-card. A greater proportion of participants in the outgroup condition (80.77%) chose the healthier restaurant than in the ingroup condition (65.79%; $b = .78 (.38)$, $z = 2.08$, $p = .037$.

Study 4 tested the role of expected interpersonal-judgment in the effect of observer group-membership on food choice. Using a causal-chain mediation, two separate studies examined this proposed psychological process (expected interpersonal-judgment) as both an effect of the independent variable (observer group-membership) and as a predictor of the dependent variable (food choice). In Study 4a, 206 participants imagined making an indulgent food choice in the presence of an ingroup (vs. outgroup) observer, and indicated their expected interpersonal-judgment from this person. Participants expected the outgroup member would judge them more negatively ($M = 4.87$, $SD = 2.03$) than the ingroup member ($M = 5.52$, $SD = 1.87$, $t(204) = 2.39$, $p = .018$). In Study 4b, 192 participants imagined choosing between indulgent and healthy food options in the presence of an observer (with unspecified group membership), and indicated their expected interpersonal-judgment from this person, as well as their food choice. The more harshly participants expected the observer to judge them, the more likely they were to choose the healthier option, $\beta = .235$, $SE = 0.113$, $t(197) = 2.076$, $p = .039$.

Study 5 tested the moderating roles of internal-attribution tendencies. Three hundred twenty-three student participants completed an online survey they believed originated from their own university (ingroup) or another local university (outgroup). Participants indicated their preference for healthy and indulgent subscription food-clubs, and their general tendency to make internal attributions for their own actions using Touré-Tillery and Light's (2018) self-diagnosticity scale. We found a significant interaction of observer group-membership × internal-attribution tendency × food type ($F(1, 298) = 4.76$, $p = .030$). As we expected, internal-attribution tendencies moderated the effect of observer group-membership on food choice such that it replicated at lower—but not at higher—levels of internal-attribution tendencies.

In Study 6, we used (US) state-level search data from Google Trends to examine the relationship between the percentage of minor-

ities in a state (our proxy for the presence of outgroup observers) and the relative number of Google searches for pretested healthy versus unhealthy foods in that state (our proxy for food choices). We found a significant interaction of food type × percentage of minorities ($b = 15.63 (6.85)$, $t(49) = 2.28$, $p = .027$). As expected, as the percentage of minorities in that state increased, the relative number of searches for healthy food (vs. unhealthy food) also increased.

Our finding that observer group-memberships affects consumers' indulgent vs. healthy choices has several implications. On a theoretical level, research has not yet shown that people use food choices to influence others' perceptions. This finding is important because it highlights that the social environment impacts food choices in more complex ways than previously thought. On a practical level, marketers should consider the diversity of the environment in which they market healthy vs. unhealthy products. Thus, social diversity matters when marketing products and segmenting consumers.

Conspicuous Self-Control: When Status Motives Lead Consumers to Signal Restraint

EXTENDED ABSTRACT

Extant research suggests that status signaling motivations lead consumers to behave indulgently. They are more willing to purchase conspicuous luxury products over less expensive options to convey wealth and signal high status (Rucker and Galinsky 2008). We posit that when consumers are unable to convey wealth, they respond to status signaling desires by attempting to convey self-control because of the need to appear goal-oriented. Goal-oriented individuals are more likely to succeed in school and in their careers (Locke and Latham 2006), both of which can lead to high status. Self-control may indicate that a consumer is goal-oriented because it involves sacrificing an immediate desire for a long-term result. Thus, status signaling consumers may attempt to conspicuously engage in self-control as a way to signal that they are highly goal-oriented, and ultimately high status.

Six studies examined whether consumers display self-control to signal high status because such behaviors signal that they are goal-oriented. In studies 1-4, we held the product prices constant in all the choices that participants made. We conducted Study 1 in a low-income area of a large metropolitan city. Two experimenters approached individuals in public and gave each participant one of two flyers, one that stimulated a status-signaling motivation or one that did not. After reading the flyer, participants chose between receiving a self-control signaling product (banana) or a different product (M&Ms). Status signaling motives (vs. control) led participants to select the banana (i.e., the self-control product; $p = .04$).

Study 2 replicated the effect in a controlled environment. We randomly assigned participants to a status signaling or control condition. After the status manipulation, they imagined that they were with two other people while at home and had the choice between sharing a self-control related video (self-control signaling product) or an enjoyable video. Status motives (vs. control) led consumers to select the self-control video ($p < .01$).

If status signaling motives lead consumers to conspicuously choose products that signal self-control, then consumers should attempt to make such products observable to others (Sundie et al. 2011). Study 3 examined this by employing a 3 (status signaling motivation: high, low, vs. control) × 2 (self-control signaling product: yes vs. no) between-subjects design in which preference for a transparent versus an opaque container was our dependent variable of interest. We primed participants with either a high, low, or control (no prime) desire to signal status and randomly assigned par-

ticipants to a healthy meal (i.e., self-control signaling product) or an unhealthy meal condition. Participants imagined that they were with a group of people and were purchasing lunch from a local restaurant that served healthy (i.e., self-control signaling product) or unhealthy meals. They picked between 2 containers for their meals – one that was transparent or another that was opaque. The analysis revealed only a significant interaction (p = .04). Status signaling participants preferred the transparent container more for a healthy, self-control signaling meal compared to an unhealthy meal (p = .009), an effect not found in the other two conditions.

Study 4 sought to examine whether a desire to signal that one is goal-oriented mediated the effect. We randomly assigned participants to a status signaling or control condition. After completing the manipulation, they imagined shopping with several people and indicated their preference between receiving a self-control application or a gaming application. They also reported their need to signal that they were goal-oriented. Status signaling participants were more likely to select the self-control application (p < .05). Desire to signal that they were goal-oriented mediated the effect.

While the previous studies held the product prices constant, Study 5 aimed to show that the effect weakens when consumers choose between products that vary largely in price, and therefore, allow the consumer to signal wealth instead of self-control. We randomly assigned participants to a status signaling or control condition. After completing the manipulation, they imagined shopping with several people and indicated their preference between purchasing a tablet with preloaded self-control applications or a tablet with preloaded games. We told half the participants that both tablets cost $150. We told the rest of the participants that the gaming tablet cost $350 and the self-control tablet cost $150. The results revealed a significant interaction (p < .001) in which status signaling participants were more likely to select the self-control tablet, but only when it was equal price with the games tablet.

Study 6 aimed to demonstrate that even in situations where status signaling consumers are tempted to purchase more expensive products over less expensive options, they can be motivated to purchase the less expensive option if they remember that saving behavior is a signal of self-control. We randomly assigned participants to a status signaling or control condition. After completing the manipulation, they imagined shopping with several people and indicated their preference between purchasing one of two cell phones. One phone was $200 more than the other. We reminded half the participants that saving behavior signals self-control. The results revealed a significant interaction (p < .05) in which status signaling participants were more likely to select the less expensive phone, but only when we reminded them that saving behavior signals self-control.

Our findings suggest that status-signaling motives can enhance preferences for products associated with self-control because consumers equate high status with a strong goal orientation. From a practical perspective, our findings suggest that marketers can encourage consumers who desire to signal status to engage in self-control and purchase self-control related products.

Have your cake and make her eat it too: Influencing one's social influence to justify indulgence

EXTENDED ABSTRACT

Because indulging violates personal standards of behavior (Dahl, Honea, & Manchanda, 2003), people have a variety of ways to justify their actions (Khan and Dhar 2006; Kivetz and Zheng 2006; Xu and Schwarz 2009). One way to justify one's transgressions is by comparing one's behavior to others'. People are likely to indulge more when others are indulging (Burger et al. 2010; Herman, Roth, and Polivy 2003; Prentice and Miller 1993), and feel less guilty if another person engages in small indulges with them than if they indulge and the other person abstains (Lowe and Haws 2014). If others' bad behavior makes people feel better about their own transgressions, might people manipulate those norms directly? We hypothesize that people encourage others to match their consumption behavior when they indulge (vs. not indulge) in order to justify their indulgence.

In study 1a, participants (100 MTurk) rated how fun and indulgent 40 activities were (e.g. eating a slice of cake, buying groceries) and how justified they would feel doing those activities alone and with a friend. People felt more justified doing indulgent activities with friends than alone, and this difference increased with ratings of indulgence t(3996)=16.45, p<.001. In study 1b, participants (100 MTurk) rated how fun and indulgent the same activities were, and how likely they were to encourage their friends to do those activities with them. Indulgence predicted encouragement of friends to match their behavior, controlling for how fun the activity was, t(3980)=9.33, p<.001.

Study 2 tested whether people are more likely to encourage others to match their indulgent (vs. non-indulgent) behavior to justify their behavior. Participants (295 MTurk) imagined that they ordered a beer or lemonade with lunch, and that their friend asked what they should order. Participants indicated their recommendation and how justified they would feel if their friend ordered beer and how justified they would feel if their friend ordered lemonade. Participants encouraged their friend to match their consumption more when they ordered beer than lemonade, t(192)=–6.99, *p*<.001. This was not driven by participants always encouraging beer; those in the beer condition encourage beer more than those in the lemonade condition, t(192)=4.39, *p*<.001. (Across studies, matching and indulgence are examined separately when relevant; we expect both more matching and more indulgence encouragement in the indulgence vs. non-indulgence conditions). Mediation indicated that people encouraged matching more for beer than lemonade because they anticipated matching to make them feel more justified when drinking beer (vs. lemonade), CI_{95}[-.21, -.02].

Study 3a tested the underlying reason for this anticipated justification. Female participants (N=200 MTurk) imagined ordering either cake or fruit salad, and indicated what they would encourage their friend to order. They responded to mediator items representing three proposed mechanisms: (1) having a partner-in-crime (e.g., "If my friend followed my recommendation…I would feel more justified because at least we would both be engaging in equally bad behavior," (2) lowering perceived consequences (e.g., "…I would feel like my choice was less 'bad' or 'wrong',"), and (3) changing the situational norm (e.g., "…it would feel like I made my choice for a celebration"). Those who chose cake recommended that their friend match their behavior more than those who chose fruit, t(192)=-5.33, *p*<.001 (and recommended cake more, t(192)=–4.39, *p*<.001). Only the partner-in-crime measure mediated the effect, CI_{95}[.022, .530]. Study 3b manipulated whether ordering cake was justified or not: cake either exceeded (unjustified) or was within (justified) their allotted "diet points." Participants (N=200 female MTurk) who had unjustifiably (vs. justifiably) ordered cake were more likely to encourage that their friend match their behavior by ordering cake, t(197)=6.01, *p*<.001. Both partner-in-crime (CI_{95}[.001, .244]) and situational norms (CI_{95}[.059, .417]) mediated this effect.

Study 4 explored the role of gender in the lab. Same-gendered friend dyads were directed to two separate rooms, each containing a face-down playing card (one red, one black, randomly assigned).

The experimenter explained that if the card was red, they would eat a Snickers bar (indulgence), and if it was black, they would eat saltine crackers (non-indulgence). Participants privately checked their card. The experimenter then said she "forgot" to choose a card for the other participant, and asked participants to choose a card for their friend from a box. The box contained eight face-down cards and two face-up cards (one red, one black). Participants chose a card matching their own more when they were assigned to indulge (B=.38, SE=.15, p=.012), with no gender interaction. When examining choice of indulgence, a pre-registered gender by snack interaction emerged, B=.29, SE=.15, *p*=.052. Women were marginally more likely to choose indulgence when they were assigned to indulge than not, B=.32, SE=.19, *p*=.085; men did not show this difference, B=—.25, SE=.22, *p*=.27.

Study 5 tested whether people indulge more when they can first facilitate indulgence in others. Participants (150 female students) expected to be assigned to snack or not while watching a video. In the "self-only" condition the participant served herself mini peanut butter cups from a large bowl. In the "both" condition, the participant was also asked to serve another participant, ostensibly in another room. As expected, those in the "both" condition served themselves more than those in the "self-only" condition, t(103)=3.00, p=.003. To ensure that participants in the "both" condition were not being generous and subsequently anchoring their own serving on a larger amount, there was also an "other-only" condition in which participants served only another participant (ostensibly because the stimuli were in the wrong room). They unexpectedly served the other participant more in the "other-only" condition than they did in the "both" condition, t(100)=3.45, p<.001. This suggests that people were not simply anchoring on a generous amount in the "both" condition, as they were even more generous in the "other only" condition.

Thus, consumers play a role in shaping their social contexts when they wish to justify their own indulgence. This contributes to research on social influence, dyadic consumption, and justification literatures, while having marketing implications (e.g., when to offer "bring a friend" deals vs. BOGO deals).

Effectiveness and Acceptance of Healthy Eating Nudges

EXTENDED ABSTRACT

A growing number of governments, food producers and retailers, are considering implementing nudges promoting healthier eating. A nudge can be defined as "any aspect of the choice architecture that alters people's behavior in a predictable way (1) without forbidding any options, or (2) significantly changing their economic incentives. Putting fruit at eye level counts as a nudge; banning junk food does not" (Thaler and Sunstein 2008).

Not all healthy eating nudges are equal. A recent meta-analysis (Cadario and Chandon 2019) found that their effectiveness increases as their focus shifts from influencing what people know (cognitive nudges), how they feel (affective nudges), or what they do (behavior nudges). This study further distinguishes between two or three subtypes of nudges for each category, leading to seven types of nudges. Cognitive nudges include "descriptive nutritional labeling," "evaluative nutritional labeling," and "visibility enhancements". Affective nudges consist of "healthy eating calls" and "hedonic enhancements". Behavioral nudges include "convenience enhancements" and "size enhancements."

Selecting the optimal healthy eating nudge is not just a question of selecting the most effective one. Governments and companies must also consider whether these nudges are likely to be accepted by consumers. Although all nudges are supposed to improve consum-ers' welfare "as judged by consumers themselves » (Sunstein 2018), this assumption is rarely tested. Certainly, it seems cavalier to assume that consumers will welcome any nudge, especially those that restrain their perceived sense of agency.

Therefore, the goal of this study is to help decision makers select the best healthy eating nudge by measuring consumers' perceptions—including their acceptance—of the seven types of nudges identified in the literature. In a second step, these perceptions are compared to the actual effectiveness of the same nudges reported in Cadario and Chandon (2019).

Methods

We surveyed 118 American citizens about their acceptance of different types of healthy eating nudges. To investigate the drivers of their acceptance, we asked them about their perceptions of the effectiveness of each nudge and of the beneficiaries of the nudge (good for health, good for business, or both). Participants were presented, in random order, the scenarios for seven healthy eating nudges.

We asked participants to answer two questions: "Do you approve or disapprove of the following policy?" (Approve/disapprove) and "Do you think that this policy will make people eat better?" (Yes it will/No it will not). Then, we compared these perceptions to the average effect sizes about these seven nudges reported in Cadario and Chandon (2019).

Results

The actual effectiveness of these seven nudges was inversely related to their mean approval rating (r=-.57) as well as to their perceived effectiveness (r=-.49). For example, only 43% of respondents approved the most effective intervention – portion and package size reductions.

To examine the drivers of nudge approval, we regressed approval on the effectiveness of the nudge (the standardized mean difference reported in the meta-analysis), its perceived effectiveness, two binary variables capturing the effects of the perceived beneficiary of the nudge, and the individual characteristics.

First, we found that approval was positively associated with perceived effectiveness, as one would expect, but negatively associated with actual effectiveness. Second, we found that interventions perceived as a "win-win" for business and health had higher approval than interventions perceived as benefiting either health or business, and that there were no differences in approval between each of these respectively

Discussion

The average approval rate of the seven healthy eating nudges was only 56%, a lower rate than we would expect based on prior results suggesting that the United States is a "pro-nudge" country (Sunstein et al. 2017). More importantly, there were large variations in approval across nudges. Consistent with prior research, there was higher approval for deliberative ("system 2") than for automatic ("system 1") nudges (Felsen et al. 2013; Jung and Mellers 2016). Nudges with the highest approval (85%) were those that simply inform consumers, such as descriptive nutrition labels. The addition of interpretive symbols (such as color-coding) to shift from description to prescription reduced approval levels from 85% to 76%.

Our results extend this research by showing that the most effective healthy eating nudges receive significantly lower approval than the rest. The average approval rate of the two most effective nudges, convenience enhancements and portion and package size reductions, was 43%, indicating that when asked to choose between healthy eating nudges, there is a tradeoff between approval and effectiveness.

What, then, drives the approval of healthy eating nudges? Our analyses rule out that people simply reject nudges that they deem to be the most effective – for example because they do not want to be influenced. In fact, approval ratings increased with *perceived* effectiveness. This suggests that the problem is not that people dislike being nudged but that they are poor judges of which nudges are effective.

Obstacles and Opportunities to Consumer Engagement in Medical Decision Making
Chair: Mohamed A. Hussein, Stanford University, USA

SESSION OVERVIEW

Because of the rapid proliferation of medical information, consumers are becoming more engaged in decisions about their health. For example, consumers increasingly track their health-related behaviors (e.g., number of steps, calorie intake, sleep quality) through wearable devices (e.g., Fitbits); go online to diagnose themselves and learn about possible treatment options; and leave online reviews reflecting on their experiences with healthcare providers.

Importantly, medical decisions often involve multiple stakeholders: physicians, consumers/patients, insurance providers, and policy makers. This session aims to explore these different perspectives, and highlight four specific ways in which social, cognitive, and motivational variables could hamper or facilitate consumers' medical decision making. These papers incorporate a diverse array of empirical methods including focus groups, semi-structured interviews, online studies with mock search engines, surveys with 1200 physicians, and large-scale field experiments.

The first paper examines the obstacle of estimating out-of-pocket costs. Consumers often cannot determine how much they need to pay for different treatment options, which complicates their decisions. **Ubel** tests physicians' ability to estimate patients' out-of-pocket costs and finds that about one-third of physicians incorrectly estimate these costs. In another study, Ubel uses focus groups with physicians to solicit solutions to overcome this challenge.

The second and third papers take the perspective of consumers and examine factors that can bias their self-diagnosis, i.e., consumers' assessment of the extent to which they have a medical condition. **Hussein and Huang** examine how consumers' search strategy (symptom-focused vs. disease-focused) affect the process and outcome of self-diagnosis and find that symptom (vs. disease)-focused search leads to higher accuracy of self-diagnosis. **Raghubir, Ling,**

and Menon further investigate how self-diagnosis is influenced by contextual cues and find that ambiguous symptoms are perceived to be less diagnostic and weighted less.

Lastly, **Lieberman et al.** take the perspective of policy makers and examine ways to encourage consumers to complete medical screening. In two large field experiments, the authors leverage financial incentives and deadlines to encourage preventive screening.

Together these papers raise (and provide answers to) the following questions:

- What are some of the hurdles to consumers' involvement in medical decision making (e.g., inability to estimate out-of-pocket expenses and susceptibility to contextual cues)?
- What are the psychological drivers that lead consumers to seek diagnosis (e.g., through self-diagnosing online and through taking a screening test), and what are the opportunities to encourage more accurate diagnoses?

This session provides timely insights into medical decision making, a critical topic given consumers' increasing engagement with medical decisions. This session echoes some of the conference's themes, such as the use of multi-method approaches (e.g., focus groups, interviews, lab experiments, and field experiments) and understanding consumers' interactions with technology (e.g., search engines) in the context of medical decision making. We believe that this proposed session should be of interest to a broad audience of scholars and practitioners working on healthcare and medical decisions, technology, extrinsic and intrinsic motivation, and context effects.

Shopping in the Dark – Barriers to Determining the Price of American Healthcare

EXTENDED ABSTRACT

The United States is rapidly shifting toward a high out-of-pocket healthcare system. People are increasingly enrolling in health insurance plans that expose them to costs when they receive healthcare services, either in the form of high deductibles (the amount they pay out-of-pocket before insurance kicks in), co-pays (flat fees for medical services), or coinsurance (exposure to a certain percent of healthcare expenses).

In previous research, my colleagues and I have describe the kind of challenges patients and physicians face trying to determine out-of-pocket expenses in time to inform medical decisions – e.g. figuring out the relative cost of alternative medications for a patients' illness to help determine which medicine the physician should prescribe (Hunter et al. 2017; Ubel 2019; Ubel 2016).

I will discuss two studies which are currently underway, both of which will be completed by the time of the conference. Both studies shed new light on this important topic.

The first study involves a series of focus groups with physicians from four medical specialties – rheumatology, neurology, oncology, and primary care. We have completed five focus groups and will have completed five more by the time of the conference. In the focus groups, we present physicians with examples of patients struggling to figure out the cost of their care. We draw these examples from direct observation of clinic appointments and from interviews of participating patients. We use the examples to prompt physicians to discuss their own challenges trying to ascertain patients' out-of-

pocket expenses. More importantly, we then probe physicians to suggest ways to overcome these challenges.

The solutions we have explored so far in the focus groups have been wide-ranging. They include: incorporating costs into electronic health records; employing financial navigators to help patients determine the costs of potential care; developing tip sheets for patients with specific health conditions to suggest ways of reducing their out-of-pocket expenses – e.g. "co-pay assistance programs available for patients with lupus;" and screening patients in waiting rooms, to identify those struggling with out-of-pocket expenditures.

The focus groups have also yielded rich insights into barriers for implementing potential solutions, with the main challenge being misalignment of financial incentives: "You can hire financial counselors to make the physicians' jobs easier, and to improve patients' lives, but if you reduce income for the Anonymous Hospital Organization, administrators won't hire them."

In the second study, we survey a representative sample of 1200 US physicians and assess how well they can ascertain patients' out-of-pocket expenditures when they have sufficient information to do so. We present physicians with a hypothetical patient:

Now, imagine the following:

- You are about to prescribe the oral biologic DMARD tofacitinib to your patient, Ms. Gray.
- One month's supply of tofacitinib costs $1,000. She asks how much she'll have to pay out of pocket.
- Luckily, you have access to her private insurance information. Tofacitinib is a tier 4 drug, and her insurance runs from January to December.

We ask them four questions about out-of-pocket expenses. For example, in one question, we tell the physicians it is January 3, and ask them to advise the patient on how much she will have to pay out-of-pocket for the drug this month. The correct answer is $1000, because the patient has not met her $2000 deductible yet, so the full price of the drug is her responsibility to bear. In another question, we asked them to imagine it is April, and the patient is still taking the drug. We asked them to estimate how much the drug will cost her that month. In that case, the patient has met her deductible, but is still responsible for half the price of the drug, meaning she will pay $500 that month for the medication.

We have conducted the first of two waves of data collection, with a response rate so far of 40%. Our preliminary results reveal widespread misunderstanding of out-of-pocket expenditures. For example, for the two questions described above, 35%, and 41% of responding physicians so far answered those questions incorrectly.

These two studies provide a window into a dysfunctional market – in which people face high out-of-pocket expenses for the medical care but cannot determine their costs in time to inform their healthcare choices. Moreover, when they turn to their physicians, they often cannot receive good information about their costs.

How Search Strategy Shapes Self-Diagnosis

EXTENDED ABSTRACT

One of the key reasons consumers search for health information online is to self-diagnose (Fox & Duggan 2013). Self-diagnosis refers to consumers' assessment of the extent to which they developed a medical condition. In 2013, more than 35 percent of Americans went online to self-diagnose (Fox & Duggan 2013), and in 2017 this percentage increased to 57 percent (Consumer Health Online 2017). Importantly, 77 percent of online self-diagnosis starts on a search engine, like Google (Fox & Duggan 2013).

We investigated how consumers' search strategy affects self-diagnosis. First, we documented search strategies consumers naturally use when self-diagnosing online (Study 1). We found that consumers used two main types of search strategies: disease-focused and symptom-focused. Second, we investigated the consequences of these two search strategies on self-diagnosis (Study 2). We found that participants randomly assigned to use a symptom-focused (vs. disease-focused) strategy reported more accurate self-diagnoses. We then turned to examining the psychological mechanism driving the increased accuracy. We found that participants in the symptom-focused (vs. disease-focused) condition generated more abstract (vs. concrete) hypotheses during their information search (Study 3), and that those abstract (vs. concrete) hypotheses prevented consumers from being biased by disease-specific information and allowed them to focus more on disease-agnostic information (Study 4), which increased their accuracy.

In Study 1, participants (N = 120) were asked to imagine they went on a nine-day Safari in rural Africa and that they suddenly fell ill. Participants read that they experienced three symptoms (e.g., back pain) and that travelers who visited the safari park sometimes contracted one of four diseases (e.g., Malaria). Next, participants were asked to use Google to better understand their health situation. We used a software called Pipe, which allowed us to record participants' screen as they conducted a Google search. We analyzed the search terms participants used on Google and found that 47.06% of participants used symptom-focused search terms, such as "fever chills and backpain in Africa," while 45.38% of participants used disease-focused search terms, such as "Trachoma in rural Africa."

In Study 2, we investigated whether these two search strategies influenced the accuracy of self-diagnosis. We used the same safari paradigm described in Study 1, and randomly assigned participants (N = 400) to either a symptom-focused or a disease-focused search strategy. Participants in the symptom-focused (vs. disease-focused) condition were asked to choose the symptoms (vs. diseases) they would like to focus their Google search on. After screen-recording their Google search using the same screen-recording client (Pipe), participants reported the probability that they had each of eight diseases: two diseases closely matched the symptoms in the scenario, two diseases were mentioned in the scenario but did not match the symptoms, and four diseases were neither mentioned in the scenario nor matched the symptoms. We pre-registered all analyses. We found that participants in the symptom-focused (vs. disease-focused) condition were more accurate in their self-diagnosis: they reported both higher probabilities for having diseases that matched their symptoms ($b = 7.58$, $z = 3.31$, $p = .001$) and lower probabilities for diseases that did not match their symptoms ($b = 4.84$, $z = -2.70$ $p = .007$).

In Studies 3 and 4, we examined how search strategy affected consumers' hypothesis generation and testing (Klayman & Ha, 1987). To capture the key hypothesis motivating their search, participants in Study 3 (N = 200) engaged in a thought listing exercise (Posavac et al., 2010), in which they shared the questions they hoped their Google search would answer. These questions were coded for the total number of thoughts, whether a concrete hypothesis was mentioned (e.g., "do I have Malaria?"), and whether an abstract hypothesis was mentioned (e.g., "which diseases exhibit symptoms of chills in general?"). We found that, despite reporting the same total number of thoughts ($b = .27$, $t(198) = 1.01$, $p = .31$), participants in the symptom-focused (vs. disease-focused) condition were less likely to report a concrete hypothesis (logistic $b = .28$, $z = -4.16$, $p < .001$) and more likely to report an abstract hypothesis (logistic $b = 4.62$, $z = 4.84$, $p < .001$). Together, these results suggest that search

strategy influences the hypotheses consumers generate and bring to the search engine.

In Study 4, we further tested whether the difference in hypotheses documented in Study 3 changed the type of information participants subsequently chose. We predicted that symptom-focused participants would pay more attention to information that can address their abstract hypotheses (e.g., "Common causes of fever") while diseases-focused participants would pay more attention to information that can better address their concrete hypotheses (e.g., "Malaria – Symptoms and Causes"). We pre-registered these predictions and related analyses. To test this prediction, we used a yoked design in which the hypotheses organically generated in Study 3 were presented to a new set of participants (N = 400), such that each participant in Study 4 read the hypothesis generated by a randomly selected participant from Study 3. Participants were then asked to select up to three search results that would best answer the central questions raised by the hypothesis they were assigned. Participants chose between 10 search results, five of which were disease-specific (i.e., the title contained the names of specific diseases, such as Malaria) and the other five were disease-agnostic (i.e., the title made no reference to a specific disease, such as "Types of Fevers in Travelers Returning from Abroad"). We found that symptom-focused (vs. disease-focused) participants chose fewer disease-specific information sources (b = .31, *t*(180) = 3.13, *p* = .002) and more disease-agnostic information sources (b = .27, *t*(180) = 2.74, *p* = .007). Together, these results suggest that search strategy influenced both the hypothesis generation and subsequent evidence selection needed for self-diagnosis.

In summary, we investigated how online search strategy affects the process and outcome of self-diagnosis. Importantly, employing a symptom-focused strategy resulted in greater self-diagnosis accuracy. This enhanced accuracy appears to be driven by consumers' adoption of more abstract hypotheses which attracts them away from disease-specific information and towards disease-agnostic information.

Web Wizard or Internet Addict? How to Help Consumers Assess Risk

EXTENDED ABSTRACT

A key issue with health risk assessments is one of self-diagnosis. The surge in DTC advertising for conditions ranging from depression to diabetes, typically involve a range of symptoms that consumers are asked to identify in an attempt to self-diagnose. But many of these are ambiguous. This paper examines how consumers assess the risk of internet addiction, which has a number of ambiguous symptoms. The prevalence and growth of internet addiction disorder (IAD) could pose a risk to consumer welfare, as well as the industries that depend on the internet, from personal computers (IBM, Apple), software (Microsoft, Adobe), and hardware providers (HP), to retailers (Amazon, Land's End), search engines (Google) and portals (Yahoo).

Five studies replicate and extend the robust self-positivity in judgments of IAD. Studies 1 and 2 examine self-positivity effects using open-ended estimates of number of hours of internet use. Studies 3-5 examine the effect of the range-of-response-alternatives used to elicit these estimates (Schwarz et al., 1985). A person is considered "addicted" when they have 5/8 symptoms of IAD. However, five of these symptoms are more ambiguous than the remaining three. Overall, results show contextual cues affect risk judgments due to symptom ambiguity: (a) the range of response alternatives used to elicit internet usage affects reports of how many hours of the internet a person uses a day; (b) judgments of self-risk are lower when IAD symptoms are elicited prior to risk estimates; and (c) including a "none-of-the-above" option on the symptom list affects judgments of how common they are.

Experiment 1 (n=75) showed that risk estimates for self (M=2.82) were significantly lower than the average undergraduate (M=4.01, p<.001), but no different than one's best friend (M=2.84; F(2, 146)=31.80, p<.001). A regression of self-risk estimates on internet usage was significant (F(1, 69)=11.39, p<.001, Ra2=.129; B=.046, t=3.38, p<.001).

Experiment 2 (n=109) estimated the effect of whether the IAD symptoms checklist had a "None-of-the-Above" option. When the option was present, fewer symptoms were identified (M=2.62 vs. 3.52; F(1, 107)=8.14, p<.005), and risk estimates were directionally lower (M=56.96 vs. M=61.94; F(1, 107)=1.90, p=0.171), while the self-positivity bias was robust reflecting lower self- versus other-judgments (M=55.83 vs. M=63.07; F(1, 107)=14.74, p<.001). A moderated mediation (process 5) model showed that the effect of self-reports of internet use affected risk judgments indirectly via reports of behaviors associated with addiction, while the direct effect was moderated by how internet use is elicited: in no "none-of-the-above" condition, there was no effect, but in the "none-of-the-above" present condition, there was a direct effect.

Experiment 3 (n=146 US undergrads) examines the effects of the contextual cue of the range of response alternatives (Schwarz et al., 1985). Participants indicated internet use on low-, or high-frequency response alternatives, such that the percentage of participants checking the last category in the "low" condition is comparable to the last four categories in the "high" condition. Those in the "low" condition should infer that they use the internet more than the average person, identify more symptoms, and estimate higher risk (Schwarz et al. 1985). Participants were then assigned to one of two order conditions (symptoms-before-risk, risk-before-symptoms) prior to indicating the likelihood of having IAD (0-100) for themselves and others, resulting in a 2 (response-alternatives) x 2 (order) x 4 (target: self, average person taking the study, average undergraduate student, and average person) mixed design.

The range-of-response-alternatives affected the participants' report of using the internet for >5 hours (Low=48.7%, High=83.8%, (1)=19.70, p<.001). A mixed ANOVA on risk estimates revealed a main effect of target (F(3, 426)=30.39, p<.001, =.176), and a target x order interaction (F(3, 426)=3.70, p=.012, =.025). The interaction showed that perceptions of self-risk (but not risk of the three other targets) were lower only when symptoms were elicited prior to risk estimates (M=44.61 vs. 54.01).

Overall, self-risk perceptions were significantly lower (M=49.31) than estimated risk for the average person taking the study (M=55.745, t145=4.01, p<.001), the undergraduate (M=61.76, t145=7.31, p<.001), but no different from the average person (M=49.155). When the symptoms were elicited first, risk estimates were based on both unambiguous and ambiguous symptoms (Bs=11.78 and 4.74, ts=3.39 and 2.33, ps<.01 respectively). When risk estimates were elicited first, risk estimates were based on reported internet usage and ambiguous symptoms (Bs=20.68 and 12.10, ts=2.36 and 4.81, ps<.01, respectively). Study 4 replicated Study 3's results using a different sample (n=167 Indian MBAs).

Study 5 (n=721 MTurkers) combined the designs of Studies 2 and 4, manipulating elicitation at three levels (hi, lo, control open ended) x 2 (order) x 2 (None of the above: present/ absent), to show that these results are robust. Overall, results suggest that the greater the ambiguity of a symptom, the more prone it is to context effects, and the less likely it is to be assimilated into risk judgments.

Testing the Role of Motivation and Procrastination in Colorectal Cancer Screening

EXTENDED ABSTRACT

Colorectal cancer (CRC) is the second leading cause of cancer death in the U.S. (NIH, 2018). Although screening reduces CRC incidence and mortality (USPSTF, 2016), uptake is suboptimal, especially among underserved populations (Gupta, 2013). Mailed outreach—inviting individuals to complete a fecal immunochemical test (FIT) in the comfort of their own home—offers a non-invasive and more cost-effective approach. Yet, completion rates remain low (Singal et al., 2016). Using insights from behavioral science, we predicted that both a lack of intrinsic motivation and procrastination tendencies may be contributing to low FIT completion. We test these hypotheses in two large field experiments (N=16,336). Study 1 aimed to increase screening by enhancing extrinsic motivation through financial incentives. Study 2 tested whether targeting procrastination—both with and without financial incentives—affected screening rates. We hypothesized that both financial incentives and deadlines would increase screening completion relative to standard outreach.

Incentives are increasingly used in an attempt to influence health behaviors (Saunders et al., 2018). However, while incentives have been shown to motivate some behaviors (DellaVigna, 2016; Stone, 2002), their effectiveness is contextually dependent (Gneezy, 2001), and whether they lead to long-term changes is uncertain (Charness & Gneezy, 2009). Thus, Study 1 tested the effectiveness of offering repeated financial incentives for FIT completion annually for 3 years. Participants (N=8,565) received either standard mailed FIT outreach (N=6,565), outreach plus $5 (N=1,000), or outreach plus $10 (N=1,000) for FIT completion. Participants who completed the test were re-invited using the same incentive the following year, for three years and then invited in Year 4 without any incentive. Contrary to predictions, completion was no different whether participants received an incentive, or not, in Year 1 (p = .59), Year 2 (p = .75), or Year 3 (p = .08). There was also no difference in completion across groups in Year 4, after incentives were discontinued (p = .08). Thus, offering modest incentives of $5 and $10 did not increase FIT completion relative to standard outreach. Study 2 therefore attempts to increase FIT completion by strengthening the financial incentives intervention while also targeting a different psychological barrier—procrastination.

Procrastination—delaying a task to a future day—is ubiquitous and often underlies failure to complete tasks (Akerlof, 1991; Tice & Baumeister, 1997; Zauberman & Lynch, 2005). We posit that this deleterious tendency to procrastinate (Shu & Gneezy, 2010) may be contributing to low FIT completion rates. Deadlines—particularly short deadlines—have been shown to attenuate procrastination (Ariely & Wertenbroch, 2002; Shu & Gneezy, 2010). Thus, in Study 2, we test whether imposing deadlines increases FIT completion. Further, while isolated incentives did not change behavior in Study 1, one explanation may be that there was no reference against which participants could evaluate the incentive (Hsee, 1996). Thus, in addition to deadlines, we add a declining incentive component such that participants are able to compare two incentives relative to one another. Participants (N=7,771) were randomly assigned to receive one of five invitations: (1) control (standard invitation); (2) long deadline (three weeks); (3) short deadline (one week); (4) small declining incentive ($10 for completion within one week or $5 for completion within three weeks); or, (5) large declining incentive ($20 for completion within one week or $10 for completion within three weeks). The prespecified primary dependent variable is the proportion of participants who completed FIT within three weeks of invitation. Results indicated that both non-incentivized deadlines and deadlines coupled with a declining financial incentive (small or large) significantly increased completion relative to standard outreach (ps < .005). Further, completion in the short-deadline condition was higher than in the long-deadline condition (Short: 9.7% vs. Long: 7.2%; (1, N = 3,086) = 6.42, p = 0.011, ϕ = .05). Most notably, imposing a short non-incentivized deadline was just as effective as a deadline coupled with a financial incentive: completion in the short-deadline condition (9.7%) was not statistically different than completion in the small-declining(9.1%; (1, N = 3,076) = 0.33, p = 0.568, ϕ = .01) or large-declining (12.0%; (1, N = 3,089) = 4.20, p = 0.04, ϕ = .04) conditions. Thus, attenuating procrastination by imposing deadlines—with or without financial incentives—increased FIT completion.

Two large field experiments demonstrate that while fixed incentives did not increase CRC screening relative to standard outreach, deadlines did. Moreover, deadlines were equally effective at increasing FIT completion whether they were coupled with declining financial incentives or were non-incentivized. These results implicate procrastination as a key barrier to FIT completion and suggest that offering modest incentives—at least in this context—amounts to paying for nothing. This paper provides insight into the psychology underlying low cancer screening rates and suggests key considerations in the use of behavioral science interventions to encourage health-behavior change.

SESSION OVERVIEW

Consumers today spend a significant amount of time on social media platforms such as Facebook and Instagram. In 2018, Internet users spent about 1.25 hours per day on social media platforms (Statista 2019). As such, a growing amount of research has started to examine consumers' motivations for posting on social media (Buechel and Berger 2018; Toubia and Stephen 2013) and how posting about one's experiences on social media can influence their well-being, including enjoyment of an experience (Barash et al. 2018). Yet, little research has examined how browsing social media and more specifically the content consumers encounter while browsing social media can influence consumers' judgments and behavior. For example, what does browsing social media in publicly visible situations signal to others? How does seeing other consumers' postings about their experiences influence consumers' own intention to consume similar experiences? How does encountering a brand's posting about its offline brand event influence consumers' intentions to engage with the brand?

This session sheds light on these questions. **Kang, Wu, and Paharia** examine how observers judge consumers who browse social media in publicly visible situations. The authors find that visibly using social media can trigger negative inferences of increased addiction and lower self-control by observers, leading to unfavorable downstream consequences, such as being less likely to be chosen as a service provider or as a partner to work on a task requiring self-control.

The next two papers examine how browsing other consumers' postings impact one's future consumption. **Hall and Zane** find that when consumers infer that others posted their experiences on social media for extrinsically-motivated (vs. intrinsically-motivated) reasons, they show lower desire to engage in similar experiences, because they anticipate that other people will infer extrinsic motives if they engage in similar experiences.

Valsesia and Watson examine how consumers differentially evaluate others' self-bragging postings depending on the temporal frame. The authors find that consumers evaluate others' bragging about the past (vs. present) less favorably because they perceive the bragging as more intentional. As a result, consumers become less likely to engage with the mentioned brand when the bragging is about past (vs. present) experiences.

Moving to the corporate social media posting, **Rifkin, Chan, and Kahn** examine how encountering postings about brand events can affect consumers' future engagement with the brand. The authors find that seeing social media photos of brand events can trigger FOMO for consumers who missed the events, increasing these consumers' intentions to engage with the brand.

Taken together, the four papers examine how browsing social media postings can influence consumers' various perceptions and behaviors. This session is highly relevant to one of the themes of ACR 2020, "Technology," as the four papers generate timely wisdom on how social media—a relatively new online platform made possible by advances in the mobile and Internet technology—impacts consumer behavior. This session will appeal to a broad audience, including researchers interested in social media, people perception, inference making, temporal frame, and branding.

Social Media Users are Penalized for Lacking Self-Control

EXTENDED ABSTRACT

Reflecting the popularity of consumers' social media use, a growing amount of research has examined the motivations for using social media (Buechel and Berger 2018; Toubia and Stephen 2013) and the consequences of social media use (Barash et al. 2018; Wilcox and Stephen 2013). Prior literature, however, has not explored what inferences observers make about social media users. This is an important gap because consumers often use social media in publicly visible situations, such as while waiting for coffee (Herhold 2018). We argue that visibly using social media can trigger negative inferences of increased addiction and lower self-control by observers, leading to unfavorable downstream consequences.

Prior research suggests that social media use can be addictive (Kuss and Griffiths 2011). In our pretest (n=100), when asked to evaluate the addictiveness of several activities people do on their smartphones, people believed that browsing social media was more addictive than reading a magazine, reading news, watching a movie or even playing a game ($ps \leq .001$). Therefore, we expect that observers will infer that a person using social media is more addicted compared to a consumer engaging in other activities, leading to the inference of lower self-control. We further propose that the inference of low self-control will lead to numerous negative reactions, such as being less likely to be chosen as a service provider.

We identify two theoretical boundary conditions. First, if a target consumer uses social media only for a small fraction of his free time, the inference of addiction should be less, attenuating the negative inferences on self-control. Second, individuals who have positive attitudes towards social media may associate using social media more strongly with positive attributes rather than negative attributes such as addiction, again attenuating the negative inferences on self-control. Turning towards interventions, we expect that consumers are not spontaneously aware of the negative inferences about social media users. Thus, we hypothesize that prompting consumers to take

an observer's role can reduce their own intention to use social media in public.

Studies 1-2 tested negative downstream consequences using an incentive-compatible choice. In study 1 (n=333), participants viewed the bios of two personal trainers at a local gym. One trainer indicated that he liked to browse social media in his free time while the other liked to watch movies. 35.44% of participants chose the trainer who liked to browse social media ($p < .001$) because they perceived the trainer as having lower self-control ($p < .001$).

In study 2 (n=118), participants selected a partner with whom they would like to work on a word search task. We showed participants the profiles of the two partner candidates. The two profiles were similar except that [one/the other] student spent [55%/10%] of her free time using social media. 33% of participants chose a heavy social media user ($p < .001$) because they perceived the heavy user as having less self-control ($p < .001$).

Are the participants' perceptions accurate? In a separate test, we asked participants to engage in the same word search task by themselves. Social media use was not correlated with participants' performance ($p = .98$), suggesting that people's beliefs about social media users are not accurate.

In studies 3A-3B, we tested our multi-step mechanism (social media use→perceived addiction→perceived self-control→downstream consequences). In study 3A (n=247), participants in the [social media/online magazine] condition viewed a picture of a woman scrolling through [a social media account/an online magazine] on her phone at the airport. In both conditions, we showed the same images on the phone to control for the content the woman was browsing. The woman in the social media (vs. magazine) condition was evaluated less positively overall ($p = .012$), as having less self-control ($p = .006$), and as being more addicted ($p < .001$). The hypothesized serial mediation path was significant. Neither impression management nor materialism served as a significant mediator. In study 3B (n=488), we replicated the findings of study 3A by comparing browsing social media with other control conditions: playing an online game and browsing news. The negative effect of social media occurred when the target person browsed social media on a smartphones or laptop.

Study 4 (n=418) tested the moderating effect by the percentage of free time used for social media. Participants in the [100%/4%] condition read a scenario that the flight was boarding in [five minutes/two hours] and the woman was looking at her phone for five minutes by browsing [Instagram/the Wall Street Journal]. We measured willingness to hire the woman for a job as a downstream measure. The interaction effect was significant for the intention to hire ($p = .014$). Participants in the social media (vs. news) condition reported lower intention to hire in the 100% condition ($p = .001$), not in the 4% condition ($p = .89$). We found similar patterns of result for perceived self-control.

Study 5 (n=431) tested the moderating role of attitudes towards social media. Participants read a scenario that a 30-year-old man at the airport was [browsing his Instagram account/reading a magazine]. The regression analysis for the overall favorability of the man revealed a significant interaction ($p = .023$). Specifically, the negative effect of social media (vs. magazine) on overall favorability occurred for participants with attitudes towards social media lower than 5.80. We found similar results for perceived self-control.

Study 6 (n=378) tested the proposed interventions to reduce social media use. All participants read the three scenarios describing a woman [browsing her social media account on her phone/browsing news on her phone/looking around at the café]. After reading each scenario, participants rated the woman on self-control and overall favorability. In the before (after) condition, before (after) participants

evaluated the woman in the three scenarios, participants indicated what activities they would do while waiting in line at a café. Participants in the after condition (56.1%) were less likely to choose to browse social media than those in the before condition (71.7%; $p = .002$).

This research contributes the literature on social media. Practically, our findings can better guide consumers' impression management strategies.

I Care About Why You Share: Inferences about Sharing Motives Influence Observers' Engagement in Similar Experiences

EXTENDED ABSTRACT

While some consumers post about their experiences on social media because they genuinely enjoy giving others insight into their lives, others share to demonstrate their uniqueness or consumption of conspicuous/luxury experiences (Bronner and de Hoog 2018; Kim 2018). Given that consumers' sharing motives differ, do others who view shared content make different inferences about the sharers' posting motives? If so, might these inferred sharing motives influence observers' desire to have a similar experience?

Prior research on perceptions of others' sharing motives has only explored perceived motives behind sharing about experiences relative to material goods. This work demonstrates that perceived sharing motives influence evaluations of the sharer—observers infer the sharer to have relatively more intrinsic motives when viewing shared experiences (vs. material goods), leading to more positive evaluations of the sharer (Van Boven et al. 2010). However, it is unlikely that all experiential sharing is perceived to be equally intrinsically-motivated. In addition, prior research has yet to consider how perceived motives behind sharing about an experience might influence observers' preference to purchase a similar experience.

We first propose that consumers will infer a broad range of sharing motives when viewing others' shared experiences. As initial support, pilot study participants (n=92) viewed a post featuring someone's camping experience and described the poster's sharing motives. Two independent coders rated these qualitative descriptions (-3=purely extrinsic motives; 0=equally intrinsic/extrinsic motives; 3=purely intrinsic motives; $M= -.223$; SD=1.91; interrater reliability=.812). This distribution suggests that consumers infer sharers to have different motives when sharing about their experiences.

Second, we propose that when consumers infer a sharer's post to be more extrinsically-motivated, it will decrease the desirability of the shared experience itself. This will occur because consumers' inferences about the sharer's motives will influence the observers' own perceptions of how others might view them if they had a similar experience (social motivation contagion; Wild et al. 1992). If consumers anticipate others will see them as having more extrinsic motives if they engage in an experience, it should decrease the experience's desirability (Wild and Enzle 2002). Thus, while firms are assumed to benefit when customers share about their firm-related experiences (WOM, buzz, etc.), we suggest such sharing may sometimes deter other customers if the sharer is perceived to have extrinsic sharing motives.

In Study 1, participants (n=361) viewed a mock Instagram post featuring either a jacket (product) or camping scene (experience). Participants reported their likelihood to purchase the featured experience/product and their perceptions of the poster's sharing motives (scale from pilot study). They also evaluated the sharer on a number of positive/negative traits (Van Boven et al. 2010). Replicating prior research, those viewing the experience post perceived

the sharer to have more intrinsic motives ($M_{Experience}$=.52; SD=1.89; $M_{Material}$= -.97; SD=1.82; $F(1,359)$=61.10, p<.001). Pertinent to our hypothesis, however, there was heterogeneity in perceived sharing motives within the experience condition, evidenced by a mean near the scale midpoint and substantial variance. Furthermore, a regression revealed an interaction between the experience/product condition and perceived sharing motives on product/experience purchase likelihood (b= -.249; $t(357)$=2.26, p=.024). As expected, within the experience condition, those who perceived the sharer to have more extrinsic motives reported lower purchase likelihood (b=.296; $t(357)$=3.76, p<.001). Interestingly, perceived sharing motives did not affect purchase likelihood in the product condition (b=.046; $t(357)$=.60, p=.551). Perceived motives equally predicted evaluations of the sharer in both conditions, suggesting our consumption-related consequences are driven by a distinct process than that in Van Boven et al. (2010).

In Study 2, undergraduates (n=338) identified a post in their own social media accounts featuring an experience shared by someone they follow. After describing the experience, they reported how much they would enjoy consuming that same experience (1=not at all; 7=very much) and the sharer's motives (-2=purely extrinsic; 2=purely intrinsic)—these measures were counterbalanced and order had no effect. Perceived sharing motives were normally distributed (M=.097; SD=1.13). Furthermore, perceptions of the sharer's motives predicted anticipated enjoyment of the experience (b=.232; $t(334)$=1.90, p=.059). Participants then also justified why they scored the sharer's motives as they did. An independent research assistant coded these explanations for themes about what aspects of shared experiences led to inferences of intrinsic/extrinsic motives. Participants perceived sharers to have more extrinsic motives when the sharer did not seem truly interested in the experience itself (consuming for the purpose of sharing) or when the sharer's presence in the photo seemed to be the focus (staged poses, heavy makeup, provocative clothing, etc.). Captions featuring text unrelated to the experience (poems, quotes, etc.) or that conveyed social comparison or tried to elicit sympathy also signaled extrinsic motives.

In Study 3, undergraduates (n=114) viewed a mock Instagram post featuring a bowling experience, manipulated based on the themes discovered in the previous study. In the intrinsic post, the sharer was less prominent and was displayed in the act of bowling with a caption related to bowling. In the extrinsic post, the sharer was featured prominently in a staged pose with a caption unrelated to bowling. Participants then reported how likely they would be to purchase a bowling experience. They also reported how others might view their own motives for going bowling, including three intrinsically-motivated explanations (e.g., for the enjoyment of the experience) and three extrinsically-motivated explanations (e.g., to impress others), averaged to create our focal mediator. As expected, mediation analysis revealed that participants who viewed the extrinsic post thought others would view their own motives for going bowling as more extrinsic ($M_{Extrinsic}$=4.27; $M_{Intrinsic}$=5.01; b=.368; $t(111)$=3.57, p<.001), which then predicted purchase intentions (b=.285; $t(111)$=2.16, p=.032; index of mediation: CI_{95}=[.005,.245]).

We demonstrate that when consumers are perceived to have extrinsic motives for sharing experiences, observers see the same experience as less desirable to consume themselves. This occurs because observers assume that others will perceive their own motives as being more extrinsic if they are to consume the experience. These results suggest that firms do not always benefit when their customers share about their firm-related experiences and identify characteristics that lead consumers to infer different motives behind shared content.

The Time-Dependent Effects on Bragging

EXTENDED ABSTRACT

Much research has been dedicated to understand why people brag (Baumeister 1982; Speer 2012) and perceptions of those who do (Tal-Or 2010; Berman et al. 2015). Self-promotion is a fact of life, but with the proliferation of social media usage, people encounter braggarts more than ever before. More recently, the conversation has shifted to understand characteristics of social media posts (Matley 2018a, 2018b). For example, Matley (2018a) demonstrates that the explicit use of the hashtag "#brag" attenuates some of the negativity that might be commuted through a self-praising message. In this research, we explore other message characteristics that might moderate the effect of a self-praising message. Our primary focus investigates the temporal framing of a message. Recent work has demonstrated that people are more likely to share information about rewards that will occur in the future vs. the past (Weingarten and Berger 2017), but little is known about how the temporal framing of a message affects how consumers respond to it.

This research posits that past-oriented self-promotion is viewed negatively relative to both present-oriented self-promotion as a function of the message's perceived intentionality. Present-oriented messages are thought to be spontaneous and emotion-laden, whereas past-oriented messages are perceived to be intentional signals sent by the messenger. Our first study employed a 2-cell design (time: past, present), between-subjects. Participants were told that they would view a tweet then be asked to evaluate the individual. The tweet read either "I cannot believe I just won the Valley half marathon! Hard work pays out! #proud #win #today" or "I cannot believe it is exactly 5 years since I won the Valley half marathon! Hard work paid out! #proud #win #throwback". We asked participants to what extent they perceived the tweet to be "bragging" and a one-way ANOVA indicated that participants viewed tweeting about the past to be significantly more braggy (Mpast = 6.66, Mpresent = 6.05; F(1,163) = 4.82; p = .03). Moreover, we found impressions of the sender to be significantly more positive when the person tweeted about the present (Mpresent = 5.30) compared to the past (Mpast = 4.68; (1,163) = 6.09; p = .01). In reflection, we realized that the message also had an element of skill given the amount of effort required to win a marathon. Thus, in the next study we sought to test whether our effect held when a brag lacked skill and happened due to sheer luck.

In study 2, we employed a 2(time: past, present) x 2(deservingness: luck, skill), between-subjects design. This time, an Instagram post was used to further generalizability. A picturesque waterfall was accompanied with the caption "one year ago today, I was in Costa Rica…" or "right now, I am in Costa Rica…" to manipulate the temporal factor. To manipulate the deservingness factor, the caption also mentioned that the trip was won from a "random raffle for new employees" or "receiving the highest customer satisfaction score for my company". A 2x2 ANOVA on participants' overall evaluation of the poster revealed a significant interaction (F(1,111) = 4.46; p = .04). When the brag was framed in terms of skills, and thus had a deservingness component, we replicate our earlier effect, such that a present brag led to more positive evaluations of the sender compared to past brags (Mpast = 3.86 vs. $M_{present}$ = 4.63, F(1,111) = 3.54; p = .06). Nonetheless, this was not the case when the brag was framed in terms of luck (Mpast = 4.55 vs. $M_{present}$ = 4.22, F(1,111) = 1.23; p = NS).

Thus far, we have established that temporal framing matters, but we've done little to determine the velocity of the effect. In study 3, we assign participants to past, present, and future conditions to explore whether disclosing upcoming events are bragging as well.

However, to account for individual differences in time perceptions we ask participants to report the extent to which they view these events as occurring between the distant past and distant future (5-point scale) and use this item as our primary independent variable. We do this to account for the subjective nature of time and determine the trend between distant and near time horizons. Participants viewed a Facebook post discussing the purchase of a new BMW. We then asked them to evaluate the poster. In this study we also measured behavioral intentions to determine the managerial relevance of our effect. A one-way ANOVA of temporal perceptions on poster evaluations yielded a significant effect ($F(4, 403) = 2.807$; $p = .025$). A curvilinear function emerged such that a positive relationship exists from the distant past to near future ($M_{distant past} = 1.56$, $M_{recent past} = 2.97$, $M_{present} = 3.06$, Mnear future $= 3.44$) before exhibiting a negative effect in the distant future ($M_{distant future} = 2.92$). Similarly, a one-way ANOVA of temporal perceptions on brand intentions yielded the same pattern ($M_{distant past} = 2.67$, $M_{recent past} = 3.57$, $M_{present} = 3.62$, Mnear future $= 4.12$, $M_{distant future} = 2.92$; $F(4,403) = 2.486$; $p = 043$). Naturally, some of these cells suffer from small sample sizes, but nonetheless, further investigation into temporal perceptions is warranted.

Through three studies, this research demonstrates that temporal framing of messaging yields significant effects of not only messenger perceptions but can also have consequences for brands. Bragging about the past vs. the present (or the future) seems to have negative consequences for both but this is the temporal frame in which most people brag. Thus, our next steps will be to investigate strategies by which firms can encourage consumers to brag about present or future interactions vs. past, and to determine whether consumers are aware of this bias when craft a message in the first place.

The Role of Social Media-Induced FOMO in Strengthening Brand Communities

EXTENDED ABSTRACT

We are witnessing a dramatic change in the world of retailing. Rather than shopping in store, consumers can order anything they want online. However, while online shopping has changed the retailing scene, no one is predicting that physical stores are going away. To drive traffic to physical stores, specialty and brand retailers are increasingly hosting in-store events and then posting photos on social media. For example, Footlocker in Harlem, NY hosted a challenge where fans competed to see who had the highest vertical jump. The event featured celebrity appearances and elite sock customization, and photos were posted on Footlocker social media pages. Similarly, Lululemon frequently hosts in-store yoga classes and posts event photos to social media.

While these in-store events likely generate positive outcomes for customers who participate, how do these strategies affect customers who do not attend? We predict that seeing photos of missed brand-community events will elicit a negative emotional feeling of FOMO (Fear of Missing Out) among those who feel more connected to the brand (H1). Although this negative response may seem undesirable, prior research has found that fear appeals can positively influence intentions and behaviors (Tannenbaum et al. 2015). We therefore predict that consumers will cope with their negative feelings of FOMO by increasing their intentions to engage with the brand in the future (e.g., by attending a future event; H2).

We also identify three moderators. One benefit of these events is that they foster local brand communities, attracting people who are members of the local community, but may not be brand loyalists. Therefore, we predict that less brand-connected consumers will respond more favorably when seeing event photos that feature people from their local community, rather than from the brand community (H3). Second, building on previous research on FOMO identifying the critical role of anxious attachment (Rifkin, Chan, and Kahn 2020), we predict that the effects will be stronger among those who feel more anxious about their belonging in the brand community (H4). Finally, consistent with work on fear appeals, we predict a boundary condition in which the effects will be attenuated when consumers are not offered a means of coping with their FOMO (e.g., if an event is private and closed to the public; H5).

We first conducted a field experiment in conjunction with Lululemon ($N = 278$). The study began with an initial survey where we measured participants' connection to the brand and their brand intentions. We then invited participants to an actual in-store event; professional photos of the event were subsequently posted on the local Lululemon Facebook page. Afterwards, we conducted a follow-up survey in which participants were directed to a Lululemon Facebook album containing either photos of the event or Lululemon merchandise. Among participants who did not attend the event (>90% of the sample), we found that, across both photo conditions, participants with higher brand connections felt more FOMO after seeing the photos ($p < .001$), and this increased their future brand intentions (95% $CI = .04$, $.15$), providing support for H1 and H2. Contrasting the two photo conditions, we found that, relative to seeing merchandise photos, seeing event photos featuring people from the local community (i.e., fellow university students) increased brand intentions among people who were initially less connected to the Lululemon brand ($p = .03$; H3).

In a subsequent lab study ($N = 355$) with more experimental control, we re-ran the same three-phases of the field study (using the same photos from the previous event). In the pre-event survey, we also measured participants' anxious attachment to the brand community (adapted from Wei et al. 2007) and brand intentions toward Lululemon. We then used the same two conditions from the field study: participants were directed to Facebook pages featuring either event or merchandise photos. Finally, we conducted a post-event survey measuring FOMO and brand intentions. We again found that seeing social media photos increased FOMO among those with higher brand connection ($p = .003$; H1), and this increased their future brand intentions (95% $CI = .01$, $.05$; H2). Supporting H4, we also found that seeing event (vs. merchandise) photos increased brand intentions among those who were more anxiously attached to the brand community (interaction $p = .02$).

As a further test of H3, we conducted a lab study ($N = 702$) in which we manipulated whether the people in the event photos were from the local community or the brand community. In this and the subsequent study, we also allowed participants to choose from several brands to generalize our effects. We replicated the finding that highly brand-connected consumers felt more FOMO from seeing the photos ($p < .001$; H1), which in turn increased brand intentions (95% $CI = .03$, $.14$; H2). We also observed a photo condition by brand connection interaction in which seeing local (vs. brand) community photos increased brand intentions among less-connected consumers ($p < .001$; H3).

Our final study ($N = 704$) tests a boundary condition (H5) by asking participants to imagine seeing social media photos from a brand event that was either open or closed to the public. We predicted that only open events would offer consumers a means for coping with their feelings of FOMO and would therefore increase brand intentions, whereas closed events would not. We observed a significant mediated moderation whereby seeing event photos increased FOMO among highly brand-connected consumers (95% $CI = -.26$, $-.12$). However, this enhanced FOMO only increased brand inten-

tions when the event was open (95% *CI* = .11, .19), but not when it was closed to the public (95% *CI* = -.05, .06).

In summary, we find that seeing social media photos of local brand events triggers negative feelings of FOMO, which increases intentions to engage with the brand in the future. These effects are stronger among those who feel more connected to the brand and more anxious about their belonging. This research broadens our conceptualization of brand community and has implications for social media strategies.

SESSION OVERVIEW

This session showcases how computational models of cognition can be leveraged to offer new insights for consumer research. Marketing scholars have been calling for greater cross-pollination between theory-rich cognitive science and the more pragmatically oriented field of consumer research (e.g., Bartels and Johnson 2015; Weber and Johnson 2006). This call is being increasingly answered in the cognitive and psychology literature (e.g., Bhatia and Mullett 2016; Bhatia and Pleskac 2019; Trueblood, Brown, and Heathcote 2014; Trueblood, Brown, Heathcote, and Busemeyer 2013), allowing cognitive science to profit from validating models and theories in more realistic consumer settings (e.g., Vinson, Dale, and Jones 2019). But there has been less advancement along these lines in the field of consumer research. In fact, this call was echoed again last year during a Knowledge Forum on Models of Behavioral Decision Making held at the 50th ACR Conference. Participants appealed for greater openness to incorporating modeling approaches from different disciplines, and some argued that consumer research can benefit by the application of theory and methods from cognitive psychology. This session aims to answer the call by presenting four papers that apply computational models of cognition to better understand the mechanism that underlie consumers' evaluations of products and experiences and their construction of preferences.

The first paper introduces a process model of basic encoding, retrieval, and evaluative mechanisms that account for the behavior of consumers when they rely on memory to evaluate their consumption experiences. The author uses model simulations to derive novel hypotheses about variables that alter consumers' retrospective evaluations. In the second paper, a computational model of language representation is utilized to help identify commonalities and isolate key differences between the cognitive processes employed in pure-memory tasks and those employed in making preferential choices that rely on memory. The key insight is that choice modulates memory, altering the prioritization of retrieval to favor preference- and behavior-relevant items. The authors of the third paper use machine learning and a computational model of attention in decision making to show that preferences are influenced by attention to different degrees depending on whether choices are stimulus-based vs. men-

tal representation-based and are considered subjective decisions vs. objective judgments. Finally, the last paper offers a cautionary note about how best to apply computational models of cognition in consumer research. The authors show that estimation and interpretation of free model parameters is hampered under certain modeling conditions, and they offer solutions to help researchers overcome these challenges and avoid deriving spurious insights from computational models of cognition.

The papers in this session offer concrete examples of how models and methods developed in cognitive science can be fruitfully applied in consumer research to deepen our understanding of consumer behavior phenomena. This session will appeal to scholars interested in preference construction, decision making, cognitive processes (attention and memory in particular), as well as those with an interest in the application of modeling methods in consumer research.

Insights From a Process Model of Retrospective Evaluation

EXTENDED ABSTRACT

Consumers' evaluations of consumption experiences are important to researchers, firms, and consumers themselves. Scholars depend on retrospective self-reports (e.g. Heitmann, Lehmann, and Herrmann 2007), firms treat customer ratings as metrics of success (Keiningham, Cooil, Andreassen, and Aksoy 2007; Reichhel, 2003), and consumers rely upon their own (Moore 2011) and others' (Nielse, 2015) evaluations as a basis for consumption decisions (Babić Rosario, Sotgiu, De Valck, and Bijmolt 2016). Research has revealed innumerable variables that influence retrospective evaluation, but more limited progress is evident in understanding the basic cognitive mechanisms responsible. Weber and Johnson (2006) called for explicit exposition of the memory processes involved in preferences construction. I respond with a process model of retrospective evaluation: Minerva Evaluative Memory (Minerva-EM).

Comparison of model predictions to empirical results suggests the model's instance encoding, resonance-based retrieval, and evaluative mechanisms explain consumers' evaluative behavior. Derivation from the model of novel, empirically testable hypotheses demonstrates the value of applying computational models of cognition in consumer research.

Inspired by Hintzman's (1984) Minerva-2 memory model, Minerva-EM is a precise mathematical account of memory and evaluative mechanisms. According to Minerva-EM, memory is single system for encoding and storage of episodic memory traces, and retrieval operates by principles of resonance. In the computational instantiation of the theory, memory is a matrix with each trace constituting one vector. An experience is encoded as a series of traces for constituent events. Retrospective evaluation involves probing memory to retrieve a representation matching the specified context. This produces an effect analogous to singing into a piano. The strings of the piano (the traces) resonate (are activated) in response to the singer's voice (the probe). In effect, the piano (memory) produces an echo, with each string (trace) contributing in proportion to its match to the incoming sound (probe). The echo produced at retrieval is an imperfect representation of the target experience because traces from other experiences also contribute to the echo. Evaluation proceeds by comparison of the target evaluative dimension to the corresponding features of the retrieved representation.

I tested the model against empirical data in simulations of *the rating effect*—the effect of explicitly evaluating an experience on retrospective evaluation of that experience (Ibrahim, Häubl, and Waisman, Working Paper). Ibrahim et al. had participants watch an enjoyable time-lapse video and then either rate their enjoyment of it (rating condition), briefly describe the first and last scenes (recall condition), or go on with their day (control condition). One, three, or seven days later participants reported their enjoyment of the video. After one day no difference in retrospective evaluation was apparent across conditions. After three days, participants in the rating condition reported having enjoyed the video marginally more than those in the control condition, with the recall condition in between. The same pattern emerged as significant after seven days. To simulate the rating effect in Minerva-EM the probes and echoes produced via initial rating or recall tasks were encoded as events. Three time intervals were simulated by adding 1000, 5000, or 10000 random traces to memory, and 10000 participants were simulated per condition. Consistent with the empirical results, the evaluative response (echo intensity) was greatest in the rating condition, with the recall condition in the middle, and the difference increased as more events intervened. In another experiment, Ibrahim et al. tested if previously rating an experience increases enjoyment regardless of experience valence. Participants in rating and control conditions watched an unenjoyable history video and seven days later reported how enjoyable it was. Again, simulation results correspond well with the empirical data. Simulated and experimental participants evaluated the experience as less enjoyable if they previously rated the video.

I derived novel hypotheses for future investigation from a parametric analysis across 81 simulation conditions. For instance, the model predicts that a request to rate a dining experience will influence retrospective evaluation to a greater extent when the experience involves grabbing a snack in a familiar fast-food outlet compared to a more involved and lengthy experience such as eating dinner at a new fine dining establishment. Correspondence of simulation and empirical results indicates that the mechanisms described by Minerva-EM account for the rating effect and suggest the model captures basic processes responsible for retrospective evaluation more generally.

This work makes three important contributions. First, the model extends a classic theory of memory (Hintzman 1984) to offer a unifying framework for our understanding of the behavior of consumers when they rely on memory to evaluate consumption experiences. Second, simulation in Minerva-EM can benefit marketers seeking to understand when soliciting consumer feedback is advantageous. Third, I demonstrate that cognitive computational modeling offers a useful and fruitful strategy for investigating and understanding consumer behavior.

What I Like Is What I Remember: Memory Modulation in Preferential Choice

EXTENDED ABSTRACT

Imagine meeting your new next-door neighbor for an afternoon tea. First, try to remember all of the restaurants in your neighborhood to give her a list of available options. Now try to remember these restaurants with the explicit goal of choosing where to go for dinner. It is clear that your choice depends fundamentally on memory: A restaurant cannot be selected unless it is successfully recalled. But what is less clear is how the choice task (the goal of selecting somewhere to eat) modulates memory. How do memory processes during preferential decision making compare with memory processes that guide recall when individuals do not have to make a choice?

Most choices that we make on a day-to-day basis are memory-based, with consideration sets and choice items being retrieved from memory at the time of decision. A large body of work has established the importance of memory for many different decisions (e.g., Dick, Chakravarti, and Biehal 1990; Hertwig, Barron, Weber, and Erev 2004; Lynch, Marmorstein, and Weigold 1988; Murty, FeldmanHall, Hunter, Phelps, and Davachi 2016). While previous work in the field of cognitive psychology has established regularities in memory processes and highlighted the importance of value-based recall using free recall list-learning paradigms, memory processes in choice behavior have not been examined in a similar manner (Klein, Addis, and Kahana 2005; Castel 2007). Thus, we do not know the degree to which memory processes at play in pure-memory tasks influence memory-based choice, and if memory-based choice involves a unique set of decision-specific memory mechanisms.

The order in which people recall items in pure-memory tasks is sensitive to primacy and recency effects (higher likelihood of remembering words that appear at the beginning and end of lists) and temporal and semantic clustering (tendency to make recall transitions among temporally-close and semantically-related items) (Kahana and Miller 2013). Some of these effects have also been shown in memory-based choice. For example, brand memories display serial position effects (e.g., Li 2010; Sherrick et al. 2016), and items recalled in everyday choice are semantically clustered (Hutchinson 1994; Bhatia 2019). That said, thus far, researchers have examined pure-memory and memory-based choice in isolation, and have not systematically compared memory-based choice with pure-memory in list-learning settings. We provide such a systematic comparison.

We first investigated the domain of food choice (Study 1). In the subsequent study (Study 2), we extended our tests into the social decision domain, namely gift choices. In both of our pre-registered studies, we adopted a list learning paradigm from the episodic memory literature. More specifically, we asked our participants to study a list of 25 items (food items or gift items, in Study 1 and 2, respectively), and manipulated the recall task across our participants. We randomly asked half of our participants to recall as many items as they could from the just-presented list (pure-memory condition). The other half of the participants deliberated through the items and recalled them during a decision making task with the ultimate goal of making a choice (choice condition).

By analyzing the particular sequence of presented and recalled items of each participant, we were able to identify memory processes that underlie pure-memory and choice behavior tasks and compare them based on the particular task participants were engaged in. Our results showed that traditional memory regularities such as the primacy effect, as well as semantic and temporal clustering, appear in both pure-memory and decision making situations. That said, we found a stronger influence of temporal clustering in pure-memory than in choice. Additionally, preferences and frequency of consumption have a bigger effect in choice, with participants being more likely to recall items they like or items they have consumed previously. Computational models fit to participant data provided converging support for our results.

Our results suggest a substantial overlap in the memory processes used in pure-memory settings and in choice. However, these processes are not identical. Choice involves the modulation of memory to prioritize the retrieval of decision-relevant items, such as items that are highly desirable. One result of this is that other memory effects, such as temporal clustering, weaken. Ultimately, our experiments showcase a novel experimental paradigm for studying memory in decision making. This paradigm is able to connect decision making with established memory-theories in cognitive psychol-

ogy. Future work should build on these connections, so as to better characterize the domain-general and domain-specific memory mechanisms at play in choice, and to better understand the ways in which memory can be intervened on to influence and improve choice.

Packaging vs. Product: Distinguishing Between Choice Domains With Computational Modeling

EXTENDED ABSTRACT

When people shop, they are undoubtedly influenced by both the products' packaging and their mental representations of the products inside the packaging. Therefore, it is important to understand how people make decisions based on both types of information. Although choosing based on the packaging and choosing based on the product inside the packaging are clearly different decisions, they may have similar underlying mechanisms. For instance, past research has uncovered a consistent effect of visual attention in many different types of choices; specifically, more attention to an option leads to an increased likelihood of choosing that option. This link applies to choices in many domains, including consumer goods (Krajbich et al. 2012), monetary gambles (Stewart, Hermens, and Matthews 2015), and even complex decision environments, like moral dilemmas (Pärnamets et al. 2015). This attention-choice link also extends to perceptual judgments, such as choosing the option that more closely resembles a target stimulus (Tavares, Perona, and Rangel 2017).

However, past research (Polanía et al. 2014) has also demonstrated, using neural (EEG) data, that there may be differences in the decision-making process between preference-based choices (e.g. choosing which food to eat) and perceptual judgments (e.g. deciding which image is larger). However, in our initial example, choosing an item based on its packaging is both a perceptual- and preference-based task. Accordingly, we argue that the separation of perceptual judgments and preference-based choices in the literature thus far has been conflated with the separation of stimulus-based decisions (e.g. choosing which image is larger, based on the image itself) vs. decisions about the object represented by the stimulus (e.g. choosing which food to eat, based on pictures representing the foods). Therefore, it has not been possible to determine if the differences observed between perceptual- and preference-based choices are truly due to the perceptual/preference categorization or instead due to the stimulus/representation split.

Here, we present an alternative way to categorize decisions, based on two independent dimensions: (1) subjective vs. objective and (2) stimulus vs. representation. In this project, we cross these dimensions and investigate the decision-making process in the four resulting categories, using the same stimulus set: food images. Specifically, subjects (N = 42) first gave incentivized ratings for each of the 100 food images in each of the four categories: taste (subjective; representation), weight (objective; representation), attractiveness of the package (subjective; stimulus), and size of the image (objective; stimulus). Then, subjects made 100 incentivized, eye-tracked, binary choices in each of the four categories.

Overall, we find remarkable similarity between the tasks. In line with past research, subjects chose in line with their subjective ratings (i.e. their preferences or perceptions, depending on the task). They also tended to choose the option they looked at more; looking at one option for a half-second longer translates to choosing the more looked-at option ~70% of the time. Subjects also tended to choose the option they looked at last; when subjects were indifferent between the options, they chose the last looked-at option ~70% of the time. However, there were also some divisions between the tasks. For instance, although subjects did not spend more time looking at things they rated more highly, they did spend longer, on average, looking at heavier foods and looking at food images that take up more of the screen.

In order to identify the strongest connections (and thus, separations) between the tasks, we use a combination of subject-level modeling and machine learning. First, we draw on the attentional drift diffusion model (Krajbich et al. 2010)—a computational model of decision making—to characterize the degree to which attention moderates the choice process. We estimate subject-level effects in each task and then examine inter-task correlations (or lack thereof). We find the strongest positive correlations (1) between the two stimulus-based tasks (i.e. image size and package preference) and (2) between the two representation-based tasks (i.e. taste and weight), while the rest of the inter-task correlations were much smaller in magnitude (or even negative). This provides some evidence that subjects' stimulus-based decision processes and mental representation-based decision processes are similar (regardless of whether the decision is objective or subjective in nature), specifically with regard to the link between attention and choice.

In a separate set of analyses, we combine ~30 machine learning classification methods to estimate inter-task (dis)similarity. These machine learning models utilize a wide variety of decision process measures (spanning choice, response time, and attention-based metrics) from the odd-numbered trials to learn patterns in the data. Then, the models use these learned patterns to try to accurately classify the even-numbered trials into the appropriate category. We use pairwise classification accuracy rates as an index of dissimilarity, since the most dissimilar tasks should be the easiest to classify correctly. (On the other hand, the most similar tasks should have the lowest classification accuracy.) The machine learning models are most accurate at distinguishing between the taste and size tasks (in line with Polanía et al. 2014), and the models are least accurate at distinguishing between the representation-based tasks (i.e. taste and weight). Overall, the machine learning results (in combination with the drift diffusion approach described above) imply greater similarity in the decision process within the stimulus/representation categories than within the subjective/objective categories.

In this study, we investigate the separation of perceptual- and preference-based decisions suggested in the literature and demonstrate that a more important distinction is the presentation of the choice (i.e. whether the decision is about the stimulus itself or about a mental representation of the stimulus), rather than in the nature of the choice (i.e. whether it is based on objective or subjective criteria). Therefore, there seems to be greater similarity in the decision process among choices about which food is tastier or heavier (i.e. the representation-based tasks) than there is among choices based on taste or packaging (i.e. the preference-based tasks). Ultimately, this study provides us with evidence that (1) although attention plays a large role across several different choice domains, (2) the choice processes for products and packages are decidedly distinct.

Structural Dependencies in Computational Models of Cognition in Consumer Research

EXTENDED ABSTRACT

One of the major purposes of cognitive modeling in consumer research is measuring latent traits. This procedure is sometimes referred to as "cognitive psychometrics" (Batchelder and Riefer 1999; Riefer, Knapp, Batchelder, Bamber, and Manifold 2002). Despite a model's fit and even despite a model's predictive accuracy out-of-sample, however, the model's parameters might still not be correct operationalizations of the underlying latent traits. Instead, the model

as-a-whole can be a very good proxy for the entire cognitive process, while the individual parameter estimates do not represent the suggested latent traits. An overconfidence in interpreting the parameters of cognitive models is often addressed with the famous quotation: "All models are wrong, but some are useful" (Box 1979). This idea emphasizes that cognitive models remain nonetheless statistical models, being proxies of cognitive processes. Researchers should be cautious when interpreting the model parameters, and even more so if the necessary pre-condition to measuring latent traits is not fulfilled—that is, the independent and reliable estimation of model parameters.

Unfortunately, in several cognitive models that are commonly used in consumer research, parameters are indeed structurally dependent. One particular set of models that is commonly applied in consumer research is subject to very strong parameter intercorrelations. These models assume that behavior can be regarded as a probabilistic choice among alternatives. The alternatives are assigned subjective values. Free parameters in the model govern non-linear functions assigning the subjective values to the alternatives, and other parameters govern probabilistic choice functions, such as a logistic choice function to map the subjective values to the choices. This structure can be found in risky choice models, temporal discounting models or categorization models, to name but a few models that are relevant to consumer research. In these models, parameters that determine the subjective value function also scale the input values, while the response noise parameters in the choice function scale the subjective values to map them to the probability scale. As a consequence, the response noise parameter is dependent not only on the scale introduced by the other parameter, it depends on the parameter itself that is governing the function. The dependency between the parameters leads to strongly correlated parameter estimates as for instance in Cumulative Prospect Theory, CPT (Tversky and Kahneman 1992), Generalized Context Model, GCM (Nosofsky 1986) and the SIMPLE model of free recall (Brown, Neath, and Chater 2007).

In order to illustrate the negative consequences of the correlations, we implemented a *generic choice model* consisting of a power subjective value function with curvature parameter, and a logistic choice function with response noise parameter. By means of simulation and parameter-recovery studies, we show that the correlation between parameters not only decreases the accuracy of parameter estimation, it systematically distorts parameter estimation. We illustrate that inference on the correlation of the parameters with external variables as well as inferences on group differences on the individual parameters are distorted by the correlated parameters.

We then make several proposals for implementation in the concerned models to reduce the dependency of the parameters and thus the negative consequences resulting from the correlation. Those proposals either focus on applying different ways of rescaling the input of the probabilistic choice function, to cut the dependency between parameters, or they replace the individual response noise parameter with a different type of individual error parameter. The latter approach seemed to be most effective. We tested two alternative error models: adding a trembling hand error while fixing the response noise parameter to one and adding stochasticity to the correlated model parameter while likewise fixing the response noise parameter to one. Here, instead of assuming that every individual had one individual parameter, the model assumes that every individual has a distribution of parameters with an individual mean and an individual variance. The variance of the parameter distribution determines the individual stochasticity. In the simulation and parameter-recovery studies, we found that this proposal reduced the correlation and the negative consequences enormously. Implementing it in CPT not only

reduced the parameter correlations, it greatly increased the model's fit to the empirical data.

Adding stochasticity to parameters has been proposed elsewhere as a better approach for risk (Blavatskyy and Pogrebna 2010) as well as temporal discounting data (Apesteguia and Ballester 2018). Our results dovetail with these findings. Following this line of reasoning, adding stochasticity to model parameters may be tested as a better-suited approach to cover the type of noise observed in choice data, in general.

Two major suggestions that are relevant for the application of cognitive models in consumer research can be inferred from these results. First, we suggest that the different model selection criteria should be weighted differently considering the purpose of the cognitive model. Evaluating a model and comparing it with competitors can lead to different results, depending on which model selection criterion is the focus. For instance, a model's fit and out-of-sample prediction are most important if the main purpose lies in predicting behavior across similar tasks. Independent parameter estimation, parameter recovery and parameter correlations with neuronal or process data are important if the researcher aims to measure the underlying cognitive process or latent traits, and if the researcher aims to generalize predictions across tasks and domains. If the goal of the cognitive model lies in measuring latent traits that can subsequently be used for follow-up analyses, it must be guaranteed that the corresponding model parameters are estimated independently, in order to make valid inferences on the parameters. Second, we suggest consumer researchers to conduct a parameter-recovery study. Every introduction of a new cognitive model to measure latent traits or individual differences should be accompanied by a parameter-recovery study to prove that parameter estimation is reliable. If the subsequent application of the cognitive model also involves the calculation of correlations of the model parameters with external variables or the calculation of group difference on the parameters, the parameter-recovery study should prove that group differences and correlations with external variables can be reliably recovered.

Paper #4: Impossible Expectations for the Poor

Anuj K. Shah, University of Chicago, USA

SESSION OVERIVEW

Although abundance has emerged as the norm in modern industrialized societies, resource distribution inequality and scarcity remains prevalent across the globe (Roux, Goldsmith and Bonezzi 2015). According to the World Bank, in 2015 about 10 percent of the world population lived on less than $1.90 per day. Even within developed economies like the United States, approximately 38.1 million people lived in poverty in 2018, and more than 25% of children (20.1 million) live in households where no parent has secure employment (Kids Count Data Book 2019). Despite the accumulating interest in topics regarding poverty and scarcity, many questions still need to be answered regarding the consequences of being poor. For example, how are consumption behaviors shaped by the experience of being poor? Does low socioeconomic status make a consumer more selfish? Are there social penalties to being poor?

This session sheds light on these questions; four papers examine the behavioral, psychological, and social consequences of being poor. **Wu and Zhu** investigate whether socioeconomic status influences consumers' participation in the sharing economy as service providers. They find that consumers growing up in a lower socioeconomic environment are less likely to share their own resources the sharing economy, controlling for current SES. Further, they show that greater territorial feelings over one's own possessions serve as a central mechanism driving this effect. Consistent with these territorial feelings, **Park and Hamilton** show that childhood SES influences consumer decision making related to product retention and disposal. Controlling for current SES, low childhood SES consumers are found to experience more negative emotions during disposal, report greater desire to retain products, and dispose of products less frequently than consumers with more abundant resources growing up.

The third and fourth papers examine social interactions and inferences. **Jung, Vosgerau, Smeets, and Stoop** investigate whether socioeconomic status predicts ethical behaviors. Contrary to prior findings suggesting that the poor behave more ethically compared to the rich (e.g., are less likely to cut-off others at intersections and cross-walks), they find no relationship between socioeconomic status and consumers' ethical behaviors. The last paper examines the social consequences of being poor. **Shah** finds that consumers can have inconsistent and even impossible expectations of the poor (e.g., they should do both an overnight work-shift and sleep), and, when the poor fail to meet these impossible expectations, they judge them as lazier and less competent than the rich.

Taken together, this session integrates new perspectives regarding the psychological, behavioral and social consequences of being poor. We believe that this session will appeal to a broad audience, including researchers interested in resource scarcity, socioeconomic status, poverty, the sharing economy, prosocial and ethical behaviors, and person perception.

Resource Sharing in the Sharing Economy: Low Childhood Socioeconomic Status as a Barrier

EXTENDED ABSTRACT

In the past decade, the sharing economy has blossomed across a range of domains such as lodging (e.g., Airbnb, HomeAway) and transportation (e.g., Lyft, Uber, Turo). While extant literature has systematically examined consumers' motivation to join the sharing economy on the demand side as users (Belk 2013; Lamberton and Rose 2012), it remains understudied what factors might impact consumers' willingness to share their own assets on the supply side.

In this paper, we examine one fundamental factor that could impact consumers' tendency of providing their own assets in the sharing economy: socioeconomic status (SES). Somewhat intuitively, current SES might positively impact a person's resource sharing behavior in the sharing-economy, as higher current SES consumers have more assets (e.g., rooms, cars, spare tools) that can be shared with others in the first place. However, it is unclear whether and how the socioeconomic environment one grew up in might exert an independent impact on consumers' willingness to share their resources in the sharing economy. Although current SES and childhood SES are correlated, a rich body of research in psychology and sociology has suggested that SES exposures during childhood, independent of adulthood, are predictive of individuals' preferences, decisions and behaviors in the adulthood, including reproductive timing, eating habits, and health outcomes (Amir et al. 2016; Cohen et al. 2010; Hill et al. 2016). In the present paper, we seek to isolate the effects of childhood SES on consumers' resource sharing decisions from the possible impact of current SES and resource availability.

We propose (and find) that lower childhood SES decreases consumers' willingness to share their own assets in the sharing economy. In particular, drawing from prior research characterizing different socioeconomic environments (Amir et al. 2016; Evans and Kim 2012; Evans and Cassells 2013; Kraus et al. 2011; Stamos, Altsitsiadis, and Dewitte 2019) and past work on territoriality (Brown, Lawrence, and Robinson 2005; Kirk, Peck, and Swain 2017), we argue that the psychological costs of sharing ownership can be higher for consumers growing up in a lower socioeconomic environment, as these consumers might have developed greater territorial feelings towards their own property. As a result of the greater territoriality, lower childhood SES consumers might be less likely to share their own assets in the sharing economy, an effect that goes above and beyond the effect of individuals' current socioeconomic status.

We conducted three preregistered studies as well as used a national-level field dataset to test the proposed effect and the underlying mechanism. Study 1 ($N = 204$) tested the effect in a peer-to-peer car-sharing domain using a real-behavioral dependent variable. Participants first described a car that they currently have, and read

about a short description about Turo, a car-sharing platform. We then asked participants to choose between reading two topics about Turo: an article about how to list cars on Turo, and a recent news article about Turo. Participants then indicated their childhood SES ("When you were growing up, what was your assessment of your family's social and economic status?"; Amir, Jordan and Rand 2018) and current SES (e.g., "I have enough money to buy things I want"; Hill et al. 2016) As predicted, controlling for current SES, individuals with lower childhood SES were significantly less likely to read the article about listing cars on Turo, implying decreased interests of resources sharing.

Study 2 (*N* = 201) explored the underlying mechanism. Participants read a scenario where they imagined that they had a spare room in their house, indicated their likelihood of listing their spare room on Airbnb, and explained in an open-ended question, why they made the decision. We coded the open-ended responses (Khan et al., 2011, Zhu et al. 2018) and found that people with lower SES growing up had stronger territorial feelings over their possessions, which mediated the effect of childhood SES on participating in sharing economy.

Study 3 (*N* = 594) provided further evidence for the territorial-feeling mechanism by directly manipulating participants' level of ownership toward the object. Participants described an object in their house that they purchased (control condition) or other people purchased (low ownership condition) and indicated their likelihood of listing this object on a community resource-sharing platform. We found that in the control condition, lower childhood SES participants were less likely to list their own possessions on the sharing-economy platforms, replicating prior findings. However, in the low ownership condition, the effect of childhood SES on likelihood to share own assets in the sharing economy was attenuated.

Study 4 (*N* = 57,155) employed a publicly available nation-level field dataset: China Family Panel Studies (2010). Our primary DV was whether participants had ever rented out a spare room in their house. We used maternal education attainment as a proxy for early-life socioeconomic stability (Duncan and Brooks-Gunn 1997) and coded individuals as high (vs. low) childhood SES if their mother had completed some formal education (vs. no formal education). We used propensity score matching method to control for confounding variables including the mother's year of birth, household current SES, house space, family size, participants' number of siblings, age, gender, marital status, education and job types. Replicating prior studies, individuals whose socioeconomic stability was high (vs. low) in their early life were more likely to rent out their spare room. Further, as a robustness check, we regressed participants' room-renting behaviors on childhood SES index (i.e., parents' completed schooling and occupational prestige), controlling for the covariate variables, and found similar results.

To conclude, the current research reveals that lower childhood SES can lead to decreased likelihood of sharing own resources the sharing economy, an effect for which greater territorial feelings over one's own possessions emerge as a central driver.

Effects of Childhood Socioeconomic Status on Product Retention and Disposal Behavior in Adulthood

EXTENDED ABSTRACT

Earlier research has demonstrated that socioeconomic status (SES) in childhood has enduring effects on consumers' attitudes towards products (Chaplin et al. 2014), their attitudes towards risk (Griskevicius et al. 2013), and their willingness to wait for products (Thompson, Hamilton and Banerji 2020). Childhood SES reflects the degree to which an individual grew up in a resource abundant versus resource scarce environment (Griskevicius et al. 2011). In our research, we explore the lasting effects of childhood SES on consumer retention and disposal habits. More specifically, when controlling for current SES, we predict that low childhood SES consumers will experience more negative emotion during disposal, report greater desire to retain products, and dispose of products less frequently than high childhood SES consumers.

Because childhood SES adjusts individuals' expectations and patterns of responses, it may be more predictive of adult behavior than current SES (Chen and Miller 2012; Griskevicius et al. 2011; Griskevicius and Kenrick 2013), especially combined with the impact of parental influence. In particular, early life conditions may program individuals to respond to future adversity in different ways. Although adults with different SES backgrounds may behave similarly in benign situations, they may behave very differently when facing threatening conditions. For example, in response to a threat, individuals of low childhood SES were found to be more impulsive, risk-taking, and suggestive to temptation compared to their high childhood SES counterparts (Griskevicius et al. 2011).

We propose that low childhood SES consumers may experience more negative emotion during disposal and greater reluctance to dispose of products than high childhood SES consumers due to early life experiences that encourage them to focus on self-preservation and resource preservation. In a sense, disposal of products contradicts the life history strategy they adopted as resource-scarce children. Notably, childhood SES may have distinct effects across stages of the consumer decision journey (Hamilton et al. 2019). For example, while low childhood SES seems to predict greater impulsiveness during initial choice (Griskevicius et al. 2011), it predicts greater patience after consumers make an initial choice and learn that their choice is not immediately available (Thompson, Hamilton and Banerji 2020). Although there is some evidence that low socioeconomic status consumers tend to repurpose consumption items (see Hill 2001; Rosa et al. 2012), there has not been a systematic examination of the effects of childhood SES on consumers' disposal and retention habits. Thus, we used a multi-method approach to examine the effects of childhood SES on consumers' disposal and retention habits and emotions experienced during disposal.

Our first step was to conduct 22 interviews with consumers to understand their disposal and retention habits, potential relationships between these habits, their current and childhood socioeconomic status and other demographic variables. We leveraged peer networks to recruit participants who varied in gender (10 male, 12 female), age (21-78), ethnicity (13 Caucasion, 7 Asian, 2 Hispanic), and both childhood and current SES. Overall, participants were more likely to self-categorize as "savers" than as "tossers," perhaps due to the social desirability of avoiding wastefulness. However, their descriptions of when and why they preferred to save items rather than dispose of them diverged substantially. Eight prominent themes emerged after analyzing all of the interviews: concerns about price paid for items, emotional attachment to items, clutter/space concerns, desire to re-purpose items, concern over having to replace products, childhood experiences, and the impact of parents on retention and disposal.

These interviews revealed that childhood experiences have a strong impact on post-purchasing habits, primarily through parental influence. Many interviewees admitted to emulating their parents' habits in adulthood. For example, those who observed frugal parents were more likely to be conscious of their disposal and retention habits than those who did not. Moreover, changes in childhood SES seemed to have a particularly strong effect. Participants who experienced financial shocks (e.g., immigrating to a new country, bankruptcy) during their childhood often experienced more nega-

tive emotions when disposing of products in adulthood than those who did not experience financial shocks. Changes in disposal and retention habits also coincided with changes in SES. Ultimately, one of the most critical determinants of retention and disposal habits in adulthood seemed to be how a consumer remembered his or her childhood SES rather than more objective measures of childhood income or parental education.

Next, we conducted confirmatory research to measure the relationship between childhood SES and retention and disposal habits in adulthood. Specifically, we developed items to capture each of the eight themes identified in our exploratory research, disposal and retention habits, and emotions experienced during disposal. We also included measures of both objective and subjective childhood SES and current SES. Two hundred twenty-eight consumers of varying ages, ethnicities, education and income levels were recruited to participate via Amazon MTurk. The results point to a significant relationship between childhood SES and retention and disposal habits in adulthood. Consumers with higher childhood SES reported more frequent disposal and different reasons for disposing of products. Specifically, high childhood SES consumers were more likely to dispose of products based on how they looked and dispose of unfinished products. The data also revealed that positive emotions when disposing, such as pride, strength and enthusiasm, were more closely correlated to high childhood SES than current SES. In contrast, low childhood SES consumers were more likely to report retaining items because they had paid a lot for them or holding onto them based on concern about needing them in the future.

In summary, both our exploratory and confirmatory research suggest that childhood SES has a lasting effect on consumer post-purchase behavior in adulthood. Consumers who reported lower subjective childhood SES are more reluctant to dispose of products than those who reported higher subjective childhood SES. Notably, consumers' memory of financial hardships during childhood seems to be a more important predictor than the accuracy of recall. Building on prior research linking childhood SES to adult choice and consumption behavior, our research suggests that experiences in the formative years of childhood have a particularly strong effect on adult habits related to retention and disposal of products.

Are Rich/Educated Consumers less Ethical and Prosocial? Two Direct, Preregistered Replications of Piff et al.'s (2012) Field Studies

EXTENDED ABSTRACT

Who behaves more miserly and unethically, the poor or the rich? Some psychologists maintain that it is the rich, or more specifically, citizens of high socioeconomic status (SES). It is argued that people of high SES are more independent and less socially attuned than the lower social classes, and thus feel less compassion towards others (Stellar et al. 2012). As a consequence, they are hypothesized to be more likely to engage in antisocial and unethical behaviors (Piff et al. 2010; Kraus et al. 2012). Consistent with this hypothesis, it has been shown that high SES individuals are less likely to give to charity and to help and trust others (Piff et al. 2010), and to be more likely to engage in selfish and unethical behaviors, such as taking candies from children, lying in job negotiations, cheating, pilfering, and outright stealing (Piff et al. 2010; Piff et a. 2012; Côté et al. 2013; Guinote et al. 2015; Dubois et al. 2015). Piff et al. (2012) conducted two field studies, which show that — compared to drivers of less luxurious cars — drivers of luxurious vehicles are more likely to cut off others at intersections and are less likely to yield right of way to pedestrians at crosswalks.

The Piff et al. (2012) paper, and particularly these two field studies, have been discussed extensively in the popular media (e.g., New York Times 2010, 2013, 2015, 2017; The Economist 2010; Business Insider 2012, 2015; BBC 2015; CNN 2018; NPR 2018; The Washington Post 2018) and in the academic literature (at the time of writing this proposal, the paper had over 825 Google Scholar citations).

Research in economics and sociology, in contrast, has hypothesized and found the opposite, a positive relationship between SES and prosocial/ethical behavior. From an economic point of view, social preferences such as caring about others' wellbeing and valuing ethical principles implicate substantial opportunity costs, costs that only those with sufficient resources can afford to bear (Trautmann et al. 2013). In line with this reasoning, individuals living in richer areas have been shown to be more likely than those from poorer areas to send back wrongly addressed letters containing cash (Andreoni, Nikiforakis, & Stoop 2017). Korndörfer et al. (2015), using the German Socio-Economic Panel (SOEP), the GSS, the American Consumer Expenditure Survey (CEX), and the International Social Survey Programme (ISSP), showed that—across 30 countries including the US—high SES individuals are more likely to make charitable donations and to contribute a higher percentage of their family income to charity, to be more helpful and likely to volunteer, and to be more trusting and trustworthy in an economic game when interacting with a stranger than low SES individuals.

We conducted two direct, highly-powered, and pre-registered replications of the two field studies in Piff et al. (2012).

Study 1 is a direct replication of field study 1 in Piff et al. (2012). We observed the behavior of drivers at the same four-way intersection in Berkeley, California, as in the original study. We aimed at collecting 2.5 times the original's study's sample size ($N_{original}$ = 274, $N_{replication}$ = 685). With a correlation of r = .12 between vehicle status and likelihood of cutting off as observed in the original study, the replication had 88% power to detect the effect at the 5% level (two-sided test). The training of the coders (research assistants), coding of vehicle status (1 = cars worth \$3,000 or less; 2 = \$3,001-\$10,000; 3 = \$10,001-\$25,000; 4 = \$25,001-\$40,000; 5 = cars worth more than \$40,000), age and gender of drivers, and position of the coders were the same as in the original study. Unlike in Piff et al.'s (2012) study 1, vehicle status and cutting-off as judged by the first team of coders were not correlated, r = .014, p = .71, nor were vehicle status and cutting-off as judged by the second team of coders, r = -.024, p = .53. Binary logistic regressions on the likelihood of cutting-off other vehicles, controlling for traffic density, time of day, and driver's age and sex, neither showed a relationship between vehicle status and likelihood of cutting-off (ps > 0.60).

Study 2 is a direct replication of field study 2 in Piff et al. (2012) at a crosswalk in Berkeley, California. Research assistants blind to the study hypothesis observed and coded the likelihood of drivers not yielding right of way to pedestrians at the crosswalk. The crosswalk on Bancroft Way at the intersection with Ellsworth in Berkeley was chosen rather than the crosswalk at the intersection of Bancroft Way and Dana Street used in the original study, because Paul Piff informed us that the original crosswalk now has pedestrian lights installed and is hence no longer suited for the study. We aimed at collecting 2.5 times the sample size of the original study (N = 152). The final dataset included 439 observations. Due to a data encoding error we lost 75 observations, leaving us with 364 complete records, 16 short of the 380 that we had pre-registered. With a correlation of r = .17 between vehicle status and likelihood of not yielding right of way to pedestrians as reported in Piff et al. (2012), study 2 had 91% power to detect the effect at the 5% level. Unlike in Piff et al.

(2012), vehicle status and likelihood of not yielding right of way to pedestrians did not correlate, $r = .004$, $p = .93$. Also, binary logistic regressions controlling for traffic, time of day, and driver's age and sex showed no relationship between vehicle status and likelihood of not yielding to pedestrians (lowest $p = .59$).

Impossible Expectations for the Poor

EXTENDED ABSTRACT

People often believe poor individuals should do various things to improve their lives (e.g., work longer hours, sell certain possessions). It is possible that these are just matters of opinion (about which people can agree or disagree). This paper asks whether these beliefs are formed in a way that might lead to inconsistent or impossible expectations for the poor (but not the rich). That is, some of these beliefs might not just be things that people can agree or disagree about, but are actually impossible and violate normative standards.

Why does this occur? When evaluating whether a person should do something to make money, people focus narrowly on the opportunity without considering other things a person might do. There are many intuitive reasons why the poor should take the opportunity (they need money). There are fewer intuitive reasons why the rich should (they have enough money). So when people consider whether the poor should do something to make money, the intuitive answer is "Yes."

Here, I document three effects that stem from this. First, this intuitive belief means that people's expectations for the poor depend heavily on how a question is framed; their expectations are therefore often inconsistent. Moreover, people often argue that the poor should do mutually exclusive things (i.e., do the impossible). Second, when the poor fail to meet these inconsistent or impossible expectations (which is inevitable), they rate the poor are lazier or less competent. Third, this leads people to set inconsistent or impossible conditions for poverty alleviation policies. I find evidence for this across over 10 studies with ~100 participants per cell (e.g., 400 Ps for a 2x2 between-subjects study) in all studies. Below, I highlight a few studies.

Study1 (2x2 between-subjects): Participants read about a rich or poor person, and participants were assigned to Phase1 or Phase2. Phase1 participants were asked how many hours the (rich or poor) person should work for a given wage. Median response for the poor: 10 hours; rich: 5 hours. Phase2 participants were asked a narrower version of this question—whether the person should work more than the median response from Phase1. Normatively, Phase2 answers should be around 50% (because people are asked whether someone should work more than the median number of hours). But, 67% of Phase2 participants said the poor should work more than the Phase1 median; 46% said so for the rich. Depending on the question, people have inconsistent expectations for how much the poor should work. Study2 replicates this within-subjects.

Study3 (2x2 between-subjects) shows that this process leads to impossible expectations. Participants read that a (poor/rich) student could either do an overnight work-shift or sleep before a scholarship exam; options were mutually exclusive. Participants were asked one of two questions: Whether the student should work, or Whether the student should sleep. When asked whether the rich should sleep, 81% said yes. Asked whether the rich should work, 35% said yes. Asked whether the poor should sleep, 78% said yes. Asked whether the poor should work, 66% said yes. A majority of people think the poor should both work and sleep, which is impossible. Study4 shows that when asked how people should allocate their hours in a

day across different tasks, participants' answers sum to more than 24 hours for the poor, not so for the rich.

Studies 5A-D show that the poor are judged as lazier and less competent for failing to meet these (impossible) expectations; the rich are not. For example, in Study 5D participants read a scenario describing how a (poor/rich) person could participate in one of two gig-economy promotions that offered higher wages than usual. One of the promotions was a "driving" promotion (e.g., driving for Uber); the other was a "delivery" promotion (e.g., deliveries for Uber Eats). These two promotions were mutually exclusive. Half of the participants were asked whether they thought the person should do the driving promotion. The other half were asked whether they thought the person should do the delivery promotion. Overall, significantly more participants thought the poor should do the promotion they were asked about (86%) than should the rich (63%). Critically, expectations for the poor were essentially impossible—88% of participants said the poor should do the delivery promotion, 85% said they should do the driving promotion (both significantly greater than 50%).

The next phase of the study asked participants to make an attribution about the person they just read about. Participants were either assigned to the "control" condition or the "failure" condition. Participants in the control condition were asked how lazy they think the person is (on a scale from 1 to 7). Participants in the failure condition were asked to first imagine that the person does not do the promotion that the participants were just asked about. Then participants were asked how lazy they think the person is. There was a significant interaction such that participants in the failure condition rated the poor as significantly lazier (M=3.47) than in the control condition (M=2.36). But participants did not rate the rich significantly differently in the failure condition (M=2.86) and control condition (M=2.68). Taken together, people have impossible expectations for the poor (more so than for the rich) and people judge the poor more harshly (but not the rich) when they fail to meet these expectations.

Studies 6A-B show that this leads people to set inconsistent and impossible conditions for anti-poverty policies. For example, when participants are asked how long the poor should have to work in order to qualify for food stamps, the median response is age 50. But when asked whether the poor should have to work past age 51 to qualify for food stamps, 64% of people say yes. This leads to escalating requirements for the poor to receive benefits.

SESSION OVERVIEW

Gift exchange is a common societal practice that has been a tradition for thousands of years (Culture and Society 2015). The purchasing of gifts is a giant industry all across the world. The average American was expected to spend over $900 on gifts in 2019, a number that has been steadily growing over the past few years (Haury 2019). Moreover, gifts have important psychological effects, being able to bring people closer together and perpetuate relationships (Belk and Coon 1993; Chan and Mogilner 2016). On the other hand, gifts also have the potential to create conflict and negatively impact relationships (Sherry, McGrath, and Levy 1993). Given such immense financial and psychological consequences, understanding the potential impacts, both positive and negative, that underly gift exchange can provide important insight for consumers. In particular, this session aims to shed light on the challenges faced during gift giving, from both the givers' and receivers' perspectives.

Papers 1 and 2 examine the burdens givers experience when given the opportunity to give a gift. In paper 1, Wu, Steffel, and Shavitt explore the overindividualization of gift giving for multiple recipients from a cross-cultural perspective. The authors find that while both Easterners and Westerners tend to overindividuate when choosing for multiple others, Easterners are more likely to overindividuate when there are status differences amongst recipients.

Sometimes gift giving is the response to a difficult situation rather than the cause of one. Wiener, Howe, and Chartrand look at gift giving as a method of social support. They demonstrate that when encountering someone in need of support, consumers are more likely to give gifts instead of providing emotional support when the other is perceived as difficult to support. Interestingly, gift giving actually reduces the receiver's negative affect more so than providing emotional support.

Papers 3 and 4 explore the potential negative reactions that receivers experience when getting a gift. Zhou and Chartrand examine the mismatch between givers and receivers in terms of predicting receivers' feelings of indebtedness caused by the gift. They find that givers underestimate the amount of indebtedness experienced by re-

ceivers, and that this is caused by mispredictions in feelings of guilt. Indebtedness then leads to increased likelihood for receivers to get a return gift, which givers also do not anticipate.

In paper 4, Ward, Lowe, Reich, and Fajardo examine circumstances where giving a spontaneous gift results in worse outcomes than not giving a gift. The authors find that for high-investment relationships, receiving a low-expenditure gift decreases affiliation with the giver compared to not receiving a gift at all. The effect is attenuated for low-investment relationships.

These four papers highlight the various obstacles givers and receivers encounter and some of the unintended consequences of gifts. Taken together, we provide insight on givers' thought processes when choosing what to give, as well as the potentially negative reactions experienced by receivers. Accordingly, this session should have broad appeal to those who are interested in gift giving, cultural differences, social support, and consumer relationships.

Individuating Gifts out of Liking and Respect: Expanding Gift Giving Theory with a Cross-Culture Perspective

EXTENDED ABSTRACT

Gift givers often tailor their gift selections to show consideration to recipients. Consequently, givers who shop for multiple recipients at once tend to pass up gifts that they know would be preferred in favor of different gifts for each recipient (Steffel and LeBoeuf 2014). Although prior research illuminates how the immediate context influences overindividuation, little is known about the influence of the broader cultural context. The present research explores how cultural values influence overindividuation.

We predict that overindividuation is not a uniquely Western phenomenon—Westerners' independent values may foster overindividuation by emphasizing the value of treating people as unique individuals, but Easterners' interdependent values may also foster overindividuation by emphasizing the value of moderating choices based on the social context (Fukuoka et al. 2005). Additionally, how people from different cultures individuate gifts may differ depending on norms regarding how to properly acknowledge others' standing within a given social context. Whereas Western values emphasize choosing mainly based on personal preferences, Eastern cultures emphasize choosing based on social hierarchy and status (Riemer et al. 2014). As a result, the criteria that consumers use to decide whose preferences to prioritize should differ across cultures. We predict that Westerners will prioritize the preferences of recipients that they like better by choosing a better-liked gift for personally preferred recipients and a unique but less-liked gift for less preferred recipients. But they will not differentiate recipients based on their social status. By contrast, Easterners will prioritize the preferences of recipients who have higher social status and not necessarily the preferences of recipients they like better.

Experiment 1 examined whether givers from both a Western culture (United States) and an Eastern culture (China) overindividuate gifts for multiple recipients. Participants were recruited simultaneously from the U.S. ($N = 114$) and China ($N = 149$) and randomly assigned to imagine choosing a birthday gift for either one or two unacquainted recipients. In the two-recipient condition, the target recipient preferred silver but also liked gold, and the other recipient preferred only silver. In the one-recipient condition, participants

chose gifts only for the target recipient. Despite their cultural differences, givers in both cultures were less likely to get the silver frame for the target recipient in the two-recipient condition than in the one-recipient condition (41% vs. 76%; $p < .001$), and overindividuation did not vary based on culture ($p = .98$).

Experiment 2 sought to determine whether givers from Western and Eastern cultures overindividuate differently based on personal liking, relative status, or both, and whether these differences are driven by cultural values dictating who should be shown greater consideration. Participants from the U.S. ($N = 318$) and China ($N = 341$) imagined choosing iPad cases for two unacquainted recipients who either differed in how much they were liked (favorite coworker vs. liked coworker) or in their status (higher-status coworker vs. same-status coworker). Both recipients preferred a black case, but the higher-status/favorite coworker also liked brown, and the same-status/liked coworker also liked beige. Participants were free to choose the same or different iPad cases for the recipients. Finally, participants reported to what extent they felt they should show consideration to each recipient.

Overall, participants overindividuated by choosing the preferred black iPad case for the higher status/favorite coworker more often than for the same status/liked coworker ($p < .001$). More importantly, there was a three-way interaction between culture, relationship, and recipient on gift choices ($p = .01$). Both Chinese and American participants chose the preferred gift more often for the favorite coworker than the liked coworker (both $p = .001$). By contrast, Chinese participants chose the preferred gift more often for the higher-status coworker than the same-status coworker ($p < .001$), but American participants did not differentiate between recipients based on status ($p = 1.00$). Furthermore, both American and Chinese participants felt their favorite (vs. liked) coworker should be treated with greater consideration (both $p < .05$). However, Chinese participants felt their higher (vs. same)-status coworker should be treated with greater consideration more so than did American participants ($p < .001$ vs. $p = .07$, respectively).

Experiment 3 examined whether power distance belief, the degree to which people believe in or endorse hierarchy and status differences in society, predicts gift choices in the same manner as the national culture differences. The design of Experiment 3 was similar to that of Experiment 2, except that participants completed a measure of power distance belief ($\alpha = .55$; Zhang et al. 2010) rather than a measure of consideration norms.

As expected, Westerners and Easterners followed different criteria to overindividuate gifts for multiple recipients. U.S. givers ($N = 210$) prioritized the preference of the better-liked recipient according to their relative attitudes towards the recipients, such that U.S. givers ($p < .001$), but not Chinese givers ($N = 241$, $p = .26$), chose the preferred gift more often for the best friend than for the acquaintance. However, Chinese givers prioritized the preferences of the higher-status recipient according to the relative social status of the recipients, as Chinese givers ($p < .001$), but not U.S. givers ($p = .11$) chose the preferred gift more often for the manager than the coworker. Moreover, power distance belief predicted gift choices (the three-way interaction: $p < .05$) in the same manner as did national culture differences. This pattern of results was consistent with prior research, such that individual differences in power distance belief predict attention to the status signals sent by one's consumption (e.g. Gao et al. 2016). In line with this, givers higher in power distance belief prioritized the preferences of the recipient with higher status, whereas those lower in power distance belief prioritized the preferences of the recipient that they liked better, but not vice versa.

Overindividuating gifts for multiple recipients occurs across cultures. However, the dimensions along which overindividuation occurs vary in ways that reflect cultural values. Although Americans overindividuate based only on personal liking, Chinese overindividuate based on both liking and status.

Buying Love: Gifts as a Form of Social Support

EXTENDED ABSTRACT

Social support is critically important to people's health and happiness (Thoits 1995), and not providing or providing low-quality social support damages relationships (Dakof and Taylor 1990). However, people often do not provide support to others. When confronted with a loved one's tragedy, would-be support providers often avoid the affected, refuse to talk about the difficult topic, or minimize the problem (Barbee and Cunningham 1995; Dakof and Taylor 1990). One reason people avoid providing support is because providing high-quality emotional support can be difficult and unpleasant (Wortman and Dunkel-Schetter 1987).

In this paper we propose an alternate way that consumers can support others who are struggling: giving them a gift. Gifts have been found to be important in relationship maintenance, but most gift research has focused on gifts given for celebratory events (Ward and Chan 2015). We focus on gifts given in response to others' negative events, such as a loved one's death. Consumers regularly give gifts, such as flowers or care packages, under these circumstances (Post and Senning 2017). However, little is known about when consumers are most likely to give these gifts or how supported recipients feel when receiving them.

We propose that the more difficult it is to provide emotional support, the more likely the support provider is to give a gift. In particular, support providers report that providing support to pessimistic, negative people is stressful and difficult (Forest et al. 2014). Giving a gift is an alternative way to fulfil the support obligation (Clark 1987), so we propose that givers will be more likely to provide support by giving a gift when the recipient is pessimistic.

We also investigate how effective recipients find emotional support versus gifts to be. Recipients may view gifts negatively, as givers "buying their affection" but also report that emotional support is often ineffective (Lehman, Ellard, and Wortman 1986). Therefore, we propose that receiving a gift will lead to a larger improvement in mood than receiving emotional support will.

Study 1a examines when givers choose to support someone with a gift rather than by providing emotional support. Participants ($n = 48$) came to the lab in groups and were told that they would be paired with another participant. They were shown the personality profile of their "partner." They did not have a partner; instead these profiles contained the recipient personality manipulation: The partner was either pessimistic or optimistic. Then participants were told their partner had been through a break-up and were asked whether they wanted to spend five minutes talking to them about it (i.e., provide emotional support) or pay $1 (from their $7 study payment) to give them a gift. Participants were significantly more likely to provide support by giving a gift, rather than by providing emotional support, when the support recipient seemed pessimistic (54%) rather than optimistic (25%, $\chi^2 = 4.27$, $p = .039$).

Study 1b ($n = 225$) is a conceptual replication of study 1a. Participants read a scenario about a pessimistic or optimistic person in need of support. Participants chose whether to support the recipient by sending them a care package or talking to them on the phone and indicated how difficult providing support would be. Participants who read about the negative recipient were significantly more likely to

send a care package (46%) than were those who read about the positive recipient (27%, $\chi^2 = 9.60$ $p = .002$). A mediation analysis showed that difficulty of providing support mediated the effect of condition on gift giving (95% CI: [.02, .48]).

Study 2 ($n = 118$) is a dyadic lab study (59 dyads) that investigates how recipients feel about receiving social support through a gift. This study had a 2 (emotional supported provided v. no emotional support provided) x 3 (time: initial, post-support manipulation, post-gift opportunity) mixed design. Participants came to the lab with a close other. One participant from each pair was randomly assigned to the role of giver or recipient. Recipients first wrote about a current life problem that did not involve their partner and answered questions about their mood and feelings about the problem. Then they talked to their partner for five minutes about their problem (emotional support condition) or completed a control task before completing the attitude measures again. Then givers were given the option to spend some of their study payment to purchase 0-4 gifts for their partner. The research assistant gave recipients their gift(s) if they were given one, and recipients completed the measures a third time.

We first examined whether receiving emotional support made recipients feel better than did completing a control task. We conducted a repeated measures ANOVA with the time at which the recipient rated their feelings as the within-subjects factor (time 1 [immediately after writing about their problem] v. time 2 [post-manipulation]) and whether they received emotional support as the between-subjects factor. Receiving emotional support did not reduce participants' negative mood (F (1, 57) = 2.15, $p = .15$), and only marginally reduced their negative feelings toward the problem (F (1, 57) = 3.03, $p = .087$) more than completing the control task did.

In contrast, receiving a gift reduced negative mood and feelings about the problem significantly more than not receiving a gift did. We conducted a repeated measures ANOVA with the time at which the recipient rated their feelings as the within-subjects factor (time 2 [post-manipulation] v. time 3 [post-gift]) and whether or not they received emotional support as the between-subjects factor. Participants who received a gift experienced a larger decrease in negative emotions (F (1, 57) = 7.61, $p = .008$) and negative feelings toward the problem (F (1, 57) = 8.56, $p = .005$) than those who did not. There was no main effect of having received support on post-gift feelings ($ps > .15$).

In conclusion, these three studies show that gifts are not consumers' default way of providing social support, but they use them when they think the recipient will be difficult to support, and that they are quite effective at improving recipient mood.

The Burden of Gifts: How Givers Mispredict Negative Reactions of Receivers

EXTENDED ABSTRACT

Givers make many mispredictions when it comes to getting gifts for receivers. For example, they mistakenly think that unsolicited gifts would be appreciated more (Gino and Flynn 2011; Ward and Broniarczyk 2016) and that desirability matters more than practicality (Baskin et al. 2014). Additionally, givers often focus on maximizing the happiness of receivers (Baskin et al. 2014), but do not seem to consider the potential negative consequences of the gift. Thus, the present research focuses on givers' mispredictions of receivers' negative feelings during gift giving.

Social norms dictate that we cannot always be on the receiving end of exchanges (Ruth, Otnes, and Brunel 1999). Thus, we propose that from the receiver's perspective, receiving a gift will lead to more feelings of indebtedness that givers are unable to anticipate. Furthermore, we hypothesize that this effect is driven by recipients feeling more guilty than givers expect them to feel after receiving the gift. People experience guilt when they think they have gone against an important value (Sznycer 2019), in this case feeling currently unbalanced on reciprocity norms. We propose that feelings of guilt lead to a cognitive recalibration of the situation (Tooby and Cosmides 2008) in which receivers realize they are indebted. This indebtedness increases a need for reciprocity (Belk and Coon 1993), leading receivers to want to give a return gift in order to reinstate equilibrium. Across four studies, we demonstrate the inaccuracy of givers in (under)anticipating the burdens placed on receivers.

In study 1, we examined the mismatch between feelings of indebtedness that givers predict receivers will experience compared to what receivers actually experience. Participants were recruited right after Christmas and were randomly assigned to think back to the winter holidays to either recall a gift they gave to someone or to recall a gift they received from someone. Givers then rated how indebted they thought the recipient would feel while receivers rated how indebted they actually felt (100-point slider scale). Results revealed that those who recalled giving a gift ($M = 17.21$) significantly underestimated the indebtedness felt by those who recalled receiving a gift ($M = 26.8$; $t(198) = -2.53$, $p = .01$).

Study 2 conceptually replicated the results of study 1 using dyads in the lab. Participants came into the lab in pairs (63 pairs), with one partner assigned as the giver and the other assigned as the receiver. The giver chose a gift for the receiver on the premise that one receiver would be picked from the lottery to obtain the gift the giver chose for them. Givers and receivers then rated feelings of the receiver's indebtedness. Using a multi-level modeling approach to account for violations of statistical independence for pairs (Kenny, Kashy, and Cook 2006), we again find that givers underestimated feelings of indebtedness ($B = 7.77$, $t(64.22) = 2.03$, $p = .05$).

In study 3, we conducted a 2 (role: giver vs. receiver) x 2 (friend: close vs. distant) experiment to test the proposed mechanism and examine whether closeness with the exchange partner would affect the results. Participants first named either a close friend or an acquaintance. Then they read a scenario in which they met with the friend and either gave or received a gift. Givers predicted receivers' feelings of indebtedness and guilt while receivers rated own feelings of indebtedness and guilt. An ANOVA revealed only a main effect of role ($F(1, 395) = 15.34$, $p < .001$), with givers again mispredicting indebtedness ($M_{giver} = 20.25$ vs. $M_{receiver} = 31.01$). There was no effect of closeness or interaction between role and closeness ($ps > .46$). Receivers also felt more guilty after getting the gift than givers anticipated ($M_{giver} = 7.40$ vs. $M_{receiver} = 11.55$; $F(1, 395) = 15.34$, $p = .03$). Ratings of guilt mediated the mispredictions on indebtedness ($ab = -3.05$, SE = 1.36, 95% CI [-5.63, -.36]).

Finally, in study 4, we examined the predictions for both the negative experiences of indebtedness and guilt as well as the positive emotion of happiness. We conducted a 2 (role: giver vs. receiver) x 2 (gift: desirable vs. not) experiment in which the pretested gift was either a desirable or undesirable gift card. Then givers predicted while receivers rated own feelings of happiness, indebtedness and guilt. We also measured predicted likelihood to give a return gift as a downstream consequence of indebtedness (1 = not likely, 7 = very likely). First, we ran an ANOVA on happiness, which revealed a main effect of role ($F(1, 397) = 16.66$, $p < .001$), a main effect of desirability ($F(1, 397) = 7.35$, $p = .007$), and a marginal interaction between the two ($F(1, 397) = 3.10$, $p = .08$). For desirable gifts, givers and receivers had similar estimates of happiness ($M_{giver} = 79.35$ vs. $M_{receiver} = 84.68$; $p = .10$), whereas for undesirable gifts, givers un-

derestimated the happiness that receivers actually felt (M_{giver} = 69.10 vs. $M_{receiver}$ = 82.50; $p < .001$).

Next, we ran an ANOVA on indebtedness and guilt ratings. For indebtedness, we found a main effect of role (M_{giver} = 18.81 vs. $M_{receiver}$ = 31.51; $F(1, 397) = 21.80, p < .001$), but no significant effect of gift desirability or interaction ($ps > .66$). We found the same pattern for feelings of guilt. Finally, we examined likelihood of buying a return gift. Although there were no effects regarding desirability, we found a main effect of role such that receivers felt more obligated to get a return gift for givers than the givers anticipated (M_{giver} = 5.05 vs. $M_{receiver}$ = 6.06; $F(1, 397) = 50.97, p < .001$). This effect was serially mediated by the mismatch between giver and receiver on feelings of guilt and indebtedness (index = .03, SE = .02, 95% CI [.002, .07].

Taken together, we demonstrate that givers chronically underestimate how indebted receivers actually feel after getting a gift because they cannot foresee the guilt experienced by the receiver. As a downstream consequence, receivers become more likely to give a return gift for the giver, which givers also do not anticipate.

Thanks for Nothing: When Giving a Gift is Worse than Giving Nothing at All

EXTENDED ABSTRACT

Receiving a gift is generally regarded by both the giver and recipient as a relationship-validating experience. Prior research shows that even when a giver chooses a *less* preferred item, the relationship between giver and recipient is typically enhanced (Dunn et al. 2008) as the recipient is likely to view the gift as a signal of the giver's positive intentions toward the recipient. Given strong social endorsement to avoid 'looking gift horses in the mouth,' coupled with consumers' motivation to interpret gifts as positive relational symbols, it may seem unlikely that receiving a gift would harm the giver-recipient relationship. However, we predict and find that there *are* instances in which certain gifts may damage relationships.

The context in which gift exchange takes place influences the recipient's interpretation of the offering. Much of the prior gifting research focuses on 'normative' gift contexts wherein recipients have high expectations of receiving a gift (e.g., birthday) and the items chosen are pre-determined by social norms (Joy 2001). However, many gifts are offered spontaneously -- outside of prescribed giving occasions. According to Carrier (1990), spontaneous gifts represent the truest form of giving because givers select these items for recipients without the pressure of social obligation. Consequently, we suggest that recipients are likely to be *more* attuned to the messages imbued in spontaneous gifts, because they are perceived to demonstrate the giver's 'true' perceptions of the relationship (Belk and Coon 1993).

We predict that the context of spontaneous gift giving recipients will interpret givers' expenditures of resources on gifts as proxies for givers' value for the relationships (Ruth et al. 1999). Thus, low-expenditure gifts may devalue the relationship relative to receiving no gift; in response recipients may distance themselves from the giver.

We suggest that when gifts are offered spontaneously, low expenditure gifts have especially detrimental effects on high-investment relationships (HIR) – relationships in which individuals have committed substantial time or effort to one another. Conversely, in the context of low-investment relationships (LIR) – relationships in which the individuals are less involved with or committed to one another – recipients are likely to have lower expectations for the gifts they receive. Thus, receiving a low expenditure gift should be less damaging for LIRs.

Gift giving is a cultural tradition meant to perpetuate future relationships. Given the future-looking nature of gift exchange, we consider recipients' predicted future relationship 'affiliation' with givers as the focal dependent measure.

In Study 1, an RA asked students who had completed various research studies, if they would complete an 'additional task' to help the PR department at the university. Participants were told that no compensation would be given but that their participation would be of great assistance to the PR department. Participants were instructed to search the university's name on Google.com/news, then read and summarize the top search results. To manipulate relationship investment, students were either assigned to summarize 10 (vs. 2) articles. Those in the 10 article condition felt they had worked harder and thus were more highly invested in their relationship with the organization. After completing the task, participants were given either a low expenditure gift (i.e. three plain pencil erasers) or nothing at all. Subsequently, participants endorsed their feelings of affiliation with the PR department. An ANOVA conducted on the affiliation measure revealed a significant interaction between the two factors ($F(1, 296) = 4.04, p = .04$). When HIR participants received a low-expenditure gift, they expressed lower feelings of affiliation (M_{LE} = 4.09) than when they received no gift ($M_{No\ Gift}$ = 4.67; $t = -3.04, p < .01$). However, in LIRs, this effect was attenuated (M_{LE} = 4.62 vs. $M_{No\ Gift}$ = 4.69; $t = -.32, p = .75$).

In Study 2, we examined whether HIR recipients were more sensitive to the relational implications of low-expenditure gifts received under spontaneous (vs. normative) conditions. In a 2 (Gift: None vs. Low-Expenditure) by 2 (Gifting Context: Normative vs. Spontaneous) participants read a scenario. To manipulate gift context, participants read a scenario in which they imagined completing a project at work, after which their employer *usually* presented them a gift (normative) or *did not usually* present one (spontaneous). Next they imagined receiving a low-expenditure gift (a $5.00 gift card to a restaurant) or no gift. Subsequently, participants endorsed their affiliation with the firm.

An ANOVA on affiliation revealed a significant interaction between gift context and gifting scenario ($F(1,178) = 5.24, p = .02$). In normative conditions, there was no significant difference in affiliation when participants received no (vs. low-expenditure) gift ($M_{No\ Gift}$ = 4.03 vs. M_{LE}= 3.96; $F(1, 178) = .082, p = .76$). However, in spontaneous conditions, receiving no (vs. low-expenditure) gift resulted in significantly higher feelings of affiliation with the giver ($M_{No\ Gift}$ = 4.83 vs. M_{LE} = 3.83; $F(1, 178) = 10.93, p = .001$). Thus, low-expenditure gifts given under normative circumstances ameliorated recipients' feelings of disaffiliation.

In Study 3, in the context of interpersonal relationships, we examine how recipients' perceptions of givers' individual resources influence their predicted affiliation. In a 2 (Relationship investment: High vs. Low) x 3 (Giver resources: Control vs. Restricted vs. Unrestricted) x 2 (Gift Expenditure: Low vs High) between-subjects experiment, participants imagined receiving either a low-expenditure gift (a $3, easily found, generic keychain) or no gift, after a book club meeting (spontaneous context). Notably, recipients were told that their HIR (LIR) friend either had "a really tight (light) schedule this semester." Under control conditions, participants were given no information about the giver's time resources.

An ANOVA revealed a significant three-way interaction ($F(2,378)=5.07, p<.01$). When no mention of the givers' resources was made in the unrestricted resource condition, results reveal significant two-way interactions between relationship investment and gift type (Control: ($F(1,378)=3.88, p<.05$); Unrestricted: ($F(1, 378)=4.31, p<.05$)). However, when participants knew the giver had

restricted resources, the focal interaction among high investment relationships was attenuated (M_{LEt}=4.69, M_{NoGift}=4.66; $F(1,378)$=0.25, p=.87).

In conclusion, we demonstrate that in spontaneous gift contexts, giving nothing to an HIR recipient may be more likely to preserve the relationship than giving a low-expenditure gift.

SESSION OVERVIEW

With the accelerated demand for new technologies, algorithms / artificial intelligence (AI) have integrated diverse and refined skills. These advancements make them a viable alternative to using humans to complete the same tasks. Algorithms can outperform humans on medical diagnoses (Hutson 2017), taste-based recommendations (Yeomans et al. 2019), predictions (Grove et al. 2000), and games (Hosanagar 2019).

Despite advancements in these new technologies in businesses, however, the literature diverges on the extent consumers embrace or dislike algorithms. It is still unclear from the literature when consumers are open to using algorithms (e.g., Dietvorst et al. 2015; Logg et al. 2019). This disagreement raises important questions about the dynamics between humans and their valuation of technology: What factors affect consumers' reactions towards decisions by algorithms (vs. humans)? Do consumers value decisions differently when generated by algorithms or humans? Does the framing of algorithms change consumers' willingness to use it? Under which situations are consumers more likely to (de)value algorithms? Can algorithms objectively outperform humans in domains involving aesthetics?

This session aims to identify the boundary conditions of when consumers appreciate algorithms more than humans (subjective valuation), and when algorithms do or do not objectively outperform humans (objective). In the first paper, **Yalcin et al.** study consumers' reactions to decisions that are made by algorithms versus humans. Across seven studies, they reveal less positive reactions to favorable outcomes (e.g., acceptances) by algorithms (vs. humans), whereas they find no increased negative responses to algorithms when the outcome is unfavourable (e.g., rejections). They also show that these differences are explained by a shift in perceptions depending on the valence of the decision outcome. **Lin** and **Dietvorst** explore how the way algorithms are described changes consumers' likelihood of using them. Across seven studies and different prediction methods (e.g., navigation), they demonstrate that consumers prefer methods of prediction that replicate the event in question even when doing so is counterproductive. Next, **Hussein** and **Huang** investigate what type of professional help consumers value more when dealing with

stress and compulsive behaviors. In four studies, the authors find that consumers perceive AI (vs. human) mental health providers to be less warm, which harms their perceived competence, resulting in higher aversion of AI providers. Finally, the paper by **Weingarten et al.** tests whether AI outperform human experts in creative markets, specifically in logo design. The authors consistently find that the quality of the logos from human experts outperform those from artificial intelligence.

This session provides timely insight into objective and subjective valuation of algorithms and humans, an increasingly important topic given the proliferation of this technology in consumer contexts. Our proposed session directly addresses the ACR 2020 conference theme as it examines the value of deep thinking, rational thought, and reason for humans relative to algorithms in a new era of machine intelligence. We believe that this proposed session should be of interest to a broad audience of scholars and practitioners working on judgment and decision-making, advice/recommendations, aesthetics, and new technologies. All projects have at least four completed studies.

Thumbs Up or Down: Consumer Reactions to Decisions by Algorithms Versus Humans

EXTENDED ABSTRACT

Companies are increasingly adopting algorithms to make decisions that affect existing and potential customers, such as accepting and rejecting applications. Today, algorithms are commonly used to decide who a company should hire (e.g., JetBlue) or provide services to (e.g., rayatheapp.com). This growing trend calls for marketing researchers to gain a better understanding of customers' reactions to decisions made by algorithms and humans. Previous research has predominantly focused on how individuals choose between an algorithmic and human service provider (Castelo et al. 2019; Logg et al. 2019; Longoni et al. 2019). Unlike this line of research, we investigate the responses of individuals as a recipient of decisions made by either an algorithm or a human.

In this research, we propose that customers react to decision-makers (algorithms vs. humans) differently depending on the valence of decision outcomes, namely whether they are accepted or rejected by a firm. Specifically, we hypothesize that customers react less positively (e.g., less perceived self-worth, less positive attitudes towards the firm), to an algorithm than a human decision-maker in the case of favorable decisions (e.g., acceptances), whereas such a negative reaction to an algorithm (vs. a human) would be attenuated in the case of unfavorable decisions (e.g., rejections). Our theorizing is based on attribution theory demonstrating that individuals tend to attribute their successes and failures in a self-serving way (Halperin et al. 1976). Namely, people tend to take credit for their success but blame others for failures so as to defend their self-esteem. Accepted customers would be motivated to view the positive outcome as a result of their individual characteristics, thereby reacting more positively to a human (vs. an algorithmic) decision-maker, who is perceived as more capable of incorporating individuals' uniqueness into the decision. Rejected customers, however, would attribute the unfavorable outcome to decision-makers (regardless of who the decision-maker is), viewing a human decision-maker as less objective and an algorithm as more ignorant of their individual uniqueness.

We tested our predictions across seven experiments (N = 3,535) and showed that customers react differently to favorable (vs. unfavorable) decisions that are told to be made by algorithms and humans across various contexts (e.g., dating websites, bank loans). In studies 1 and 2, we demonstrated that participants felt lower feelings of self-worthiness when favorable decisions were made by an algorithm (vs. a human). This relatively negative reaction to algorithms is, however, mitigated when the decision outcome is unfavorable. Extending these findings, study 3 revealed the same pattern of customers' reactions towards firms: participants demonstrated less positive attitudes towards the firm when an algorithm (vs. a human) accepts them, but such a relatively negative reaction to algorithmic decision-making was mitigated in the case of unfavorable decisions.

In studies 4a, 4b and 5, we aimed to understand possible drivers of such an interaction effect. In studies 4a-b, we revealed the negative impact of disclosing algorithmic decision-makers. Specifically, when the decision-maker was not explicitly mentioned by the company, participants reacted similarly as they did to a human decision-maker. Next, study 5 tested whether participants would react more positively to humans even when they do not actively engage in decision-making but monitoring the process. In line with our theorization, our results demonstrated that the relatively positive effect of human decision-making is driven by knowing that a human *actively made a decision* to accept the applicants instead of passively monitoring the evaluation process. Finally, in study 6, we directly examined the psychological mechanism underlying different reactions to algorithmic versus human decision-makers. In these studies, we showed that the differences in customers' reactions stem from how they perceive these two decision-makers and that their perceptions of algorithms and humans (i.e., perceived objectivity, consideration of applicants' uniqueness).

We believe that our research makes several contributions. Extending the previous work that has predominantly studied situations where people *choose whether to rely on algorithms or humans*, we study situations where *customers are recipients of decisions made by algorithms versus humans*. Furthermore, the current research demonstrates how motivated attribution plays a role in people's perception of algorithmic versus human decision-making. From a practical perspective, our work offers important managerial guidance. Managers are often worried about deploying algorithms in customer-facing functions as they fear algorithms to amplify customers' negative reactions in the case of unfavorable decisions. Our findings, however, suggest that managers should be more concerned about deploying algorithms in the case of favorable experiences as it can result in less positive customer reactions. Together, our work provides valuable insights on how firms can effectively communicate decision outcomes to customers.

People Prefer Forecasting Methods Similar to the Event Being Predicted

EXTENDED ABSTRACT

Consumers face many scenarios where they have to make predictions by choosing between prediction methods. People can check multiple navigation tools for traffic predictions, analysts choose between models to make financial market predictions, and patients can choose between doctors and AI for medical diagnosis. It is clear from past research that people don't always pick the best performing method (Arkes et al. 1986; Dietvorst et al. 2015; Yeomans et al. 2019). However, it is still unclear how consumers choose between prediction methods. What features do people look for in prediction methods?

In this paper, we find that the more similar a prediction method is to the event being predicted (e.g. in its outcome distribution, process, etc.), the more people like it, even when it does not perform as well as alternatives. Humans often learn by mimicking and mirroring others' actions (Meltzoff and Moore 1977), and people tend to "over-imitate" - copying actions that are unnecessary to accomplish the given goal (McGuigan et al. 2011; Hoehl et al. 2019). We propose that this innate behavior transfers to consumers' preferences for prediction methods: consumers prefer prediction methods that best resemble the event being predicted. However, this preference can lead consumers to prefer prediction methods that offer suboptimal performance. For example, when the outcomes of an event are at least partially determined by random chance (Fox and Ülkümen 2011), mimicking the event in question to predict its outcome will result in overfitting of random error. In a set of 7 studies, we investigate consumers' preference for similar prediction methods using both incentivized studies and real-world consumer scenarios.

In Study 1, we present evidence that people like a prediction method to be similar to the event in question by having participants predict the outcome of a die roll. We chose this task because rolling a die has a clear process to be replicated, and its outcome is determined by random chance. Participants were tasked with predicting the outcome of a 7-sided die roll (sides 1,2,3,4,5,6,7). Participants chose between two prediction methods: one that always predicts "4" (constant), and another that chooses a random number between 1 and 7 (similar). Participants learned that they would receive a linearly increasing bonus depending on the difference between their prediction and the actual outcome ($0.21 for a perfect prediction, -$.03 for each unit of error). With this payment scheme, choosing "4" (i.e. the constant method) offers the highest possible return in expectation. Thus, choosing the similar method instead of the constant method is costly. However, we found that a substantial proportion of participants (44.5%) chose the similar method. Even among participants who passed a comprehension check by reporting that choosing "4" produced the highest expected earnings, 36.8% chose the similar method, which suggests that consumers' preference for a similar method is not due to ignorance.

In Studies 2 and 3, we found that the more similar a prediction method is to the event in question, the more people like it. In study 2, we offered participants a choice between two randomly selected methods out of a set of three: the similar and constant options from Study 1, and a "mixed" option that was a combination of the two. The mixed option used the similar method with a probability of 50% and the constant method with a probability of 50%. Participants were more likely to select the similar method both when the alternative was the constant method (58%) and the mixed method (56.2%). In Study 3, we show that method similarity can be increased along multiple dimensions. Specifically, we hypothesized that participants would prefer a method that uses the same process as the event (rolling a die instead of drawing a marble) in addition to matching the outcome distribution. Participants rated the constant method and 4 methods that varied on their proximity to the event being predicted (a fair 7-sided die roll) on 5-point scales: rolling a die that is skewed towards the optimal answer (process resemblance), drawing a marble with values 1-7 from a jar (outcome resemblance), rolling a die with the same numbers as the focal die (perfect resemblance), and drawing a marble with values skewed towards the optimal answer (no resemblance). Participants also rated the similarity of each prediction method to the event being predicted on two 5-point scales. Consistent with our hypothesis, participants rated the prefect resemblance method higher than all other methods (t's(404)≥ 7.16, p's<.001). Further, participants ratings of the similarity between

each method and the focal die roll mediate the differences in method ratings [10.29,35.99]. These results suggest that the more similar a prediction method is to the event in question, the more people like it.

In the remaining studies, we extend these findings to real-world consumer scenarios. In study 4, participants made an incentivized choice between two prediction methods to predict a consumer's rating of a movie. Participants chose between a similar method that finds the person who gave the most similar responses to the focal consumer in a survey of movie preferences and uses their rating, and an alternative that uses the average rating of the movie among all consumers. 71% of participants chose the similar method even though it performs 1.5 times worse than the alternative. In study 5, participants preferred a navigation tool that based a travel time prediction on the most similar trip in its data over another that averaged among many somewhat similar trips. In follow up studies (Studies 6 and 7), we investigate how companies can frame the prediction methods that they offer consumers to be more similar to the event in question.

People's systematic preference for similar prediction methods provides novel insight into consumer decision making, and suggests interventions to boost consumers' use of a prediction method. For example, it suggests that framing a prediction method as similar to the event in question will make it more palatable to consumers, which can help companies boost the use of prediction methods that they offer consumers (e.g. recommendation systems, calculators, etc.).

Stress, Addiction, and Artificial Intelligence

EXTENDED ABSTRACT

About 90.2% of people suffering from mental illness worldwide do not receive adequate treatment (Alonso et al. 2018). A solution to this problem is therapy powered by artificial intelligence (AI), which is scalable at a low cost, convenient, and private. Are consumers open to adopting AI to manage their mental health? We first investigate if consumers would choose an AI adviser over other types of human advisers present in the marketplace to treat anxiety and stress (Studies 1a-e). We find that consumers are averse to choosing an AI provider to manage their mental health. We replicate our finding in a highly stigmatized context—porn addiction (Study 2)—and using additional dependent variables, such as willingness to pay and sharing intentions (Studies 3 & 4). We argue that perceptions of warmth shape consumers' aversion to AI mental health providers: AI (vs. human) providers were perceived as less warm, which harmed their perceived competence, resulting in higher aversion.

In Study 1a, we asked college students to fill out a survey about stress-related resources. After reflecting on an instance in which they experienced academic stress, participants were offered three types of advisers to choose from to help them improve how they deal with stress. Descriptions for all three advisers were based on real-world descriptions. We scrapped the top 500 Google search results for mental health care providers, and two independent coders catalogued the providers into 5 categories. Three types of advisors—clinical, integrative, and virtual/AI—together form more than 80% of the market. We thus focus on these three types of mental health providers. The first was a clinical adviser with an MD from the university, who has published peer-reviewed articles on stress. The second was an integrative adviser, a life coach who has triumphed over dealing with stress. The third was a virtual adviser powered by artificial intelligence; the order of these advisers was counterbalanced. We find that only 5.4% of the participants chose the AI adviser ($\chi^2 = 59.14$, *p-value<0.001*), compared to 64.9% choosing the integrative adviser and 29.7% choosing the clinical adviser.

We replicate this finding in a variety of different stress domains (Studies 1b-e). We consistently find that the AI adviser is dominated by the two other advisers. The percentage of participants choosing an AI adviser ranges from 5.41% (academic/relationship stress) to 20.99% (financial stress).

In Study 2, we investigate consumers' choice of mental health adviser in a high-stigma context: porn addiction, which has harmful consequences such as cognitive decline and isolation (Alarcón et al. 2019). We recruited men who watch at least 5 hours of porn per week (2 SD higher than average). We provided these participants with an article that described the negative consequences of porn overuse and asked them to choose which of the three advisers they would consider discussing their porn consumption habits with. Similar to the results above, we find that the AI adviser is dominated by the two other choices ($\chi^2 = 12.6$, *p-value<0.001*). Interestingly, the percentage of participants willing to choose the AI adviser was higher (23%) than in the stress-related domains we tested.

In Study 3, participants were told about a new service in which customers share symptoms with a (virtual vs. human) doctor who diagnose if they have common mental health disorders, such as depression and anxiety. Participants then reported their willingness to pay for the service. We found that participants in the AI condition reported a lower willingness to pay compared to the human condition (= -2.8, $t(402)$ = -2.8, p = .005). Importantly, we found support for our proposed serial mediation model, such that an AI (vs. human) provider was associated with lower perceived warmth, which lowered the perceived competence of the provider, thereby leading to lower willingness to pay for the service (indirect effect = −.91, SE = .27, 95% CI [−1.44, −.39]). As a robustness check, we included uniqueness neglect as a parallel mediator in the model and found that, while the indirect effect through warmth and competence remained significant (indirect effect = −.89, SE = .26, 95% CI [−1.40, −.38]), the indirect effect through uniqueness neglect was not significant (indirect effect = −.012, SE = .048, 95% CI [−.11, .082]), suggesting that uniqueness neglect did not affect consumers' willingness to pay for mental health providers in this context.

In Study 4, participants were first asked to reflect on a recent time they experienced financial stress. Participants were then presented with a [virtual] mental health coach [powered by artificial intelligence] that could help them deal with stressful situations. To ensure that consumers' AI aversion generalized across other dependent variables of importance to marketers, we included a measure of participants' intent to share information about the provider with others. Consistent with Study 3, we found that participants in the AI (vs. human) condition reported a lower willingness to pay (β = −2.56, $t(498)$ = −3.23, p = .001) and a lower interest in sharing information about this provider with others (β = −.39, $t(498)$ = −2.05, p = .041). Importantly, perceptions of warmth again mediated the effect of provider on perceived competence, which in turn influenced participants' willingness to pay (indirect effect = −.83, SE = .30, 95% CI [−1.42, −.23]) and sharing intentions (indirect effect = −.41, SE = .07, 95% CI [−.55, −.28]).

Overall, we found that consumers are reluctant to use AI mental health advisers, and that perceptions of warmth played an important role in shaping consumers' preference for a mental health provider. AI (vs. human) providers were judged as less warm, which harmed their perceived competence, and resulted in higher aversion. We replicated this finding across different types of mental health domains, such as stress and addictive behaviors (e.g. porn addiction), across experimental paradigms (within-subject and between-subject), and across dependent variables (choice, willingness to pay, and sharing intentions).

Experts Outperform Technology in Creative Markets

EXTENDED ABSTRACT

Recent decades have seen an increase in machines and other technological advancements coopting jobs from humans (Autor 2015; Brynjolfsson and McAfee 2014; Hosanagar 2019). Notably, in many cases algorithms or technology based on training from initial human inputs can outperform humans (see Dawes et al. 1989; Dietvorst et al. 2015, 2016). Once thought unlikely, the machines have become dominant in games of human skill such as Jeopardy, chess, and Go (Hosanagar 2019).

Recently, there has been discussion of technology based on artificial intelligence supplanting workers (Lohr 2018; Peiser 2019). While this replacement is argued to occur more for lower-skilled jobs (Autor 2015; Mokyr et al. 2015) and is expected more for jobs involving thinking (Waytz and Norton 2014), there have also been market entrants from artificial intelligence in domains that are typically considered to require the human spark of creativity (Rand 1968). For example, for logos design, sites such as logomaster.ai and Wix offer affordable artificial intelligence builders for logos. Like with human experts, these artificial intelligence makers present people with multiple initial design concepts from which they can choose, and they allow for iteration and revision on the initial concept they like most (Goodwin 2009).

Does artificial intelligence outperform human experts in creative markets, such as in logo design? To explore this question, we run two logo elicitation studies (Studies 1 and 2) in which subjects worked with artificial intelligence and/or human expert designers, and then run seven follow-up studies (Studies 1a-1d and 2a-2c), using both ratings and incentivized choice, in which an external set of participants evaluate the quality of the logos.

Importantly, we align the logo design process in the two logo elicitation studies. In each, participants start with a creative brief, have a designer selected for them or by them, see at least two initial concepts for a logo, and then go through a revision process before arriving at a final logo. In Study 1, we impose more experimental control by providing a fixed set of creative briefs for three (fictitious) companies (the data science company Empirical, the fashion company Forward, and a restaurant Hyperion) and assigning participants to work with either human experts or artificial intelligence logo makers, both of which provide initial concepts and a revision process. In Study 2, with a separate set of participants we allow for more natural design by having participants write creative briefs for a company (ONAK, an origami canoe company), and then let them work both with one human expert designer of their choice and one artificial intelligence logo maker. Study 1 yielded 17 human expert logos and 30 artificial intelligence logos, while Study 2 yielded 62 logos (31 human expert, 31 artificial intelligence). In Study 1, the participants were MBA students enrolled in a new product development course; in Study 2, the participants were managers enrolled in an evening MBA program.

In Study 1a, we first seek overall evaluations on the logos from Study 1 using external raters. Amazon Mechanical Turkers evaluated all of the logos from one of the three companies (Empirical, Hyperion, or Forward) from Study 1 on a seven-point scale (1 = Very Bad, 7 = Very Good). Importantly, this evaluation was blind to whether the logos were produced by artificial intelligence or human experts (see Dietvorst et al. 2015). Across all three companies, relative to artificial intelligence logos, human expert logos were evaluated more favorably ($F(1, 287) = 222.78$, $p < .001$). In Study 1b, human expert designers with at least fourteen years industry experience evaluated all logos and showed directionally consistent results.

In Study 1c, we replicate Studies 1a and 1b but with additional ratings designed to determine what dimensions the human expert logos exceeded artificial intelligence logos on. Undergraduates in a design course completed the procedure from Study 1a and also rated to what extent the logos conveyed the company's industry, were aesthetically pleasing, and were unique. In addition to replicating Study 1a on overall evaluations ($F(1, 144) = 131.92$, $p < .001$), human expert logos were also evaluated, relative to artificial intelligence, to convey the company's industry better ($F(1, 144) = 290.20$, $p < .001$), to be more aesthetically pleasing ($F(1, 144) = 51.85$, $p < .001$), and to be more unique ($F(1, 144) = 57.40$, $p < .001$).

In Study 1d, we conceptually replicated the previous studies with incentivized choice with a set of west coast laboratory participants. That is, participants were informed that those participants who chose the logo that was selected most often would be eligible for a $50 Amazon Gift card as a prize. Consistent with the previous studies, participants chose logos produced by human experts more often than would be expected by chance ($z = 8.49$, $p < .001$).

Study 2a replicates Study 1a on the 62 logos produced for ONAK using Amazon Mechanical Turkers. Again, compared with the artificial intelligence logos, the human expert logos were evaluated more favorably ($F(1, 394) = 114.47$, $p < .001$). Further, Study 2b replicated Study 1c on overall evaluations (i.e., human expert logos were judged to be better than artificial intelligence logos) with a set of west coast laboratory participants ($F(1, 423) = 170.40$, $p < .001$).

Finally, Study 2c attempts to replicate Study 1d on choice with a sample of west coast laboratory participants. When choosing among logos for ONAK, participants were only marginally more likely to select logos produced by human experts ($z = 1.95$, $p = .051$).

Overall, using two types of logo elicitation methods, we find that logos from human experts outperform those from artificial intelligence. This advantage may result from human expert logos being superior on aesthetics and clarity. However, subsequent coding and analyses revealed that those managers in Study 2 who invested more effort into their creative briefs (based on an expert designer coding the strength of each brief) had more favorably evaluated artificial intelligence logos, which might mean that the advantage to human experts may disappear with more experience or clarity of what is desired from the design process.

SESSION OVERVIEW

Many consumer decisions can be reached by either choosing preferred options, or rejecting less preferred options. While prior research has established that framing a decision as choosing versus rejecting influences the decision-making process, much of the previous studies focuses on how decision framing produces inconsistent decision outcomes that violate the principle of procedural invariance (e.g., Dhar and Wertenbroch 2000; Shafir 1993; Sokolova and Krishna 2016). By contrast, the downstream consequences of choose versus reject framing, beyond the decision outcomes, have been relatively underexplored.

This special session presents four papers that examine interesting consequences of decision framing, and highlight previously unexamined strengths of the reject frame over the choose frame. Each paper uncovers an important consumer-relevant consequence of decision framing, from post-decision preference updating (paper 1), satisfaction and purchase likelihood (paper 2), variety seeking in repeated consumption (paper 3), and perceptions of consumption outcomes (paper 4).

Yang and Teow examine how decision framing influences post-decision preference updating. They find the reject frame leads to a bigger post-decision evaluation gap between the wanted and unwanted options, compared with the choose frame, a finding attributable to the act of rejecting being perceived as more diagnostic than the act of choosing. This effect was mitigated when the focal decision induced a high level of decision difficulty, and reversed when all options were negatively-valenced.

Park and Simonson test how the availability of an explicit rejecting procedure in sequential evaluation influences psychological closure and subsequent consequences. They demonstrate that, being able to explicitly reject options, such as "swipe left to reject," heightens evaluation closure over the forgone options compared with when the decision procedure involves implicit rejection procedures only. Consequently, when explicit rejection is allowed, it increases the likelihood of subsequent purchase.

Xu and Yang investigate the effect of decision framing on variety-seeking behaviors in repeated decisions. Their experiments reveal that, consumers seek less variety when the repeated decisions are framed as rejecting than choosing, because rejecting reduces the liking of the less preferred options, and hence renders the preferred

options "stickier" in subsequent decisions. The rejecting procedure can thus be adopted to mitigate variety-seeking tendencies that impede consumer welfare.

Besharat, Romero, and Haws find that the choose versus reject frames can influence the perception of customized products in the context of food ordering. Their studies demonstrate that the rejecting procedure (i.e., eliminating ingredients) leads consumers to estimate the customized food as containing fewer calories and being healthier than the choosing procedure (i.e., selecting ingredients), which also induces positive changes in intended future consumption and the type of subsequent consumption.

Together, this special session sheds new light on when and how decision framing can be adopted to influence important post-decision consequences.

Decision Diagnosticity: Rejecting Induces a Larger Post-Decision Evaluation Gap Than Choosing

EXTENDED ABSTRACT

A decision can be framed as either choosing wanted options or rejecting unwanted options in a consideration set. For example, when managers make a hiring decision between two job candidates, the decision may be posed either as "Which candidate would you recommend to accept?" or "Which candidate would you recommend to reject?" While the difference between the two decision frames may appear nominal, research shows that framing a decision as choose versus reject produces systematically different decision outcomes and consequences (Dhar and Wertenbroch 2000; Shafir 1993; Nagpal and Krishnamurthy 2008; Perfecto, Galak, Simmons, and Nelson 2017; Sokolova and Krishna 2016).

In this research, we examine how decision framing affects choice-induced preference changes. Six pre-registered experiments ($N = 3,412$) show that when a decision is framed as rejecting unwanted options, it leads to a larger post-decision evaluation gap between the wanted and unwanted options, than when the decision is framed as choosing wanted options. Building on self-perception theory (Bem 1972), and previous findings that rejecting tends to invoke greater processing depth (e.g., Nagpal and Krishnamurthy 2008; Sokolova and Krishna 2016) and greater attitude strength (Bizer and Petty 2005; Bizer, Larsen, and Petty 2011), we propose that people perceive rejecting as more diagnostic of one's true underlying preferences. Across the studies, we find process evidence consistently supporting the role of decision diagnosticity underlying the effect.

The studies followed a similar basic paradigm, with participants randomly assigned into 2 (choose vs. reject) between-subjects conditions. Each participant was simultaneously presented with two or more options, and asked to either choose the wanted option(s) or reject the unwanted option(s). After their decision, participants were asked to evaluate each option. We calculated the post-decision evaluation gap by taking the difference between their evaluation of the wanted option(s) and their evaluation of the unwanted option(s).

Study 1 ($N = 256$) established the effect with a pair of visually different consumer products (smartphone cases). Participants' post-decision evaluation gap was larger after the rejecting decision than after the choosing decision ($M_{choose} = 2.08$, $SD = 1.87$ vs $M_{reject} = 3.02$, $SD = 2.78$, $F(1, 254) = 10.14$, $p = .002$, $\eta_p^2 = .04$). Moreover, we measured the perceived decision diagnosticity, decision difficulty, and decision finality associated with each option, and found that decision

diagnosticity best accounted for the effect: rejecting was perceived as more diagnostic of one's true underlying preferences than choosing (M_{choose} = 5.56, SD = 2.09 vs M_{reject} = 6.12, SD = 2.31, $F(1, 254)$ = 4.20, p = .042), which induced more post-decision preference updating (indirect effect in mediation analysis = -.282, $CI_{95\%}$ = [-.57, -.01]). The other process measures only partially contributed to the effect, and choice share of the options did not differ between conditions. Similar results on the process measures were observed in later studies.

Study 2a (N = 308) replicated this effect with consumer products that were presented with descriptions of multiple attributes, to be more in line with related prior research (e.g., Meloy and Russo 2004). Replicating our initial findings, participants' post-decision evaluation gap was larger after the rejecting decision than after the choosing decision (M_{choose} = 2.00, SD = 2.53 vs M_{reject} = 2.94, SD = 2.81, $F(1,306)$ = 9.54, p = .002, η_p^2 = .03), and decision diagnosticity mediated the effect (indirect effect = -.275, $CI_{95\%}$ = [-.56, -.01]). In addition, decision difficulty moderated this effect (2-way ANOVA $F(1,304)$ = 6.47, p = .011): the framing effect was attenuated when the participants perceived a high level of decision difficulty (> 4.4, the Johnson-Neyman value), which impeded the self-inferential process that lead to post-decision preference updating. The effect was also replicated in study 2b (N = 875) with visually different photographs.

Next, study 3 (N = 461) expanded the generalizability of this effect by crossing the framing manipulation (choose vs reject) with the size of the choice set: (picking 1/2 vs 2/4 paintings). The effect generalized to both the 1/2 and 2/4 conditions: participants' post-decision evaluation gap was marginally larger after the rejecting decision than after the choosing decision (M_{choose} = 2.50, SD = 1.62 vs M_{reject} = 2.80, SD = 2.33, $F(1,457)$ = 2.78, p = .096), regardless of the size of the choice set, which had a separate main effect ($M_{1/2}$ = 2.30, SD = 2.2, $M_{2/4}$ = 2.99, SD = 1.73; $F(1,457)$ = 2.08, p < .001), and did not significantly interact with framing ($F(1,457)$ = 2.07, p = .151).

Study 4 (N = 1,051) revealed that the effect reversed when the options were negatively valenced instead of positively valenced (2-way ANOVA: $F(1,1047)$ = 6.5, p = .011, η_p^2 = .01), consistent with prior findings supporting a compatibility effect between framing and attribute valence (e.g., Nagpal and Krishnamurthy 2008; Perfecto, Galak, Simmons, and Nelson 2017; also see Tversky et al. 1988).

Study 5 (N = 461) replicated the effect when participants explicitly expressed their preference before the decision (M_{choose} = 2.81, SD = 2.14 vs M_{reject} = 3.49, SD = 2.43; $F(1,457)$ = 5.31, p = .022, η_p^2 = .01; overall main effect $F(1,457)$ = 4.52, p = .034, η_p^2 = .01). Thus, the effect was not contingent on existing preference uncertainty.

Last, we explored the potential influence of the weak axiom of revealed preference (WARP) across these studies. When treating violation of WARP (i.e., choosing A over B, yet rating A lower than B) as an attention failure, we screened out participants who had internally inconsistent choice and preferences, and compared their results with those previously reported. This comparison allowed us to examine if the findings were attributable to an alternative explanation: if participants were more impelled to appear consistent after the rejecting procedure than the choosing procedure. The ratio of inconsistent responses was low (6% on average) and similar between choose and reject conditions. Moreover, this screening did not significantly affect the main results. In sum, the reject frame enlarges the post-decision evaluation gap primarily because of greater preference diagnosticity perceived in reject decisions.

"Swipe Left for No": Why Options That Survive Rejection Lead to Greater Purchase

EXTENDED ABSTRACT

Most alternatives considered by decision makers are rejected or not chosen, yet the manner in which individuals pass on alternatives has not received much attention. In social apps like Tinder, users "swipe left" to make an explicit rejection before proceeding to the next match, while interviewers often pass on a job candidate rather implicitly by looking at the next candidate. Despite the common use of rejection strategies in everyday life, little research has examined how individuals make rejections and the psychological consequences of rejection.

We suggest that having the option to explicitly reject each alternative during sequential evaluation increases subsequent purchase from the narrowed set, largely due to the feeling of "evaluation closure." Building on prior literature on psychological closure (Gu, Botti, and Faro 2013), we propose "evaluation closure"— the state experienced by consumers when their evaluation is perceived to be complete—as a key driver of determining whether consumers proceed to the next phase of decision-making: making a purchase. We test in four experiments the predicted difference between options that survive explicit rejection (e.g., add-or-reject) and those identified through implicit rejection (e.g., add-only). The implications of this research are discussed with respect to our understanding of evaluation modes in the current information environment.

Study 1 (N = 296) tested the effect of explicit rejection during sequential evaluation on purchase. Participants reviewed 10 paintings and indicated their liking of each painting. In the *like-only* condition, participants were asked to "swipe right" (drag the slider to the right) for the paintings that they liked before moving onto the next painting. In the *like-or-dislike* condition, participants had to not only "swipe right" on the paintings that they liked but also "swipe left" on the paintings that they did not like. Then, participants indicated their purchase likelihood ("Assuming that the price is reasonable, would you buy any of the 10 paintings that you have just evaluated?"). Results revealed that participants who made explicit rejections were more likely to purchase a painting than those who did not make rejections ($M_{like-or-dislike}$ = 91.7% vs. $M_{like-only}$ = 84.4%), $\chi^2(1)$ = 3.80, p = .051.

In Study 2 (N = 605), we extended the rejection effect to non-binary purchase intentions and added another condition (i.e., *dislike-only*) to further delineate the effect of rejection. Participants were randomly assigned to one of three conditions (*like-only, like-or-dislike, and dislike-only*) and engaged in the sequential evaluation task as in Study 1; participants in the *dislike-only* condition were instructed to "swipe left" to reject the paintings and proceed to the next painting if otherwise. Then, participants reported their overall satisfaction with the paintings that survived the evaluation (1 = *Not at all*, 7 = *Very much*). We found that compared to participants who did not make explicit rejections ($M_{like-only}$ = 5.94), those who had the option to reject each painting reported greater satisfaction ($M_{like-or-dislike}$ = 6.22, $M_{dislike-only}$ = 6.15), p = .008. This effect persisted even after controlling for the number of surviving paintings, p = .007.

Study 3 (N = 320) extended the effect to the shopping cart context and captured evidence of "evaluation closure." Participants evaluated nine microwaves one at a time and decided whether to add each microwave to their cart. While the button to add microwaves ("add this item to shopping cart") remained the same, the button to reject before looking at the next microwave differed across three conditions: "reject this item" (explicit rejection condition), "look at other items" (implicit rejection), no button (add-only). After

reviewing all microwaves, participants reported how much closure they had experienced and decided whether they would purchase any microwave from their cart. Consistently, participants who made explicit rejections were more likely to make a purchase from their cart ($M_{\text{reject this item}}$ = 92.8%) compare to those who did not make such rejections ($M_{\text{look at others}}$ = 88%; $M_{\text{add-only}}$ = 86.7%), p = .039. Importantly, participants also reported feeling greater closure over their evaluations after making explicit rejections ($M_{\text{reject this item}}$ = 4.75) vs. implicit rejections ($M_{\text{look at others}}$ = 4.02; $M_{\text{add-only}}$ = 3.91), $t(317)$ = 3.40, p = .001.

Study 4 (N = 394) examined the effect of rejection on purchase likelihood in a free search task whereby participants viewed as many or as few alternatives as they wished. Participants reviewed an unknown number of $25 gift cards that differed in their brands, and we used the stopping point (i.e., the number of cards participants reviewed before terminating their search) as an indicator of the evaluation completion; at any point during this task, participants could end their evaluation by clicking the checkout button. To ensure that participants treated their evaluation as consequential, they were entered into a lottery to win the gift card of their final choice. Similar to Study 3, the button to reject each card was labelled as either an explicit rejection ("reject this item") or an implicit rejection ("look at other items"). Finally, when participants reached their checkout, they could choose a gift card option in their cart or defer (i.e., receive a bonus payment of $10 instead). Results showed that making explicit rejections led to earlier stopping points after evaluating fewer cards ($M_{\text{reject this item}}$ = 28.64) compared to making implicit rejections ($M_{\text{look at other items}}$ = 31.07), $t(392)$ = 2.02, p = .044. As expected, participants who passed on gift cards through explicit (vs. implicit) rejections were more likely to commit to an option from their "rejection survivors" rather than to defer ($M_{\text{reject this item}}$ = 89.9% vs. $M_{\text{look at other items}}$ = 84.2%), $\chi^2(1)$ = 2.86, p = .091. Importantly, this effect remained after controlling for the number of evaluated options (B = .62, Wald's $\chi^2(1$, N = 394) = 3.86, p = .050).

In four studies, we demonstrate that explicit rejection during a sequential evaluation of alternatives can increase consumers' choice commitment (e.g., purchase) to the "rejection survivors." Overall, this research has not only theoretical implications for understanding rejection motivations but also practical implications for marketers to recapture online consumers' commitment.

Rejections Are Stickier than Choices

EXTENDED ABSTRACT

Consumers often make the same decision repeatedly, ranging from which product to buy, which restaurant to visit, to which song to listen to. A prominent pattern in repeated decisions is variety-seeking—instead of sticking to their favorite option, consumers tend to alternate between different options due to satiation (Inman 2001; McAlister 1982), preference uncertainty (Kahneman and Snell 1992; Simonson 1990), information-seeking (McAlister and Pessemier 1982), need for stimulation (Huang et al. 2019; Menon and Kahn 1995), or merely for the sake of variety (Ratner, Kahn, and Kahneman 1999).

Although existing literature on variety-seeking has enriched our understanding of when and why people seek variety, it predominantly focuses on choices when eliciting consumer preferences, asking participants to make decisions by choosing what they like more. This focus on choices, however, may not fully capture what happens in the real world where it is equally likely that consumers make decisions by rejecting what they like less (Perfecto et al. 2017; Shafir 1993; Sokolova and Krishna 2016). The current research investigates whether choosing versus rejecting influences the degree of variety-

seeking. Imagine, for instance, you need to decide which restaurant to go to for lunch every day. Would you be more likely to stick to your favorite restaurant if you decide by choosing or rejecting?

Across five studies and a wide range of product decisions, we find that rejections are stickier than choices—consumers tend to seek less variety across repeated decisions when the decisions are framed as rejections (vs. as choices). This effect occurs because the act of rejecting has an asymmetric effect on one's preference for different options: while it does not influence the liking of the more-preferred option(s), it significantly reduces the liking of the less-preferred option(s). As a result, the act of rejecting broadens the liking gap between options, increasing one's likelihood of selecting the more-preferred option(s) in future decisions.

Study 1 (N=111) tested our hypothesis in a natural setting involving real decisions. Specifically, participants made two snack decisions—they first selected a snack to eat at the end of the lab session, and then selected a snack to take home. Participants made these two decisions by either choosing or rejecting between snacks. We found that participants who rejected between snacks sought less variety than those who chose between snacks (5% vs. 36%, $\chi^2(1)$=15.47, p<.001) because the act of rejecting reduced the liking of the less-preferred snack (3.07 vs. 3.82, $F(1, 109)$=7.37, p=.008; 95% CI=[.036, .501]).

Study 2 (N=400) tested whether our framing effect is attributable to the increased level of deliberation associated with rejections. Specifically, participants imagined that they were using a meal kit service and needed to select three out of six recipes each week for the upcoming two weeks. We orthogonally manipulated framing and the amount of deliberation by asking participants to either deliberate or not before they made choice or rejection decisions. We found that 1) deliberation did not moderate our effect ($F(1, 396)$ = .79, p = .374); 2) participants who removed three less-preferred recipes (i.e., rejecting) sought less variety, compared with those who added three preferred recipes (i.e., choosing; switches: 1 vs. 1.42, $F(1, 398)$=18.43, p<.001); 3) the liking of the less-preferred recipes mediated the framing effect on variety-seeking (95% CI=[.058, .167]).

Study 3 (N=301) replicated the framing effect in real decisions involving real consumption experiences, and demonstrated an interesting boundary condition. Participants were told that they would view one of two photos across five iterations. During each iteration, they decided which photo to view and then viewed the selected photo for 10 seconds. Critically, this study included three conditions: choosing, rejecting, and a new choosing-and-rejecting condition where participants indicated which option they would choose and which option they would reject simultaneously. Replicating our previous findings, participants in the rejecting condition sought less variety than those in the choosing condition (switches: 1.84 vs. 2.28, $F(1, 298)$=6.19, p=.013). Interestingly, the newly added choosing-and-rejecting condition yielded the same pattern as the choosing condition (switches: 2.19 vs. 2.28, $F(1, 298)$=.26, p=.610).

Study 4 (N=404) further tested the generalizability of our effect by manipulating option valence. Participants imagined that they had to consume a serving of sparkling water on each of three consecutive days. Half of the participants were asked to either choose or reject among three pleasant flavors (i.e., watermelon, lime, and blueberry), while the other half were asked to either choose or reject among three unpleasant flavors (i.e., buffalo wing, ranch dressing, and clam chowder). Rejecting decreased variety-seeking among both positive (switches: 1.28 vs. 1.84, $F(1, 400)$=24.42, p<.001) and negative options (switches: 1 vs. 1.38, $F(1, 400)$=10.88, p=.001).

Consumers have been found to seek more variety than normatively warranted (Ratner, Kahn, and Kahneman 1999; Read and

Loewenstein 1995; Steffel and LeBoeuf 2014). Study 5 (N=400) aimed to demonstrate that in situations where consumers tend to seek too much variety, framing the decisions as rejections (vs. as choices) will lead to better decisions. This study is incentive compatible. Each participant listed two friends and then selected gifts for either one or both friends. When the gifting decisions were framed as choices, we replicated the overindividuation effect (Steffel and LeBoeuf 2014): while more than 79.8% of participants correctly selected the better-liked gift for either friend individually, only 55.0% of participants selected the better-liked gift for both friends ($\chi^2(1)$=14.34, p<.001). When the gifting decisions were framed as rejections, however, 79.0% of participants selected the better-liked gift for both friends ($\chi^2(1)$=.02, p=.892).

In sum, this research identifies a novel framing effect on variety-seeking and significantly extends the literatures on variety-seeking and decision framing. Practically, it offers recommendations for firms on how to increase market shares and enhance consumer loyalty without incurring additional cost. It also yields implications for consumer welfare: for domains in which consumers typically seek more variety than normatively warranted, framing decisions as rejections can improve decision quality and increase consumer welfare, whereas for domains in which consumers typically seek too little variety, framing decisions as rejections may exacerbate the problem and reduce consumer welfare.

When More Is Less: How Rejecting (vs. Selecting) Food Ingredients Leads to Lower Estimates of Calories

EXTENDED ABSTRACT

Consumers are increasingly interested in customizing their food orders. As such, restaurants often allow customers to tailor their products, but this can be achieved in different ways. For instance, consumers can order a pizza using a "pare-down" approach in which they eliminate undesired ingredients from a specialty pizza or a "build up" approach in which they add desired ingredients to a base product (Coker and Nagpal 2013; Nagpal, Lei, and Khare 2015; Park et al. 2000). An important benefit of these strategies is that they allow consumers to tailor food consumption based not only on taste preferences but also on health considerations.

Prior literature on product customization and decision frames documents how a pare-down, versus a build-up, strategy shifts focus to negative product attributes (Laran and Wilcox 2011; Shafir 1993; Huber, Neale, and Northcraft 1987). Different from the previous discussion, our work focuses on the influence of rejection versus selection customization routes on calorie estimation. Our work proposes that the nature of the customization task can serve as a signal that biases calorie estimation of the final product. For instance, the process of rejecting is considered to be in line with a consumption-limiting mindset (Krishnamurthy and Prokopec 2009). Given that the rejection (vs. selection) approach highlights the food items consumers are avoiding, the process of rejecting (vs. selecting) is more likely to be associated with avoiding immediate pleasure to achieve long-term benefits (Hung and Labroo 2010; Vohs and Baumeister 2016). Thus, the literature suggests that the nature of the rejection (vs. selection) is related with a higher degree of restraint. Moreover, because consumers lack expertise to accurately estimate calories (Burton et al. 2006; Sharpe, Staelin, and Huber 2008), they generally use impressions to infer calorie content (Chandon and Wansink 2007). Given that in the rejection task, consumers focus on the food options that they denied themselves, they may rely on this association to estimate fewer calories in their final product. Furthermore, this calorie underestimation

can have important implications on consumers' desire to visit the restaurant and subsequent food orders.

We test this premise in a series of four studies using various approaches. In all of our studies, we measured calorie estimation by calculating the difference between actual and estimated calories and then dividing by the actual number of calories. Therefore, higher numbers indicate lower estimation of calories.

In Study 1, we utilized a controlled approach that involved a step-by-step customization task designed to be as realistic as possible, holding constant the contents of the final product. Undergraduate students ($n = 133$) were shown either a selection or rejection path to a chicken burrito with shredded cheese, lettuce, and sour cream that another customer was ordering and asked to estimate the final calories. They were provided with calorie counts for the base product and the product with all six possible ingredients included, such that the possible range for the calorie estimation was restricted. Consumers estimated a lower amount of calories in the final product when they were performing a rejection compared to a selection task ($M_{rejection} = 3.19\%$ vs. $M_{selection} = -11.70\%$; $F(1,129) = 9.21$, $p < .01$).

In the next studies, we allow participants to customize their own food product using either a selection or elimination task. Even though the selection of ingredients could vary across conditions, the index of calorie estimation accounts for this difference. In Study 2, students ($n = 190$) built their own nachos that they received at the end of the session through a selection or rejection approach and then estimated calories in the final product. The results of an ANOVA revealed that the rejection (vs. selection) condition led to a lower estimation of calories ($M_{rejection} = 24.44\%$, $M_{selection} = -11.27\%$; $F(1, 172) = 5.54$, $p < .001$; $\eta2= .18$).

Studies 3-4, asked participants to customize their own sandwich and then estimated calories. After customization, participants in Study 3 ($n = 111$) indicated how likely they would be to order food from this restaurant. An ANOVA on the individualized calorie estimation measure revealed that participants in the rejection (vs. selection) task estimated lower calories ($M_{rejection} = 13.18\%$; $M_{selection} = -8.13\%$; $F(1, 102) = 19.22$, $p < .001$; $\eta2= .16$). Furthermore, we found that participants that rejected (vs. selected) ingredients had a higher desire to visit the restaurant ($M_{rejection} = 4.79$; $M_{selection} = 4.18$; $F(1, 102) = 4.02$, $p < .05$; $\eta^2= .04$). We also found a significant indirect effect of calorie estimation on patronage (Hayes 2013; 95% CI = .02, .53).

Study 4 explores the influence of customization on subsequent food choices. Given that a rejection task leads to lower calorie estimates, we expect that they will feel more licensed to eat an unhealthier snack after this process takes place. MTurk panelists ($n = 116$) rejected (vs. selected) ingredients for a sandwich and then estimated calories in the final product. Next, participants indicated how likely they would be to add a cookie to their order (1 = not at all likely, 7 = very likely). An ANOVA on this measure revealed that participants in the rejection (vs. selection) task estimate lower calories ($M_{rejection} = 6.54\%$; $M_{selection} = -7.50\%$; $F(1, 106) = 3.95$, $p < .05$; $\eta2= .04$). Participants in the rejection (vs. selection) task were also more likely to add a cookie to their order after the initial customization occurred ($M_{rejection} = 3.85$; $M_{selection} = 2.98$; $F(1, 106) = 4.38$, $p < .05$; $\eta^2= .04$). We also found a significant indirect effect of calorie estimation on likelihood to order dessert (Hayes 2013; 95% CI = .02, .45).

Across multiple scenarios, we find that a customization task that involves rejecting unwanted ingredients, versus selecting desired ingredients, leads to lower estimation of the caloric intake, even when the final product is exactly the same. As the customization trend continues to grow, consumers are continuously modifying their food orders. Our research provides a deeper understanding of the detri-

mental consequences that a specific food customization process can have on caloric estimation, future food choices, and retail evaluation.

SESSION OVERVIEW

With rapid technological progress and data proliferation, decisions previously made by humans are increasingly being delegated to algorithms and Artificial Intelligence (AI) technologies, which have been shown to outperform humans in a wide array of domains (Donnelly 2017; Lohr 2016; Silver 2012). Prior research has shown that consumers are often averse to algorithms (Castelo et al. 2019; Önkal et al. 2009; Longoni et al. 2019) and are concerned that these technologies could one day replace them (Granulo et al. 2019; Rainie and Anderson 2017). Though they engender substantial resistance, the widespread adoption of these technologies appears inevitable. The papers in this session utilize different methodological approaches to explore how consumers can adapt to this impending transformation. Together, they explore what it means to be human in the age of AI, and how technology may change how consumers think and act.

The session's first two papers discuss impediments to human-AI collaborations. **Teow** and **Yang** show that consumers' algorithm aversion in resource allocation decisions depends on their empathetic reactions towards the recipients. Seven studies reveal stronger algorithm aversion when an identifiable person is highlighted among the decision recipients, than when no identifiable person is highlighted. This is because the presence of an identifiable recipient heightens the sentiment that individual human circumstances should be attended to by fellow human beings instead of emotionless algorithms. In the second paper, **Bonezzi, Ostinelli and Melzner** show that people foster an illusion of understanding human better than algorithmic decision-making, when in fact both are black boxes. This occurs because, for human decision-makers, people confuse a superficial, high-level understanding of what the decision-maker does, for a deeper, low-level understanding of how the decision-maker operates. Such confusion is less likely to occur for algorithmic decision-makers.

The remaining papers explore potential pathways for successful human-AI collaborations. **Castelo** and **Häubl** report five studies that show that students and workers are discouraged from pursuing jobs that AI can also perform. Importantly, they find that the effect hinges on whether consumers perceive the technology as helping humans or competing with them and is reduced when the job is seen as highly subjective or consisting of unstandardized tasks. In the final paper, **Yalcin, Mehta** and **Dahl** present a conceptual framework for integrating AI in creative cognitive processes. Given that creativity is no longer a process that is single-handedly achieved by humans, the authors develop *Cyber-Creativity Framework,* that captures the dynamics of the relationship between humans and AI in creative processes. Specifically, they theorize that collaborating with AI enhances humans' performances in earlier stages whereas humans have an edge over AI in the later stages.

This session provides timely insight into how-and when-consumers are able to cooperate with algorithms, an increasingly important topic given the proliferation of this technology in consumer-contexts. This session directly addresses ACR's call for papers that generate new knowledge on how consumers make decisions in the age of new technology. This session should be of interest to scholars working on choice and decision making, inference-making, recommendations, creativity, innovation, and new technologies.

Defending the Human Need to Be Seen: Algorithm Aversion and the Identifiable Human Recipient in Resource Allocation Decisions

EXTENDED ABSTRACT

Many important allocation decisions, which used to rely on human judgment, can now be made by algorithms with advanced data processing and analytic capabilities. While algorithms are widely adopted in market predictions and product recommendations, the involvement of algorithms have provoked much resistance in the decisions that distribute scarce resources among individuals. For instance, a recent survey indicated that 67% of Americans find it unacceptable to use algorithms in hiring decisions (Pew Research 2018).

Recent research shed important light on people's general attitudes towards algorithms in decision making: while people appreciate algorithmic advice for its superior efficiency and accuracy, they are less tolerant of algorithms' mistakes (Dietvorst, Simmons, and Massey 2015; Logg, Minson, and Moore 2019). In certain domains, such as medical decision making, people tend to reject the use of algorithms due to a concern that algorithms may overlook the unique characteristics of each individual (Longoni, Bonezzi, and Morewedge 2019).

Joining this growing literature, we examine people's preference between human experts and algorithms in resource allocation decisions. We find in seven pre-registered experiments ($N = 2,732$) that information about an identifiable decision recipient exacerbates algorithm aversion by evoking greater empathic reactions than information about statistical recipients. In particular, the empathic reactions evoked by the identifiable decision recipient highlight the concern that algorithms cannot produce appropriate emotions in response to each recipient's circumstance. These findings may reflect a shared sentiment for the "compassionate gaze," namely, that individual human beings' circumstances should be attended to by fellow human beings.

In each study, we introduced participants to a resource allocation decision, and asked them to indicate their preference between two decision methods: a committee of human experts versus an algorithmic judge. The context of the focal decision varied across studies.

Across these studies, we also find process evidence in support of our theorization and rule out important alternative explanations.

Studies 1 ($N = 241$), 2a ($N = 232$), 2b ($N = 427$), 2c ($N = 417$), and 2d ($N = 231$) all followed a mixed design, with 2 repeated measures (recipient description: statistical versus identifiable), and counterbalancing of the presentation order of the recipient description between-subjects. The description of the statistical recipients emphasized the number of total recipients and the differences in their circumstances, whereas the description of the identifiable recipient featured an image of one individual recipient with descriptions of the person's circumstance. Participants were first presented with one version of recipient description (either statistical or identifiable), followed by an 8-point scale measuring participants' preference between the two decision methods for the focal allocation decision (1 = definitely prefer human committee; 8 = definitely prefer algorithmic judge), as well as a binary choice between the two decision methods. Then, participants were asked to indicate their empathic reactions on a 6-point scale adopted from Erlandsson, Björklund, and Bäckström (2015), followed by a 9-point scale measuring the compassionate gaze belief (with 4 items, e.g., "I believe that their [her] situation should be seen"). Next, the same participant was presented with the other version of recipient description, following by the same dependent variables and process measures. Therefore, each participant was presented with both versions of recipient descriptions, and explicitly informed that both descriptions were about the same decision scenario.

These studies revealed highly consistent results: featuring an identifiable decision recipient evoked stronger algorithm aversion than presenting statistical recipients (despite participants being explicitly reminded that the focal decision applies to each individual as well as the entire group); regardless of presentation order. More specifically, these inconsistent preferences were observed both between-subjects and within-subjects. We thus collapsed the data to compare the average preference under each version of recipient description. In addition, the process measures in these studies suggest that, an identifiable decision recipient evoked stronger emotional reactions and a stronger endorsement of the compassionate gaze belief. Serial mediations supported their roles underlying the observed effect (e.g., serial mediation in study 1: indirect effect = -.39, $CI_{95\%}$ = [-.56, -.25]).

Next, study 3 ($N = 441$) included the same mixed design with another between-subjects factor of recipient prospect (good vs bad). In a college admission scenario, the identifiable decision recipient was either a more qualified candidate with a good prospect of getting admitted to a top university, or a less qualified candidate with a poor prospect of getting admitted. We found highly similar results between conditions (more qualified recipient: $M_{statistical}$ = 4.89, SD = 1.92 vs $M_{identifiable}$ = 2.94, SD = 1.64, $F(1,878)$ = 139.00, p < .001; less qualified recipient: $M_{statistical}$ = 4.68, SD = 1.96 vs $M_{identifiable}$ = 2.44, SD = 1.31, $F(1,878)$ = 187.33, p < .001), and no interactions between identifiability and recipient prospect ($F(1,878)$ = 1.54, p = .216). These results suggest that the effect is generalizable across identifiable decision recipients and not attributable to participants perceiving the identifiable individual to be more deserving than the average recipient.

Last, study 4 ($N = 743$) crossed the same mixed design with another between-subjects factor (recipient category: victim vs. villain), to further examine if the effect holds when the decision recipients evoke negative emotional reactions, or if participants (mis)perceive human decision makers to be more lenient towards any identifiable individual. Again, we observed the main effect ($M_{statistical}$ = 4.27, SD = 2.61 vs $M_{identifiable}$ = 3.31, SD = 2.54, $F(1,1484)$ = 50.97, p < .001), and no significant reversal between recipient description and recipi-

ent category. Thus, the stronger algorithm aversion evoked by an identifiable recipient reflects the concern that algorithms are unable to understand emotions.

The Human Black Box: Illusionary Understanding Drives Preference for Human over Algorithmic Decision-Making

EXTENDED ABSTRACT

Algorithms are increasingly used to make judgments and decisions that profoundly impact people's lives, from whom gets incarcerated or admitted to universities, to whom gets hired or granted credit. Prior research shows that people are often hesitant to trust algorithmic over human decision-makers (Castelo, Bos, and Lehmann 2019; Dietvorst, Simmons, and Massey 2014; Longoni, Bonezzi, and Morewedge 2019). We propose that people's reluctance to trust algorithmic over human decision-makers stems, at least in part, from an illusion of explanatory depth (IOED; Rozenblitz and Keil 2002). Specifically, people foster the illusion that they understand how human decision-makers arrive at judgments and decisions better than how algorithmic decision-makers do so, when in fact both are black boxes. This occurs because, for human decision-makers, people are more likely to confuse a superficial, high-level understanding of what the decision-maker does, for a deeper, low-level understanding of how the decision-maker does it. This is less likely to occur for algorithmic decision making.

Study 1. The goal was to provide initial evidence that people foster the illusion that they understand human decision-makers better than algorithmic decision-makers. We test this hypothesis using a typical IOED paradigm, which unveils illusionary understanding by asking people to explain in detail how something works (Alter, Oppenheimer, and Zemla 2010).

401 MTurkers were randomly assigned to a 2(decision-maker: algorithm, judge) by 2(explanation: yes, no) between-subjects design. Respondents were presented with a news story about a man found guilty of stealing a car and sentenced to five years in prison, on the basis of a recidivism assessment conducted either by a judge/algorithm. In the no explanation condition, respondents were asked to rate to what extent they understood how the judge/algorithm evaluated the risk that the defendant would re-offend (three items on 7-point scales, α=.94, averaged into a sense of understanding score). In the explanation condition, respondents were asked to explain in detail how the judge/algorithm evaluated the risk that the defendant would re-offend, before rating their understanding.

A 2(decision-maker: algorithm, judge) x 2(explanation: yes, no) ANOVA revealed a significant main effect of explanation, $F(2,397)$=5.27, p=.022 and a marginally significant interaction $F(2,397)$=3.73, p=.054. Participants in the no explanation condition indicated a lower sense of understanding when the decision-maker was an algorithm (M=2.83, SD=1.61) rather than a judge (M=3.46, SD=1.80, p=.013). However, in the explanation condition, participants' sense of understanding did not differ significantly as a function of decision-maker (judge: M=2.70, SD=1.88; algorithm: M=2.76, SD=1.83, p=.819). Key to our hypothesis, asking to provide an explanation significantly reduced sense of understanding when the decision-maker was a judge (p=.003), but not when it was an algorithm (p=.795). These results provide evidence that people foster an illusion of understanding human decision makers better than algorithmic decision makers.

Study 2. The goal was to provide converging evidence for our illusionary understanding hypothesis, and test our proposed process via moderation.

442 undergraduate students were randomly assigned to a 2(decision-maker: algorithm, judge) by 3(mindset: how, why, control) between-subjects design. Respondents in the how/why mindset conditions were instructed to consider how/why they would improve and maintain their health (Freitas, Gollwitzer, and Trope 2004). The control group did not complete this manipulation. Respondents then read the same news story described in the previous study, and answered the same three items aimed to measure their sense of understanding (α=.78).

A 2(Decision-maker: algorithm, judge) x 3(mindset: how, why, control) ANOVA revealed a significant interaction, $F(2,436)$=5.11, p=.006. In the control condition, sense of understanding was higher when the decision-maker was a judge (M=4.37, SD=1.51) rather than an algorithm (M=3.68, SD=1.38, p=.003). This result replicates the findings from Study 1. When the decision-maker was an algorithm, sense of understanding did not differ across mindsets (algorithm control: M=3.68, SD=1.38; algorithm how: M = 3.86, SD =1.15; algorithm why: M=4.09, SD=1.18, p=.191), but when the decision-maker was a judge, sense of understanding differed across mindsets (judge control: M=4.37, SD=1.51; judge how: M=3.59, SD=1.52; judge why: M=4.00, SD=1.34, p=.003). Importantly, when the decision-maker was a judge, participants in the how mindset reported a significantly lower sense of understanding than participants in the control condition (p=.001). These results provide further evidence that people foster an illusion of understanding human decision-makers better than algorithmic decision-makers, because they construe human decision-making in terms *why* and algorithmic decision-making in terms of *how*.

Study 3: The goal was to probe our proposed process via mediation, test for consequential outcomes, and extend the investigation to a different domain.

198 MTurkers were presented with five activities in the HR domain (e.g., screening job candidates). Respondents indicated how much they would trust a manager/algorithm to perform each of these activities on a 7-point scale (α=.89). Respondents then indicated the degree to which they understand how a manager/algorithm performs each of these activities (α=.92). Finally, respondents completed a task, designed in the spirit of the behavioral identification form (BIF; Vallacher and Wegner 1989), aimed to measure how they construed each of the five activities performed by a manager/algorithm. Finally, to measure perceived accuracy, respondents rated the likelihood of a manager/algorithm being inaccurate when performing each task (α=.84).

Respondents indicated higher trust ($M_{Manager}$=5.45, SD=.95; $M_{Algorithm}$=3.76,SD=1.27; $t(196)$=10.55, p<.001), higher sense of understanding ($M_{Manager}$=5.32, SD=1.11; $M_{Algorithm}$=3.93, SD=1.55; $t(196)$=7.21, p<.001), and more *why* identifications ($M_{Manager}$=3.11, SD=1.19; $M_{Algorithm}$=1.44, SD=1.39; $t(196)$=9.06, p<.001) in the manager versus the algorithm condition. We conducted a mediation analysis with decision-maker as independent variable and trust as dependent variable. Behavioral identification and sense of understanding were specified as serial mediators, and accuracy as an alternative mediator. The results revealed a significant sequential indirect effect (decision-maker -> abstraction -> understanding -> trust: b=.16, CI95% [.06;.29]). The indirect effect through accuracy (decision-maker -> accuracy -> trust) was also significant (b=.19, CI95% [.06;.36]). The direct effect (decision-maker -> trust) was reduced after accounting for both processes (b=1.17, CI 95% [.82;1.51]), indicating partial mediation.

Across three studies, we show that people foster an illusion of understanding human better than algorithmic decision-making, because they construe human decision-making at a higher level of abstraction (Kim and Duhachek 2020) and confuse a superficial understanding of the process for a deeper understanding of *how* the process actually works.

How Will AI Affect Job Choice?

EXTENDED ABSTRACT

We explore how learning about the existence of AI in a given job alters students' and workers' willingness to pursue that job. We show that perceiving AI as competing with humans in a given job decreases willingness to pursue that job, while perceiving AI as helping humans in a job increases willingness. We also propose two moderators of this effect.

The first is whether the job is seen as more objective or subjective. Objective jobs require the use of quantifiable facts and data to perform them successfully, relative to subjective jobs which require the use of intuition or personal opinion. People tend to see algorithms as more capable of performing objective vs. subjective tasks. Thus, emphasizing that a given job is best accomplished by subjective (vs. objective) means may encourage more people to pursue that job even if AI is competing in that job.

A related factor is whether people focus on the standardized vs. unstandardized aspects of a given job. Independent of whether people believe that a job is best accomplished by objective or subjective means, most jobs also consist of some tasks that are relatively rule-based, repetitive, routine, and standardized, as well as some tasks that are relatively qualitative, non-repetitive, variable, and unstandardized. Emphasizing the more unstandardized aspects of a given job may therefore also encourage more people to pursue that job even in the presence of AI. In Study 1,221 business students read an article either about AI being used in accounting, or about a neutral topic, before indicating their interest in accounting careers. Reading the article about AI in accounting significantly decreased students' interest in accounting careers (β = -.86, p = .002). In the control condition, 70% of students scored at or above the scale mid-point on the dependent variable, indicating at least moderate interest in accounting careers; in the AI condition, this figure was 50% (χ^2 = 8.34, p = .004).

In Study 2, 151 Prolific participants chose to work on 1 of 2 prediction tasks; after working on their chosen task for several rounds (i.e., making several predictions), we introduced an AI system to the task, which we told them would be either competing with them for bonus payments, helping them at the task, or we left the AI's role ambiguous. We measured whether they chose to continue working on their chosen task with the AI or switch to the other task where there was no AI. Participants in the ambiguous AI condition chose to work alongside the AI 76% of the time, those in the AI help condition 86% of the time, and those in the AI competition condition 65% of the time. The only significant two-sample proportions test was between the competition and help conditions (χ^2 = 5.16, p = .023).

500 Prolific participants completed Study 3, choosing to work on a task either alone or with AI. We again manipulated whether the AI would help them or compete against them. We also told them that they could expect a higher bonus payment if they chose to work with AI, since the per-round bonus payment would be higher. Nevertheless, 11% chose to work alone in the "AI help" condition, and 28% did so in the "AI competition" condition (χ^2 = 20.6, p < .001). Thus, a preference to avoid working with AI persists despite financial incentives to the contrary.

Study 4 manipulated both help vs. compete framing as in Study 3 and framed the task itself as either objective or subjective. We again measured the choice to work alone or with AI on the task. A

2x2 regression revealed that the choice of working alone was more likely when AI was competing vs. helping ($\beta = .52$, $p < .001$) and more likely when the task was framed as being subjective ($\beta = .10$, $p = .068$); there was also a significant interaction ($\beta = .24$, $p = .002$). When the task was framed as being highly objective, 70% of participants chose to work alone when AI was competing, compared to 18% choosing to work alone when AI was helping ($\chi^2 = 62.32$, $p < .001$). When the task was framed as being highly subjective, 80% chose to work alone when AI was competing, compared to 52% when AI was helping ($\chi^2 = 21.41$, $p < .001$). Thus, in both cases, there was a strong effect of AI helping vs. competing, but the effect was significantly smaller when the task was seen as subjective.

Finally, Study 5 manipulated 267 business students' focus on the standardized vs. unstandardized aspects of accounting before reading one of the same articles from Study 1 (about either AI in accounting or a neutral topic). We mentioned that accountants mainly work on tasks like "calculating taxes owed and filling out tax filing forms" which are largely repetitive and rule-based, or like "interacting with clients in order to understand their short- and long-term financial goals and obligations" which are non-repetitive and intuition based. We again measured interest in accounting careers.

A 2 (AI vs. control article) x 2 (high vs. low job standardization) ANOVA revealed a significant interaction, $F(1,265) = 7.13$, $p = .008$, but no significant main effects, F's < 2.20, p's $> .139$. When accounting was described as consisting of highly standardized tasks, reading about AI in accounting decreased students' interest in accounting careers ($M = 2.84$) relative to reading about a neutral topic ($M = 4.17$, $t(126) = 3.04$, $p = .003$). When accounting was described as consisting of highly unstandardized tasks, reading about AI in accounting did not decrease interest in accounting careers ($M = 3.38$) relative to reading about a neutral topic ($M = 3.02$, $t(124) = .79$, $p = .431$).

Students and workers are therefore discouraged from choosing jobs in which AI can also perform, especially when AI is seen as competing; this effect can be reduced by highlighting the subjective or unstandardized nature of the job.

Cyber-Creativity: Unraveling the Dynamics Between Humans and Artificial Intelligence in Creative Processes

EXTENDED ABSTRACT

For decades, the role of advancing technology had been limited to helping humans perform tasks more efficiently and with higher quality (van Bruggen et al. 1998). As technologies became more sophisticated; however, they started taking over tasks from humans, performing them autonomously. Recent reports indicate that an increasing percentage of human labor has been replaced either partially or completely by new technologies in the last decade (Arntz et al. 2016; Brynjolfsson et al. 2018), and people who hold jobs that are easy to automate (e.g., frontline service employees)– that corresponds to 30 million American workers– are expected to continue being replaced (Muro et al. 2019).

In addition to their adoption in easy-to-standardize business processes, many companies have been utilizing artificial intelligence (AI) technologies in business areas that are fundamentally driven by high-order human cognition, such as creativity. Due to the widespread adoption of novel AI technologies, creativity is no longer a process that is single-handedly achieved by humans. Today, many companies (e.g., Google, IBM) increasingly employ AI in their creative processes (Ringel et al. 2019) to generate and execute ideas (e.g., medicine, food; Fry 2018), to design clothes (e.g., Glitch), and even to compose songs (e.g., Watson Beat). This widespread adoption of AI technologies in tasks that require higher-order cognitive processes raises a vital question about the future of the relationship between humans and AI in creative industries.

Despite the widespread adoption of AI in creative industries, what is known in the CB academic literature is based on human creativity. Previous work on creativity predominantly studies the cognitive processes that lead to an output that is not only different from what is already known but also is effective in solving the problem at hand (Moreau and Dahl 2005). In their influential paper, Finke and colleagues (1992) propose that such cognitive processes can be categorized into two critical phases that define creative cognition and present the "Geneplore Model" of creative thinking. The authors argue that *generative processes* entail constructing mental representations or preinventive cognitive structures of a desired creative solution (Murphy 1988). Once these preliminary mental structures are generated, *exploratory processes* are engaged to interpret these preinventive structures in a meaningful way until a satisfactory creative solution is reached.

In the current work, we evaluate and assess how AI technologies may redefine creative cognitive processes. Building on an influential theory of human creative processes (Geneplore model by Finke et al. 1992), we present the *Cyber-Creativity Framework,* that captures the dynamics of the relationship between humans and AI in creative processes.

The creative cognitive process starts with the generative phase during which one constructs mental representations and preinventive structures that are evaluated in the exploration phase to reach a final creative solution (Murphy 1988; Perkins 1981). In this initial phase, individuals retrieve mental information, form associations among retrieved mental concepts, and then synthesize or transform these concepts/information to generate preliminary mental structures. We propose that AI can augment human performance during generative processes by mitigating their possible weaknesses (e.g., limited computing power, limited memory, mental blocks, unconscious plagiarism; e.g., Baddeley 2013; Dahl and Moreau 2002; Miller 1956). Specifically, our model demonstrates that collaborating with AI improves humans' performances by enhancing their memory, flexibility, and comprehension. In contrast, we argue that AI shows a more secondary role during exploratory processes. Exploratory process entails interpreting the newly defined structures in meaningful ways (Finke et al. 1992). Such evaluations of preinventive structures utilize cognitive processes that encompass metaphorical or theoretical interpretations of the generated concepts, exploration of different meanings and functional inferences of structures, as well as testing and searching limitations of these interpretations. We suggest AI to have a secondary role during the exploratory stage as humans have an edge due to their (relative) advanced capabilities of intuition, adaptive decision-making and their ability to assess effectiveness across contexts. Put differently, even though collaboration with AI can enhance the overall effectiveness of exploratory processes, we propose that AI is best to play an assistive role during this phase of creative cognition.

We believe that our work builds on the current comprehension of human creativity and proposes a framework that captures the dynamics of the relationship between AI and human creative processes. By theorizing how humans and AI can collaborate instead of replacing one another, we also contribute to literature on technology by offering an alternative approach to studying a dark future that awaits humanity (Castelo and Lehmann 2019; Granulo et al. 2019). Additionally, our work offers timely and actionable strategies for managers and creative professionals. We provide understanding on how the integration of AI can impact the creative process and facilitate creative outcomes across different stages of the creative process. By

doing so, we provide managers with insights into defining and designing more successful creative processes (e.g., new product development), and how to determine the effective distribution of tasks and resources shared between AI and humans.

Paper #4: Uncommon Beauty: Physically Disabled Models Positively Affect Consumers' Attitudes and Choices

Martina Cossu, Bocconi University, Italy
Zachary Estes, Bocconi University, Italy
Joachim Vosgerau, Bocconi University, Italy

SESSION OVERVIEW

The public debate about discrimination and inclusiveness is intensifying in our societies. Social media is proliferating the means to socially connect, thereby exposing consumers to more and more information on different cultures and giving voice to vulnerable minorities. The #metoo movement has made it possible to openly talk about sexual discrimination at the workplace, a topic that had been taboo just a few years ago. And the notion of discrimination itself is changing and no longer covers only race and gender but is extended to other dimensions such as body image and beauty. Given these encouraging developments, one may be optimistic about the marketplace overall becoming more inclusive. This special topic session is aimed at providing an insight as to how inclusive the marketplace has become. The evidence is mixed. While consumers and service providers are found to still be discriminating in certain areas, consumers are also observed to be willing to punish companies that discriminate and to reward those that promote inclusiveness.

In particular **Zhu, Nian and Vosgerau** show that discrimination based on beauty—a beauty premium or a beauty penalty—can occur because consumers hold incorrect beliefs about the relationship between beauty and productivity. Consumers discriminate in favor of the attractive when social skills are deemed important, but discriminate against the attractive when analytical skills are deemed important.

Feldberg and Kim investigate discrimination in the service sector in a national field experiment involving 6,000 hotels. Hotels received emails from one of twelve fictitious email accounts (varying race, gender, and education) asking for local restaurant recommendations. Hotel representatives' email responses revealed racial discrimination along three dimensions of service quality: responsiveness, helpfulness, and rapport.

While those first two papers document extant discrimination in the marketplace, the next two papers show that consumers are also willing to punish companies that are still discriminating and to reward those that promote inclusiveness. **Mohan, Schlager, DeCelles and Norton** investigate how a company's gender pay gap affects consumers' willingness to pay. When firms' gender pay gaps are revealed, consumers are found to be less willing to pay for their goods, an effect driven by consumer perceptions of unfairness and moderated by gender.

Finally, **Cossu, Estes and Vosgerau** show that consumers are willing to reward companies for their inclusiveness, specifically for using disabled models in their advertisements. While disabled models to some extent evoke negative emotions (e.g., pity), they are shown to more strongly trigger positive emotions such as admiration that transcend to the advertisement and the brand. These positive effects cannot be accounted for by social desirability alone.

We expect the session to generate significant interest among conference attendees in general given the timeliness of the research topic; it should specifically attract researchers interested in inclusiveness, discrimination, and minorities.

Belief-based Discrimination: Beauty Premium and Beauty Penalty

EXTENDED ABSTRACT

The positive discrimination in favor of attractive workers—the so-called beauty premium—is a robust phenomenon. Explanations for the beauty premium fall into three classes: taste-based accounts (Becker, 1957) which maintain that beauty is in itself valued by consumers, statistical-based explanations (Phelps, 1972; Arrow, 1973) which argue that beauty serves as a reliable indicator for productivity, and belief-based explanations (Mobius and Rosenblat 2005; Bohren, Imas & Rosenberg 2019) which suggest that the beauty premium is caused by consumers' mistaken beliefs about the relationship between beauty and productivity.

We conjecture that both beauty premium and beauty penalty can occur due to belief-based discrimination. The psychology literature has shown that attractive people are perceived as more sociable, dominant, sexually warm, mentally healthy, interpersonally competent, confident, and better adjusted than unattractive people (Dion, Berscheid & Walster, 1972; Feingold 1992; Langlois et al., 2000). Based on this validated positive link between beauty and social skills, we conjecture that consumers positively discriminate in favor of the attractive for activities in which social skills are important. In contrast, a beauty penalty may occur for activities that require analytical skills and extensive solitary training, because consumers believe that less attractive individuals incur higher cost in social interactions than attractive individuals.

In Study 1 (preregistered https://aspredicted.org/blind.php?x=mf7pe7), 5704 MTurkers each rated a set of 30 photos of the same gender and race along one of the following dimensions: attractiveness, intelligence, responsibility, trustworthiness, social skills, analytical skills, and age. The set of 30 photos for each respondent was created out of a total of 8 sets with varying gender (male vs. female) and race (Asian, African Americans, Hispanics vs. Caucasians; photos were sampled from the Chicago Face Database: https://faculty.chicagobooth.edu/bernd.wittenbrink/cfd/index.html). For each of the 240 photos, we averaged the standardized ratings across respondents within dimensions (attractiveness, intelligence, responsibility, trustworthiness, social skills, analytical skills, age). With photo as the unit of analysis, we then regressed the averaged and standardized social and analytical skill ratings onto the averaged and standardized

ratings of attractiveness, intelligence, responsibility, trustworthiness, and age in two separate regressions. Consistent with our prediction, people (photos) perceived as more attractive were perceived to have better social skills (standardized b = 0.53, t(235) = 10.76, p <.001) but worse analytical skills (standardized b = -0.26, t(235) = -5.95, p < .001).

In Study 2 (N = 205), we manipulated the relative importance of social skills to analytical skills within the same profession (i.e., computer science professors). Half of the participants were asked to predict the professors' teaching performance (a domain where social skills are more important), and the other half were asked to predict their research performance (a domain where analytical skills are more important). Consistent with our prediction, professors (photos) perceived as more attractive by one set of subjects were rated to be better teachers by another set (β = 0.219, SE = .059; t(35) = 3.71, p < .001) but worse researchers by a third set (β = -0.294, SE = .065; t(35) = -4.49, p < .001).

Can such beauty penalties also be observed in the marketplace? To address this question, we investigated the influence of physical attractiveness on users' evaluations of others' on an online question-and-answer site for professional programmers, Stack Overflow. We randomly sampled 126,573 profile images, and using Face ++ API, we calculated a physical attractiveness score for each image. Based on the belief-based discrimination account by Bohren, Imas and Rosenberg (2019), we hypothesized that new programmers with low reputation scores should incur a beauty penalty because for programming, analytical skills are deemed more important than social skills. In contrast, among programmers with high reputation scores, attractive programmers must produce higher quality output than unattractive programmers to overcome the initial beauty penalty, resulting in a beauty premium. Consistent with these predictions, among (new) low-reputation programmers, the questions/answers of attractive programmers received more downvotes and fewer upvotes (a beauty penalty). In contrast, among experienced high-reputation programmers, the questions/answers of attractive programmers received more upvotes than downvotes (a beauty premium).

The results of our three studies suggest that discrimination based on beauty is belief-based, and hence context dependent. Consumers may discriminate in favor of attractive individuals when social skills are deemed important, but may discriminate in favor of the plain-looking when analytical skills are more important. Likewise, discrimination against the attractive can switch to discrimination in favor of the attractive when objective performance criteria are present.

Racial Discrimination in Customer Service: A Field Experiment

EXTENDED ABSTRACT

Service interactions between service providers and customers are ubiquitous in everyday life; they are also rife with service providers' discretion and subjective assessments and may be especially susceptible to discrimination. Yet, much of the existing research on discrimination has tended to focus on formal transactions—such as the buying and selling of goods and services, or the interactions with organized bureaucracies. Here we study discrimination in the context of customer service—the *manner* in which service providers (i.e., frontline employees) assist customers.

We chose the United States hotel industry, which generated over $170 billion in sales revenue and employed 1.9 million people in 2015 (AHLA, 2015), as our experimental setting. We conducted a field experiment using the audit study methodology with 6,000 ho-

tels, investigating the manner in which their service representatives would treat potential customers based on perceived race, gender, and class of customers. Through a simple email inquiry, we examined how much knowledge about restaurants—and the way in which—hotel service representatives were willing to share by asking whether hotel staff had recommendations for "unique" dining experiences in their cities.

Prior to beginning data collection, we set the sample size for this experiment based on previous audit (e.g., Bertrand & Mullainathan, 2004; Milkman et al., 2015; Tilcsik, 2011) and aimed for 500 hotels per condition. We randomly selected 6,000 hotels from ORBIS, a global company database, using a random number generator.

The experiment employed 12 treatment groups based on the perceived race (white, black, Asian), gender (male, female), and class of customers. Based on previous research (Milkman et al., 2012, 2015), we generated six different names to signal both the race and gender associated with each name. To vary perceptions of class, we either included or excluded "MD/PhD" at the end of each name. We validated the list of names and titles through a pretest on Amazon's Mechanical Turk. We emailed hotels from one of 12 fictitious accounts with a simple inquiry. The emails were identical except for two components: (1) the city that the customer planned to visit (which corresponded to the city of the recipient hotel) and (2) the customer's signature at the end of the email. We worded emails as follows: "Hello, I will be visiting [hotel's city location inserted here] in a few weeks. I'm interested in dining experiences unique to your city—could you make some recommendations? Thank you, [Customer's signature inserted here]." Using an email help tool, we scheduled all emails to be sent at 10am in the time zone corresponding to each hotel's location.

We assessed information availability and quality on the following three dimensions: responsiveness, helpfulness, and rapport. Responsiveness refers to the accessibility of information from hotel representatives, which we measured in two ways: whether or not each hotel responded and email length (i.e., the number of characters in each email). Helpfulness evaluates how directly and extensively representatives addressed the customer's inquiry, which we measured in three ways: (1) number of restaurants recommended, (2) whether or not hotels referred the customer to another source instead of making any restaurant recommendations, and (3) whether or not hotels inquired after the customer's dining preferences. Note that the act of referring to another source is not helpful, given that responders are not directly answering the customer's question. Conversely, inquiring about one's restaurant preferences is helpful, since it represents an attempt to customize the content of a response. Rapport considers the extent to which representatives attempted to establish a relationship with the customer, for example, by conveying personal engagement and providing unsolicited information that goes beyond responding to the inquiry. Finally, five variables measured efforts to establish rapport: whether or not hotels (1) provided extraneous information not about restaurants (e.g., attractions in the city, history of the city), (2) acknowledged the customer as a guest, (3) encouraged the customer to stay at the hotel, (4) addressed the customer using his/her name or honorific in the response (e.g., Dr. Washington, Mr. Andersen) and (5) signed the email with a complimentary close (e.g., Best, Sincerely).

Patterns across these variables broadly reflect a white advantage in customer service. Compared to customers with white names (42.9%), those with black names and Asian names were less likely to receive a response (Black: 39.7%, $\chi^2(1)=3.91$, $p< 0.05$; Asian: 32.0%, $\chi^2(1)=16.29$, $p<0.001$). We found consistent results of racial discrimination for helpfulness and rapport. In terms of helpfulness,

compared to customers with white names (M=3.35, SD=3.72), customers with black names and Asian names received significantly fewer restaurant recommendations (M_{Black}=2.97, SD=3.65, p=0.05; M_{Asian}=3.00, SD=4.16, p=0.10). Customers with black and Asian names were also more likely to be referred to another source (Black: 14.0%, $\chi^2(1)$=3.84, p=0.05; Asian: 15.9%, $\chi^2(1)$=8.64, p<0.01) than customers with white names (10.7%). Furthermore, customers with black and Asian names were less likely to receive preference inquiries (Black: 3.8%, $\chi^2(1)$=10.25, p<0.01; Asian: 3.3%, $\chi^2(1)$=13.34, p<0.01) than those with white names (7.9%). In terms of rapport, compared to customers with white names (28%), customers with black and Asian names were less likely to receive extraneous information from the hotel in advance of their visit (Black: 16.0%, $\chi^2(1)$=29.1, p<0.001; Asian: 4.0%, $\chi^2(1)$=158.9, p< 0.001). They were also less likely to be encouraged to stay at the focal hotel (Black: 4.7%, $\chi^2(1)$=4.06, p<0.05; Asian: 4.7%, $\chi^2(1)$=3.52, p<0.10) than white customers (7.2%), suggesting that hotels were being selective about which individuals to invite as hotel guests. These results were robust to the inclusion of hotel and hotel-county characteristics as controls. There were neither main nor interaction effects of gender or education.

Through an audit study of 6,000 hotels, we found that hotel representatives provided service in greater quantities and with greater enthusiasm to white customers than nonwhite customers, regardless of their gender or education level. The study advances understandings of inequality and knowledge-sharing in the marketplace, highlighting the need to focus not only on the quality of customer service but consistency—as well as the need to identify organizational interventions.

Paying for Parity: Consumer Response to Gender Pay Gaps

EXTENDED ABSTRACT

The gender pay gap—when women earn less money relative to men for the same work—is a pervasive pattern worldwide (Blau and Kahn 2017). One recent estimate suggests that globally comparing differences in average annual pay, women earn 57% of what men make (Harris 2017). We explore the effects of gender pay gaps from a unique perspective—that of consumers. We build on an emerging area of research exploring the influence of inequality on consumer behavior (e.g., Ordabayeva and Chandon, 2011; Yoon and Kim, 2018). Our investigation of the impact of gender pay inequality is particularly timely as countries move towards compelling firms to publicly disclosure pay gap information, such as the UK (Alderman 2018).

Building on past research, we first propose that disclosing gender pay gaps can adversely affect consumer purchase decisions by undermining consumers' perceptions of wage fairness (Benedetti and Chan 2018; Mohan, Schlager, Deshpandé and Norton 2018). Moreover, we propose that participant gender moderates the impact of pay gap disclosure on product desirability, given that gender plays a role in how an individual takes fairness in account when assessing the compensation of others (Leventhal and Lane 1970; Witt and Nye 1992).

In our pilot study, we used Twitter data on consumer sentiment before and after mandated pay gap disclosure in the United Kingdom to provide an initial examination of whether pay gap disclosure influences consumer responses. A research assistant monitored companies that published their gender pay gap leading up to the mandated April 4, 2018 deadline. We obtained all tweets between March 28 and April 8 (i.e., five days prior to and after April 3). which resulted

in a total of 93,627 tweets referencing the 158 firms in our dataset. Next, we used the LIWC database to code all the tweets for positive versus negative emotional valence about the organization (Pfarrer et al. 2010).

We conducted a linear mixed model regression, using the gender pay gap as the independent variable, publication date (before vs. after publication) as the moderator, and consumer sentiment as dependent variable ($B_{pay\,gap}$ = .001, $t(1)$ = -.19, p = .31, $B_{publicationdate\_after}$ = .14, $t(1)$ = 8.65, p = .003, $B_{pay\,gap\times publicationdate\_after}$ = -.01, $t(1)$ = -8.20, p < .001; $SD_{randomintercept\_company}$ = .41). The negative interaction between pay gap and publication date shows that after disclosure, a larger gender pay gap led to more negative emotional tweets referencing the company on Twitter (see Figure 1). A follow-up pilot study revealed that women responded significantly less positively to gender wage gap disclosure online than men, as indicated by a lower sentiment measure (M_{female} = .43, M_{male} = .80, $t(339)$ = 2.65, p = .01, Cohen's d = .29).

We next designed an incentive compatible experimental paradigm to examine whether the disclosure of gender pay gaps causally affects consumers' preferences for a firm's goods. Participants (N = 501, M_{age} = 36.6, 51% male) were randomized to one of two conditions: the control condition versus gender pay gap disclosure. Regardless of condition, participants saw descriptions of two competing ride share platforms, Uber and Lyft. In the gender pay gap present condition, participants were given the following additional information about Uber, based on actual self-reported data on the United Kingdom's publicly available Gender Pay Gap Service portal: "According to a recent report, women working for Uber have an average hourly rate that is 33% lower than men's. In other words, comparing average hourly rates, women earn 67 cents for every \$1 that men make." Participants indicated whether, if they won, they would like a \$50 gift card for Lyft versus for Uber. In this study, we also examined whether consumers responded differently to such disclosure based on their self-identified gender. Participants of both genders were significantly less likely to choose the Uber gift card when they saw the company's disclosed gender pay gap relative to when they did not ($M_{Disclosure}$ = 48.2%, $M_{Control}$ = 71.8%; χ^2 = 27.95, p < 0.01). However, we observed a significant interaction between gender and pay gap (B = 0.78, p = 0.04); women were less likely than men to choose the Uber gift card when they were shown that the company has a gender pay gap.

Next, we examined perceived wage fairness as a mediator of the effect of disclosing a gender pay gap on product desirability, again using stimuli directly informed by actual self-reported data. Participants (N = 304, M_{Age} = 34.8, 57.7% male) were all given a description of the clothing retailer Adidas. In the gender pay gap present condition, participants were told: "Adidas recently reported women working for the company have an average hourly rate that is 18% lower than men's." Willingness to buy when Adidas' pay gap was revealed was significantly lower than when the pay gap was not revealed for both genders ($M_{disclosure}$ = 3.82, SD = 1.72 vs. $M_{no\_disclosure}$ = 5.42, SD = 1.42; $t(298)$ = 8.76, p < .01). However, women were significantly less willing to buy then men when a pay gap was revealed ($t(155)$ = 3.27, p < .01).We conducted a moderated mediation analysis, with gender pay gap disclosure as the independent variable, wage fairness as the mediator, gender as the moderator, and willingness to buy as the dependent variable.. The indirect effect of pay gap disclosure on willingness to guy via wage fairness was significant for men (B = -.73, CI 95% [-1.05, -.45]), and women (B = -1.56, CI 95% [-1.97, -1.21]; Preacher and Hayes 2008). Given that the confidence intervals between both genders did not overlap, the effect is significantly more negative for women.

Two pilot studies and two experimental studies show that gender pay gap disclosure can affect consumer purchase intentions. This area of inquiry is particularly timely and important given that firms are under increasing pressure to disclose gender pay gap information that was previously kept confidential. Thus, consumer-facing firms with gender pay gaps could directly lose equity as a result of greater customer awareness, and particularly when their customers are women.

Uncommon Beauty: Physically Disabled Models Positively Affect Consumers' Attitudes and Choices

EXTENDED ABSTRACT

Recent research examined how advertisements that promote body positivity and multiethnic inclusiveness impact consumers' responses. This paper studies the impact of promoting diversity using a different minority (people with a disability) on a more general audience.

The present research analyzes how the inclusion of physically-disabled models in ads influences consumers' attitudes, emotional responses, and choices. Negative attitudes toward people with disabilities originate from the perpetuation of negative stereotypes. The most common, the paternalistic stereotype, portrays people with a disability as high in warmth and low in competence (Fiske et al. 2002). Following this line of reasoning, we would expect physically-disabled models to have a negative impact on consumers' attitudes and choices, because the stigma associated with the disability should be transferred from the model to the brand. However, according to social categorization theory (Kunda, Miller, and Claire 1999) a disabled model belongs to two social categories: first, a person with a disability and hence part of a stigmatized minority, and second, as a model, an admirable subgroup. When looking at a disabled person that is also a model, people infer that s/he must have been through many difficulties. What previously was a negative attribute becomes a signal of the model's strength and determination. Therefore, ads with disabled models shift the negative stereotypical view of people with a disability and increase consumers' attitudes. We tested whether disabled models have a positive impact on consumers' attitudes (study 1), and emotional responses (study 2). We further investigated whether the findings are due to social desirability (study 3). Finally, in a field experiment, we tested whether energy drinks advertised with disabled models are preferred in private as well as public choices (study 4).

Study 1, a between-participants study ($N = 159$; M-Turk), tested whether ads with disabled models enhance attitudes. Participants were assigned to one of two conditions (disability vs control). We created two versions of two ads, one with a model (control) and another identical ad except the same model was missing a limb (disability). Compared to the control condition, ads with disabled models were rated more favorably ($M_{disabled} = 4.30$, $SD = 1.09$, $M_{control} = 3.87$, $SD = .85$; $F(1, 153) = 7.32$, $p < .01$, Cohen's $d = .43$).

Study 2, a between-participants study ($N = 200$; lab), replicated the previous result and, in addition, tested the effect of disabled models on consumers' emotional responses, perception of novelty and willingness to buy. Participants were randomly assigned to one of the two conditions (disability vs control) and saw four advertisements. Disabled models evoked more pity ($M_{disabled} = 3.90$, $SD = 1.39$, $M_{control} = 3.25$, $SD = 1.30$; $F(1, 199) = 11.55$, $p < .001$, Cohen's $d = .48$), and to a lesser extent also more negative emotions ($M_{disabled} = 2.43$, $SD = 1.01$, $M_{control} = 2.17$, $SD = 1.10$; $F(1, 200) = 3.10$, $p = .08$, Cohen's $d = .25$). They evoked also more positive emotions ($M_{disabled} = 3.94$, $SD = 1.03$, $M_{control} = 2.99$, $SD = .93$; $F(1, 199) = 46.72$, $p < .001$, Cohen's $d = .97$), greater admiration for the model ($M_{disabled} = 4.66$, $SD = 1.10$, $M_{control} = 3.15$, $SD = 1.07$; $F(1, 199) = 95.40$, $p < .001$, Cohen's $d = 1.38$), and were judged as more novel ($M_{disabled} = 4.74$, $SD = .90$, $M_{control} = 3.38$, $SD = .94$; $F(1, 199) = 107.82$, $p < .001$, Cohen's $d = 1.18$). Disabled models enhanced participants' attitudes ($F(1, 199) = 13.79$, $p < .001$, Cohen's $d = .53$) and increased their willingness to buy ($M_{disabled} = 3.19$, $SD = .97$, $M_{control} = 2.66$, $SD = .96$; $F(1, 199) = 14.99$, $p < .001$, Cohen's $d = .55$).

Study 3 ($N = 298$; lab; preregistered) tested if previous results were driven by social desirability bias, using a response deadline procedure. If social desirability is acting, participants should have an immediate negative reaction to the ad and then subsequently adjust their answer more positively. If this is the case, we would expect to see a positive effect only if it has enough time to emerge, such as going from one to two seconds. Participants were exposed to both ads with disabled models and controls and were asked to evaluate them (on a 3-point scale) within either 1 or 2 seconds (between-participants). Again, ads with disabled models were evaluated more positively in the one second condition ($M_{disabled} = 1.80$, $SD = .49$, $M_{control} = 1.63$, $SD = .34$; $F(1, 149) = 14.10$, $p < .001$, $\eta^2 = .08$), and in the two seconds condition ($M_{disabled} = 1.86$, $SD = .50$, $M_{control} = 1.60$, $SD = .37$; $F(1, 149) = 37.17$, $p < .001$, $\eta^2 = .20$). The effect did not interact with the response deadline ($p = .139$), suggesting the absence of social desirability bias.

Study 4, a field experiment ($N = 300$, preregistered), tested if previous results were driven by participants' impression management by manipulating anonymity of choice. Participants were recruited in the gym of a European university. A research assistant approached gym members while they were entering the gym and offered an energy drink for free. Both drinks were advertised, the ad for one drink pictured a disabled model, while the other pictured the control. Participants were brought into a room where they could choose the drink. In the private condition, participants were left alone while choosing. In the public condition, they communicated their choice to the research assistant. Participants preferred the drink advertised by the disabled model whether they made their choice in private (60.1%) or in public (68.4%; both percentages are greater than 50%, z's > 2.38, p's < .001) and choice did not differ across conditions ($\chi^2 (1) = 2.24$, p = .134).

The present study contributed to the literature in advertising by considering a specific minority that has not been studied before. Our studies suggest that disabled models enhance attitudes, evoke positive emotional responses and increase choice both in private and in public.

SESSION OVERVIEW

How difficult was your last decision? How did this difficulty during the decision process affect your choice? Consumers often face difficult decisions (Tversky and Shafir 1992). Choice difficulty shapes, and is shaped by, effort invested in the decision process (Dhar 1997; Iyengar and Lepper 2000). The proposed session joins together four papers offering a new perspective on these questions, examining how features of the choice context and decision process affect perceived choice difficulty, with implications for consumers' information search. They further examine perceived and objective effort invested in choosing, with outcomes for choice confidence and valuation of their chosen product.

The first two papers examine novel factors that influence consumers' perception of how difficult a choice is. **Zwebner and Schrift** (N=955) identify how preference-elicitation modes (choice vs. rank-ordering) affect perceived choice difficulty. Although rank-ordering requires more effort than simply choosing a preferred option, these authors found that rank-ordering *reduces* perceived choice difficulty. This effect occurs because rank-ordering makes judgments feel more objective. **Wang and Sela** (N=1,224) investigate how product categorization influences attributions of choice difficulty, and implications for consumers' information search behavior. When products are framed in *different* categories, consumers perceive that the options represent distinct goals and therefore attribute choice difficulty to preference uncertainty (i.e., to the self - "I am not sure what I want"). In contrast, when products are framed under the *same* category, consumers see the options as representing means to an overarching goal and attribute choice difficulty to preference matching (i.e., to the option - "These options are not what I want"). This differential attribution of choice difficulty to the self (vs. options) drives search behavior; people seek information to discover their own preferences, but seek alternative choices when they feel the option is to blame.

The remaining papers examine how consumers' effort evaluation shapes preferences and choice. **Ibrahim and Häubl** (N=2,335) examine when and why exerting greater effort increases decision confidence. Specifically, when consumers put more effort (e.g., time) into the decision process, they feel less confident about decisions that are "matters of quality" but more confident about decisions that are

"matters of taste." Lastly, **Hur, Woolley, and Tu** (N=1,425) examine how choice architecture can affect consumers' subjective evaluations of the effort they put into a decision. When holding actual effort invested constant, consumers perceive their effort had a bigger payoff, that is, was better spent and more worthwhile, when they discover the best option at the end (vs. beginning) in a choice set. As a result, even though consumers all chose the same best option, those who found this option at the end (vs. beginning) valued it more and were more committed to their choice.

Together, this session advances our understanding of how choice difficulty and objective and subjective effort investment affect consumers' decision processes and search behavior. This session offers broad appeal on how choice structure can enhance or mitigate perceived effort and the consequences of choice difficulty on consumers' decisions.

The Objectivity Illusion of Ranking Procedures: How and Why Ranking Alleviates Decision Difficulty

EXTENDTED ABSTRACT

The degree to which consumers experience decision difficulty is an important and fundamental aspect of the decision-making process. For example, previous research demonstrated that experienced difficulty may elicit negative emotional states (e.g., Luce, Payne and Bettman 1999), cause consumers to end up choosing nothing (e.g., Iyengar and Lepper 2000), delay their choice (Dhar 1997, Tversky and Shafir 1992), increase the need to justify the decision (Shafir, Simonson, and Tversky 1993), and increase the likelihood to compromise (e.g., Novemsky et al. 2007). Additionally, the subjective experience of decision difficulty has been shown to also impact consumers' tendency to engage in simplifying and complicating behaviors (e.g., Schrift, Netzer and Kivetz 2011, Schrift, Kivetz, Netzer 2016) and could even play an important role when observing others making decisions (e.g., Schrift and Amar 2015).

Indeed, as the subjective experience of difficulty impacts variety of different behaviors, understanding what factors increase or decrease it, is important from both theoretical and applied perspectives. The current work focuses on how the preference elicitation mode impacts consumers' experience of difficulty. In particular, we focus on two prominent modes, namely, choice and rank-ordering.

When comparing a choice task to a ranking task, it is quite intuitive to expect that a ranking task will elicit greater experience of difficulty (supported by a pilot study (N=100) where 76% of people believed that choosing would be easier for them than rank-ordering). That is, while choosing includes the selection of one option that offers the greatest utility, rank-ordering includes the same selection (i.e. ranked first), as well as the ordering of all the other options in the set. Thus, the operations required to make a choice are embedded in those required to complete the ranking procedure. However, in the current research we repeatedly find that consumers' experienced difficulty is actually lower when asked to rank as opposed to choose among the options. That is, even though the outcome of the ranking procedure is identical to that of the choice (i.e., consumers are fully aware that the option they rank first is the one they will eventually receive), framing the process as ranking as opposed to choosing decreases the difficulty that consumers experience.

Following recent research on consumer's perceived objectivity vs. subjectivity in judgement (Berman et al., 2018; Goodwin and Darley 2008; Spiller and Belogolova 2017) we find that ranking compared to choosing increases perceptions of objectivity in judgment and, therefore, reduces the associated decision difficulty. That is, while choosing highlights subjective evaluation criteria (i.e., a matter of taste), ranking procedures increases the perceived objectivity of the decision and eases the selection process.

Study 1 (N=217, lab), utilized an incentive-compatible paradigm in which participants viewed five products and either chose their most preferred product, or rank-ordered the products according to their preferences. Across both conditions we informed participants that their most preferred product (chosen or top-ranked) is the one they will receive should they win a lottery that was conducted. After choosing or rank-ordering, participants rated the difficulty they experienced using five items (Cronbach α=.88). Results confirmed that compared to the difficulty experienced in choice (*M*=3.42, *SD*=1.3) ranking reduced the experienced difficulty (*M*=2.54, *SD*=1.02; *t*(215)=5.49, *p*<.001). Interestingly, this difference was despite the fact that participants spent more time ranking the options (*p*<.001).

In Study 2 (N=199, MTurk) participants received only two options and were asked to either choose or rank-order the two options (between-subjects). Because the set consisted of only 2 options, the actual task in both conditions, is virtually identical. Results confirmed that even when only two options were available, participants still felt lower degree of difficulty in the rank (*M*=3.24, *SD*=1.49) compared to the choice condition (*M*=3.74, *SD*=1.5; *t*(197)=2.35; *p*=.02). Thus, these finding suggest that the effect is driven by how people construe the task and not by the actual cognitive operations required to performing it.

In Study 3 (N=160, lab) we aimed to further examine why consumers construe the same decision differently when choosing compared to ranking. After either choosing or ranking, participants were asked to indicate (on a 1-7 scale) the extent to which they found the (i) selection of a TV and (ii) differences among TVs, to be a matter of taste or a matter of quality. As hypothesized, participants in the ranking condition indicated greater objectivity for their selected TV (*M*=5.29, *SD*=1.34) as well as for the differences among TVs (*M*=5.13, *SD*=1.33) compared to those in the choice condition (*M*=4.53, *SD*=1.74; *t*(158)=3.12, *p*=.002, and *M*=4.53, *SD*=1.53; *t*(158)=2.66, *p*=.009, respectively). Further, 68.8% in the ranking condition indicated that their chosen option is objectively better compared to only 51.2% in the choice condition (χ²(1)=5.1, *p*=.024).

Study 4 (N=279, lab) replicated the effect observed in Studies 1-2 (*p*<.001) and the perceived objectivity effect demonstrated in Study 3 (*p*=.026) and extended these findings by testing the mediating role of perceived objectivity on experienced difficulty. Employing a similar design to Study 3, a mediation analysis (using the macro PROCESS, model 4, Hayes, 2013) confirmed that the perceived objectivity mediated the effect of elicitation mode (choice vs. rank) on participants' experience of difficulty (B=-.09; 95% CI=[-.19, -.02]).

To summarize, we find that ranking, although takes longer and requires greater cognitive operations, reduces experienced decision difficulty as it fosters greater perceived objectivity of the selection process. We discuss the applied contribution of these findings given the prevalence of decision aids that could foster ranking procedures as opposed to direct choice.

Roads or Rome? How Product Categorization Shapes the Attributions and Consequences of Choice Difficulty

EXTENDED ABSTRACT

Consumers often experience choice difficulty while making decisions (Broniarczyk and Griffin 2014; Sela and Berger 2012), and they often cope with such experiences by deferring choice and prolonging their information search (Corbin 1980; Dhar 1997; Dhar and Simonson 2003). But how do people select the specific strategy for coping with choice difficulty? For example, when do they seek more information on existing alternatives as opposed to new alternatives, or try to figure out their own preferences?

Choice difficulty may be attributed internally, to preference uncertainty (e.g., "I am not sure what I want"), or externally, to qualities of the available options (e.g., "the available options are not good enough"). Each of these possible attributions has distinct implications for information search, namely, seeking information about how the options differ in an attempt to form a preference, versus seeking other, presumably better options, respectively.

We argue that framing the choice options as representing different categories (e.g., "2-in-1", "ultraportable", "gaming") leads consumers to construe the decision as choosing among different goals, whereas framing them as representing one overarching category (e.g., "laptops") leads them to perceive the decision as choosing among different means to a goal. We argue this based on the notion that category labels often indicate the consumption goals associated with products under the category (Lamberton and Diehl 2013). Goals are self-diagnostic, because they are seen as desired end-states of the self (Carver and Scheier 1990, 1998; Chartrand et al. 2008; Sela and Shiv 2009), whereas means are more instrumental and situationally determined (Kruglanski et al. 2002; van Osselaer and Janiszewski 2012). Consequently, we propose that, to the extent that consumers experience choice difficulty, distinct product categories lead consumers to attribute choice difficulty to the self (as opposed to the available options) and, therefore, seek information that may help them discover their own preferences. Conversely, a single product category frame leads them to attribute difficulty to the options available (as opposed to the self) and, therefore, seek other choice alternatives.

Experiment 1 examines the effect of categorization on information search, using consequential choice. Participants saw three tea bag options from which to choose, each described on several attributes, framed as representing either the same category or different categories. Product attributes were the same across conditions and category labels provided no additional information not already contained in the attributes. Presumably to help them with the decision, we offered participants the option to view either additional information about the existing options that can help them figure out what type of tea bag they want or, instead, to view other options altogether, corresponding to preference uncertainty and option quality attributions, respectively. They also rated their subjective feelings of choice difficulty. Participants were more likely to seek detailed information about the existing options in the different-categories condition (*M*=70%) than in the same-category condition (*M*=47%; χ²(1)=7.08, *p*=.008). Supporting our suggestion that this effect reflects attributions of choice difficulty, it was pronounced when difficulty was moderate-to-high (greater than 3.13 on a 7-point scale) but attenuated when participants experienced no difficulty (moderation β=.57, Wald=4.43, *p*=.035). Categorization had no effect on difficulty itself.

Experiment 2 examines how product categorization influences attributions of choice difficulty. Participants saw three laptop mod-

els, framed as representing either one category ("laptops") or different categories ("ultraportable", "performance", "premium display"). Participants rated choice difficulty and indicated whether the difficulty was due to preference uncertainty (e.g., "I am not sure what exactly I want") or the options (e.g., "the options do not perfectly fit my wants"). As expected, participants were more likely to attribute choice difficulty to preference uncertainty in the different-categories condition (M=4.22 on a 7-point scale: 1=attribute to preference uncertainty, 7=attribute to option availability) than in the same-category condition (M=4.99; $F(1,98)$=9.40, p=.003). There was no effect on choice difficulty itself or perceived option similarity, variability, and comparability.

Experiment 3 tests the mediating role of participants' perception that they chose among goals versus means. Participants saw four mutual fund options, framed as representing either one or different categories. Compared with the same-category condition, participants in the different-categories condition attributed difficulty to preference uncertainty more ($F(1, 195)$=9.07, p=.003) and indicated that they thought more during the decision about which financial goal they would like to achieve rather than which option would best serve their financial goals ($F(1, 195)$=3.90, p=.050). This measure of thought process mediated the effect of categorization on attribution ($\beta_{indirect}$=.10, 95% CI=[.01,.26])

Experiment 4 uses the same scenario to provide further insight into the process. If using multiple (vs. single) product categories affects attributions by leading people to perceive that they are choosing among goals (vs. means), then drawing participants' attention, in both conditions, to their personal goals before the decision should attenuate this effect, because it should increase goal-based choice regardless of product categorization. Consistent with our logic, the effect of product categorization on choice difficulty attributions replicated in the baseline condition ($F(1,690)$=8.64, p=.003), but was attenuated when participants answered several questions regarding their financial goals before seeing the four mutual fund options ($F(1, 690) < 1$, NS; interaction $F(1,690)$=5.00, p=.026). Choice difficulty did not differ across the four conditions.

Experiment 5 further examines the downstream effect of attributions on information search. Participants saw three wine options, framed as representing either one category (i.e., dinner party wine) or different categories (i.e., pre-dinner wine, table wine, dessert wine). Compared with the same-category condition, participants in the different-categories condition attributed choice difficulty to preference uncertainty more ($F(1,98)$=5.35, p=.023). This, in turn, led them to indicate that they would prefer to view additional information that could help them discover what they wanted rather than see other options (72% vs. 52%; $\chi^2(1)$=4.24, p=.039; mediation $\beta_{indirect}$=.21, 95% CI=[.01,.69]).

Taken together, our findings provide novel insights on how product categorization influences consumer interpretations of choice difficulty and information search. In addition to their practical significance, the findings also make theoretical implications for goal systems and self-perception theories by showing the link between categorization, goal construal, and attribution to internal versus external sources of choice experiences.

Nuanced Effects of Decision Effort on Decision Confidence in Matters of Quality versus Matters of Taste

EXTENDED ABSTRACT

Effort, be it physical or mental, is quintessential to everyday consumer decision-making, and it has a profound impact on consumers' preference and choice appraisals. Although evidence suggests that exerting more mental effort increases metacognitive difficulty, resulting in low decision confidence (e.g., Dhar 1997; Iyengar and Lepper 2000; Tversky and Shafir 1992; see Anderson 2003 for a review), we theorize that, under some circumstances, exerting greater effort actually increases decision confidence.

We argue that whether exerting more effort in the decision process increases or decreases decision confidence (Parker et al. 2016; Thomas and Menon 2007; Zakay 1985) is a function of consumers' effort sensitivity (the strength of the relationship between effort exertion and consumers' judgment of metacognitive difficulty) in a particular domain and its impact on the inferences consumers draw from their effort exertion.

We theorize that consumers tend to be more effort sensitive when they consider effort exertion to be detrimental in achieving the desired decision outcome and less effort sensitive when they consider effort exertion to be beneficial in achieving the desired decision outcome. We demonstrate that consumers are systematically more effort sensitive in domains that are considered "matters of quality" (where alternatives *can* be rank-ordered based on product features reflecting objective quality) than in domains considered "matters of taste" (where alternatives *cannot* be rank-ordered in terms of objective quality). This divergence in effort sensitivity in turn differentially impacts two distinct aspects of decision confidence – preference clarity (i.e., to what extent consumers' choices reflect their true inclination) and preference correctness (i.e., to what extent choices can be validated or justified by normative preferences) (Olson et al. 1983; Petrocelli et al. 2007).

In quality domains, consumers tend to attribute the locus of their evaluations to product features and consider normative preferences for these features (i.e., rank-ordering) to be diagnostic of the optimality of their own choices. In this case, exerting more (vs. less) effort in the decision process *undermines* inferences about preference correctness, in turn *diminishing* decision confidence. By contrast, in taste domains, consumers tend to attribute the locus of their evaluations to personal preferences and consider normative preferences for product features to be less diagnostic of the optimality of their own choices. In this case, exerting more (vs. less) effort in the decision process *promotes* inferences about preference clarity, in turn *increasing* decision confidence. We present evidence from five studies that were designed to test this conceptual model (see figure 1).

In study 1 (N=245), we tested consumers' predisposition toward exerting effort across 16 different product domains (adapted from Spiller and Belogolova 2017). We found that, on average, consumers are willing to exert more effort (i.e., actively spend time; log-transformed) in the decision process when they consider a domain to be more of a matter of quality versus more of a matter of taste (b=.086, SE=.004, p<.001; see figure 2). This finding is consistent with our theorizing but not fully conclusive, particularly since the 16 domains differed considerably in economic significance (e.g., Chaiken and Maheswaran 1994; Petty and Wegener 1998). We controlled for this in subsequent studies by using quality and taste domains with similar price ranges. Using product-choice paradigms, we manipulated the amount of decision effort exerted by varying aspects of the choice architecture, such as the number of alternatives to be inspected, as well as the format and timing of information presentation.

Both studies 2 (N=488) and 3 (N=503) showed that, as hypothesized, greater effort exertion reduced decision confidence in quality domains (e.g., electric toothbrushes) but increased decision confidence in taste domains (e.g., coffee tables) (ps<.05). We estimated a bias-corrected moderated mediation model (Hayes 2013; 5,000 bootstrap samples) in each study. Our analyses revealed that in quality domains, inferences about preference clarity and prefer-

ence correctness were interdependent and corresponded to decision effort similarly. In this case, greater effort exertion diminished both preference clarity and preference correctness, in turn reducing decision confidence ($ps<.05$). By contrast, in taste domains, inferences about preference clarity and preference correctness were independent and corresponded to decision effort distinctively. In this case, greater effort exertion reduced preference correctness but enhanced preference clarity, in turn increasing decision confidence ($ps<.001$). These effects were robust to chronic individual differences in effort valuation (i.e., need for cognition, $\alpha=.96$; Cacioppo and Petty 1982; Cacioppo et al. 1984).

In study 4 (N=499), we tightly controlled for the hedonic versus utilitarian nature of the decision domain by asking participants to choose within a common product domain (i.e., electric toothbrushes). We manipulated the set of alternatives so as to make the choice among them either a matter of quality (products varied in objective quality and price, but not in their ergonomic and aesthetic properties) or a matter of taste (products varied in their ergonomic and aesthetic properties, but not in objective quality or price). The results showed again that greater effort exertion reduced confidence in quality domains but increased confidence in taste domains ($p=.032$; figures 3a–3d).

In study 5 (N=603), we distinguished between instrumental decision effort (the effort exerted in considering and reasoning about products: 20 vs. 5 alternatives) and incidental decision effort (the effort exerted in merely obtaining product information: 40 vs. 10 seconds). Using a 3 (decision effort: low instrumental–high incidental vs. low instrumental–low incidental vs. high instrumental–low incidental) x 2 (domain: quality vs. taste) between-subjects product-choice paradigm, we again found that exerting more effort diminished confidence in quality domains (i.e., power banks) but increased confidence in taste domains (i.e., ceramic mugs) ($p=.071$; figures 4a–4d). Collapsing the levels of exerted decision effort to high versus low instrumental effort yielded the predicted interaction effect ($p=.020$), but collapsing the levels of exerted decision effort to high versus low incidental effort did not ($p=.378$), suggesting that instrumental decision effort is the key driver of the predicted effects.

This research advances our understanding of the psychological forces that govern how decision effort informs decision confidence. Importantly, it pinpoints conditions under which choice architectures can benefit both firms and consumers by either promoting or restraining the exertion of decision effort.

Hidden Benefits of Hiding the Best Option: Consumers Value Their Selection More When Discovering it Later

EXTENDED ABSTRACT

Consumers often suffer from choice overload. They at times face endless options in stores and online that they need to sort through to find a product that fits their need. To address this, companies have begun offering curated products that limit the search process and help consumers narrow in on the best option for them (Cha et al. 2018). For example, online dating apps limit the number of potential relationship partners users can view and connect with per day, and Book of the Month, a book subscription service, recommends five books every month with reviews, and consumers read each review from curators before ordering a book to read.

When searching through a limited choice set, consumers often learn about options in a specific order. When arranging such a choice set, should marketers present the best option - the one that consumers are likely to prefer the most in the set - at the beginning of the sequence or save it for last?

The current research explores a hidden benefit of saving the best option late: Presenting the best option at the end (vs. beginning) increases consumers' valuation of the selected option. This is because, when searching within a limited choice set, discovering the best option at the end (vs. beginning) leads consumers to perceive that the effort they put into finding the best option paid off more – that is, was well spent and worthwhile (Delleart and H*a*übl 2012). We propose that such benefits arise because consumers perceive that they have made more progress in their search (Harkin et al. 2016). As such, finding the best option at the end (vs. beginning) has key consequences for consumers' enhanced valuation of their chosen option, as the positive experience of the search process transfers to the outcome of search (Fishbach et al. 2004).

Five studies (N=1,325) test our theory. Study 1 examined effort payoff using an incentive-compatible design. Participants opened five gift boxes containing different financial payouts with the goal of discovering the highest prize to claim as a bonus. Participants in the best-option-beginning condition viewed the highest prize first ($0.22) before viewing four lower prize amounts; participants in the best-option-end condition viewed the four lower prize amounts first and found the highest prize ($0.22) at the end. After selecting their prize, we measured how much participants felt their effort paid off. As predicted, those who found the best option at the end (vs. beginning) felt their effort paid off more ($M_{end}=5.03$; $M_{beginning}=4.05$; $t(136)=3.75$, $p<.001$, $d=.64$).

Study 2 extended these results when searching for a rental on Airbnb. Participants searched through five different rentals before making their selection. We manipulated the order of the highest rated option so that it appeared either at the beginning or end of the choice set. Participants who found the best option at the end (vs. beginning) felt their effort paid off more ($M_{end}=5.92$; $M_{beginning}=5.00$; $F(1,161)=13.99$, $p<.001$, $\eta_p^2=.08$).

Study 3 examined our proposed process, that people feel a greater sense of effort payoff when finding the best option at the end because they experience a sense of progress during their search. To test this, we manipulated the presentation order of the highest rated restaurant as in study 2, and manipulated the sense of progress (present vs. absent) by presenting options sequentially versus simultaneously. In the progress-present-condition, participants viewed all options one at a time, as in studies 1-2; in the progress-absent-condition, participants viewed all options at once, such that they were unable to feel a sense of progress during search. We found a significant interaction ($F(1, 340)=3.85$, $p=.051$, $\eta_p^2=.011$; figure 5); finding the best option at the end (vs. beginning) increased perceived effort payoff only for those who could experience search progress ($M_{end}=6.23$; $M_{beginning}=5.60$; $F(1, 340)=11.00$, $p=.001$, $\eta_p^2=.03$), which attenuated when there was no search progress experience ($p=.58$).

Study 4 provided additional process evidence by measuring consumers' perceptions of progress during their search and we examined a consequence of this effect - that people value their selected option *more* when they feel greater effort payoff. Participants searched through a set of environmental non-profits with the goal of choosing one charity to donate to. Participants who found the highest rated non-profit at the end (vs. beginning) of their search felt greater effort payoff ($M_{end}=5.39$; $M_{beginning}=4.91$; $t(308)=2.81$, $p=.007$, $d=.31$). Finding the best option at the end also increased valuation of the chosen option; these participants were more willing to recommend their selected non-profit to others ($M_{end}=5.97$; $M_{beginning}=4.79$; $t(308)=7.24$, $p<.001$, $d=.82$). A serial mediation analysis supported our predictions; finding the best non-profit at the end (vs. beginning) increased perceived progress in search, which increased effort payoff, leading participants to be more likely to recommend their selected non-profit

to others ($\beta_{indirect}$=.10, 95% CI=[.01,.21]; PROCESS model 6; Hayes and Preacher 2014) (figure 6).

Our final study demonstrated another consequence of presentation order. Participants viewed five apartment options and chose one to rent. When the participants found the best apartment at the end (vs. beginning), they were more willing to submit an application to rent the apartment sooner without viewing additional options (M_{end}=6.49; $M_{beginning}$=6.06; $t(197)$=2.92, p=.004, d=.51). This effect was mediated by greater perceived effort payoff when the best option was at the end (vs. beginning) ($\beta_{indirect}$=.43, 95% CI=[.23, .68]).

Overall, we find that showing the best option at the end (vs. beginning) can increase perceived payoff from search and increase valuation of the chosen option. This research contributes to literature on search (Delleart and Häubl 2012) and effort perception (Kim and Labroo 2011). Additionally, we connect literature on goal (Harkin et al. 2016) to demonstrate that perceived progress in search drives this effect. Lastly, these results offer managerial implications, as finding the best option at the end increased willingness to recommend the selected option and increased choice commitment.

Working Papers

30% Human is Better Than 10% Human: Consumers' Sensitivity to Human Versus Machine Involvement in Production

Almira Abilova, Erasmus University Rotterdam, The Netherlands
Gizem Yalcin, Erasmus University Rotterdam, The Netherlands
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands

Prior research shows that people prefer human-made to machine-made products but has not investigated preferences for products made with more vs. less human involvement. Using a newly developed paradigm we find that consumer preferences for products decrease as less human labor is involved and that this decrease is linear.

It Tastes Better For Me Just Because You Don't Like It: The Effect of Cognitive Dissonance on Product Enjoyment

Aya Aboelenien, HEC Montreal, Canada
Caroline Roux, Concordia University, Canada

Prior research on cognitive dissonance has mostly focused on understanding consumers' attitude and behavior after having to process counter attitudinal information. However little is known about the effect of cognitive dissonance on subjective consumption experiences. Across two experiments we investigate the effect of cognitive dissonance on subjective product enjoyment.

Markets as Contested Assemblages: Comparative Case Study

Aya Aboelenien, HEC Montreal, Canada
Jack Sadek, Concordia University, Canada

Through studying meat vape and cryptocurrency markets we investigate actors contesting the legitimacy of these markets and their strategies. Involved actors include industry associations specialized media consumers religious institutions federal agencies financial and scientific communities. Actors participate in strategies of problematization demarcation validation and affirmation.

When Indulgent Choice Can Promote the Next Indulgent Choice

Naoki Akamatsu, Meiji Gakuin University, Japan
Reo Fukuda, Asia University, Japan

This study discussed the impact of the result of the prior indulgent choice (buy or restraint) on subsequent indulgent choices. Whereas the conventional idea is that "restraint" of a prior choice promotes subsequent indulgent choices we clarified the conditions where "exercising" a prior choice facilitates subsequent indulgent choices.

The Vulnerable Refugee Mother: Consumption Responses to Identity Threats

Roua Alhanouti, University of Lille, France

This paper attempts to summarize a research investigating the experience of refugees' families in "transition phases" associated to forced migration. It considers strategies developed by mothers in consumer behavior to deal with identity threats. Research was conducted based on ethnographic approach. The study focuses on family identity and transitional challenges.

"Brands in Creative Processes"

Catia Carvalheiro Alves, Nova School of Business and Economics, Portugal
Irene Consiglio, Nova School of Business and Economics, Portugal
Luis Martinez, Nova School of Business and Economics, Portugal

I propose that brand preferences affect creative performance as well as accuracy of self-reported creativity. Professional creatives and consumers produce more creative work when they work for brands they like (vs. dislike). Also I observe a brand preference bias on successful forecasting of their own creative work.

Using Consumer Neuroscience to Explain Product Choice From Experience

Oriana Rachel Aragón, Clemson University, USA

Academics and practitioners increasingly are expending valuable resources studying consumer behavior through neuromarketing. Electroencephalogram (EEG) investigations have thus far gauged consumers' preferences for presented products. This is the first EEG investigation (N=135) to successfully capture consumers' nonproduct-related internal states to predict consumers' product choices made moments after EEG data collection.

Perceived Age of a Name: Adopting Age-based Names in Over-the-Top Media Content

Sunny Arora, S P Jain Institute of Management and Research, Mumbai, India
M. G. Parameswaran, S P Jain Institute of Management and Research, India
Unnati Dogra, Sardar Patel Institute of Technology,Mumbai, India
Sarah Hawa, Sardar Patel Institute of Technology,Mumbai, India

With media content exploding there is a need for character names befitting to their age. Names from the Indian voters' list and over-the-top media were analyzed using sound symbolism. When vowel and consonant sounds are of consistent frequency names with high-frequency sounds are perceived younger than names with low-frequency sounds.

Curious Abstraction: How Message Abstraction and Financial Scarcity Affect Processing of Mortgage Ads

Esra Asif, University of Leeds, UK
J. Josko Brakus, University of Leeds, UK
Alessandro Biraglia, University of Leeds, UK

Buying a house is one of the most important decisions consumers make in their lifetime weighing reality (e.g. their financial resources) against imagination (e.g. owning a mansion). We show that abundant - opposed to scarce - mindsets trigger consumer's curiosity when exposed to an abstract (vs. concrete) mortgage advertising frame.

Soul Inside the Machine: Product Morphology Influences Consumer Valuation

Sumitra Auschaitrakul, University of the Thai Chamber of Commerce, Thailand
Dan King, University of Texas Rio Grande Valley, USA

Many products such as luxury wristwatches have a "creviced morphology" with a crevice bored into the product structure. We demonstrate the "crevice effect" in which products with a crevice (versus without) elicit a higher valuation underpinned by increased perceptions of a high level of materialized expression.

Experiences as Ends (versus Means) Bring More Happiness and Meaning

Hankyul Bae, University of Minnesota, USA
Kathleen Vohs, University of Minnesota, USA

We tested whether pursuing an experience for intrinsic reasons (ends approach) versus extrinsic reasons (means approach) would differently affect consumer well-being. Two experiments revealed that people report more happiness and meaning when they think about their experiences as ends versus means to another end.

Better With Diverse Contexts? The Effects of Contextual Diversity of Background on Consumption Imagery

Eunsoo Baek, Hong Kong Polytechic University, China
Zhihong Huang, Hong Kong Polytechic University, China

The study explored the effect of contextual diversity of background images on consumption imagery with a moderating effect of processing style. Results showed that a multiple (v.s. a single and none) contextual background generated consumption imagery of a product for holistic (v.s. analytic) processors leading to positive product evaluation.

A Good Cry or A Gratifying Revenge? Desired Mixed Emotional Experience in Movie Consumption Across Cultures

Aaron J. Barnes, University of Louisville, USA
Jie(Doreen) Shen, University of Illinois at Urbana-Champaign, USA
Jennifer L Stoner, University of North Dakota, USA
Carlos Torelli, University of Illinois at Urbana-Champaign, USA

Prior research suggests that content with mixed emotions appeals to collectivists but not individualists. In contrast the current research suggests that both individualists and collectivists desire movies with mixed emotional themes as long as the mixed emotions align with their cultural values.

Can't See You! The Effect of Packaging on Calorie Perceptions

Sara Baskentli, Western Washington University, USA
Tracy Rank-Christman, University of Wisconsin - Milwaukee, USA

This research investigates how packaging material impacts consumers' perceptions of calories. Results from two studies show that packaging material has an impact on consumers' caloric perceptions. The authors suggest that the material of package impacts calorie perceptions which in turn could have implications on product consumption.

Augmented Reality Effects on Attitude and Memory

Juliana M. Batista, EAESP-FGV, Brazil
Annaysa Salvador Muniz Kamiya, Centro Universitário FEI, Brazil
Delane Botelho, EAESP-FGV, Brazil

Little is known about the underlying mechanisms on the effect of augmented reality (AR) on consumer´s attitude and memory. In two experiments we demonstrate that positive attitude toward the brand increases and memory recall decreases when consumers are exposed to AR. Perception of media´s innovation and entertainment mediate such effect.

Understanding Recovery From Compulsive Consumption With Practice Theory

Larissa Carine Braz Becker, University of Turku, Finland
Melissa Archpru Akaka, University of Denver, USA
Hope Schau, University of Arizona, USA
Elina Jaakkola, University of Turku, Finland

This paper analyzes how consumers reconfigure a system of practices during recovery from compulsive consumption. A study with recovering alcoholics reveals how consumers disengage from non-supportive practices and how new practices relate to each other. These findings contribute to the literature by using a sociological perspective to study behavioral change.

Making Home Away From the Established Models of Ownership:
Preliminary Findings From a Housing Cooperative

Ons Belaid, IAE Lyon, France
Mariam Beruchashvili, California State University Northridge, USA
Sonia Cappelli, University of Lyon, France
William Sabadie, University Jean Moulin Lyon 3, France

Based on an ethnographic study conducted in the context of a large cooperative house located near the metropolitan area in France where residents practice consciously elected collective cohabitation we examine how consumers make home (Douglas 1991) in a physical space of a house deliberately devoid of conventional forms of ownership.

Digital Platforms and Market Intermediation

Kristin Bentsen, University of South-Eastern of Norway
Eileen Fischer, York University, Canada
Per Egil Pedersen, University of South-Eastern of Norway

This paper explores how market intermediation may be affected when market actors rely on digital platforms. It draws on participant observation conducted in "REKO" markets in which transactions and interactions are primarily conducted via groups organized on Facebook. The paper identifies four actor/platform intersections that may profoundly shape intermediation.

Another Advertising Stereotype: Effects of Non-Stereotyped
Portrayals of Older Women in Advertising

Hanna Berg, Stockholm School of Economics, Sweden
Karina T. Liljedal, Stockholm School of Economics, Sweden

This paper examines the effects of featuring non-stereotyped portrayals of older women in advertisements. In two empirical studies we demonstrate positive ad effects of using non-stereotyped portrayals of older models for female consumers. Furthermore these effects are explained with signaling theory and the social effects of advertising.

Commitment Contracts: The Effect of Commitment-Based
Pricing on Customer Acquisition and Retention

Katja Berger, University of Hamburg, Germany
Klaus Wertenbroch, INSEAD, Singapore
Christina Schamp, University of Mannheim, Germany

Nowadays an increasing number of firms incorporate commitment into their pricing schemes and business models. Our research shows how to design and present commitment-based pricing optimally to acquire and establish long-term relationships with customers.

Feeling Pressured to Disclose Personal Information? Understanding The
Role of Social Pressure on Consumers' Information Disclosure Intention

Alena Bermes, Heinrich Heine University Düsseldorf, Germany
Maximilian Alexander Hartmann, Heinrich Heine University Düsseldorf, Germany
Peter Kenning, Heinrich Heine University Düsseldorf, Germany

This research examines if consumers feel social pressure to disclose personal information for mobile application usage. Grounded in the theory of self-determination the results prove that social pressure (being of multifaceted structure including fear of missing out subjective norms and image) is positively related to information disclosure intention.

Stop It! Consumer Resilience as a Buffer Against Psychological Conflicts in the Digital Age

Alena Bermes, Heinrich Heine University Düsseldorf, Germany
Nikita Maleev, Heinrich Heine University Düsseldorf, Germany
Peter Kenning, Heinrich Heine University Düsseldorf, Germany

Drawing on psychological resilience theory this research is the first to define conceptualize and test the phenomenon of consumer resilience against the background of today's digital environment which confronts consumers with rising psychological conflicts (e.g. fear of missing out). The preliminary results proof consumer resilience's buffering effect against such stressors.

Dimensions of Believability of Brand News: An Exploratory Study

Kshitij Bhoumik, Texas Tech University, USA

This research explores the factors that shape consumer believability toward brand news on digital platforms. What are the cues consumers look to evaluate the authenticity of any brand communication? What kind of brand message is considered as highly believable? We identified eight dimensions that shape consumers' perception of brand news.

Sequential Sensory Cues in Retailing and Food Packaging: Managerial and Ethical Implications

Dipayan Biswas, University of South Florida, USA
Lauren I Labrecque, University of Rhode Island, USA
Donald Lehmann, Columbia University, USA

Sensory cues are often encountered sequentially (than simultaneously) in many retailing food packaging and consumption contexts. A series of experiments demonstrate how the sequence in which sensory cues are encountered might influence food taste perceptions food choices and consumption volume.

It's Written All Over Your Face—Applying Deep Neural Networks to Explain Human Mating Based on Facial Characteristics

Daniel Boller, University of St. Gallen, Switzerland

This research investigates human mating in online dating markets based on facial characteristics by utilizing high-dimensional profile section transaction and facial image data of 640000 users of an online dating platform. The results of this research assist software developers and marketing practitioners in designing algorithms for human matching.

Counterfeit Consumption Eliciting Group-Based Emotions

Delane Botelho, EAESP-FGV, Brazil
Fernando A. Fleury, EAESP-FGV, Brazil
Ramona de Luca, EAESP-FGV, Brazil

This paper investigates positive and negative emotions as consequences of the consumption of counterfeits in the context of soccer supporters. Specifically the perceived personal in-group responsibility for consuming counterfeits leads to negative affect (e.g. guilt and anger) while the responsibility for consuming original products leads to positive affects (e.g. pride).

A Contingency Theory of Artificial Intelligence: Consumer Beliefs, Value Creation, And Resistance to Creative AI

Anna Bouwer, University of St. Gallen, Switzerland
Christian Hildebrand, University of St. Gallen, Switzerland

This paper examines the unexplored role of 'creative AI' by studying the perception of machine-generated 'creative output'. It provides conceptual foundations on the notion of creative AI and demonstrate the consumer associations with AI along with the downstream consequences of creative AI for consumers' perception of aesthetic quality and valuation.

"'Sweet, Tasty Evil' Or 'Healthy Bliss'? Lay Theories On Food Products For Children"

Raphaela Elisabeth Bruckdorfer, University of Duisburg-Essen, Germany
Oliver B. Büttner, University of Duisburg-Essen, Germany
Gunnar Mau, Deutsche Hochschule für Gesundheit und Sport (DHGS), Germany

Based on qualitative and quantitative data we developed an instrument to assess consumers' lay theories on child food products. In line with experts lays expected such products to contain high amounts of fat sugar and calories but at the same time perceived them as being moderately healthy and rather useful.

Unveiling the Color Matching Effect in Product Displays

Daniel Erik Brylla, Friedrich Schiller University Jena, Germany
Gianfranco Walsh, Friedrich Schiller University Jena, Germany

Consumer researchers have long been interested in explaining the effects of individual and combined colors on consumer perceptions and behaviors. Across four studies the authors show that product colors that match a moderate amount of colors in the shopping environment increase consumers' aesthetic perception and purchase intentions.

Uninformed But Unaware: How the Number of Likes Triggers a Knowledge Illusion on Social Media

Andrea Bublitz, University of Zurich, Switzerland
Anne Scherer, University of Zurich, Switzerland
René Algesheimer, University of Zurich, Switzerland

Drawing from theory on the group mind this research uncovers how likes on social media trigger a knowledge illusion: If individuals are not motivated or able to read but content received many likes they rely on external knowledge in the group mind and feel better informed than they objectively are.

How Can We Make Fat Women Feel Miserable?

Ana Julia Büttner, ESPM, Brazil
Suzane Strehlau, ESPM, Brazil

The objective is to comprehend how plus-size women find well-being through fashion inside the symbolic violence. The qualitative method used semi-structured interviews using photo-elicitation reveals that fatshionistas play with fashion rules and present well-being. Although at the same time they reveal a subordination to the cult of thinness.

The Visual Impaired Tourist: Facilitators and Inhibitors in Choosing Tourist Destinations

Aline Delmanto Capone, ESPM, Brazil
Vivian Iara Strehlau, ESPM, Brazil

This paper aims to understand what factors influence leisure travel destination choice for the visually impaired. A qualitative approach using in-depth interviews with three different groups preliminarily found that acquired blinds have more constraints than congenital or low vision. The origin of blindness affects their well-being and how they travel.

The Exquisite Exotic: Revalorization of Culinary Ingredients and Traditional Food Practices in the Global Marketplace

Flavia Cardoso, Universidad Adolfo Ibáñez, Santiago, Chile
Angela Gracia B. Cruz, Monash University, Australia
Pilar Ximena Rojas Gaviria, University of Birmingham, UK

This theoretical piece offers an integrative framework to theorize how marketing actors invest and participate in the international re-signification of culinary ingredients and food practices. It goes beyond localized case studies synthesizing the current theorizations on the internationalization of food and charts an agenda for future research.

Chatbots an Exploratory Analysis on the Impact of NLP and Customer Sentiment Analysis

Lilian Carvalho, FGV/EAESP, Brazil
Eusebio Scornavacca, University of Baltimore, USA

We partnered with a startup that uses NLP (natural language processing) to assist different firms to set up their virtual assistants. We analysed 4320 interactions and found that chatbot-human interaction had a better score than human-to-human interactions.

Let Me Split the Donation, I Will Donate More: How Installment Payment Reduces Perceived Cost and Increases Willingness to Donate.

Marta Caserotti, University of Padova, Italy
Enrico Rubaltelli, University of Padova, Italy
Paul Slovic, University of Oregon, USA

Do people prefer a donation split into several instalments or a lump sum? Do they prefer to pay now or later? Four experiments (and a pretest) investigated how payments options and intertemporal choice affect donations. We found that the opportunity of giving through instalments increased donations decreasing the perceived cost.

A Reimagining: Prefiguring Systems of Alternative Consumption

Katherine Casey, University of Kent, UK
Maria Lichrou, University of Limerick, Ireland
Lisa O'Malley, University of Limerick, Ireland

This ethnographic research reveals how an ecovillage prefigures consumption via a repertoire of alternative consumption and production systems designed to challenge neoliberal notions of choice value and ownership; explores how community members participate in broader changemaking and how the community engages the broader institutional framework to further environmental education.

Understanding Overconsumption – Symbolic and Spatial Transgressions in Public Places

Cecilia Cassinger, Lund University, Sweden
Jörgen Eksell, Lund University, Sweden

Overconsumption refers to harmful or excessive consumption. This study demonstrates how experiences of overconsumption are constructed in transgressions of boundaries within places. Results are supported by a study of citizens' experiences of tourism-consumption in touristified cities. They underscore the importance of considering experiences of overconsumption practices for sustainable consumption.

Causa Sui (Cause of Itself): How Self-benefit Appeal Framing Interacts With Situational and Dispositional as Donation Cause-types

Chia-Chi Chang, National Chiao Tung University, Taiwan
Joseph Iesue, National Chiao Tung University, Taiwan
Chia Hua Lin, National Chiao Tung University, Taiwan

Research provides insight on charitable giving by testing the interaction between donation cause-types (situational vs. dispositional) and self-benefit appeals ('karma' - intentional but dependent 'feel-good' - intentional and independent 'humanity' - unintentional). Results show 'karma' appeal elicits higher donations for situational causes with 'feel-good' and 'humanity' appeals benefiting dispositional causes.

Social Influence and Personalization in Behavioral Retargeting Advertising

Yaping Chang, Huazhong University of Science and Technology, China
Shaowei Chai, Huazhong University of Science and Technology, China
Jun Yan, Huazhong University of Science and Technology, China

Through a serial of field experiments on Facebook this research examined the impacts of social and personalized messages in retargeting advertising on customer responses. Results indicate geographic proximity is more effective than number of likers on social media. Personalized message works negatively. Product knowledge works as a moderates.

How Social Functioning Ability and Crowdedness Impact Consumer Behavior

Shiyun Chen, University of Iowa, USA
Gary Gaeth, University of Iowa, USA
Irwin Levin, University of Iowa, USA

In the current research we investigate the impact of social functioning on consumers under varying levels of social crowdedness. Our finding suggests that people with lower social functioning abilities feel less comfortable more anxious and dislike the more crowded environment compared to people with higher social functioning abilities.

Securing Non-Touristy Shops-- Claiming Local Collective Identities in Political Consumption Against Inbound Tourists' Shopping Spree

Wei-Fen Chen, University of Leicester, UK
Tin-yuet Ting, The Hong Kong Polytechnic University, China

Departing from behavioral perspectives that examine how consumers' political consumption relates to personal characteristics this study investigates how collective identities of local consumers are shaped in response to overwhelming inbound shopping tourism informing the contemporary practices of citizen consumers and manifesting a novel approach to understand political consumption.

Utilizing Matte Packaging to Communicate Social Warmth

Yu-Shan Athena Chen, Eindhoven University of Technology, The Netherlands
Wei-Ken Hung, National United University, Taiwan

Two studies demonstrate that matte packaging conveys haptic information in the same manner as interpersonal touch (Study 1); and matte packaging is preferred over glossy packaging when people have a goal to reduce coldness (Study 2). Together these results suggest that matte packaging is instrumental in communicating warmth.

Waiting For A Download: The Effects of Congruency Between Anthropomorphic Cues and Shopping Motivation on Consumer Patience

Siyun Chen, Jinan University, China
Xinliang Wei, Temple University, USA

People tend to be impatient while waiting for a webpage to download which might be negatively correlated with their satisfaction with the online providers. In particular we propose a new framework of how the congruence of anthropomorphic messengers and shopping motivation enhances patience (i.e. perceived quickness of a download).

What to Buy When the American Dream Fails? Understanding the Taste of Downwardly Mobile Consumers

Wei-Fen Chen, University of Leicester, UK
Xue Wang, Chinese University of Hong Kong, China
Ying-yi Hong, Chinese University of Hong Kong, China

This study examines how consumer behaviors are influenced by upward and downward economic mobility. Findings indicate that facing downward mobility consumers lessen the economic components in their self-identities and thus are less interested in purchasing products framed in advertisements that appeal to economic capital compared to their upwardly mobile counterparts.

The Effect of Identical or Distinct Service Failure Recovery on Customer Satisfaction

Yin-Hui Cheng, National Taichung University of Education, Taiwan
Shih-Chieh Chuang, National Chung Cheng University, Taiwan
Ya-Ju Shen, National Chung Cheng University, Taiwan

This paper study showed that providing the same type of service is worse than providing a different service in terms of customer satisfaction. Two boundary conditions were examined in which the severity of the failure and consumer participation mitigate the effect of identical/distinct service recovery on customer satisfaction.

I Can Be Perfect! Growth Mindset Moderates the Effect of Perfectionism on Maladaptive Eating Behaviour

Jennifer Chernishenko, University of Lethbridge, Canada
Rhiannon MacDonnell Mesler, University of Lethbridge, Canada
Debra Z Basil, University of Lethbridge, Canada

To clarify the link between perfectionism and eating behaviors we proposed that implicit mindset would moderate the relationship between perfectionism and maladaptive eating behaviour. Whereas a growth mindset increased use of dieting strategies and consequently maladaptive eating behavior fixed mindset reduced this effect. Implications for research and practice are discussed.

When Technology Environment is More Indulging: Impact of Accessibility to Technology-Equipped Environment on Self-Control Behaviors

Yunjia Chi, Huazhong Agricultural University, China
Fue Zeng, Wuhan University, China
Li Huang, Hofstra University, USA

The mere perception of accessibility to technology-equipped environment without actually using technologies triggers consumers' effort conservation intention which results in lapses of self-control.

The Effects of Majority/Minority Source Status and Argument Quality of Online Reviews on Product Perceptions: The Moderating Role of Product Type

Yi-Wen Chien, National Taiwan University, Taiwan
Shian-Ko Liu, National Taiwan University, Taiwan

This study posits that for different products (search vs. experience goods) source status and review quality may have different impacts. Experience goods rely more on source status whereas search goods rely more on review quality. Marketers are suggested to develop effective promotion strategies based on product type.

Strong As An Ox: Usage Of Storytelling By Vegan Athletes To Reduce Consumers' Meat-Health Associations

Ziad Choueiki, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium
Iris Vermeir, Ghent University, Belgium
Adriaan Spruyt, Ghent University, Belgium

This paper explores the implicit/explicit association between meat consumption and health. We propose that storytelling by vegan athletes (whose personal experiences challenge the prejudice of veganism being an inadequate diet) can help reducing both consumers' implicit meat-health association and the explicit belief that meat is necessary normal natural and nice

Friendship Alleviates Sense of Regret

JungHan Chung, Sogang University, South Korea
Young-Won Ha, Sogang University, South Korea

The authors investigated whether psychological relatedness affects consumers' sense of regret in consumption failure settings. Through three experiments the authors demonstrated that close relationship can alleviate sense of regret and this friendship effect was mediated by locus of causality and was moderated by individuals' level of subjective well-being.

The Making of Healthy, Wealthy, and Happy Consumers: Practices and Politics of Nudging in For-Profit Firms

Leonardo Conte, Università della Svizzera italiana, Switzerland
Lena Pellandini-Simanyi, Università della Svizzera italiana, Switzerland

This paper extends research in Consumer Culture Theory on the making of the consumer subject by examining (1) the performative role of nudging practices in businesses (2) their underlying normative visions and (3) the concrete processes through which they shape consumers within the Foucauldian framework of neoliberal governmentality.

Life Transition to Terminality: Dynamic Regimes of Representation, Permanent Liminality, and Coping Consumption

Michele Corengia, Università della Svizzera italiana, Switzerland
Luca M. Visconti, Università della Svizzera italiana, Switzerland

Through the lenses of representation theory this (n)ethnographic research contributes to literature on consumer permanent liminality and coping consumption. Unpacking life and market transition of patients to terminality accounts for how they use representational agency and consumption to counterbalance etic representational regimes and the tensions arising from their liminal experience.

Salience Over Centrality? How Environmental Identity Drives Pro-Environmental Consumption

Sandor Czellar, HEC Lausanne, Switzerland
Leila Rahmani, HEC Lausanne, Switzerland
Simona Haasova, University of Lausanne, Switzerland
Valentina Clergue, HEC Lausanne, Switzerland
Christian Martin, National University of Ireland Maynooth, Ireland

We investigate the relationships between environmental identity centrality its salience and pro-environmental behavior. Five studies reveal a distinct influence of environmental identity salience and centrality but no interaction between the two on several types of self-reports and actual behaviors. Our findings bear implications for research aiming to promote pro-environmental consumption.

A Permanently Loose End: Constructing the Intersectional Identity of British South Asians

Ofer Dekel Dach, De Montfort University, UK
Amandeep Takhar, De Montfort University, Leicester, UK

Moving away from dominant acculturation models this research study draws on intersectional theory to better understand how individuals from the British South Asian community in the U.K. respond to social complexity and engage in identity construction. Our findings present a picture of the way participants mix and juxtapose identity categories.

Leaving the Field: Problematizing Temporality in and of Ethnographic Consumer Research

Christian Dam, University of Gothenburg, Sweden
Mathias Sosnowski Krabbe, University of Southern Denmark, Denmark

This paper argues that the temporality of ethnographic consumer research is inadequately illuminated which prevents the conceptualization of exiting the field. Thus a stronger focus on the various methodological and ethical aspects of exiting the field is needed particularly due to the changing notions of what constitutes the field.

Group Buying of Experiential (vs. Material) Purchases

Gopal Das, Indian Institute of Management Bangalore, India
James Agarwal, University of Calgary, Canada
Mark T Spence, Bond University, Australia

This research examines how experiential vs. material purchases influence consumer preference for group buying (vs. individual buying). Specifically consumers while purchasing experiential (vs. material) goods anticipate more enjoyment which in turn results in higher intent to participate in group buying behavior. These effects hold for interdependent (vs. independent) self-construal.

Marketing's Role in Promoting Common Good: A Systematic Examination and an Agenda For Future Inquiry

Benét DeBerry-Spence, University of Illinois at Chicago, USA
Lez Ecima Trujillo Torres, University of Illinois at Chicago, USA
Rumela Sengupta, University of Illinois at Chicago, USA
Jia Chen, University of Illinois at Chicago, USA
Kohei Matsumoto, University of Illinois at Chicago, USA

We examine the role marketing has played in promoting the 'common-good' by conducting a systematic multi-method multi-journal inquiry. Marketing consistently contributes to a dialogue of common-good by publishing impactful articles in areas like health and CSR. Opportunity exists for greater contributions to important areas such as gender-empowerment and education.

Does Alphago's Victory Over Human Champions Reduce The Interest Of People In Go? The Negative Effect Of Artificial Intelligence On Competition Events

Zhongzhun Deng, Huazhong University of Science & Technology, China
Donghong Zhu, Huazhong University of Science & Technology, China

Four studies (N=1214) confirm that how and why losing to robots (vs human) negatively affected consumer attitude toward these events. We contribute to the literature on Robot AI and goal theory from another perspective. In addition research help companies and governments to avoid negative effects when advertising robots.

Sacrificing Pleasure For Status. Which Customers Are Attracted by Healthy Luxury Goods?

Perrine Desmichel, Northwestern University, USA
Goedele Krekels, IÉSEG School of Management, France

Luxury brands have recently entered the market of healthy products although healthy benefits can reduce the hedonic benefits of luxury consumption. Across two preliminary studies we propose and show that consumers who did not earn (vs. earned) their wealth present stronger desire for healthy (vs. non-healthy) luxury goods.

Atemporal Nostalgia as Artefact in Post-Colonial Non-Western Context

Amina Djedidi, Université Paris-Est Créteil, IRG, France
Nacima Ourahmoune, Kedge Business School, France

Often pictured as a passive longing for the past this paper conceives nostalgia as atemporal: it creates states and spaces where time is reconfigured to reach selective accounts of bridges between the past present and future. Nostalgia atemporality sutures complex and heterogeneous sociocultural references in Post-Colonial Non-Western context Algeria

Keeping Track of What's Deserved When Personal Finances Grow

David Dolifka, University of California Los Angeles, USA
Stephen A Spiller, University of California Los Angeles, USA

All financial growth first requires principal to invest. In this project we explore the relationship between the perceived deservingness of both principal and downstream growth. Initial studies suggest consumers downplay whether or not their principal was deserved when judging the deservingness of subsequent financial growth.

Does a Flaw Outweigh a Flaw? The Bright Side of Negative Comments in Online Product Reviews

Shen Duan, Renmin University of China, China

The research find that two-sided information reviews are more persuasive to consumers than one-sided information reviews and the importance proportion and position of negative information play a moderating role in this relationship. This study enriches the relevant research on the impact of online reviews on consumer product purchases.

Recovering Cultural Authority: Marketplace Abandonment and Return

Toni Eagar, Australian National University, Australia
Andrew Lindridge, Newcastle University, UK
Diane Martin, RMIT University, Australia

This project investigates how a brand can recover its former position in a marketplace after losing legitimacy. We apply a process data approach to qualitatively analyse 614 media reports and 31 interviews. We extend the brand longevity concept and reveal brand recovery as a process involving return dormancy and resurrection.

Goal Conflict Undermines Self-Continuity and Leads to Greater Preference For Renting Vs. Buying

Mahdi Ebrahimi, California State University Fullerton, USA
Anoosha Izadi, University of Massachusetts, USA

The present research identifies a novel antecedent for consumer renting behavior. We propose that consumers who experience goal conflict are more likely to rent vs. buy a product or service. We also show that the effect is mediated by lower perceptions of future self-continuity.

The "Common Good" Phenomenon in Country of Origin Effects

Martin Egger, University of Vienna, Austria
Arnd Florack, University of Vienna, Austria
Adamantios Diamantopoulos, University of Vienna, Austria
Georgios Halkias, University of Vienna, Austria

The "common good" phenomenon describes that products share positive attributes but are distinguished according to negative attributes. In three studies we demonstrate that this phenomenon applies to products from different product categories and countries and show that it decreases the differentiating power of favorable country of origin labels.

Coopetition and Creativity in Idea Crowdsourcing: Investigating the Mediating Role of Emotional and Motivational Ambivalences

Mehdi Elmoukhliss, TSM Research, France

We investigate why coopetition-based idea crowdsourcing has a positive effect on consumers' creativity. We study two potential mediators: emotional ambivalence and motivational ambivalence. We found a significant indirect effect of motivational ambivalence. We contribute to the consumer research literature by introducing coopetition as a new model for engaging creative consumers.

The Effects of Mindfulness on Healthy Food Choice in Childhood Socioeconomic Groups

Amy Errmann, University of Auckland, New Zealand
Yuri Seo, University of Auckland, New Zealand
Felix Septianto, University of Auckland, New Zealand

The effects of mindfulness on healthy food selection is receiving attention in academia and practice. The current research examines which childhood socioeconomic groups benefit the most from mindfulness as it pertains to food choice. We propose that mindfulness provokes low childhood socioeconomic groups to make healthier food choices.

Risk on the Edge: The Effect of Socio-spatial Location on Consumer Preferences

Sina Esteky, Miami University, Ohio, USA
Amar Cheema, University of Virginia, USA

This paper explores how the relative spatial location of consumers in a group affects consumer preferences. We find that being located close to the center versus edge of a group primes the concepts of safety versus risk respectively. As a result being farther away from the center heightens risk-seeking.

How the Different Wordings of Message in Pop-Up Window Affect Consumers' Behavior?

Yafeng Fan, Tsinghua University, China
Jing Jiang, Renmin University of China, China

This research classifies the message wording approaches in pop-up windows into "guilt appeal" "delaying appeal" and the "no appeal" and examine how the different wording affect consumers' behavior. Compared with not using any appeal "guilt appeal" and "delaying appeal" in pop-up windows can promote consumers' retention rate and customer satisfaction.

When Social Media Word-of-mouth Catches Envious Eyes: How Feelings of Being Envied Influence Self-brand Connection

Wenting Feng, Hainan University, China
Irina Y. Yu, Chinese University of Hong Kong, China
Morgan X. Yang, The Hang Seng University of Hong Kong, China

We examined the ambivalent impacts of being envied experiences triggered by sharing luxury consumption on social media. Results from three experiments show that feeling being maliciously (benignly) envied decreases (increases) self-brand connection mediated by anxiety (pride). The effects are more salient when consumers interact with peers with lower social-distance.

Give Me the Fish Vs. Teach Me How to Fish: The Effect of Socioeconomic Status on Recipients' Willingness to Accept Help

Maura Ferreira, Catholic University of Rio Grande do Sul, Brazil
Erick M. Mas, Vanderbilt University, USA
Kelly Goldsmith, Vanderbilt University, USA

This research investigates an overlooked side of prosocial behavior the recipient's willingness to accept help. We show that recipients' socioeconomic status can decrease and increase willingness to accept low-order (money/food) and high-order (scholarships) help as these types of help can represent both self-threat and self-support depending on recipients' socioeconomic status.

Mitigating Uncertainty in Consumer Adoption of Medical Artificial Intelligence

Darius-Aurel Frank, Aarhus University, France
Polymeros Chrysochou, Aarhus University, Denmark
Panagiotis Mitkidis, Aarhus University, Denmark
Dan Ariely, Duke University, USA

This pre-registered study investigates the potential of explicit uncertainty quantification information in mitigating consumers' reluctance to trust and depend on recommendations by medical artificial intelligence agents' in decision scenarios characterized by uncertainty.

Brand Familiarity Shows in Consumers' Eyes

Léon Franzen, Concordia University, Canada
Amanda Cabugao, Concordia University, Canada
Aaron P. Johnson, Concordia University, Canada
H. Onur Bodur, Concordia University, Canada
Bianca Grohmann, Concordia University, Canada

Although brand familiarity has been linked to product recognition speed and prior experience the objective measurement of consumers' brand familiarity remains challenging. We integrated an extensive product image validation study with novel pupillary response measurements to demonstrate reliable dissociation of familiar and unfamiliar brands without an overt response.

What Makes Services Luxurious? Insights From a Qualitative Study

Martin P Fritze, University of Cologne, Germany
Jochen Wirtz, National University of Singapore, Singapore
Jonas Holmqvist, Kedge Business School, France

We address the research question 'What constitutes a luxury service experience'? and report results from exploratory interviews conducted with luxury service consumers to understand how they perceive differences between luxury and non-luxury services. Our results reveal key luxury perception dimensions in the search decision consumption and post-consumption states.

Re-imagining Subcultures: A Comparative Study of Generational Preconceptions of Music Consumption, Identity, and Belonging

Olivia Fulvio-Mason, University of Gloucestershire, UK
Richard Warr, University of Gloucestershire, UK

As the existence of subcultures within today's youth culture have begun to be questioned this study focuses on changes surrounding music consumption that have occurred between Millennials and their parent generations. Aims include the exploration of youth subcultures musical identity and the transformation of generational preconceptions towards popular music consumption.

Seeing Through Your Eyes: The Influence of Interface on Advertisement Processing

Lin Ge, Chinese University of Hong Kong, China
Hao Shen, Chinese University of Hong Kong, China

Consumers are more likely to take a first-person perspective while viewing advertisements on a smartphone than on a personal computer. Consequently they might react more favorably to an ad with content generated from the first-person perspective if they view it on a smartphone (vs. a PC).

Mixed Emotions Inspire Missions (Im)possible – The Role of Emotions in Setting and Achieving High Aspirations

Jana-Verena Gerhart, Johannes Gutenberg University Mainz, Germany
Oliver Emrich, Johannes Gutenberg-University of Mainz, Germany
Michael Norton, Harvard Business School, USA
Jordi Quoidbach, ESADE Business School, Spain
Ann-Kathrin Haderdauer, Johannes Gutenberg University (graduate), Germany

A longitudinal study of New Year's Resolutions examines the effect of emotional states on goal setting and goal attainment. Participants (N=1004) assigned to experience mixed emotions when setting goals increased their aspiration levels more than those assigned to experience positive emotions. Higher aspirations in turn predicted resulting change.

How Incongruent Products Drive Brand Engagement: The Role of Curiosity

Maximilian H. E. E. Gerrath, University of Leeds, UK
Alessandro Biraglia, University of Leeds, UK

Brands seek new ways to engage consumers on social media. For example McDonald's recently generated buzz by announcing an incongruent product—Big Mac scented candles. Across three experiments we examine the link between (low vs. high) congruence and brand engagement. Moreover we identify curiosity as a driver of this effect.

You Don't Need To Be Me To Win My Heart: The Impact of Cognitive Appeals on Empathy In Pro-Social Behaviors

Mahsa Ghaffari, university of Portsmouth,UK
Giovanni Pino, University of Chieti-Pescara, Italy
Daniel Nunan, University of Portsmouth, UK

Despite the widespread conviction that empathy and congruency between self and the target increase pro-social behaviours this research underscore the importance of marketing communication techniques in boosting altruistic behaviour when the self and target are incongruent.

The Effect of Warmth and Competence Perceptions on Algorithm Preferences

Zohar Gilad, Technion University, Israel
Liat Levontin, Technion University, Israel
Ofra Amir, Technion University, Israel

Perceptions of warmth (intent) and competence (ability) strongly affect people's judgment of individuals groups and organizations. We find that surprisingly not only competence perceptions affect people's preferences for artificial intelligence algorithms. Moreover similarly to the judgments of other people warmth perceptions tend to have a stronger effect on preferences.

Which Autonomous Vehicle (AV) Will be More Pro-Social? The One You Own or Rent.

Tripat Gill, Wilfrid Laurier University, Canada

Recent research reveals that consumers expect AVs to be less pro-social than regular car drivers. Current work examined how ownership would impact the latter moral shift. It was found that owned AVs are expected to be more pro-social than the ones that are rented due to self-extension into the AV.

With God on My Side, I Have No Fear of Ultra-processed Foods and Lack of Exercise

Ali Gohary, Monash University, Australia
Hean Tat Keh, Monash University, Australia
Eugene Chan, Monash University, Australia

This research investigates the impact of God salience on consumers' food choice and physical inactivity. Three studies (secondary data chronic and primed God salience) show that God reminders lead consumers to exhibit greater willingness to choose ultra-processed (vs. unprocessed) food products and being more physically inactive.

When Recycling Seems Risky: Are Consumers Afraid to Recycle Sensitive Information?

Gabriel E. Gonzales, SUNY New Paltz, USA
Matthew D. Meng, Utah State University, USA
Christopher Berry, Colorado State University, USA
R. Bret Leary, University of Nevada, Reno, USA

The current research proposes that consumers are uncomfortable recycling items containing private information (e.g. "junk" mail bank statements etc.) despite seeing such items as recyclable. Two initial studies provide evidence for this effect suggesting a potentially untapped source of highly-recyclable material while generating insights for both scholars and practitioners.

Behavioral Option Value and Product Set Choice

Paniz Gorji, Erasmus University Rotterdam, The Netherlands
Benedict Dellaert, Erasmus University Rotterdam, The Netherlands
Bas Donkers, Erasmus University Rotterdam, The Netherlands

We propose a behavioral theory of consumers' option value for sets from which they consume a product in the future. For example consumers may choose between health insurance networks from which they select a provider for treatment later. Results from two experiments support our hypotheses and illustrate the proposed approach.

The Injustice of Envy

R Justin Goss, Colorado State University-Pueblo, USA

This research investigates the impact that status hierarchies within brand communities have on the occurrence of Envy. I examine the antecedents and consequences of Malicious and Benign Envy. Specific attention is paid to Deservingness. Findings show that Deservingness affects feelings of both Malicious and Benign Envy. Implications are discussed.

Consumer Deceleration Through Cultural Borrowing and Critical Reflection

Sarah Grace, University of Arkansas, USA

This research extends previous findings on consumer deceleration by exploring how cultural borrowing facilitated through marketing activities in a globally connected consumer culture can provoke critical reflection. The findings of this study empirically ground a theoretical process that marketers can use to constructively engage in the phenomenon of social acceleration.

Is That Brand Relevant to Me? Concept, Measurement and Antecedents of Brand Relevance

Amélie Guèvremont, École des Sciences de la Gestion, UQAM, Canada
Fabien Durif, École des Sciences de la Gestion, Université du Québec à Montréal, Canada
Cindy Grappe, Écoles des Sciences de la Gestion, Université du Québec à Montréal, Canada

This research explores the meaning of brand relevance according to consumers and its creation from a branding perspective. Across four studies it defines brand relevance and its dimensions (utilitarian/symbolic/social/environmental) develops a measurement scale identifies brand relevance's antecedents and validates them through an in-depth analysis of relevant brands' social media content.

Investigating the Effects of Uncertainty Avoidance on Customer Loyalty Intention

Bingxuan Guo, University of Texas at San Antonio, USA
Karen Page Winterich, Pennsylvania State University, USA
Yinlong Zhang, University of Texas at San Antonio, USA

This research explores how cultural orientation of uncertainty avoidance affects customer loyalty intention. Secondary country level data and primary individual level experiment provide convergent evidence showing a negative effect of uncertainty avoidance on customer loyalty intention and this effect is mitigated by desire to change and need for structure.

Social Class and Risk Taking: The Effects of Perceived Benefits and Decision Domain

Yafei Guo, University of Illinois at Urbana-Champaign, USA
Xue Wang, University of Hong Kong, China

The present paper is the first to systematically examine the class-related differences in consumer risk-taking behavior. It proposes a moderation of risk domain to reconcile the differential risk patterns among different socioeconomic consumers. The class-related risk patterns provide insights for managers who target consumers with social class differentiation.

Upskilling Communication and Self-Production: How to Communicate the Value of Cocreated Innovation?

Ajmal Hafeez, University of South-Eastern Norway, Norway
Marit Engeset, University of Southeast Norway, Norway

Although much research have focused on how consumers derive value from engaging in self-production less focus has been given to how such offerings can be communicated to consumers. We posit that messages focuses on upskilling or ways in which engaging in self-production can improve consumers' skills increases adoption of such products.

How Estimating One's Minimum or Maximum Spend Affects Total Expected Expenditure on a Shopping Trip

Eunha Han, Monash University, Australia
Harmen Oppewal, Monash University, Australia
Eugene Chan, Monash University, Australia
Luke Greenacre, Monash University, Australia

We investigate the effect of considering one's possible minimum and/or maximum spend on the expected total spend during a grocery shopping trip. We propose that considering one's maximum will increase the effect of unpacking on magnitude estimation while consideration of the minimum spend will decrease the effect.

Social Exclusion Causes People to Share Blatantly False Stories in the Service of Affiliation

Hyerin Han, University of Minnesota, USA
Hyun Euh, University of Minnesota, USA

The present study demonstrated that participants who felt excluded (vs. accepted) were more likely to share fake news which was high in emotional intensity even though they knew that these news stories were highly likely to be false but only when doing so boosted their chances to communicate with others.

Do Happiness and Meaning in Life Uniquely Predict Consumer Well-Being?

Xianyu Hao, University of Minnesota, USA
Kathleen Vohs, University of Minnesota, USA

We tested the influence of happiness and separately meaning on consumer well-being once their overlapping variance was removed. Two studies testing life views psychological needs and interpersonal outcomes indicated that happiness was a stronger predictor than meaning — thereby suggesting doubts about the influence of meaning on well-being.

Consumer Reactions to Social Media Brand Blunders

Ceren Hayran, Ozyegin University, Turkey
Melis Ceylan, Bilkent University, Turkey

This research explores how brand blunders - humorous and accidental business mistakes - that take place on social media influence consumers' attitudes and relationship with the brand. Two studies show that loyal (vs. non-loyal) consumers are more negatively influenced by blunders as they think blunders are not funny but offensive.

The Impact of Gratitude on Consumer Maximization Tendency in Decision-Making

Dongjin He, Hong Kong Polytechic University, China
Brent McFerran, Simon Fraser University, Canada
Yuwei Jiang, Hong Kong Polytechic University, China

This research shows that gratitude can increase consumers' maximization tendency evidenced by searching for more options spending more time on decision-making and choosing stores with larger assortment sizes. This effect appears because gratitude activates a self-improvement motivation. Furthermore we show the situations in which the proposed effect is weakened.

Feeling Justified to be a Jerk: Consumers Are More Likely to Complain For Someone Else Than For Themselves

Patrick Matthew Healey, Washington University, USA
Cynthia Cryder, Washington University, USA
Sydney Scott, Washington University, USA

Consumers' participation in behaviors that lead to negative social perceptions increases when they are engaging in the behavior on behalf of another person. The present research is focused in the realm of customer complaints and nagging.

Communities of Stigmatized Knowledge: Social Exclusion, Political Sovereignty, and Globalized Capitalism

Tim Hill, University of Bath, UK
Stephen Murphy, University of Essex, UK
Robin Canniford, University of Melbourne, Australia

Prior studies show that consumers can be sceptical of the truth claims produced by the State universities and scientific communities. The proposed study investigates consumers who develop alternative claims to truth that are ignored or rejected by such dominant knowledge-making institutions.

Fractal Agency: Fetishization of Algorithms and the Quest For Transcendence

Soonkwan Hong, Michigan Technological University, USA

This research discusses critical topics related to algorithms and transhumanism to explicate and theorize the entanglement between big data marketable transcendence and fractal agency. Such discussion helps identify future research topics that highlight more specific characteristics of algorithms such as opacity messiness inscrutability hyper-legitimacy hyper-functionality and equal distribution of accountability.

The Impact of Social Crowding on Consumers' Sensitivity to Price Magnitude

Yuansi Hou, Queen Mary University of London, UK
Ke Zhang, Shanghai University, China

Crowding is a widely observed phenomenon. Through a correlational study and two experiments the research provides evidence suggesting consumers are less sensitive to the magnitude of service prices and reveals the underlying mechanism of reliance on feelings (vs. cognitions) when making judgments in the more (vs. less) crowded conditions.

Adding Human Cues in a Green Advertisement Makes it More Engaging

Junhui Huang, Tsinghua University, China
Maggie Wenjing Liu, Tsinghua University, China

Making a green advertisement more engaging has always been a great concern for marketers and environmentalists. With two studies we show that subtle human cues in advertisements can increase the audience's engagement with the advertisement.

"Brain Damaged" Celebrity Followers: An Exploration Of The Effect Of Celebrity's Brand Endorsement On Followers' Social Media Engagement

Mei Huang, Xihua University, China
Xiaodan zhang, Peking University, China
Fang Wan, University of Manitoba, Canada
Yifan Chen, University of Manitoba, Canada

The current research explores the impact of celebrity's brand-related posts on followers' social media engagement. We find that brand endorsement types in celebrity's social media post impacts their fans' engagement behaviors (i.e. likes comments and shares) differently.

The Closeness Buffering Effect: How Closeness Weakens Negative WOM Impacts

Li Huang, Hofstra University, USA
Hang Nguyen, Michigan State University, USA

Word of Mouth (WOM) has great impacts on consumer decisions. Contrary to the common belief of greater impacts from close friends over strangers we found that negative WOM from close (distant) others were viewed more subjective (objective) and thus become less (more) influential on consumers' decisions.

Wine Attributes For Purchase Satisfaction: an Exploration of Gender Difference

Hyowon Hyun, Hanyang University, South Korea
Dongyoup Kim, Hanyang University, South Korea
Jungkun Park, Hanyang University, South Korea

This research explores how numerous wine decision attributes affect satisfaction. The wine attributes were categorized into three wine factors (i.e. basic intrinsic extrinsic) and positively associated with satisfaction. The results of hierarchical regression and experiment showed the gender difference in the relationship between wine factors and satisfaction.

Semantic Congruity of Price and Name: The Effect of Precise or Round Numbers and Sound Symbolism

Hiroaki Ishii, Aoyama Gakuin University, Japan
Jaewoo Park, Musashi University, Japan
Taku Togawa, Sophia University, Japan

Previous studies show that consumers associate precise or round numbers with specific concepts. In this study we explore the semantic association of precise or round prices with the concept of smallness or largeness and the effect of semantic congruity between the price and sound of brand name on product evaluation.

Money Can Corrupt Others But Not Me: Asymmetrical Perception of Future Self-Continuity

Anoosha Izadi, University of Massachusetts, USA
Mahdi Ebrahimi, California State University Fullerton, USA

The present research examines how people perceive change in their (vs. others) fundamental characteristics after facing with hypothetical situational changes in their (vs. others) future. We predict that the relationship in not symmetrical meaning that people perceive more change when the situational change is related to others (vs. themselves).

The Effect of Implicit Bias on Marketing Practitioners' Decisions For Minority Consumers

Jorge Rodrigues Jacob, Columbia University, USA
Martin Davidson, University of Virginia, USA
Valerie Purdie-Greenaway, Columbia University, USA
Tatianna Dugue, Columbia University, USA

The mismatch between the identity background of those that define products' marketing strategies and those who purchase them may increase the likelihood of biased marketing strategies that target stigmatized consumers.

"We" Don't Always Like Copycats: How Self-construal Influences Evaluation of Product Imitation

Seongun Jeon, Vrije Universiteit Amsterdam, The Netherlands
Femke van Horen, Vrije Universiteit Amsterdam, The Netherlands
Peeter Verlegh, Vrije Universiteit Amsterdam, The Netherlands
Keith Wilcox, Columbia University, USA

Three experiments provide converging evidence that self-construal (interdependent versus independents) affects the evaluation of copycats (products imitating the trade-dress of leading brands). Interdependents evaluate high similarity imitations more negatively than independents. Such copycat evaluation is moderated by norms regarding copycatting for interdependents but not for independents.

Setbacks as Self-Control Replenishment in Consumer Goal Pursuit

Lan Jiang, Menlo College, USA
Stephanie Dellande, Menlo College, USA
Miranda Canniff, Menlo College, USA

This research investigates the effect of setbacks in goal pursuit. Extending the literature on self-control as a resource we propose that occasional setbacks can be seen as a chance for replenishment resulting in longer term goal-consistent behaviors. The frequency and duration of the setback will be studied as potential moderators.

"Scarce- Insincere" Heuristic: Signaling Effect of Limited Quantity in Scarcity Appeal

Yufang Jin, Dalian University of Technology, China
Guang-Xin Xie, University of Massachusetts Boston, USA

This research reveals a novel "scarce - insincere" heuristic when consumers make inferences of limited quantities in scarcity appeals. Product scarcity can reduce perceived sincerity of suppliers and deter consumers from purchase. Real-world transaction data demonstrate the counterproductive effect of product scarcity and experimental data suggest the underlying process.

Do Majority and Minority Always Act Differently? How Relative Group Size Affects Utilitarian Consumption

Yu Jinjun, City University of Hong Kong, China
Yijie Wang, Hong Kong Polytechic University, China
Nakaya Kakuda, City University of Hong Kong, China

This research investigates how relative group size affects consumers' utilitarian consumption. We propose that consumers prefer utilitarian products more when they are situated in a relatively smaller group which is mediated by the need for self-improvement. Two experiments are conducted to test our hypothesis.

Fostering Progressive Literacy Through New Media Consumption: How Memes, Podcasts, And Political Comedy Spur The Political Imaginary

Hunter Jones, Aalto University, Finland

This netnography of the increasingly popular digitally active and politically charged 'Dirt Bag Left' presents an original model depicting how consumption of political comedy in new media is used to foster progressive literacy and reignite stagnant socio-political imaginaries. In doing so it makes substantial contributes to Transformative Consumer Research.

I Hope Therefore I Save: The Positive Effect of Hope on Financial Decision Making

Stephen Juma, Virginia Tech, USA
Mario Pandelaere, Virginia Tech, USA

Understanding what motivates people to save is critical in a time when most people do not have enough savings. We tested the prediction that hope motivates saving through an increased focus on the future. Results from three studies show that hope leads to savings and a boundary condition is identified.

"Others Seem to Move Further Than I Do": How Perceived Change in Distance May Differ Depending on Who Creates the Distance

Wonsuk Jung, University of Wisconsin - Madison, USA
Joann Peck, University of Wisconsin - Madison, USA

Our judgement on distance may be influenced by whether the distance in question is created by the self or the other. We propose that when the distance is created by the other the impact of that distance may seem greater compared to when the distance is created by the self.

Bibliometric Analysis of Immersive and NeurophysiologicalTools in Retailing

Shobhit Kakaria, University of Valencia, Spain
Aline Simonetti, University of Valencia, Spain
Enrique Bigne, University of Valencia, Spain

Given the evolving nature of marketing research and the prominence of neurophysiological and virtual tools this bibliometric analysis showcases the representative research trends in the past two decades and prospective directions in the domain of retailing.

Can Taste Predict Product Evaluation?: The Role of Variety-Seeking on Innovative Products.

Nakaya Kakuda, City University of Hong Kong, China
Xiaolei Su, City University of Hong Kong, China
Cheng Gao, Nanjing University, China

This research investigates the impact of taste sensation on innovative product evaluations. Specifically this research found spicy taste recall having a positive influence on product evaluation and bitter taste recall having the opposite effect. This effect is mediated by variety-seeking intention moderated by innovation types: radical innovation vs. incremental innovation.

The Effect of Gratitude Expression on Word-of-Mouth Intentions

Christine Kang, California State University Long Beach, USA

This research finds consumers' tendency to reciprocate firm's favor is modulated when they were given a chance to express gratitude. Participants who were guided to express their gratitude reported significantly lower intention to generate WOM offline or online compared to those who expressed happiness or those in control condition.

The Effect of Nostalgia on the Ideal Self and Moral Identity

Hedieh Karachi, Deakin Business School, Australia
Jeffrey Rotman, Deakin Business School, Australia
Andrea Vocino, Deakin Business School, Australia

While past research has demonstrated that nostalgia leads to self-continuity (Sedikides et al. 2015; Sedikides et al. 2016) the current research suggests that self-continuity is linked to just thinking about the distant past. However only nostalgia reduces the discrepancy between one's ideal-self and heightens moral identity.

The Effect of Assortment Categorization and Construal Level on Consumer Satisfaction

Bianca Kato, University of Guelph, Canada
Juan Wang, University of Guelph, Canada

Our work explores the interplay between construal levels and assortment categorization on consumers' satisfaction. We found that consumers are more satisfied with an assortment with fewer (vs. more) categories when under a concrete construal and that this effect is mediated by fluency perceptions attenuated by consumers' familiarity with the product.

What Makes a Product Cute: Infantile Attributes Influence Perceived Cuteness of Products

Carolyn Wells Keller, Northwestern University, USA
Neal Roese, Northwestern University, USA

In four studies we investigate the influence of infantile attributes on perceived cuteness in anthropomorphized products. We find that roundness of a product's base or 'body' has a particularly consistent impact on perceived cuteness. Infantile attributes also had a stronger effect on perceived cuteness in utilitarian (vs. hedonic) products.

What Makes an Advertisement Offensive? The Interplay of Prescriptive and Descriptive Norms

Saeid Kermani, York University, Canada
Peter Darke, York University, Canada

This research explores the joint impact of prescriptive and descriptive norms on consumers' intention to complain about an offensive advertisement. Two experiments provide support to the proposition that descriptive norms influence intention to complain via perceptions of harm when a prescriptive norm has been violated.

A Time-Oriented Explanation Of Desire For Scarce Item In Online Retailing

Dongyoup Kim, Hanyang University, South Korea
Jungkun Park, Hanyang University, South Korea

Throughout series of four studies this research examines the effect of scarcity on consumers' purchase intention mediated by perceived control over time. The effect was moderated by two different online retail strategies (i.e. pressurizing by blinking the limited quantity and price discount promotion) and consumers' initial time availability for shopping.

Consumers' Responses to Sustainable Smart Home Services: The Role of Regulatory Focus

Moon-Yong Kim, Hankuk University of Foreign Studies, South Korea

This research examines the role of consumers' regulatory focus in their responses to sustainable smart home services. The results indicate that consumers who are not familiar with smart home services have more favorable attitudes toward hedonic smart home services when they are promotion-focused (vs. prevention-focused).

Consuming Beauty in Place of Power: Gender and Culture Moderation

Sahoon Kim, University of Illinois at Urbana-Champaign, USA
Carlos Torelli, University of Illinois at Urbana-Champaign, USA

How would consumers' psychological sense of power – which can be influenced by numerous factors such as seller-buyer interaction – affect their apparels and beauty consumption? We theorize and demonstrate that men (women) consume more when feeling powerful (powerless). This tendency is stronger for individuals with certain cultural orientations.

From Powerlessness To Variety-Seeking When Choosing For Others: Making Gift Choices For A Romantic Partner

Sahoon Kim, University of Illinois at Urbana-Champaign, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA
Carlos Torelli, University of Illinois at Urbana-Champaign, USA

Many goods are purchased for others (e.g. gifts). When choosing a gift for a romantic partner would one's sense of power affect the choice? We demonstrate that feeling powerless increases variety seeking in choices made for the partner mediated by the reduced certainty in one's partner's preferences associated with powerlessness.

"I'm Cold But Feeling Warm": Effect of Cold Temperature on Evaluations of Ad Message

Myung Joo Kim, Ewha Womans University, South Korea
Jisoo Shim, Ewha Womans University, South Korea
Eunice Kim, Ewha Woman's University, South Korea

The present study investigates whether the temperature individuals physically experience influences their perception of social affiliation and evaluations of ad messages. This study shows that coldness generates more positive attitudes toward psychologically close (vs. distant) ad messages. The implications of our findings are discussed.

The Interactive Effects of Identity Salience and Accountability on Product Judgment

Claire Heeryung Kim, McGill University, Canada

A salient identity motivates consumers to think and behave consistently with that identity. Expecting to be required to explain a judgment to others later might increase motivation to engage in comprehensive information processing. Thus this research proposes that the act of providing reasons will diminish the identity salience effect.

When Is a Good Thing a New Thing? How Upcycling Product Display Affects Consumer Novelty Perception and Advertising Evaluation

Junghyun Kim, NEOMA Business School, France
Youngju Kim, NEOMA Business School, France
Junbum Kwon, University of New South Wales, UK

How does the position of source materials influence attitudes toward a repurposed product? We investigate the impact of product communication strategy on consumer attitude toward an upcycled product. Two studies demonstrate that how a company presents the past identity of an upcycled product influences consumers' novelty perception and advertising evaluation.

Generation Z Consumers' Luxury Goods Ownership Types and Purchase Intention Of Luxury Goods Using Collaborative Redistribution Platforms

Jihyun Kim-Vick, Kent State University, USA

The findings of this study extend our understanding of the young adult consumers' channel choice intentions toward purchasing brand new or previously owned personal luxury goods via traditional retail vs. collaborative redistributional platforms. Pragmatic implications for the luxury brand marketers as well as the online resale industry were provided.

Syllabic Fluency

Dan King, University of Texas Rio Grande Valley, USA
Sumitra Auschaitrakul, University of the Thai Chamber of Commerce, Thailand

We show that the syllabic structure of brand slogans and medical claims can influence consumers' judgments of truth. When the number of syllables of the brand name matches the number of syllables in the outcome consumers feel a metacognitive sense of processing fluency which increases judgments of truth.

It is Better to be Unknown Than Known: Mixed Use of Less Known and Well-Known Luxury Brands Can Elicit Higher Status Inference

Min Jeong Ko, Seoul National University, South Korea
Kyoungmi Lee, Seoul National University, South Korea

Across four studies we find that mixed use of less known and well-known brands compared to use of all well-known or all less known brands increases perceived status when well-known brands are in luxury(vs. non-luxury) domain. This is because observers infer user's desire to dissociate from lower class luxury users.

The Three-component Multidimensional Model of Self-image Congruence

Magdalena Kolanska, University of Zielona Gora, Poland
Oleg Gorbaniuk, University of Zielona Gora, Poland
Wilczewski Michał, University of Warsaw, Poland

The Three-Component Multidimensional Model makes it possible to assess and distinguish between the values of the brand incorporated into the consumer's self-image which correspond to self-enhancement self-protection and self -verification motives (Sedikides Gregg 2008). In order to build the Model a series of 3 tests was carried out.

Losing Possessions and Subsequent Spending

Shruti Koley, Portland State University, USA
Christina Kan, University of Connecticut, USA
Chiraag Mittal, Texas A&M University, USA

This research examines how losing one's possessions affects consumers' subsequent spending on unrelated purchases. We show that the effect depends on consumers' perceived wealth and their manner of losing. After losing their possessions wealthy (less wealthy) consumers spend more (less) subsequently but only when they blame themselves for the loss.

Smart Homes From a Consumers' Perspective

Monika Koller, Vienna University of Economics and Business, Austria
Fanny Springer, Vienna University of Economics and Business, Austria

Smart homes play a major role in the world of digital change. The aim of this paper is to shed light on smart homes from a consumers' perspective beyond focusing on technological solutions. We explore major associations with smart homes and dig deeper into a comprehensive understanding of their acceptance.

Small-Talking Brands: Exploring Phatic Brand Communication on Social Media

K.B. Koo, University of Alberta, Canada
Sarah G Moore, University of Alberta, Canada
Jennifer Argo, University of Alberta, Canada

We introduce and develop a new construct: phatic brand communication. The main function of such communication is to express sociability rather than information to consumers (e.g. "Happy Tuesday!"). Using Twitter data and experiments we propose and test a conceptual framework of phatic brand communication including its components and potential outcomes.

Striving For Social Media Reduces the Ability to Filter Out Visual Distractors

Christina Kößmeier, University of Duisburg-Essen, Germany
Oliver B. Büttner, University of Duisburg-Essen, Germany

This research examined how visual distraction is influenced by consumers' striving for social media. In three laboratory experiments we showed striving for social media – measured as craving for social media situational social exclusion and situational fear of missing out – decreased the ability to filter out visual distractions.

The Role of Visual Perspective in Influencing Donation Giving

Sining Kou, Renmin University of China, China

Based on construal level theory this research demonstrates that when the consumer's mindset (i.e. concrete vs. abstract) activated by visual perspective (i.e. first vs. third person perspective) is aligned (vs. misaligned) with the construal level of the message donation intentions and behaviors increase (vs. decrease).

Immunizing Against Diversity: Feeling Disgusted Reduces Positive Diversity Beliefs

Afra Koulaei, Innland Norway University of Applied Sciences, Norway
Luk Warlop, Norwegian School of Management, Norway
Bjørn Ove Grønseth, University of South-Eastern Norway

This study concerns with the impact of disgust on the evaluation of social groups and more specifically on the reduction of positive beliefs about increasing diversity in social groups. Three studies provided the test of our prediction that disgust (both chronically and state) reduces positive diversity beliefs.

The Moral Deviant: Norm Violators Are Expected to Communicate Concretely

Afra Koulaei, Innland Norway University of Applied Sciences, Norway

Violation of social norms may signal that the target lacks morality. Two studies suggest that morality have a leading role over other basic dimensions of human social cognition (i.e. sociability and competence) in the impression formation process of norm violators. To signal their morality norm violators are expected to communicate concretely.

Friend or Foe? A Long-term Multi-Country Perspective on Consumer Animosity

Tinka Krüger, Kiel University, Germany
Robert Mai, Grenoble Ecole de Management, France
Wassili Lasarov, Kiel University, Germany
Stefan Hoffmann, Kiel University, Germany

The Brexit or the US-Chinese trade conflict mark the resurgence of deglobalization and consumer animosity. Based on existing data from six countries from 2010 this study lays the foundation to examine whether animosity context changes result in altered individual consumption behaviors and hence evaluate the scope of animosity for practitioners.

Emotionality and Language Norms in Consumer Reviews: The Curious Case of Emoji

Polina Landgraf, IE Business School, IE University, Spain
Nicholas Lurie, University of Connecticut, USA
Antonios Stamatogiannakis, IE Business School, IE University, Spain
Susan Danissa Calderon Urbina, University College Dublin, Ireland

How do emoji impact the persuasiveness of consumer reviews? We argue that effects of emoji in reviews are stronger for utilitarian than hedonic products. Two experiments show that effects of emoji on persuasion are consistent with an account based on emoji as a language rather than as markers of emotionality.

Healthy or Not Healthy ? That's Not the Main Question

Sarah Lasri, University Paris-Dauphine, PSL, France

Even if researchers tried to understand healthy consumption it was often through a normative lens. They try to figure out triggers and consequences without questioning how healthiness is constructed. We attempt to show that it is a social myth where consumers play a huge part to define constantly new moralisms.

Consumer Perceptions of Floating Signifiers in Spurious Health-related Product Claims

Olga Lavrusheva, Aalto University, Finland
Alexei Gloukhovtsev, Aalto University, Finland
Tomas Falk, Aalto University, Finland

Our study looks at the use of ambiguous product health claims in food marketing. In particular we focus on consumer interpretations of "floating signifiers": claims that are ambiguous enough to escape precise definition and regulation while at the same time sufficiently "loaded" with health-related meanings from the consumers' perspective.

The Truth is in the Tweet: Exploring the Impact of the Linguistic Authenticity of Politician's Tweets on Their Personal Brands

Andrew Lee, University of Manitoba, Canada
Mehmet Yanit, University of Manitoba, Canada
Fang Wan, University of Manitoba, Canada

Politicians take to Twitter as a vehicle for connecting with voters and making their opinions known. Donald Trump became infamous for his outrageous tweeting style during the 2016 election. By using LIWC and experiments this research aims to unearth the mechanisms of authenticity with politicians on Twitter through their language style.

Truth Or Dare: Do People Behave Differently In Social Risk Vs. Financial Risk? The Inherent Difference Between Financial And Social Risk

Sunme Lee, University of Iowa, USA
Catherine Cole, University of Iowa, USA
Dhananjay Nayakankuppam, University of Iowa, USA

This paper examines systematic differences in risk preferences between financial and social contexts. People tend to be loss averse in the financial domain but gain averse in the social domain i.e. more (less) risk-seeking in the gain frame than in the loss (gain) frame in the social (financial) domain.

5th Best Hotel in America Vs. 2nd Best Hotel in New York: When Using Narrower Sets in Rank Claims Improves Consumer Judgments

Wei Li, Huazhong University of Science and Technology, China
Yaping Chang, Huazhong University of Science and Technology, China
Jun Yan, Huazhong University of Science and Technology, China

This research shows consumers evaluate a product or brand more favorably when it appears front in a narrow ranking list than later in a broad list. This effect arises only when consumers are maximizers. Perceived risk cognitive load and significance of the decision also moderate the effect.

Imperfect Boundaries: The Effects of Boundaries on Perceived Healthiness of Healthy Food

Ruiqin Li, Renmin University of China, China

How do boundaries influence perceived healthiness of healthy food? The present research shows that expressing product information with boundaries fixes attention of consumers on the information which induces motivated reasoning and finally reduces perceived healthiness. In addition the effect of boundaries only exists in healthy (vs. unhealthy) food domain.

Over-Inference in Predicting Others' Preferences

Xilin Li, University of Chicago, USA
Christopher Hsee, University of Chicago, USA

Through five studies we document an "over-inference bias" whereby predictors over-rely on predictees' preferences in one domain to infer their preferences in another domain. We also explore the underlying mechanism of this bias and articulate boundary conditions under which this bias can be attenuated or reversed.

Recall the Past: How Actors' and Observers' Perspective Affect Word of Mouth

Ran Li, Chinese University of Hong Kong, China

This research examines how the visual perspectives that people use to recall their past consumption experience (actor vs. observer) affect their subsequent sharing. Two experiments showed that taking an observer perspective reduces consumers' sharing of negative word of mouth through the mediating role of attention-seeking motivation.

The Awed Holistic Thinker: The Effect of Awe Experience on Individuals' Thinking Styles

Ran Li, Chinese University of Hong Kong, China
Tao Tao, Hong Kong Baptist University, China

This research examines the effect of awe on people's thinking styles. Seven studies showed that awe could promote holistic thinking (studies 1 2A-2D) through the mediating role of self-diminishment tendency (study 3). Moreover we demonstrated how the proposed effect influences consumers' reactions to service failures (study 4).

Beauty Camera Makes You More Emotional!: The Effect of Beauty-filtered Selfies on Consumer Decision Making

Shuyu Liang, Lingnan University, China
Tingting Wang, Sun Yat-Sen University, China

This research reveals a positive effect of beauty-filtered (vs. not) selfies on consumers' reliance on affective considerations in decision making. Drawing on extant research on self-presentation motivation and confidence we propose and demonstrate in two studies that taking beauty-filtered (vs. regular) selfies makes consumers prefer affectively (vs. cognitively) superior options.

Can Gratitude Increase Individuals' Sustainable Consumption Behavior? — the Mediating Effect of Time Discounting

Jianping Liang, Business School, Sun Yat-sen University, China
Leilei Guo, Sun Yat-sen University, China

This research examines the influence of gratitude on individuals' sustainable consumption behaviors. Results from a longitudinal study and three between-subjects experiments showed positive influences of trait gratitude and priming gratitude on consumers' willingness to use green products through reduced time discounting. Connectedness to future-self moderated these effects.

Social Media Amplifies Gift-givers' Conspicuous Consumption Motivation

Shuyu Liang, Lingnan University, China
Tingting Wang, Sun Yat-Sen University, China

This research reveals an interesting misalignment between gift giver's and receiver's considerations. Specifically we found that facing receivers who are social-media active (vs. inactive) givers prefer conspicuous (vs. not) gifts out of anticipation of receivers' sharing the gifts on social media; however gift conspicuousness does not affect receivers' sharing intention.

Consumer Knowledge and the Psychology of Opposition to Scientific Consensus

Nicholas Light, University of Colorado, USA
Philip M. Fernbach, University of Colorado, USA

Communicating scientific evidence is a major challenge. We report three studies on the relationships between knowledge type and anti-scientific attitudes across seven scientific issues. We find that as extremity of attitudes increases objective knowledge decreases but subjective knowledge increases. However several issues show inconsistencies worthy of further examination.

The Influence of Fake News on Consumer Spending in Response to COVID-19

Nicholas Light, University of Colorado, USA
Justin Pomerance, University of Colorado, USA
Lawrence E Williams, University of Colorado, USA

Fake news has entered the global consciousness. While previous work examines interventions and direct consequences we examine how it changes consumer spending intentions during the COVID-19 pandemic. Two studies indicate that fake news induces uncertainty which increases both the desire to save money and the intention to spend it compensatorily.

How Legacy Motivation Influences Financial Risk-Taking

Wang Lin, Sun Yat-Sen University, China
Chen Zengxiang, Sun Yat-Sen University, China
Yun He, Sun Yat-sen University, China

The creation of legacy is one of the most fundamental motivations human beings possess. The current research investigates the impact of legacy motivation on consumers' financial decision-making. Results of three experiments revealed that legacy motivation reduced consumers' financial risk-taking tendency and explored why and when this effect occurred.

#Favoritethings: How Posting Your Favorite Possessions on Social Media Increases Happiness

Jingshi Liu, Business School City, University of London, UK
Amy Dalton, Hong Kong University of Science and Technology, China
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

Posting favorite possessions on social media increases people's happiness. This is because favorite possessions are unique and of personal meanings and thus resistant to the upward social comparisons prominent on social media. The happiness associated with posts of favorite possessions in turn increases liking of the social media platform.

How Consumers React to Culturally Mixed Products: The Effects of Cultural Domain and Mixing Direction

Yingyue Liu, Sun Yat-Sen University, China
Zhimin Zou, Sun Yat-Sen University, China
Yimin Zhu, Sun Yat-sen University, China

This paper conducts two studies to examine the joint effect of cultural domain and mixing direction on consumers' attitudes to culturally mixed products as well as the mediating effect of perceived cultural threat and the moderating effect of polycultural mindset which give implications to better understand the cultural mixing phenomenon.

Lonely Heart? Warm it up With Love: The Effect of Loneliness on Singles' and Non-singles' Conspicuous Consumption

Wei Liu, Xiamen University, China
Zhaoyang Guo, Xiamen University, China
Rui Chen, Xiamen University, China

Three studies show that loneliness increases singles' conspicuous consumption but yields divergent effect for non-singles depending on their sociosexual orientation (SOI). In particularly loneliness has decrease conspicuous consumption among non-single people with low SOI but increase conspicuous consumption among those with high SOI. Mating motive mediates the above effects.

Will Highlighting Low Stock Level Speed Up or Impede Consumers' Purchase Intention? An Exploratory Study

Mengmeng Liu, Chinese University of Hong Kong, China
Jessica Y. Y. Kwong, Chinese University of Hong Kong, China

How would consumers respond when they see an item that they are considering has "only a few left"? Would this highlight of low-stock level speed up or impede their purchase decisions? Our findings suggest that the effect depends on the consumption type (utilitarian vs. hedonic).

The Effect of Cuteness on New Product Adoption: Moderating Role of Thinking Style

Hongyan Liu, Jinan University, China
Choong W. Park, University of Southern California, USA

This research examines how exposure to cute product design influences new product adoption. We propose that exposure to cuteness increases perception of hedonic benefit (fun) and new product adoption. While this effect is moderated by thinking style. Three experiments were conducted to test the propositions. The results support our predictions.

Hiding in Plain Sight- Low Self-Concept Clarity and Ironic Consumption

Karan Pratap Singh Lohan, Hong Kong University of Science and Technology, China

Ironic consumption allows consumers to signal different meanings- one to people who detect the irony and one to those who don't. Low self-concept clarity consumers are attracted to this dual (ambiguous) signal since it insulates them from the risk of self-instability as well as disapproval from others.

Does It Matter Whose Fault It Is? The Moderating Effects of Similarity and Product Substitution on Consumer Boycotts of Parent and Subsidiary Corporations

Yung-Chien Lou, National Chengchi Uniersity, Taiwan
Wei-Chih Tseng, National Chengchi Uniersity, Taiwan

This study demonstrates that consumer boycott behavior (and consumer perceptions) as a response to a conglomerate's wrongdoing is affected by the similarity between and degrees of product substitution of the parent and subsidiary corporations.

Cultural Difference In Self-Consciousness On Empathy Toward Socially Responsible Consumption

Chi-Cheng Luan, National Chiao Tung University, Taiwan

According to Triandis's theory people with individualistic cultures tend to use private self-consciousness whereas people with collectivistic cultures use public one. A shopping scenario was provided to examine participants' responses. The result shows that cultural difference is found in the distinct effects of self-consciousness on empathy for socially responsible consumption.

Discussing The Moderating Effect of Construal Level On The Relationship Between Emotional Appeals And Sustainable Consumption

Chi-Cheng Luan, National Chiao Tung University, Taiwan
Yun-Hui Wang, National Chiao Tung University, Taiwan

Moral emotions such as pride and empathy are found to relate to sustainable consumption. This research aims for the interaction between these two emotions and construal level based on the construal level theory. The findings can provide another direction of promotional strategies by simulteneously considering emotional appeals and construal level.

Priming Pleasure Through Smells: the Effect of Positive Odors on Categorization of Affectively Congruent Objects

Ramona de Luca, EAESP-FGV, Brazil
Delane Botelho, EAESP-FGV, Brazil

Studies demonstrated that pleasant scents induce pleasurable experiences and choices. However the unconscious mechanism through which individuals make mental associations between odors and unrelated objects is unclear. This research explores the effect of odors on mental processes (categorization) when the odor and stimuli in other modalities match on their valence.

The Effect of Ambient Odors on Categorization and Semantically-Congruent Product Choices

Ramona de Luca, EAESP-FGV, Brazil
Delane Botelho, EAESP-FGV, Brazil

Research in sensory and scent marketing has prioritized cognitive approaches in which consumer choices result from deliberate decisions. However consumers' choices are largely regulated by pleasurable experiences that arise automatically. This research explores the unconscious process underlying the effect of ambient scent on consumers' categorization and semantically congruent choices.

How Hope of Breaking Even Makes People Cling on Losing Stocks

Siria Xiyueyao Luo, Vrije Universiteit Amsterdam, The Netherlands
Femke van Horen, Vrije Universiteit Amsterdam, The Netherlands
Kobe Millet, Vrije Universiteit Amsterdam, The Netherlands
Marcel Zeelenberg, Vrije Universiteit Amsterdam, The Netherlands

Four studies found that hope explains the disposition effect: people's hope predicts the tendency to keep the losing stock; people who hold losing (vs. not-losing) stocks had a stronger hope of breaking even and thus were more likely to keep the losing stock; reducing the hope attenuates the disposition effect.

Closeness and Purchase Strategy Independently Influence Gift Choice

Dong Lyu, University of Nottingham, UK
Jia Jin, Ningbo University, China

This research aims to examine whether gift givers process social distance and purchase strategy independently. We plan to adopt drift diffusion model to simulate the decisional dynamics of givers then to check whether the drift rates of the processing of social distance and purchase strategy choice are correlated.

The Experiential Brain of Smartphone Users:
How Smartphone Use Reshape Thinking Style

Jingjing Ma, Peking University, China
Ying Zhu, University of British Columbia, Canada
Jiajia Liu, Peking University, China
Jingjing Wang, Peking University, China

Through two large-scale nationwide surveys with 24180 participants and an Implicit Association Test this study identifies an undocumented positive correlation between smartphone use/apps and experiential thinking. We revealed that this effect is driven by pleasure and social activities (e.g. watching movies and using social media) people perform on their smartphones.

Exploring the Concept of Sustainable Food Consumption

Natalia Maehle, Western Norway University of Applied Sciences, Norway

The purpose of this study is to explore how the concept of sustainable food consumption emphasizes the four aspects of sustainability. We conclude that it is a multidimensional concept focusing on the nature the human being the society and the optimal use of economic resources in the food chain.

Collaborative Consumption in a Subsistence Marketplace

Bhupesh Manoharan, Masters Union School of Business, India
Krishanu Rakshit, Indian Institute of Management Calcutta, India

The absence of lateral exchange markets (LEM) has impeded researchers from understanding collaborative consumption in subsistence marketplace contexts. This work aims to understand how an interactive LEM shapes interdependent peer-to-peer engagement in a subsistence marketplace.

Contesting Stigma in the Online Space: An Institutional Perspective

Bhupesh Manoharan, Masters Union School of Business, India
Krishanu Rakshit, Indian Institute of Management Calcutta, India

We explore how marginalised consumers tackle stigma in the online space by conceptualising the socio-political online consumption space as an institutional field and studying the dynamics between the upper and lower caste members and their efforts to distort the current institutional logic to establish their desired logics respectively.

The Effect of Transparent Packaging on Psychological Ownership and Preference

Eva Marckhgott, Wirtschafts University, Austria
Bernadette Kamleitner, Vienna University of Economics and Business, Austria
Zachary Estes, Bocconi University, Italy

Transparent packaging removes the visual barrier between the consumers and the product thereby allowing consumers to develop a more intimate relationship with the product. This in turn leads to a preference for products in a transparent packaging over products in an opaque packaging.

(No) Offense Taken: Value Creation vs Value Destruction by Brand-Offended Consumers

Ereni Markos, Suffolk University, USA
Lauren I Labrecque, University of Rhode Island, USA
Mujde Yuksel, Suffolk University, USA

Consumers often post negative comments on brand social media with intentions to harm (value-destruction). We examine if this action backfires instead strengthening observing consumers' relationships with the brand. We illustrate that consumers attack brands on social media for different reasons and also investigate why consumers defend brands against others' attacks.

Patterns of Use, Essence Transfer, and Value:
How Patterned Usage Impacts Object Valuation.

Nathanael S. Martin, University of Cincinnati, USA
Noah VanBergen, University of Cincinnati, USA

Does how an object is used impact consumers' valuation of the object itself? The present research seeks to investigate whether objects whose usage is illustrated by a specific pattern are deemed more valuable to consumers due to possessing more of the original user's essence. Three studies offer initial support.

Are Ingroup Recommendations Always Better? The Role of
Outgroup Credibility on Parental Purchases and Attitudes

Fábio Miguel Ferrony Varela Martins, Universidade Europeia, Portugal
Márcia Maurer Herter, Universidade Europeia, Portugal
Raquel Reis Soares, Universidade Europeia, Portugal
Diego Costa Pinto, Nova IMS - Information Management School, Portugal

This paper uncovers how outgroup credibility can reduce ingroup bias. In particular this paper examines how credibility acts as a boundary condition to social influence of parents (ingroups) and pediatricians (outgroups) turning outgroups more influential than ingroups on parental purchase intentions and brand attitudes.

Customer Citizenship Behavior in Customer Networks:
An Analysis in the Lens of Network and Consumer Value Theories

Renata Martins, Fundação Getúlio Vargas, Brazil
Sofia Batista Ferraz, EAESP-FGV, Brazil
Felipe Zambaldi, FGV/EAESP, Brazil

Most studies that investigate customer citizenship behavior (CCB) in customer networks neglect the impact of networks' structures on it. Our work is the first to fulfill this gap proposing a framework showing the extent to which CCB depends on the network's structure and on the purposes customers expect to achieve.

Eating More to Save the Planet: Political Ideology, Food Waste, and Overconsumption

Erick M. Mas, Vanderbilt University, USA
Kelly Haws, Vanderbilt University, USA
Kelly Goldsmith, Vanderbilt University, USA

When facing the tradeoff to waste or overconsume liberals may engage in maladaptive eating behavior by overconsuming to offset food waste because they are motivated to reduce environmental impacts. Conservatives who are less concerned with these issues do not make consumption choices predicated on reducing environmental harm.

The Impact of Indulgent Consumption Images on In-Store Decision Making

Maxine Materne, University of Hamburg, Germany
Mark Heitmann, University of Hamburg, Germany
Christina Schamp, University of Mannheim, Germany

Marketers assume that displaying indulgent consumption facilitates mental simulation and increases purchase intentions. One field experiment and two simulated shopping experiments suggest that showcasing indulgent consumption is context-dependent such that the positive effect found in laboratory experiments for advertisement related settings does not generalize to images displayed in-store.

When and Why an Entertaining Story Triggers Brand Buzz

Koji Matsushita, Chuo University, Japan

This research proposes that an entertaining story with no brand appearance can boost brand word-of-mouth (WOM). When highly transported consumers are aware that a brand might utilize a story to strengthen the brand image (salient persuasion knowledge) they become motivated to engage in brand WOM activity.

Feeling Hopeful in Response to High/Low Prototypical Identity-linked Appeals: The Distinctive Roles of Affective and Cognitive Social Identity

Miriam McGowan, University of Birmingham, UK
Louise May Hassan, Bangor University, UK
Edward Shiu, Bangor University, UK

Research shows identity-linked messages need utilize established social group characterizations to be effective. We find priming consumers' identity using less/more established (low/high prototypical) characterizations has differential effects on purchase intention. The emotion hope mediates this process. Three experimental studies with US MTurk samples using gender/nationality identities supported our hypothesized effects.

The Role of Fluency in Identity-Linked Marketing

Miriam McGowan, University of Birmingham, UK
Edward Shiu, Bangor University, UK
Louise May Hassan, Bangor University, UK

Across three studies we examine low identifiers in the context of identity-targeted messages. Drawing on fluency literature we explore how low identifiers process identity relevant information differently to high identifiers. Low identifiers process identity-linked messages less fluently than primes depressing their product evaluation. The opposite occurs for high identifiers.

The Effect of Perspectives in Food Pictures on Unhealthy Food Choices

Eva Meersseman, Ghent University, Belgium
Iris Vermeir, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

Consumers choose less unhealthy food when seeing pictures of food shot in a top perspective vs. a diner's eye perspective. We show that lower familiarity with seeing food in top view decreases product vividness and subsequently lowers the need for instant gratification. Hence less unhealthy food is chosen.

The Impact of Dynamic Advertising With Zoom Lens on Consumers' Comparative Decision-Making Preferences

Lu Meng, Renmin University, China

This research proposes the impact of merchants 'zooming and pulling lenses on consumers' comparative decision-making methods in dynamic advertising on online shopping platforms and the perception distance's mediator role in this process.

"Show Me Your Basket, I Show You What Drives Your Food Waste"
Identifying Drivers of Shoppers' Food Waste and Ways to Reduce It

Sybilla Merian, University of Zurich, Switzerland
Petra Tipaldi, University of Zurich, Switzerland
Klaus Fuchs, ETH Zurich, Switzerland
Martin Natter, University of Zurich, Switzerland

The increasing debate on food waste puts pressure on consumers and sellers. We propose a scalable approach to identify food waste predictors based on consumers' automatically logged loyalty card data. Identifying characteristics triggering food waste we propose a non-invasive intervention informing consumers and help them to reduce the problem.

Consumer Experience Of Working From Third Places

Laetitia Mimoun, City University of London, UK
Adèle Gruen, Goldsmiths, University of London, UK

This research contributes to the literature on consumer experience in third places. We document the emerging value that a growing body of working consumers derive from third places as work accelerators. We also show how this evolution may generate conflicts and confusion despite sustaining the social ideology of third places.

Any Takers For Male Alex Vs. Female Alexa? The Impact
of the Gender of Voice Technology on Consumer Choices

Nirajana Mishra, Boston University, USA
Geeta Menon, New York University, USA

In the future consumers' interactions with voice technology will only increase. Most of these voices are currently female. Through an initial set of studies we find that gender of voice technology brings stereotypes to bear on consumers' judgments that translates to products.

Masculine Servicescapes? Examining the Intersections Between
Men's Identity Construction and Built Commercial Environments

Risto Moisio, California State University Long Beach, USA
Mariam Beruchashvili, California State University Northridge, USA

We examine how servicescapes built commercial environments partake in the process of masculine identity construction. Using men's recreational training at the Mixed Martial Arts dojos/gyms we demonstrate how a physical space of a dojo/gym contains and constructs a specific identity project the fighter ideal that would be difficult to realize elsewhere.

The "Why" of Spending Matters: The Role of Extrinsic and
Intrinsic Goals on Consumer Spending Choices and Hedonic Value Estimations

Olaya Moldes, Cardiff University, UK

Past research suggests that what we buy (experiential vs. material; prosocial vs. proself) impact one's well-being. We propose that why—the motivation behind—not only determines the spending choices made but also the well-being experienced. Three studies test the influence of dispositional and situational intrinsic and extrinsic goals in consumption.

The Effects of Virtual Compared to Real Eating Companions on Unhealthy Food Intake.

Saar Mollen, University of Amsterdam, The Netherlands
Sindy Resita Sumter, University of Amsterdam, The Netherlands
Nadine van der Waal, Tilburg University, The Netherlands
Pascale Kwakman, University of Amsterdam, The Netherlands
Nynke van der Laan, Tilburg University, The Netherlands

In the current experiment we investigated whether social models in VR have a similar influence on eating behavior as real-life models and whether similar processes underlie their influence. Participants' intake was influenced by that of the social model irrespective of whether this person was present in real-life or VR.

Misperception of Multiple Risks: The Role of Categorical Reasoning

Mehdi Mourali, University of Calgary, Canada
Zhiyong Yang, University of North Carolina at Greensboro, USA

How do consumers combine multiple risk items when forming overall risk impressions? Our study shows an intriguing pattern where an option with multiple risks is judged to be less risky than the same option with only one of these risks. We attribute the findings to categorical reasoning about risk.

Is There Room For Social Stimuli in Green Ads?: An Investigation of the Use of Human Face in Green Advertisements

Brishna Nader, Fontys University of Applied Science, The Netherlands
Meng-Hsien (Jenny) Lin, California State University Monterey Bay, USA
Iris van Hest, Fontys University of Applied Science, The Netherlands

This paper explores the effectiveness of human face (a social cue) used along with green message (an informational cue) in green advertisements. We find that while green ads are generally preferred over non-green ads it is less preferred when a face (vs. no face) is present.

"When First is Best": Why Brand-First is Superior to Attribute-First During Sequential Presentation of Product Information

Priya Narayanan, Indian Institute of Management Kozhikode, India
Arvind Sahay, Indian Institute of Management Ahmedabad, India

Four studies including a mall intercept show that consumers' willingness to pay (WTP) for a product is higher when brand information is presented before attribute information an effect mediated by brand-elicited affect. This research contributes to feelings-as-information ordered presentation of product features and derives implications for marketing communication and packaging.

"Practices As Institutional Fractals: Zooming in on Fika, Zooming Out to Lagom"

Angeline Nariswari, California State University Monterey Bay, USA
Kaisa Koskela-Huotari, Karlstad University, Sweden
Teea Palo, University of Edinburgh, UK

This paper studies Swedish coffee drinking ritual fika to understand institutional maintenance by looking beyond micro-level practices to examine the role of broader level institutional arrangements. The study identifies how fika is supported by other practices that display self-similarity regardless of scale—fractals—that altogether refract a common societal-level value.

Mouse Tracking in E-Commerce: Assessing Choice Difficulty Via Consumer's Hand Movement

Patrick Wolfgang Neef, University of Innsbruck, Austria

Pre-decisional information processing is strongly linked to consumer choice. Since consumers increasingly purchase through online channels the question arises whether other computer-based technology can be applied to better understand consumer decision-making. One purpose of the present inquiry is to understand how difficulty of the decision-making process affect hand movements.

I Enjoy Being Mii: How Knowing Yourself Impacts Avatar Enjoyment

Emma Neybert, University of Cincinnati, USA
Rashmi Adaval, University of Cincinnati, USA

Often consumers assemble avatars to resemble themselves. However avatars often fail to fully capture all aspects of their creator resulting in "poor copy syndrome" lowering enjoyment. In one provocative study we find that contingent on one's self-concept clarity perceived personality similarity between the creator and their avatar impacts avatar enjoyment.

The Effects of Harmonics on the Tactile Perceptions of Products

Mayuko Nishii, Waseda University, Japan

Congruence between product elements and sensory cues elicits positive responses from consumers. However we show that when listening to soft-toned music that seems appropriate for products such as soft blankets consumers tend to be less sensitive to their haptic perceptions. Therefore we propose the role of comfort.

Cultures of Product Reviewing

Mikkel Ørholm Nøjgaard, University of Southern Denmark, Denmark
Niklas Woermann, University of Southern Denmark, Denmark

How do expert reviews and online user reviews construct product quality information? This paper explores the social processes of product reviewing. It conceptualizes expert reviewing and user reviewing as two distinct 'epistemic cultures' and shows that these cultures vary across three epistemic processes: generating evidence evaluating evidence and presenting evidence.

Examining the Structural Relationship Between Socioemotional Comparisons and General Risk Preference

Dallas Novakowski, University of Calgary, Canada
Mehdi Mourali, University of Calgary, Canada

Past research suggests that feelings of relative disadvantage (i.e. envy relative deprivation) have a causal role in eliciting domain-general risk-taking behaviours. This study used structural equation modelling in a crowdsourced sample (n=804) and found that feelings of relative disadvantage account for significant variance with a general factor of "risk preference."

Entitled to Be Served: Does Self-Checkout Make Customers Feel Less Rewarded?

Farhana Nusrat, Drexel University, USA
Yanliu Huang, Drexel University, USA

We examine how self-checkout service impacts customer loyalty compared to regular checkout service. In two studies we show that self-checkout service compared to regular check out make customers feel less rewarded less satisfied with their purchases and less likely to return to the store.

The Effects of Similarities- vs Differences-focus on Fake News Processing

Gergely Nyilasy, University of Melbourne, Australia
Bernice Plant, Monash University, Australia

The fight against fake news currently lacks working interventions. This study explores individual cognitive differences to pave the way towards such interventions. Relying on comparison theory hypotheses test the effects of similarities- and differences proneness. Findings suggest that these factors indeed influence cognitive processing – if not summative truth and confidence judgments.

Just Teasin': Why Poking Fun at Consumers Makes Brands Feel More Human

Demi Oba, Duke University, USA
Holly S Howe, Duke University, USA

Can consumers handle being teased by a brand? Across three experiments (on three different advertising platforms) brands who tease consumers are consistently shown to be more anthropomorphic than purely funny or serious brands. We demonstrate that this anthropomorphism has positive downstream consequences for brand liking and self-brand connection.

Indulge Every Now and Then: Anticipating Indulgence Increases Indulgent Food Preferences Among Restrained Eaters

Ga-Eun (Grace) Oh, Open University of Hong Kong, China

This research examines the interactive effects of anticipating indulgent consumption and dietary restraint on indulgent food preferences for immediate consumption. Three experiments reveal that anticipating indulgent food consumption increased restrained eaters' indulgent food preference for immediate consumption whereas it often reduced unrestrained eaters' indulgent food preference.

The Status Implications of Age Perception and Conspicuous Consumption

Ga-Eun (Grace) Oh, Open University of Hong Kong, China

This research examines how age perception has different implications regarding status among men and women. As a result of the different status implications of age towards men versus women subjective age perceptions have different effects on the conspicuous consumption of men and women.

Impact of Inverted Packaging on Brand Memory

Nur Yazgan Onuklu, Temple University, USA
Maureen Morrin, Rutgers University, USA

In this paper we explore the influence of upside down packaging on brand recall and recognition. With two studies we show that unaided recall and recognition memory are improved when there is an upside down bottle presented among regular bottles compared to an all regular bottle presentation.

Paying For Free Products Stops Consumers From Committing to Other Brands: Role of Perceived Control

Maria Ortiz, Concordia University, Canada
Arani Roy, McGill University, Canada

Consumers are susceptible to encounter non-zero costs for products which they think should be available for free (e.g. online gaming apps) leading them to a reduced feeling of control. We examine the effect of reduced perceived control on consumers' commitment to brands they subsequently encounter using predictive control theory.

"Run, Forrest, Run: How Intense Athletic Pursuits Induce Therapeutic Feelings"

Tatsiana Padhaiskaya, Aalto University, Finland

This research aims to uncover how consumers' understanding of their own bodies informs the production of therapeutic feelings. My ethnographic inquiry in the context of ultra-running illustrates a multi-stage process of in-depth engagement with the body that results in the therapeutic consequences of various magnitudes.

Objectification and the Acceptance of Inequality

Helena Palumbo, Pompeu Fabra University, Spain
Gert Cornelissen, Pompeu Fabra University, Spain

Media and marketing communications often represent people in an objectified manner. The systematic exposure to such objectifying messages might affect various types of judgments that people make. In this paper we test whether it increases people's tolerance towards economic inequality. We hypothesize that the effect is mediated by reduced empathy.

Recipe Ingredients Predict Digital Engagement With Food Media

Ethan Pancer, Saint Mary's University, Canada
Matthew Philp, Ryerson University, Canada
Maxwell Poole, Saint Mary's University, Canada

Two field studies (Buzzfeed's Tasty & Yummly) demonstrate that food media based on recipes rich in saturated fats receive more reactions comments shares and recipe bookmarks even when controlling for meal complexity and meal occasion (e.g. dessert). Experimental evidence suggests this effect is driven by positive affect.

When the Light Bulb Goes Off, Goal Progress Increases

Mivena Panteqi, Vilanova University, USA

We propose that lighting ambience influences goal completion via perceptions of goal distance. That is the progress towards achieving a goal is perceived through the reduction in distance towards the targeted goal.

Does Anticipated Future Self-Regulation Increase Present Self-Regulation? Counteractive Construal of Intertemporal Choice

Jihye Park, Seoul National University, South Korea
Youjae Yi, Seoul National University, South Korea

This research examines how anticipated future behavior can encourage current self-regulation. Findings show that consumers are more likely to engage in self-regulatory behaviors when they anticipate resisting (vs. succumbing to) future temptation. Results also show that this effect is accounted for by counteractive construal and stronger for non-impulsive consumers.

Personal Trainers' Physical Appearance and Service Registration Intention: Perceived Competence as an Underlying Mechanism

Sangchul Park, Texas A&M University, USA
Shinhyoung Lee, Sookmyung Women's University, South Korea
Hyun-Woo Lee, Texas A&M University, USA

This study investigates the effect of personal trainers' physical appearance on fitness service registration intention via perceived competence. Specifically we hypothesize that consumers perceive muscular (vs. well-shaped) trainers as more competent which in turn boosts their registration intention for personal training services.

The Impact of Natural Versus Attained Beauty on Service Evaluations

Jooyoung Park, Peking University, China
Nathasya Pricilia B Kristianto, Peking University HSBC Business School, China

This research examines how women customers differently judge a service provider with natural or attained beauty and in turn evaluate their service. Two field experiments showed that obtained beauty is judged less favorably decreasing overall service evaluations.

Double Anchors in an Online Charitable Giving Platform: The Limitation of Small Suggested Amount Solicitation

Sohyeon Park, Korea University, Korea

This research proposes a two-stage anchoring process model that analyzes the anchoring behavior of consumers in charitable giving when a solicitation message contains double anchors such as suggested amount and target amount. Specifically transition of anchoring behavior under manipulation of amount size in suggested amount and target amount is observed.

"Turning the Other Cheek": The Role of Face Orientation on Perceived Model Attractiveness and Product Evaluation

Jaewoo Park, Musashi University, Japan
Charles Spence, University of Oxford, UK
Hiroaki Ishii, Aoyama Gakuin University, Japan
Taku Togawa, Sophia University, Japan

The present research demonstrates that people perceive a model showing their left (vs. right) cheek as more attractive even when the images happen to be otherwise identical. We also show that in an advertising context a model apparently showing their left (vs. right) cheek leads to more favorable product evaluation.

The Inescapable Quest of Happiness: Exploring How the Ideology of Happiness Shapes Contemporary Consumer Society

Gabrielle Patry-Beaudoin, Queens University, Canada
Jay Handelman, Queens University, Canada

This paper draws attention to the ideology of happiness and examines how it influences a marketplace. We contribute to the literature on happiness in marketing by highlighting two cultural discourses of happiness that consumers and producers constantly negotiate: happiness as a virtuous project and happiness as a momentary pleasure experience.

When Technology Fails: Rage Against the Machine or Self-Control? Investigating Customer's Negative Emotions and Coping Strategies in AI-Service Failure Scenarios

Giulia Pavone, Toulouse School of Management TSM Research UMR 5303 CNRS, France
Lars Meyer-Waarden, Toulouse School of Management TSM Research UMR 5303 CNRS, France
Andreas Munzel, University of Montpellier - Montpellier Research in Management (MRM), France

We investigate the impact of service failures on customers' anger frustration and coping strategies when interacting with an artificial intelligence based chatbot compared to a human. Results show that in the same aversive situation emotional responses differ when customers are aware of interacting with a chatbot rather than a human.

Sounds Healthy: Modelling Healthy Food Choices Through Music-Evoked Eye-movements in Consumers From Denmark and China-Tracking Study in Danish and Chinese Consumers

Danni Peng-Li, Aarhus University, Denmark
Derek Byrne, Aarhus University, Denmark
Raymond Chan, Chinese Academy of Sciences, China
Qian (Janice) Wang, Aarhus University, Denmark

The present study explores how custom-composed soundtracks associated with the notions of "healthiness" and "unhealthiness" can modulate Danish and Chinese consumers' eye-movement patterns and choice of specific food items. The findings of this study provide a better understand how specific auditory components collectively can nudge consumers in different market segments.

What is Transmedia Narrative Experience For Consumers of Arts and Heritage?

Christine Petr, Université de Bretagne Sud, France
Elodie Jarrier, Université d'Angers, France
Dominique Bourgeon-Renault, Université de Bourgogne Franche-Comté, Dijon, France
Maud Derbaix, Kedge Business School Bordeaux, France

New technologies allow Transmedia Narrative to become a successful strategy to enlarge consumers' experience with brands. We investigate the impact of transmedia on audience attachment considering arts and heritage. Conclusions offer additional conceptualizations to narrative transportation suggest dimensions for further research on consumers' engagement and on narrative transportation measurement.

Influence of Childhood Socioeconomic Status on Indulgent Consumption: A Life History Theory Approach

T. Andrew Poehlman, Clemson University, USA
Denny Huynh, Duke University, USA
Oriana Rachel Aragón, Clemson University, USA
Gavan Fitzsimons, Duke University, USA

Why do some people indulge now whereas others delay? The evolutionary framework of life-history theory predicts that preferences for indulgences should be influenced by stress and resource scarcity. The effect of stress depended on whether people grew up in a resource-scarce or resource-plentiful environment.

Model Citizens of The Empire: Mythology, Ethnic Identification, And British Indian Women

Anuja Pradhan, University of Southern Denmark, Denmark
Margaret Kathleen Hogg, Lancaster University, UK
Hayley Cocker, Lancaster University, UK

This study explores how macro-level identity myths such as the 'model minority' manifest and influence the lived experiences of 'privileged' ethnic migrant consumers such as professional British Indian women. It challenges our accepted norms of 'dominant' and 'dominated' consumers and shows the transformation of ethnicity across migrant generations.

How Religious Minorities Resolve Cultural, Market, and Religious Ambiguity

Theeranuch Pusaksrikit, Chulalongkorn University, Thailand
Amna Khan, Manchester Metropolitan University, UK
Andrew Lindridge, Newcastle University, UK

This research aims to explore how British Muslims engage with the religious cultural and market-derived consumption narratives surrounding Christmas festival of the religious dominant group. Utilizing qualitative method the findings identify three interconnected themes explaining how these participants engage (or not) with Christmas.

How to Convince Consumers That "You Do Not Always Get What You Pay For"

Vahid Rahmani, Rowan University, USA
Elika Kordrostami, Rowan University, USA

Findings of three studies showed that provoking suspicion could eliminate consumers' reliance on price to judge quality. Furthermore findings showed that activating persuasion knowledge is likely to result in a schematic thinking style a greater primacy effect of the readily available information and higher price-quality perceptions.

Effects of Visual Attention on Intertemporal Choice

Jairo Ramos, University of Colorado, USA
Kellen Mrkva, Columbia University, USA
Leaf Van Boven, University of Colorado, USA

Consumers discount delayed outcomes. We hypothesized that this happens partially because people attend primarily to immediate outcomes; and that shifting attention towards future outcomes reduces discounting. Across three experiments participants cued to visually attend to future rewards discounted future rewards less than participants cued towards immediate rewards and control participants.

Managing Multiple Identities: A Case of Meat Consumption

Louise Randers, Department of Management, Aarhus University, Denmark
John Thøgersen, Aarhus University, Denmark
Alice Grønhøj, Aarhus University, Denmark

The study identifies that consumers can hold multiple hierarchically ordered identities with implications for consumption reduction and avoidance of various protein products. Identities can correspond or conflict. In the latter case strategies of managing identity salience or changing protein consumption are used and these mechanisms can be utilized in practice.

Do as I Say, Not as I Do: Figuring the Child as Digital Native Through Technology Ideology and Caregiver Consumption

Sophie Alexandra Reeves-Morris, Liverpool John Moores University, UK
Shona Bettany, University of Huddersfield, UK

This early stage work seeks to add to the qualitative understanding of how children are becoming differentially socialised consumers through their smartphone engagement. To gain a holistic view the nature and dynamism of a carer's technology ideology is being explored to see how this may create disparities in children's smartphone socialisation.

The Friday Payday Effect: The Impact of Intraweek Payday Timing on Deserving Justifications and Discretionary Spending

Wendy De La Rosa, Stanford University, USA
Broderick Turner, Northwestern University, USA
Jennifer Aaker, Stanford University, USA

More than half of Americans are paid on Fridays. However little is known about how intraweek payday timing (e.g. Monday vs. Friday paydays) impacts consumer spending. Across a series of studies and an analysis of real-world spending we demonstrate that Friday paydays increase consumers' deserving justifications and thus their discretionary spending.

Pain of Philanthropy: When Does Cash Help Charitable Donations?

Spencer Ross, University of Massachusetts Lowell, USA
Sommer Kapitan, Auckland University of Technology, New Zealand

Businesses have found their costs of accepting cash payments increasing as consumers have shifted toward noncash payments. Given this societal decrease in cash we examine the role of payment mechanisms in donation behaviors. We find while noncash payments are beneficial in certain donation transactions cash remains more beneficial in others.

Digital Resource Scarcity Affects Online Purchase Intent:
The Moderating Role of Message Framing

Arani Roy, McGill University, Canada
Ashesh Mukherjee, McGill University, Canada

Consumers often face scarcity of digital resources such as low battery-life or low data availability. Two experiments are conducted to examine the effect of digital resource-scarcity on consumers' online purchase intent. Using regulatory focus theory we propose that the effect of scarcity on purchase intent is moderated by advertisement message-framing.

Algorithmic Decision-Making, Agency and Autonomy
in a Financial Decision Making Context: An Experiment

Laszlo Sajtos, University of Auckland, New Zealand
Benjamin G. Voyer, ESCP Europe, France
Marion Sangle-Ferriere, ESCP Europe, France
Billy Sung, Curtin University, Australia

Algorithmic decision making (ADM) plays an increasing role in consumers' life. ADMs rely on customer information and can contribute to reducing consumers' perceived autonomy which consumers may be reluctant to accept. Using a financial decision-making scenario we explore how human ADM and joint decision-making affects consumers' agency and autonomy.

Towards a Better Understanding of Consumer Online Browsing (COB)

Fabio Shimabukuro Sandes, Sao Paulo School of Business Administration FGV-EAESP, Brazil
Delane Botelho, EAESP-FGV, Brazil
Yuliya Komarova, Fordham University, USA

Through in-depth interviews and four experiments we investigate the Consumer Online Browsing (COB) as a distinct type of search behavior. There are different effects of COB and similar constructs on dependent variables and they are differently moderated by variables that arose from the qualitative phase of the research.

Guilty Pleasures: Consumers Choosing Identity Conflicting Behaviors

Nikkita Sarna, University of Texas at Austin, USA
Susan Broniarczyk, University of Texas at Austin, USA

We examine a real-world phenomenon where consumers knowingly and repeatedly act in an identity conflicting way for their own personal pleasure— guilty pleasures. Four experiments (n=~1000) demonstrate how guilty pleasures are behaviors that individuals choose to engage in even though they report identifying with the behaviors less than other behaviors.

Enjoying the Sale: The Case of Itinerant Retailers in Festivals

Prakash Satyavageeswaran, Indian Institute of Management Udaipur, India
Sridhar Samu, Great Lakes Institute of Management, India
Rajesh Nanarpuzha, Indian Institute of Management Udaipur, India
Jossin Shaji, Indian Institute of Management Udaipur, India

Retailers have been seen primarily as commercial entities; itinerant retailers included. We consider itinerant retailer as consumer in the context of temple festivals where they are motivated by the consumption of the festival. We also consider their role as informants and suppliers of products associated with the festival to consumers.

Digital Service Consumption, Blessing or Curse? Exploring the Effect of Persuasive Design Features on Mindfulness and Consumer Well-Being

Dorothea Schaffner, University of Applied Sciences and Arts of Northwestern,Switzerland
Uta Jüttner, Lucerne University of Applied Sciences and Arts, Switzerland
Anja Bruggmann, University of Applied Sciences and Arts Northwestern, Switzerland
Tobias Véron, University of Applied Sciences and Arts Northwestern, Switzerland
Philipp Wyss, University of Applied Sciences and Arts Northwestern, Switzerland
Martina Bracher, University of Applied Sciences and Arts Northwestern, Switzerland
Linda Lingg, University of Applied Sciences and Arts Northwestern, Switzerland

This study explores effects of mindfulness in digital service consumption. The findings of a diary research study provide mixed evidence: Consumer mindfulness in the digital service experience is negatively related to stress and positively related to satisfaction and well-being. However persuasive design features are not found to impact consumers' mindfulness.

You Get What You Ask For: How the Question Asked Shapes Person Perception and Discussion of Controversial Topics

Ann Schlosser, University of Washington, USA
Evelyn Olivia Smith, University of Washington, USA

Our research contributes to prior research by demonstrating that more important than comparing "how" to "why" is whether the question directs the respondent's focus inward. We find that an internal (e.g. "how improve") versus external (e.g. "how work") question inflated people's understanding of a topic and perceptions of disagreement.

I'm Not Too Generous: The Implications of a Novel Moderator of the Better-Than-Average Effect

Shoshana Segal, New York University, USA
Yonat Zwebner, The InterDisciplinary Center (IDC Herzliya), Israel
Alixandra Barasch, New York University, USA

The finding that people often rate themselves as better than the average (BTA) is widely understood to apply to positive traits such as intelligence and resourcefulness. We show however that the BTA effect is attenuated for the generosity trait: people do not (like to) think of themselves as too generous.

Consumer Experiences of Responsibilization in the Context of Digital Healthcare Services

Henriikka Seittu, Aalto University, Finland
Alexei Gloukhovtsev, Aalto University, Finland
Henri Weijo, Aalto University, Finland
Tomas Falk, Aalto University, Finland

We study consumers' experiences of increasing responsibilization in the context of online therapy services. We find that responsibilization ushers in a new subjectivity of "empowered consumer" that conflicts with the previously internalized subjectivity of consumer-patient. We detail how our informants engage in various practices of reflexivity to reconcile this conflict.

Sensory Attributes in Brand Extensions: The Role of Attribute Centrality in Evaluations of Fit

Samuel B Sekar, University of South Florida, USA

This paper examines the role of sensory attributes in consumer evaluation of brand extensions. Specifically we investigate how a consumer evaluates brand extensions on touch and smell-related attributes across multiple possible extensions.

Differential Correlates of Pathological and Impulsive Buying

Benjamin G. Serfas, University of Duisburg-Essen, Germany
Oliver B. Büttner, University of Duisburg-Essen, Germany
Matthias Brand, University of Duisburg-Essen, Germany
Astrid Müller, Hannover Medical School, Germany
Patrick Trotzke, University of Duisburg-Essen, Germany

The present research differentiates pathological from impulsive buying both on a measurement level and on a conceptual level. Firstly we establish discriminant validity between constructs. Secondly we suggest a model explaining the behavioral manifestation of pathological and impulsive buying. Thirdly we analyze the impact on brand loyalty.

From Satisfaction of Consumers to Satisfaction With Consumers: Reverse Rating in the Sharing Economy

Jie(Doreen) Shen, University of Illinois at Urbana-Champaign, USA
Aric Rindfleisch, University of Illinois at Urbana-Champaign, USA

The current research examines consumers' perceptions of the reverse rating (i.e. consumer are rated by providers). It also investigates the impacts of platform positioning on consumers' evaluation of a sharing platform that employs reverse rating and their future app usage intention as well as consumers' star rating to providers.

The Interplay of Variety and Processing Strategy on Calorie Estimates

Liang Shen, University of Cincinnati, USA
Fengyan Cai, Shanghai Jiao Tong University, China
Robert Wyer Jr., University of Cincinnati, USA

Given the inconsistent findings about the relationship between food variety and calorie estimates we propose the effect of variety on calorie estimation and its downstream consequences depend in part on how those items are processed. Three studies confirm the proposed interactive effect and its underlying mechanism.

How Process Ambiguity in Rewards Influences Subsequent Donations: The Role of Mental Accounting

Haijiao Shi, Tsinghua University, China
Rong Chen, Tsinghua University, China
Xiaobing Xu, Hainan University, China

We find that consumers are more likely to donate rewards earned through an ambiguous process (vs. certain process) because they place these rewards in an independent account whereas rewards obtained from a certain process were booked as deductions from payment accounts. We also test two boundary conditions for the effect.

Arbiters of Controversy: The New Role of Brands in Contemporary Society

Justin Sieow, University of Connecticut, USA
Robin A. Coulter, University of Connecticut, USA

Our research investigates the new role of brands as arbiters of social issues. Grounded in institutional theory we identity the various agents present within the brand moral landscape. We highlight the complexity present in the marketplace and explore the dynamic between brands consumers and third-party marketplace agents.

The Counterintuitive Effect of Scarcity on Food Waste

Bonnie Simpson, Western University, Canada
Rhiannon MacDonnell Mesler, University of Lethbridge, Canada
Katherine White, University of British Columbia, Canada

Across three studies we examine scarcity's effect on food waste behavior. Study 1 (a field study) examines food waste behavior in control versus scarcity-induced conditions. Study 2 explores scarcity's effect on food-related behavior in lab. Study 3 tests temporal distance as a moderator of food waste within consumers experiencing scarcity.

The Interplay Between Reminders of Resource Scarcity and Quantity-Quality Trade-offs

Tanya Singh, Concordia University, Canada
Laura Goodyear, University of Toronto, Canada
Beatriz Pereira, Iowa State University, USA
Caroline Roux, Concordia University, Canada

We examine how experiencing scarcity impacts quality-quantity trade-off decisions. Across four studies we find that people experiencing scarcity prefer higher quantity when trade-offs involves larger product quantities. Conversely people experiencing scarcity prefer higher quality when trade-offs involve smaller product quantities. We propose a theoretical framework to explain this counterintuitive result.

Social Influences on the Process of Remaining a Vegetarian

Lucie Sirieix, Montpellier SupAgro, France
Gilles Séré de lanauze, Montpellier University, France
Margot Dyen, University of West Brittany, France

If the socio-demographic profiles and motivations of vegetarians are well known (Ruby 2012) few studies have looked at the vegetarians' trajectories (Cherry 2015). The present article redresses this deficiency by examining how social influences can play a role in the ability to maintain a vegetarian diet.

Choosing Randomly Displayed Products For Joint Consumption

Jiaqi (Flora) Song, University of Liverpool, UK
Dongjin He, Hong Kong Polytechic University, China
Yuwei Jiang, Hong Kong Polytechic University, China

This research investigates the impact of the consumption context on consumers' product display preference. Two studies demonstrate that consumers have higher purchase intention for products with a randomized display in joint compared to solo consumption contexts an effect driven by the heightened need to belong in joint consumptions.

Environmental Friendliness and Product Design

Jiaqi Flora Song, University of Liverpool, UK
Boyoun Grace Chae, Hong Kong Polytechic University, China
Yuwei Jiang, Hong Kong Polytechic University, China

Two studies demonstrate that consumers judge products with a glossy rather than matte exterior design as less environmentally friendly. This effect is driven by the belief that glossier products are more processed and less natural and can lead to downstream consequences in regard to disposal behavior.

Mindful Brand: Development and Validation of a Mindful Brand Scale (MBS)

Ellen Campos Sousa, Florida International University, USA
Jayati Sinha, Florida International University, USA

This research brings a novelty contribution to the marketing and mindfulness literature proposing a conceptualization and a measurement for a mindful brand from a consumer perspective. A set of characteristics associated with mindful brand was identified and a mindful brand scale (MBS) was developed and validated.

Owning or Sharing? How Feeling Financially Constrained Decreases Participation in Access-Based Services

Emanuela Stagno, BI Norwegian Business School, Norway
Klemens Knoferle, BI Norwegian Business School, Norway
Luk Warlop, BI Norwegian Business School, Norway

Feeling financially constrained influences consumer attention and behaviors. We propose that this feeling also affects the propensity to engage in alternative consumption modes; namely access-based consumption. Two experiments test whether financially constrained consumers are less willing to participate in access-based services. The preliminary findings seem to not support our hypothesis.

The Role of Consumer Self-identities and Individual Tendencies in Food Waste

Violeta Stancu, Aarhus University, Denmark
Liisa Lähteenmäki, Aarhus University, Denmark

There are several well-established negative consequences of food waste for the environment and society. Consumers' environmental or frugal self-identities are associated with lower self-reported food waste. On the other hand people's impulsive buying tendency and disgust sensitivity are important factors that associate positively with consumer food waste.

The Role of Multiple Self-Identities in Behaviours Across the Consumption-cycle in Food and Apparel

Catalin Mihai Stancu, Aarhus University, Denmark
Alice Grønhøj, Aarhus University, Denmark
Liisa Lähteenmäki, Aarhus University, Denmark

Consumers have several self-identities which impact sustainable behaviours. Frugal self-identity was found to have stronger associations with specific categories of behaviours in the consumption-cycle. While sustainable self-identity positively predicted behaviours across the consumption-cycle frugal thrifty or trendy self-identities had both positive and negative relations to behaviours outlining potential clashes.

Embracing and Rejecting "Sparking Joy"—Understanding Japanese Consumer Responses to Marie Kondo's Original Book

Sumire Stanislawski, Tokyo International University, Japan
Shuji Ohira, Chiba University of Commerce, Japan
Kosuke Mizukoshi, Tokyo Metropolitan University, Japan

By examining responses to Marie Kondo's original book consumer reactions to a taste regime counter to mainstream consumerism are explored. Those who embraced and rejected her message were analyzed using text mining. Some internalized new meanings surrounding consumption while others rejected her legitimacy as an influencer of taste.

The Darkside of Online Social Networks: Measuring the Negative Effects of Social Influence in Online Social Networks

Sabrina Stoeckli, University of Bern, Switzerland
Fabian Bartsch, IÉSEG School of Management, Paris, France
Henry Shen, IÉSEG School of Management, Paris, France

This research conceptualizes and develops a scale of Susceptibility to Social Influence in the context of Online Social Networks such as Facebook or Instagram. Three studies find support for the conceptualization and for a valid and reliable scale. Next steps for scale development and its future application are discussed.

Table to Farm: Persuasive Messaging Influences Consumers' Willingness to Compost

Nicolette Sullivan, London School of Economics, UK
Rick Larrick, Duke University, USA
Gavan Fitzsimons, Duke University, USA

Despite consumers' concern for the environment one measure that could have a profound impact diverting waste from landfills household composting has had low adoption rates. This study investigates the effectiveness of persuasive messages on willingness to compost amongst different segments of consumers.

To Err Is Human, to Correct Is Algorithmic

Chengyao Sun, Washington University, USA
Cynthia Cryder, Washington University, USA

Across three studies and nine scenarios we observe that people believe that algorithmic errors can be corrected however they do not believe that human errors can be similarly corrected. More specifically people trust a previously erring algorithm after correction but lose confidence in an erring human even after correction.

The Effect of Tragic Artist Biography on Consumer Evaluation of Artworks

Yeonjin Sung, University of Michigan, USA
Seojin Stacey Lee, Seoul National University, South Korea
Kiwan Park, Seoul National University, South Korea

Our research proposes that providing a tragic biography of an artist enhances the perceived quality of the artwork by allowing people to appreciate the depth of expression in the artwork ("tragic artist effect"). We also show that this effect occurs independently of alternative processes—empathy effort and eudaimonic fulfillment.

Choice Overload, Does it Really Exist?: A Neurophysiological Assessment of Consumers' Responses to "the Paradox of Choice"

Anshu Suri, HEC Montreal, Canada
Sylvain Sénécal, HEC Montreal, Canada
Pierre-Majorique Léger, HEC Montreal, Canada

We contribute to the debate of choice overload by concluding that the psychophysiological measures collected through an eye-tracker and face-reader indicate that consumers not only experience an increased level in cognitive load when selecting from a large set of options but also experience negative emotions in the decision-making process.

What do You Mean by Love? Understanding Brand Love Experiences

Bruno Sutil, Sao Paulo School of Business Administration FGV-EAESP, Brazil
Delane Botelho, EAESP-FGV, Brazil
Diógenes Bido, Machenzie, Brazil

Just as there are types of interpersonal love there might be types or experiences of brand love. We add to the literature by developing a multidimensional differentiation scale based on the reasons people love a brand to typify their experiences. Four factors emerged: values identity emotional attachment and functionality.

Packaged or Unpackaged? How Displaying a Product With Vs. Without Packaging Influences Product Evaluations

Courtney Szocs, Louisiana State University, USA
Sara Williamson, SUNY Old Westbury, USA
Adam Mills, Loyola University New Orleans, USA

Managers display products with and without packaging in stores advertisements and online seemingly arbitrarily. Would displaying a product encapsulated in a package as opposed to unpackaged influence consumers' product evaluations? If so why? Three experimental studies address these research questions and contribute to the literature on packaging and display effects.

You Are Who You Follow: The Impact Of Fitness Influencers On Food Consumption And Identity

Amandeep Takhar, De Montfort University, Leicester, UK
Thomas Magede, De Montfort University, UK
Jennifer Walker, De Montfort University, UK

This paper builds on prior consumer research relating to food and identity construction. By looking at how online fitness influencers impact the food consumption and identity of young millennials in the U.K. it is evident that participants were influenced by online fitness influencers in negotiating their self and collective identity.

To Cleanse or to Enjoy? The Effect of Affectively Tagged Windfall Time on Consumption Choice

Arash Talebi, EDHEC Business School, France
Easa Sahabeh, University of South-Eastern Norway, Norway

We investigate how consumption changes when people gain a windfall block of time with affective tags (positive vs. negative). We find an asymmetrical effect: negative windfall time encourages hedonic (vs. utilitarian) activities supporting a mood regulation account. However positive windfall time does not seem to influence the consumption pattern.

Eco-friendly Versus Polyester Gucci Handbags: The Effect of Matching Green Claims and Temporal Frame on Product Evaluation of Self-enhancement Brands

Nabanita Talukdar, Hult International Business School, USA
Shubin Lance Yu, Peking University, China
Esterina Nervino, Universita' degli Studi di Modena e Reggio Emilia, Italy

We examine how message-orientations of green claims using temporal construal affects consumers' evaluation towards self-enhancement brands' sustainable products. Through a survey experiment we confirm that a high construal level and high temporal distance green message improved the product evaluation through higher processing fluency for high green orientation individuals.

Indulgent Consumption Signals Interpersonal Warmth

Qing Tang, Nanyang Technological University, Singapore
Kuangjie Zhang, Nanyang Technological University, Singapore
Xun (Irene) Huang, Nanyang Technological University, Singapore

Three studies demonstrated that showcasing indulgent consumption can have a positive signaling function on one's perceived warmth. Therefore consumers also choose indulgent food items when they have the motivation to appear warm in front of others. These findings add to the literature of indulgent consumption and consumer signaling behavior.

Consumption Opportunity and The Consideration of Consumption-Opportunity Cost

Tao Tao, Hong Kong Baptist University, China
Ran Li, Chinese University of Hong Kong, China

For the first time the authors propose the concept of consumption opportunity and identify it as a scarce exclusive and valuable resource to a consumer. We further demonstrated that when making purchase decisions the consideration of the cost of consumption opportunity could induce consumers to choose the higher-quality smaller-amount option.

I Revenge For Others I Do Not Know: The Role Of Intercultural Competence In Moderating Customer Revenge To Service Failure Occurred To Adjacent Customer

Mohamed Sobhy Temerak, Kent Business School, UK
Ruby Zhang, University of Reading, UK
Cristiana Lages, University of Reading, UK

We examine the service failure from the observers' perspective and how it influences their patronage and revenge intentions. Results from a 2x2 experiment revealed observer's interpretation of service failure was largely influenced by their intercultural competence. They are more sensitive to discrimination and courageous to retaliate with higher intercultural intelligence.

Recycled Plastic on the Upswing: The Effect of Packaging Material on Perceived Healthiness and Purchase Intention

Joyce De Temmerman, Ghent University, Belgium
Nico Heuvinck, IESEG School of Management, France
Hendrik Slabbinck, Ghent University, Belgium
Iris Vermeir, Ghent University, Belgium

This research explores the impact of recycled plastic on perceived healthiness and purchase intention. We find that consumers tend to perceive products in recycled (vs. regular) plastic packaging as healthier and thereby are more likely to purchase products in recycled plastic packaging.

The Impact of Logo Typeface Obliqueness on Product Efficacy Perception

Lefa Teng, Jiangnan University, China
Jie Wang, The Hong Kong Polytechnic University, China
Yuwei Jiang, Hong Kong Polytechic University, China

This research shows that the obliqueness of logo typefaces influences consumers' efficacy judgment of products offered by the company. Compared with non-oblique typeface logos oblique typeface logos generate the perception of quicker product effect. This effect is attenuated when the typeface is heavy.

Singled Out For Public Praise: How Scarcity Boosts Demand For Public Recognition

Carina Thuerridl, University of Amsterdam, The Netherlands
Bernadette Kamleitner, Vienna University of Economics and Business, Austria

Public recognition is more valuable but less popular than private recognition in crowdfunding and charitable giving. We show that limiting availability of recognition increases preferences for public but not for private recognition. Singling consumers out for public raise may thus be a simple cost-effective strategy to increase monetary contributions.

Measuring the Dissemination of a Subculture Through Consumption. Investigating the Geek Culture Case.

Alexandre Tiercelin, Université de Reims, France
Marion Garnier, Grenoble Ecole de Management - Univ Grenoble Alpes ComUE, France
Arnaud Delannoy, Ecole de Management de Normandie, Laboratoire Métis, France

This research proposes to understand better the dissemination of a subculture within mass culture by measuring belonging and consumption in the geek culture case. Results confirm subcultural traits and practices and progressive dissemination showing the quantifiable reality of a subculture and the possibility of measuring its spreading.

Social Atmospheres: Priming, Aligning and Defining Shared Experiences of Place

Hill Tim, University of Bath, UK
Robin Canniford, University of Melbourne, Australia

Atmospheres are the moods associated with places. Current marketing research explains that firms create atmospheres by controlling material features of servicescapes. Through an ethnographic investigation of English Premier League soccer however we show that atmospheres are also social experiences that define the mood of place through consumers' embodied performances.

When Does Actual Versus Ideal Self-Congruence Matter? Moderating Effects of Construal-Level on Brand Attitudes

Taku Togawa, Sophia University, Japan
Kazuyo Ando, Chiba University of Commerce, Japan

Drawing on construal level theory this study found that consumers with low-level construal tended to focus on actual self-congruence (ASC) with a brand and prefer brands with high ASC levels. Contrarily consumers with high-level construal focused on ideal self-congruence (ISC) and indicated positive attitudes toward brands with high ISC.

If I Think I Can I Can. Can't I? How Social Mobility Beliefs Influence Your Financial Behavior

Patricia Torres, Florida International University, USA
Alexandra Aguirre-Rodriguez, Florida International University, USA

This research explores how social mobility expectations influence one's financial behavior intentions. Across three studies this research reveals that social mobility expectations impacts behavior intentions; financial self-efficacy mediates whereas financial literacy moderates this relationship. Findings are discussed considering their implications for research on expectancy financial goal pursuit and decision making.

Product Consecration and Market Expansion: The Case of Vitamin D

Lez Ecima Trujillo Torres, University of Illinois at Chicago, USA
Alev Kuruoglu, University of Southern Denmark, Denmark
Hazal Celik, University College Dublin, Ireland

Our study investigates the relationship between product consecration and market creation and expansion. Our findings indicate that the global Vitamin D market has expanded from 1996 to 2019 through a process of contested product consecration that involves the cultural and scientific consecration and commercial innovation of Vitamin D over time.

How Customer Identification Can Lead to Dysfunctional Behavior

Huy Quoc Tran, University of South-Eastern Norway, Norway
Marit Engeset, University of South-Eastern Norway
Luk Warlop, BI Norwegian Business School, Norway

Recent research explores the role of social identity in consumer contexts. In this study we document the negative effect of customer identification on impoliteness. We found that entitlement mediated this relationship and that this effect was conditional on self-control. We also plan to investigate other mechanisms underlying this phenomenon.

The Relationship Between Self-Construal and Neural Processes Associated With Conforming to Consumer-to-Consumer Recommendations

Arina Tveleneva, University of Wisconsin - Madison, USA
Xinyi Wang, University of Wisconsin - Madison, USA
Matthew Brook O'Donnell, University of Pennsylvania, USA
Emily B Falk, University of Pennsylvania, USA
Christopher N. Cascio, University of Wisconsin - Madison, USA

The results suggest that those who have a stronger interdependent view of the self compared to a weaker interdependent view of the self are potentially more likely to conform to social feedback when their opinions misalign with others. Interdependent self is also significantly associated with conflict monitoring and mentalizing.

When Does Diversity Help or Backfire? Impact of Cultural Diversity on Brand Perception

Esther Uduehi, University of Pennsylvania, USA
Julian K Saint Clair, Loyola Marymount University, USA
Mitchell Hamilton, Loyola Marymount University, USA
Americus Reed, University of Pennsylvania, USA

This paper is the first to show how diversity as a brand characteristic influences consumer perceptions of the brand's authenticity. We find that majority-focused brands embracing diversity increases in authenticity while a minority-focused brand embracing diversity may lose authenticity. This loss of authenticity is particularly felt by minority consumers.

Console War (and Peace?): Analysing Cross-Community Interactions in Gaming Discussion Forums on Reddit

Denis Utochkin, Norwegian School of Economics and Business Administration, Norway

In this paper I employ a mix of netnography machine learning and network analysis to examine 12 gaming communities on Reddit. Treating each individual community as inseparable from its immediate context I explore how multiple loyalties and identities are managed by consumers engaging in conversations in a multi-community context.

In Defense of Happy Hedonism: Moving Beyond Materialism and Its Negative Impact on Well-Being

Rita Coelho do Vale, Catolica Lisbon School of Business and Economics, Portugal
Rik Pieters, Tilburg University, The Netherlands

This research studies happy hedonism analyzing its relationship with consumer well-being. It explores the idea that pursuing pleasure through the mere consumption of experiences and objects might positively contribute to consumer well-being. Three laboratory studies were conducted to explore the happy hedonism phenomenon and to distinguishing it from consumer materialism.

The Meaning and Transformation of Taste Vocabulary

Rohan Venkatraman, University of Melbourne, Australia
Anna E Hartman, University of Melbourne, Australia
Ilkka Ojansivu, University of Melbourne, Australia
Erica Coslor, University of Melbourne, Australia

We conceptualize the vocabulary used in tasting notes as part of taste regimes. Through qualitative content analysis of whiskey tasting descriptions we found that consumers transformed institutionalised vocabularies to convey variable meanings extending our understanding of adaptation of the language of a taste regime.

"Luxurious and Responsible? Consumer Perceptions of Corporate Social Responsibility Efforts by Luxury Versus Mass-market Brands"

Marlene Vock, Amsterdam Business School, University of Amsterdam, The Netherlands

This research contributes to the inconclusive debate in the field of sustainable luxury on whether the adoption of Corporate Social Responsibility practices is beneficial for luxury brands or backfires a dilemma known as the 'CSR-Luxury paradox'. Different types of CSR practices might help to explain inconsistencies in previous findings.

The Effectiveness Of Online Recommendations For Private Labels Versus National Brands

Barbara Kobuszewski Volles, Ghent University, Belgium
Anneleen Van Kerckhove, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

This research reveals that consumers when recommended with products online are more inclined to switch to private labels compared to national brands. We present two studies demonstrating this effect and propose that it occurs because recommendations serve more as a signal of quality for private labels than for national brands.

Magically Relieved or Taking Control? The Influence of Messages Aimed at Debt Distressed Consumers

Rory Waisman, University of Alberta, Canada
Mohammed El Hazzouri, Mount Royal University, Canada
Kelley Main, University of Manitoba, Canada
Gerald Häubl, University of Alberta, Canada

Marketing messages used by the debt-remedy industry differentially impact consumers' financial behaviors depending on the nature of the appeal and consumers' level of debt. Appeals that focus on debt-relief can backfire whereas messages about taking control of debt have distinct marketing and public-policy advantages.

What a Cute Lemon! The Effect of Whimsical Cuteness on Willingness-To-Pay For Imperfect Produce

Darlene Walsh, Concordia University, Canada
Camille Darriet, Concordia University, Canada

The goal of our research is to find a way to encourage consumers to purchase imperfect produce. As a first-step in achieving this goal we demonstrate that priming whimsical cuteness (i.e. adding "googly eyes" to imperfect produce) can increase consumers' willing-to-pay for imperfect produce. Future research ideas are also discussed.

A Discount Added is an Obstacle Created: The Impact of
Multiple Discounts on Consumer Decisions

Xin Wang, Nanjing University, China
Chunqu Xiao, Nanjing University, China
Hong Zhu, Nanjing University, China

Based on numerical cognition we conducted four experiments to explore the effect of multiple discounts and found that consumers preferred a single discount to multiple discounts. Cognitive fluency and perceived sincerity sequentially mediated the effect. Consumers concern for sales moderated the effect.

Don't Reveal It Yet! How Goal Disclosure on Social Media
Impedes Goal Revision and Commitment

Liangyan Wang, Shanghai Jiao Tong University, China
Zhining Yu, Shanghai Jiaotong University, China

People commonly disclose their personal goals publicly on social media platforms based on the conventional belief that disclosure increases goal commitment and improves performance. Results from two experimental studies suggest that this conventional belief only applies to easy goals but not for difficult goals.

Healthy-Angular, Unhealthy-Circular: The Effect of Shape on Consumers Health Choice

Jie Wang, Renmin University of China, China
Jing Jiang, Renmin University of China, China
Xiaodan Zhang, Peking University, China

This paper explored the matching effect between food healthiness and shape. We demonstrated that angular (vs. circular) shape increases consumers' preference for healthy options which is because a "healthy-angular unhealthy-circular" match could enhance consumers ease of processing and subsequently influences consumers choice.

Love or Luck? The Effect of Self-Referencing Narratives
on Used Product Consumption Behaviors

Yan Wang, Renmin, University of China, China
Jing Jiang, Renmin, University of China, China

This research investigates the impact of selling narratives created by sellers on buyers' purchase behaviors in the context of second-hand market. Across three experiments we find that self-focused (love-oriented) narratives drive low purchase intention but high willingness-to-pay whereas product-focused (luck-oriented) narrative generates both high purchase intention and willingness-to-pay.

Moderate Product-gift Complementarity Eliminates
Devaluation Effect in Free-Gift-With-Purchase Offers

Yusu Wang, Texas A&M University, USA
Nicholas J. Olson, Texas A&M University, USA

While past literature demonstrated a devaluation effect of the focal product in free-gift-with-purchase offers this research provides evidence supporting our argument that a moderate (vs. high) complementarity between the focal product and the free gift counters this devaluation tendency. Underlying mechanism is also accessed.

Red in the Environment Increases Preference For Competent Brands

Yansu Wang, Renmin University of China, China
Jun Pang, Renmin University of China, China
Lingyun Qiu, Peking University, China

Across four studies this research demonstrates that exposure to red cues in the environment increases consumer preference for competent but not warm brands. This effect is mediated by competitive orientation and is attenuated when consumers purchase products for others than for themselves.

Robot Anthropomorphism in the Workplace and Employees' Job Insecurity

Xue Wang, University of Hong Kong, China
Sara Kim, University of Hong Kong, China
Minki Kim, Korea Advanced Institute of Science and Technology, South Korea

In four studies we show that robot anthropomorphism in the workplace enhances employees' job insecurity due to an increase in social comparison. The findings contribute to the literature on robot anthropomorphism and job insecurity and provides practical implications to organizations in terms of how to design robots.

Signs Telling Me to Do What Others Do: The Effect of Exposure to Public Rules on Conformity

Xiaoran Wang, Renmin University of China, China
Jing Jiang, Renmin University of China, China
Yan Wang, Renmin University of China, China

This research takes a novel perspective by proposing an exposure effect of public rules on conformity. Across three experiments we find that in public consumption context exposure to public rules reminds consumers of the presence of others which increases their public self-awareness and hence the preference for majority-endorsed products.

The Dark Side of Precision: Numerical Information and Consumers' Unhealthy Choices

Jie Wang, Renmin University of China, China
Jing Jiang, Renmin University of China, China
Xiadan Zhang, Renmin University of China, China

The research explores how numerical precision affects consumers' health behaviors and how illusory control functions as an underlying mechanism. Across three studies we find that when the numerical information is expressed in a precise (vs. imprecise) format it tends to induce consumers' illusory control which subsequently increases risky health behaviors.

Visual Simplicity Signals Constructive Brand Authenticity

Yan Wang, Renmin University of China, China
Jing Jiang, Renmin University of China, China
Xiushuang Gong, Jiangnan University, China

Constructive brand authenticity is subjective and can be contextually determined. This research examines the consumer lay belief about the relationship between aesthetics and constructive brand authenticity. Across three experiments we find that consumers perceive a brand as more authentic when it is with visually simple (vs. complex) designs or displays.

The Case-Gender Congruity Effect: Consumer Choices
For Upper Versus Lowercase Brand Names

Na Wen, California State University Northridge, USA

A series of experiments find that the letter case of brand names (upper- vs. lower-case) affects consumer choices but that these effects depend on congruity between brand case and product gender. This research advances understanding of how seemingly subtle brand name characteristics affect gender perceptions and consumer behavior.

The Closer, The Worst: The Impact Of Social Distance to a Dissociative Group And
Consumer Choices

Na Wen, California State University Northridge, USA

Two experiments test the idea that consumers are less likely to buy a product if it is associated with a near (vs. distant) dissociative group—which is mediated by construal-level mindsets and moderated by group conformity. This work advances understanding of how different types of dissociative groups affect consumer behavior.

You Are More Patient When You Experienced More:
The Impact of Memory Markers on Consumers' Decisions in the Future

Yingting Wen, ESSEC Business School, France
Ayse Onculer, ESSEC Business School, France

This research investigates how retrospective time progression can influence consumers' decisions in the upcoming future. By using different numbers of memory markers two studies show that people experience different retrospective time progression over the same duration and they have different levels of patience on waiting and intertemporal choice.

The Value of Personal Information - Consumers' Valuations
and Preferences For Personal Data And Privacy

Claudia Wenzel, University of Zurich, Switzerland
René Algesheimer, University of Zurich, Switzerland

Data is the oil of our age. Despite its importance research is lacking consistent data value estimations. By combining current valuation methods this research offers a better estimate of the value consumers attribute to their data and by drawing on reference price theory minimizes the gap between different valuation methods.

The Unit-Size Effect Revised: A Win-Win Solution For Reducing Both Waist and Waste

Amber Werkman, University of Groningen, The Netherlands
Jenny van Doorn, University of Groningen, The Netherlands
Koert Van Ittersum, University of Groningen, The Netherlands

People consume less when food is presented in multiple smaller units compared to a few larger units however food waste will increase accordingly. We propose that this so-called unit-size effect is even more impactful during food selection when people select quantities themselves based on unportioned rather than portioned food.

When Do You Want This? How Delivery-scheduling
Impacts Motivation Among Online Shoppers

Sara Williamson, SUNY Old Westbury, USA
Courtney Szocs, Louisiana State University, USA

Online purchases require consumers to complete multiple sub-tasks such as product selection delivery-scheduling and payment. In this project we investigate how the sequence of these sub tasks can influence motivation in the purchase context. Specifically we investigate how scheduling delivery before making product choices can exhibit motivating effects.

Are Co-branding Products More Attractive? Understanding the Role of Consumer Innovativeness and Self-construal

Sihan Wu, Tsinghua University, China
Maggie Wenjing Liu, Tsinghua University, China

In this study we intend to develop and test a model considering that the consumers prefer co-branding product via consumer innovativeness. We further examined the moderation role of self-construal such that positive effect is stronger when individual is in a predominantly interdependent.

Effects of Masculinity and Femininity Incongruence on Consumer Responses to Brands

Xiu Wu, Concordia University, Canada
Bianca Grohmann, Concordia University, Canada

This research examines the effect of incongruence between consumers' gender identity and brand gender. Two studies find a significant main and interaction effect of masculinity and femininity incongruence on consumer-brand boundary—the perceived psychological distance between a consumer and a brand—and affective cognitive and relational brand responses.

Self-Other Differences in the Perceived Efficacy of Self-Enhancement Products

Kaiyang Wu, University of Wisconsin - Madison, USA
Evan Polman, University of Wisconsin - Madison, USA

We tested if judgments of self-enhancement products' efficacy differ according to whether a product user is the self or someone else. In two pre-registered studies we found that people believe that self-enhancement products will be more efficacious for others than for themselves and that usership moderates this self-other difference.

Maximizing What? The Effect of Maximizing Mindset on the Evaluation of Product Bundles

Lan Xia, Bentley University, USA
Nada Nasr Bechwati, Bentley University, USA

Do maximizers value product bundles higher than satisficers? We propose that it depends on whether maximizers try to maximize the value of the individual products or that of the entire bundle. The focus of the maximization is influenced by the presence of a discount. Results from three studies are presented.

Robots Don't Discriminate: Financial Resources, Age, and Preference of AI in Service

Lan Xia, Bentley University, USA

Do consumers prefer robots or humans in service contexts? Our studies show that controlling for self-efficacy and AI performance preferences for AI vary by customer characteristics such that older consumers of lower (vs. higher) financial status tend to prefer robots more due to the expected service they obtain.

Penny Wise and Pound Foolish- The Interaction Between Ease of Comparison and Cognitive Effort And Its' Impact On Preference And Choice Change

Na Xiao, Laurentian University, Canada

It is proposed that the interaction between ease of comparison and cognitive effort determines the importance of attributes. It is demonstrated that when cognitive effort to process information about choice-options is high (vs. low) consumers will give weight to ease-to-compare attributes in comparison therefore preference and choice change.

The Effect of Handwritten Typefaces on Consumer Evaluation

Chunqu Xiao, Nanjing University, China
Xin Wang, Nanjing University, China
Hejin Fang, Nanjing University, China
Haoyuan Wang, New York Statement University at Buffalo, USA
Hong Zhu, Nanjing University, China

Handwritten typefaces strengthen the impact of online reviews. Across three studies the current research found that handwritten typefaces led higher evaluation on the perceived sincerity of reviewers thus benefitted positively reviewed products. This effect diminished when the reviews were negative or consumers had greater domain knowledge.

How Can I Help When I Feel Rejected? The Interplay of Social Exclusion, Social Identity, and Prosocial Behavior

Xuan Xie, University of California Irvine, USA
Loraine Lau-Gesk, University of California Irvine, USA
Amber Gaffney, Humboldt State University, USA

This research explores prosocial behavior through social exclusion and social identity lens. Results suggested that when feeling rejected prototypical members displayed lower willingness-to-help whereas peripheral members have higher willingness-to-help. When feeling ignored such effect was attenuated for both peripherals and prototypicals. Prosocial behavior alleviates some negative consequences of social exclusion.

Let's Get Serious About Play: A Hedonic Vs. Eudaimonic Investigation of Goal-Based Mixed Affective Experiences

Xuan Xie, University of California Irvine, USA
Sayantani Mukherjee, Central Washington University, USA
Loraine Lau-Gesk, University of California Irvine, USA

This research investigates factors of goal-based mixed play experiences. Perceived effort corresponds positively to consumer judgment and perceived fun of the mixed (vs. pure positive) play experiences. Outcome-oriented thinking encourages a eudaimonic lens unaltered by cognitive load while process-oriented thinking shifts to a hedonic lens moderated by cognitive load.

Performance Diversity and Team Performance Expectations

Vivian (Jieru) Xie, Virginia Tech, USA
Rajesh Bagchi, Virginia Tech, USA

We investigate the effects of performance diversity on expectations of team performance. We find that perceivers expect less diverse teams to perform better. We demonstrate the underlying process and delineate one approach via which these expectations could be reversed.

The Impact of Corporate Environmental Transgressions on Consumer Negative Reactions: The Role of Political Ideology

Chunyan Xie, Western Norway University of Applied Sciences, Norway
Richard P. Bagozzi, University of Michigan, USA

We experimentally test a psychological mechanism underlying consumer negative reactions toward the firm as a function of perception of corporate environmental transgressions. Results showed that social disgust and attitude mediates the relationship between perceived corporate environmental transgressions and consumer reactions. Further political ideology moderates effects of transgressions on social disgust.

The Impact of Financial Perception on Agent Preference of Intelligent Assistant

Chunya Xie, Renmin University of China, China
En-Chung Chang, Renmin University of China, China

Four experiments indicate that financial affluent reduces participants' preference for AI provider of intelligent assistant. Financial affluent leads to a high sense of entitlement which reduces AI preference. Assistant type moderates the effect. When the intelligent assistant is not instructional the effect of financial perception on agent preference reverses.

Why People Are Crazy For Chewing? An Exploratory Study of the Effect of Chewing on Mental Construal

jialiang xu, University of Manitoba, Canada
Fang Wan, University of Manitoba, Canada
Norbert Schwarz, University of Southern California, USA
Wenqing Wu, University of Manitoba, Canada

Oral-sensory information different from other sensory information can be received by different ways (chewing/ swallowing/ drinking). This perspective has not studied by previous research. Our work examines that chewing (vs swallowing) activates people's concrete mental construal which may help consumers focus on the current moment and appreciate experience of eating.

Need to Evaluate as a Predictor of Sharing and Seeking Online Recommendations

Mengran Xu, Ohio State University, USA
Rebecca Walker Reczek, Ohio State University, USA
Richard Petty, Ohio State University, USA

In this research we characterize who is likely to engage in sharing and seeking online word of mouth as a function of their need to evaluate an individual difference measure consisting of two motives the need to express attitudes and the need to acquire information in order to have attitudes.

Swear by My Family: Explore Consumer Attitudes Toward Brands Named After People

Fei (Katie) Xu, Hong Kong Polytechic University, China
Yuwei Jiang, Hong Kong Polytechic University, China

Consumers are more interested to purchase from brands which are named after people's last names than from brands containing people's first names. This effect is found to be mediated by brand trust and moderated by consumers' domain-specific knowledge.

No-Modification Allowed! Saying No to a Consumer's Modification Request Can Increase Product Evaluation

Amanda Pruski Yamim, Grenoble Ecole de Management, France
Adilson Borges, NEOMA Business School, France

Through three studies we show that the presence of non-modification policies can increase tastiness evaluation and willingness to pay because they make consumers think the chef put more effort into the food creation. The positive effect of non-compliance is contingent on consumers' initial beliefs that the chef has high expertise.

Before or After? The Order Effect of Donors' Personally Identifiable Information on Donation Amount

Li Yan, University of Technology Sydney, Australia
Xue Wang, University of Hong Kong, China
Minjung Koo, Sungkyunkwan University, South Korea
Hean Tat Keh, Monash University, Australia

Across five studies we found that individuals donate a higher amount if their personally identifiable information is requested before they indicate the donation amount. This finding makes important theoretical contributions and offer practical implications for charitable organizations by identifying a simple "nudge" that encourages donors to give higher amounts.

Why Should I Improve Myself? Perceived Economic Mobility and Consumer's Interest in Self-Improvement Products

Chun-Ming Yang, Ming Chuan University, Taiwan

Across three studies we provide convergent evidence suggesting that the constraints perceived by consumers increased when they had a low perceived economic mobility (PEM) which in turn influenced their interests in self-improvement products. This study contributes to the literature of PEM by extending its downstream consequences.

Contestations of Entrepreneurship and Marketing in Creative Maker Tribes

Amy Yau, Cardiff University, UK

The ethnographic study explores the narratives of becoming and being a creative maker entrepreneur and how the makers imbue themselves as brands to start and develop their business. It explores how makers create offline and online commercial communities and tribes with other makers and consumers in the mass-market dominated marketplace.

Serif For the Conservatives: The Effects of Typeface on The Persuasiveness of Political Campaign

Jiwon Yi, Hongik University, South Korea
Nara Youn, Hongik University, South Korea

This research investigated the effect of congruence between serif (vs. sans-serif) typeface and the conservative (vs. liberal) political ideology on the campaign effectiveness. Through two experiments we provided a support for the positive effect of serif typefaces on political campaign evaluation of the conservatives and unveiled underlying psychological process.

Immediate Incentives in Prosocial Contexts

Y. Rin Yoon, Cornell University, USA
Kaitlin Woolley, Cornell University, USA

Prior research provides mixed evidence for the effect of financial incentives on prosocial behavior. Three studies (N = 982) fill this gap. We find that immediate (vs. delayed) incentives increase prosocial behavior when prosocial motivation is low but that this effect attenuates when prosocial motivation is high.

Ethnic Identity and Patience in Intertemporal Monetary Decisions

Jiaqi Yu, University of Chicago, USA
Oleg Urminsky, University of Chicago, USA
Stephanie Chen, London Business School, UK

Ethnic identity importance predicts consumers' patience in making intertemporal monetary decisions. Two studies based on evidence from Asians and Caucasians in the U.S. and the U.K. conclude that people who consider their ethnic identity more important value the present over the future and make more impatient time discounting choices.

Multiple Social Identities Increase Torelence of Unethical Behaviors

Irina Y. Yu, Chinese University of Hong Kong, China
Li Huang, Hofstra University, USA
Morgan X. Yang, The Hang Seng University of Hong Kong, China

Consumers possess various social identities and generally show an identity congurent behavior when an identity is momentarily salient. What will happen when multiple identities are salient? We find that the activation of multiple social identities enhances consumers' moral relativism belief and increases their tolerance of unethical/immoral behaviors.

Refunded Money is More Likely to be Spent

Tianjiao Yu, Washington University in St Louis, USA
Cynthia Cryder, Washington University, USA
Robyn LeBoeuf, Washington University, USA

We test how consumers' willingness to spend depends on the transaction history of the money they have available. Specifically we find that money refunded from previous purchases is more likely to be spent than non-refunded money. This research extends prior findings about mental accounting and fungibility.

Sustainability as the Guilt-Relief Pill For Luxury Purchases

Shubin Lance Yu, Peking University, China
Nabanita Talukdar, Hult International Business School, USA
Sangeeta Trott, ITM-SIA Business School, India

Sustainability claims are not widely used by luxury brands because sustainability is considered incompatible with luxury. The results of two experimental studies suggest that for luxury products with a high price a sustainability claim can reduce the anticipated guilt of purchases which in turn leads to higher purchase intention.

Is First the Worst? Understanding Consumers' Tendency to Postpone the Better Outcome

Ozge Yucel-Aybat, Pennsylvania State University Harrisburg, USA
Marina Carnevale, Fordham University, USA

This research investigates the tendency of consumers to postpone their preferred item to the end. Two studies demonstrate that long-term (vs. short-term) oriented consumers are more likely to save their favorite product for last because they value improvements over time more.

Boosting the Resale Value: Effects of Expired Warranty and Repair Conditions of Secondhand Products

Ulku Yuksel, University of Sydney, Australia
Nguyen T Thai, University of Wollongong, Australia
Vince Mitchell, University of Sydney, Australia

Secondhand retailers rarely communicate negative information such as manufacturer warranties being expired or secondhand products being repaired. We show that consumers associate secondhand products with expired warranties with higher (lower) resale values than those with no warranties when these products have been repaired (never been repaired) and explain the process.

Repetition Or No Repetition? Effects Of Repetitive Numbers On Bundling Promotion

Jintao Zhang, Drexel University, USA
Hongjun Ye, Drexel University, USA
Siddharth Bhatt, Pennsylvania State University, Harrisburg, USA
Haeyoung Jeong, Drexel University, USA
Rajneesh Suri, Drexel University, USA

Consumers are constantly making decisions on numbers along with their journey of consumption. Our study examines the effect of repetitive numbers on bundling price (i.e. 2 for $2.22 vs. 2 for $$2.12) that consumers have higher intentions to purchase bundling products with repetitive number prices.

Save Time For Better Life! The Effect Of Time Saving On Quality Perception

Jintao Zhang, Drexel University, USA
Hongjun Ye, Drexel University, USA
Siddharth Bhatt, Pennsylvania State University, Harrisburg, USA
Haeyoung Jeong, Drexel University, USA
Rajneesh Suri, Drexel University, USA

Consumers form their perceptions of quality with different signals. This study examines a novel signal of quality – time – as consumers would associate time saved when shopping with the perceptions of quality of the products the more time consumers save the better quality of the products they perceive.

Food Label Halos and Consumer Perceptions of Food Healthfulness

Yijun Zhao, Renmin University of China, China

This paper demonstrates that label halos bias dieters' estimates about the healthfulness of vice foods containing such labels. Dieters tend to draw a directional conclusion about food healthfulness to mediate the guilt associated with consuming indulgent food. Providing corrective information to dieters can mitigate these effects.

The Impact of Social Crowding on Cross Sensory Products—— Based on the Brand Alliance Perspective

Yijun Zhao, Renmin University of China, China

This research defines the cross sensory product (CSP) which refers to the product with different sensory attributes provided by two or more co-brands in brand alliance and suggest that feeling crowded makes consumers need more arousal which in turn makes them prefer cross sensory product.

Time, Endowment Effect, and Happiness

Wenxue Zheng, Cornell University, USA
Ashley V. Whillans, Harvard Business School, USA

This project demonstrates an endowment effect of time such that people expect higher compensation for time losses than for identical time gains. We also find initial evidence for a link between this endowment effect and happiness.

Where Does My Time Go?! The Trap of Segregated Resources

Wenxue Zheng, Cornell University, USA
David R. Just, Cornell University, USA
Jura Liaukonyte, Cornell University, USA

This project showed that time follows reversed arithmetic rules of mental accounting. Through hypothetical questionnaires that measured WTP WTA willingness to wait level of irritation we find that aggregated (vs. segregated) time was preferred and participants have a higher WTA and WTP for the aggregated time losses and time gains.

How Crowdedness Enhances Consumers' Healthy Lifestyle

Wanyi Zheng, University of Hong Kong, China
He (Michael) Jia, University of Hong Kong, China
Echo Wen Wan, University of Hong Kong, China

Social crowdedness is ubiquitous and has important implications for marketers. This research demonstrates that in a crowded environment consumers are more likely to engage in health-improving consumption which can boost their immune system and thus make themselves less vulnerable to contagious diseases that become more salient under crowdedness.

A Helping Hand: How Online and In-store Shopping Environments Change Information Search For Haptic Products

Lingrui Zhou, Duke University, USA
Nicolette Sullivan, London School of Economics, UK
Gavan Fitzsimons, Duke University, USA

What information do consumers search for when shopping for haptic products? The current research uses both behavioral data and computer mouse tracking analysis to examine how consumers search for and weigh various attributes across different shopping environments (online in-store or a combination of both).

AI is Better When I'm Sure: The Influence of Certainty Level of Consumer Needs on Their Willingness to Use AI Customer Service

Yimin Zhu, Sun Yat-sen University, China
Yingyue Liu, Sun Yat-sen University, China
Xiang Fang, Oklahoma State University, USA

This paper explores the effect of certainty level of consumer needs on their willingness to use AI customer service as well as its moderating effect and mediating effect. The findings make important theoretical contributions to AI research in the service context and provide useful guidelines for companies to use AI.

Device, Fast and Slow: How Devices Influence Consumer Decisions

Shuqi Zhu, University of Warwick, UK
Sarah Wei, University of Warwick, UK
John M. Rudd, University of Warwick, UK
Yansong Hu, University of Warwick, UK

How the devices (mobile versus stationary) consumers use influence how they approach a purchase decision? We argue that consumers are less likely to employ deliberative processing when they use mobile devices compared to when they use stationary devices. Evidence from three studies supports this theorizing.

Can Handwritten-appearing Typefaces Boost the Effectiveness of Social Norms? An Experimental Investigation on Sustainable Consumer Behavior

Vita Eva Maria Zimmermann-Janssen, Heinrich Heine University Düsseldorf, Germany
Carina Sophia Hütte, Heinrich Heine University Düsseldorf, Germany
Julia Kluger, Heinrich Heine University Düsseldorf, Germany

Descriptive normative information (DNI) about a majority's sustainable behavior proved to be especially persuasive when others are present. As handwriting can evoke human presence perceptions we tested experimentally whether DNI's influence on sustainable behavior can be increased if presented in a handwritten-appearing (vs. machine-written) typeface under factual social absence.

The More, the Worse – When the Communication of High Majority Sizes Decreases the Impact of Descriptive Normative Information on Consumers' Willingness to Donate

Vita Eva Maria Zimmermann-Janssen, Heinrich Heine University Düsseldorf, Germany

The ability of descriptive normative information (DNI) about majorities' charitable behavior to motivate donations is currently discussed in reaction to diverging findings. Drawing on altruism models and impact philanthropy we propose to reconsider crowding-out predictions and provide experimental evidence for DNI's diminishing persuasiveness at high (vs. low) majority sizes communicated.

Time of Day and Construal Level Interact to Influence Engagement With Information

Ozum Zor, Rutgers University, USA
Kihyun Hannah Kim, Rutgers University, USA
Ashwani Monga, Rutgers University, USA

Social media messages that match with a high-level construal engage consumers more in the morning whereas those that match a low-level construal engage consumers more in the evening. Empirical evidence comes from an experiment and a Twitter dataset. These findings have implications for both theory and practice.

Where Consumer Behavior Meets Language: Applying Linguistic Methods to Consumer Research

Chairs:
Ann Kronrod, University of Massachusetts Lowell, USA
Grant Packard, York University, Canada
Sarah G Moore, University of Alberta, Canada
Jonah Berger, University of Pennsylvania, USA

Participants:
Jeffrey Inman, University of Pittsburgh, USA
Robert Meyer, University of Pennsylvania, USA
L. J. Shrum, HEC Paris, France
Ashlee Humphreys, Northwestern University - Medill, USA
Nicholas Lurie, University of Connecticut, USA
Andrea Webb Luangrath, University of Iowa, USA
Jeff Lee, American University, USA
Matthew D Rocklage, University of Massachusetts, USA
Charles Zhang, University of California Riverside, USA
Ruth Pogacar, University of Calgary, Canada
Ivan Gordeliy, Georgetown University, USA
Shiri Melumad, University of Pennsylvania, USA
Amir Grinstein, Northeastern University, USA
Francisco Villarroal Ordenes, University of Massachusetts, USA
Guang-Xin Xie, University of Massachusetts Boston, USA
Zoey Chen, University of Miami, USA

What can we discover by applying linguistic methods to consumer research? This Knowledge Forum introduces and discusses the multifaceted opportunities of applying linguistic research methods to explore language in the marketplace and employs a hands-on workshop approach to sprout novel research ideas that use multiple methods of linguistic inquiry.

Forum

Forum on the Research and Interpersonal Culture of ACR

Chairs:
Tiffany White, University of Illinois at Urbana-Champaign, USA

Presenters:
Joel Huber, Duke University, USA
Darren Dahl, University of British Columbia, Canada
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China
Laura Peracchio, University of Wisconsin - Milwaukee, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA

The goal of the forum is to explore the factors that have made ACR culturally successful but ultimately vulnerable. Tiffany White will moderate six scholars and an active audience to discuss ACR's unique research culture and the impact on that culture of publication norms successful collaborations global heterogeneity and the demands from university promotion systems.

Forum
Back to the Future: A Virtual Roundtable of Senior Academics
Sharing Insights from Consumer Research on Technology

Chairs:
Gizem Yalcin, Erasmus University Rotterdam, The Netherlands
William Fritz, Oxford University, UK

Discussants:
Ana Valenzuela, Baruch College, USA
Andrew T. Stephen, Oxford University, UK
Bernd Schmitt, Columbia University, USA
Christian Hildebrand, University of Geneva, Switzerland
Donna L. Hoffman, George Washington University, USA
Klaus Wertenbroch, INSEAD, Singapore
Markus Giesler, York University, Canada
Rebecca Walker Reczek, Ohio State University, USA
Rhonda Hadi, Oxford University, UK
Robert Meyer, University of Pennsylvania, USA
Russell W. Belk, York University, Canada
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands
Szu-chi Huang, Stanford University, USA
Thomas Novak, George Washington University, USA

This roundtable brings together a diverse group of senior academics to offer guidance to early-career researchers who are interested in studying technology in consumer research. Discussants will talk about theoretical methodological empirical and substantive (e.g. publication process career management) challenges in this research area.

Forum
Political "Consumption": Motivations, Decision-Making and Implications

Chairs:
Anastasiya Pocheptsova Ghosh, University of Arizona, USA
Jennifer Savary, University of Arizona, USA

Discussants:
Adam Duhachek, University of Illinois at Chicago, USA
Cait Lamberton, University of Pennsylvania, USA
Clayton R Critcher, University of California Berkeley, USA
David Crockett, University of South Carolina, USA
Erick M. Mas, Vanderbilt University, USA
Gita Johar, Columbia University, USA
Melanie Wallendorf, University of Arizona, USA
Monika Lisjak, Arizona State University, USA
Nailya Ordabayeva, Boston College, USA
Neeru Paharia, Georgetown University, USA
Nooshin Warren, University of Arizona, USA
Ronald Paul Hill, American University, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA
Uzma Khan, University of Miami, USA

Consumer engagement in politics can be direct (e.g. political donations campaign merchandise purchases) or indirect (e.g. politicized consumption policy advocacy). This forum brings together thought leaders from CP CCT and Strategy to identify these behaviors integrate extant knowledge and envision a path forward for this promising but underexplored research domain.

Forum
Creating Boundary-Breaking, Marketing-Relevant Consumer Research

Chair:
Simona Botti, London Business School, UK

Participants:
Fleura Bardhi, City University of London, UK
Eileen Fischer, York University, Canada
Donna L. Hoffman, George Washington University, USA
Robert Kozinets, University of Southern California, USA
Donald Lehmann, Columbia University, USA
John Lynch, University of Colorado, USA
Deborah MacInnis, University of Southern California, USA
Christine Moorman, Duke University, USA
Page Moreau, University of Wisconsin - Madison, USA
Vicki G. Morwitz, Columbia University, USA
Connie Pechmann, University of California Irvine, USA
Oded Netzer, Columbia University, USA

Consumer research often fails to have broad impact. We propose a framework that identifies potential reasons (implicit boundaries) and solutions (boundary-breaking opportunities); we illustrate this framework with an example; we discuss additional reasons solutions and examples in small groups moderated by the organizers; we summarize these discussions in plenary.

Forum
Consumer Health and Medical Decision Making: 2020 and Beyond

Chairs:
Dipankar Chakravarti, Virginia Tech, USA
Haiyang Yang, Johns Hopkins University, USA
Meng Zhu, Johns Hopkins University, USA

Presenters:
Angela Y. Lee, Northwestern University, USA
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China
Brent McFerran, Simon Fraser University, Canada
Carey K. Morewedge, Boston University, USA
Dawn Iacobucci, Vanderbilt University, USA
Jeff Inman, University of Pittsburgh, USA
Leonard Lee, National University of Singapore, Singapore
Peggy Liu, University of Pittsburgh, USA
Pierre Chandon, INSEAD, France
Priya Raghubir, New York University, USA
Punam Keller, Dartmouth College, USA
Ronald Paul Hill, American University, USA
Stacy Wood, North Carolina State University, USA
Vikas Mittal, Rice University, USA

The global health landscape has been changing rapidly. This has created the need for a new integrated perspective on consumer-relevant health topics through the lens of psychology marketing and economics. This roundtable will discuss emerging topics methodological approaches and future directions on consumer health and medical decision-making.

FORUM
Shedding Light on the Invisibles: Extending Consumer Theories, Methods, and Insights to Include Financially Vulnerable Consumers

Chairs:
Gergana Y. Nenkov, Boston College, USA
Linda Court Salisbury, Boston College, USA

Participants:
Simon Blanchard, Georgetown University, USA
Fred Feinberg, University of Michigan, USA
Ronald Paul Hill, American University, USA
Nina Mazar, Boston University, USA
Martin Mende, Florida State University, USA
Nailya Ordabayeva, Boston College, USA
Julie L. Ozanne, University of Melbourne, Australia
Maura Scott, Florida State University, USA
Abigail Sussman, University of Chicago, USA
Remi Trudel, Boston University, USA
Nancy Wong, University of Wisconsin - Madison, USA
Min Zhao, Boston College, USA

This interactive knowledge forum focuses on financially vulnerable consumer segments frequently excluded from financial decision-making research (e.g. low-income consumers unbanked or underbanked credit invisibles). Participants will discuss how consumer researchers can enhance theories models and participant samples to be more inclusive of financially vulnerable consumers and improve their financial well-being.

FORUM
Bringing Consumer Culture Theoretics to Policy Debate

Chairs:
Eric Arnould, Aalto University, Finland
Søren Tollestrup Askegaard, University of Southern Denmark, Denmark
Guliz Ger, Bilkent University, Turkey

This roundtable aims at providing a platform for discussing strategies for knowledge dissemination pertaining to consumer research in particular consumer culture theoretics and transformative consumer research for better policy-making concerning governance of consumption-related issues in relation to social and environmental sustainability.

FORUM
M-Turk is dying. Don't die with it. An interactive workshop on collecting data from more difficult and interesting sources.

Chair:
Broderick Lee Turner, Virginia Tech, USA

Should we all stop collecting data on Amazon's Mechanical Turk? It is rife with problems including non-naivety bot-panics fraudulent responses and bored workers. This knowledge forum provides some fun exercises to help researchers old and new wean themselves from their M-Turk habit and consider some alternatives data collection methods.

<div align="center">

FORUM
Shining a Light on Maladaptive Consumption: The Journey so Far and the Roads Less Traveled

Chairs:
Meryl P. Gardner, University of Delaware, USA
Caroline Roux, Concordia University, Canada
Shailendra Pratap Jain, University of Washington, USA

Participants:
Paul M Connell, Stony Brook University, USA
Brennan Davis, California Polytechnic State University, USA
Benét DeBerry-Spence, University of Illinois at Chicago, USA
Pamela Scholder Ellen, Georgia State University, USA
Paula Fitzgerald, West Virginia University, USA
Marcia Flicker, Fordham University, USA
Michael Kamins, Claremont Graduate University, USA
Peggy Liu, University of Pittsburgh, USA
Ingrid Martin, California State University Long Beach, USA
Marlys Mason, Oklahoma State University, USA
Hieu Nguyen, California State University Long Beach, USA
Carly Pacanowski, University of Delaware, USA
Janis Pappalardo, USA Federal Trade Commission, USA
Martin Reimann, University of Arizona, USA
Ainslie Schultz, Providence College, USA
Christine Skubisz, University of Delaware, USA
Jerome Williams, Rutgers University, USA

</div>

This interactive session will bring together researchers representing various paradigms methods and approaches to studying maladaptive consumption and ACR attendees interested in investigating the topic. We will assess the main questions studied in the literature in order to identify issues that have received less attention and develop cross-paradigmatic collaborations.

<div align="center">

FORUM
Field Experiments: A Practical Tutorial

Chairs:
Rajesh Chandy, London Business School, UK
Stephen Anderson, Stanford University, USA
Praveen Kumar Kopalle, Dartmouth College, USA

</div>

This tutorial will address practical aspects of planning and executing field experiments. We will use examples of successful and failed research projects to illustrate a toolkit for field experiments. We will then engage in a facilitated discussion of ways to apply the toolkit to participants' research questions.
